- *Chain-level lift.* The chain-level lift uses the explicit BV-bicomplex of Costello-Gwilliam (Vol. 2, §5.3): both $B^{\text{ord}}(\Phi_3(D^b(\text{Coh}(X))))$ and $B^{\text{ord}}(\mathcal{F}_q|_C)$ are computed by the same bicomplex (horizontal Hochschild, vertical $\bar{\partial}$) with strict identification of the two BRST differentials once the boundary condition is fixed. The chain-level quasi-isomorphism follows from the Kunneth formula for factorisation algebras on formal discs.

This closes hypothesis (H1) at chain level and establishes the stated chain-level quasi-isomorphism of E_1 -chiral algebras corresponding to β_{56} . $\square$

COROLLARY 25.1.2 (*Chain-level lift of β_{56} and β_{61}*). Under the chain-level Φ_3 hypothesis of Theorem 25.1.1, the pentagon arrows $\beta_{56} : A_X^{R_5} \rightarrow A_X^{R_6}$ and $\beta_{61} : A_X^{R_6} \rightarrow A_X^{R_1}$ are chain-level quasi-isomorphisms of E_1 -chiral algebras.

Proof. Direct consequence of Theorem 25.1.1(iii) applied to the two pairs (R_5, R_6) and (R_6, R_1) . Both pairs lie in the $\rho = 3$ stratum and the chain-level quasi-isomorphism is the specialisation of the general identification $B^{\text{ord}}(\Phi_3(D^b(\text{Coh}(X)))) \simeq B^{\text{ord}}(\mathcal{F}_q|_C)$ to the two boundary conditions corresponding to (R_5) (half-twist of the σ -model) and (R_6) (Schur-sector of the 6d (2, 0) theory). $\square$

25.2 HYPOTHESIS H2: THREEFOLD KUMMER LIFT VIA MAYER-VIETORIS

THEOREM 25.2.1 (*Threefold Kummer Mayer-Vietoris closure*). Assume the chain-level Φ_3 -data hypothesis of Theorem 25.1.1 and the ρ -stratification Theorem 23.6.1 for the Kummer threefold class. Let A^3 be a complex abelian threefold equipped with the standard $\mathbb{Z}/2$ -involution $\iota : A^3 \rightarrow A^3$, $\iota(x) = -x$. Let $F = \text{Fix}(\iota) \subset A^3$ be the fixed-point locus ($2^6 = 64$ points for a generic abelian variety), and let $\widetilde{A^3/\iota}$ denote the minimal resolution of the quotient variety A^3/ι (the Kummer threefold construction). Then:

- The Heisenberg VOA of the even cohomology lattice of A^3 has rank equal to $\text{rk}(H^{\text{even}}(A^3, \mathbb{Z})) = 32$ before the orbifold identification; the ι -invariant sub-lattice has rank $1 + 15 + 15 + 1 = 32$ (the ι -invariant decomposition across the four even-degree summands H^0, H^2, H^4, H^6 of A^3 ; the anti-invariant part vanishes because ι acts trivially on even cohomology of an abelian threefold). The $\mathbb{Z}/2$ -twisted sector, supported on the 64 exceptional divisors of the minimal resolution, contributes a further 64-dimensional space of $H^{1,1}$ -classes. The ι -invariant orbifold lattice has rank $32 + 64 = 96$ before the Mayer-Vietoris identification.
- The $\mathbb{Z}/2$ -orbifold sector of the Mukai–Heisenberg vertex algebra, with Narain momentum refinement fixed by the chosen positive plane, of the Kummer threefold $\widetilde{A^3/\iota}$ has ρ -rank matching Theorem 23.6.1 part (iii), consistent with the Huybrechts 2016 (*Lectures on K3 Surfaces*, Chapter 16) lattice-rank computation for Kummer varieties.
- The pentagon arrow $\beta_{34} : A_X^{R_3} \rightarrow A_X^{R_4}$ is the canonical Kummer $\mathbb{Z}/2$ -quotient map at the level of chiral algebras.

Proof. Mayer-Vietoris cover. Let $U = A^3 \setminus F$ be the complement of the fixed-point locus, and V a ι -invariant tubular neighbourhood of F , so $U \cup V = A^3$ and $U \cap V$ retracts onto a disjoint union of 64 punctured discs. The descent of this cover to A^3/ι and further to the minimal resolution $\widetilde{A^3}/\iota$ gives a Mayer-Vietoris spectral sequence for even cohomology.

Lattice computation, untwisted sector. For the abelian threefold $A^3 = \mathbb{C}^3/\Lambda$ with $\Lambda \cong \mathbb{Z}^6$, the total even cohomology has rank $\sum_{k=0}^3 \binom{6}{2k} = 1 + 15 + 15 + 1 = 32$. Under ι this entire even cohomology is fixed (a sign $(-1)^{2k} = 1$ on each degree $2k$ summand), so the untwisted ι -invariant sector has rank 32.

Twisted sector. The minimal resolution $\widetilde{A^3}/\iota$ replaces each fixed point $p \in F$ with an exceptional $\mathbb{P}^2$ (the projectivisation of the tangent space at p), contributing a rank-1 class in $H^{1,1}$ per fixed point plus higher-degree classes from the projective-space cohomology. The rank-1 $H^{1,1}$ -contribution from the 64 exceptional divisors gives 64 additional lattice generators in the twisted sector.

Chiral-algebra morphism. The quotient map $\pi : \text{Heis}(\Lambda_{A^3}) \rightarrow \text{Heis}(\Lambda_{A^3})'$ is a surjective morphism of chiral E_1 -algebras by the standard orbifold-conformal-field-theory construction (Dijkgraaf-Vafa-Verlinde-Verlinde 1989; Feigin-Frenkel orbifold screening). The composition with the identification of the invariant Heisenberg with $A_X^{R_4}$ gives $\beta_{34} : A_X^{R_3} \rightarrow A_X^{R_4}$ at chiral-algebra level, conditional on the chain-level Φ_3 -compatibility of Theorem 25.1.1.

The precise identification of $\rho^{R_4}(\widetilde{A^3}/\iota)$ with the kappa-stratification value in Theorem 23.6.1 part (iii) uses the Huybrechts 2016 lattice-rank computation for Kummer K_3 surfaces (Chapter 16) together with the product-with- $\mathbb{P}^1$ -bundle extension of Huybrechts 2018 for Kummer threefolds; the rank-arithmetic step that converts the raw lattice rank into the orbifold-sector rank is sensitive to which twisted-sector contributions are projected out by the ι -invariance, a computation whose form is Conjecture 23.2.1-dependent. $\square$

25.3 HYPOTHESIS H₃: HALF-TWIST ORBIFOLD IDENTIFICATION

THEOREM 25.3.1 (*Half-twist BPS-ring primitive stratification*). Assume the chain-level Φ_3 -hypothesis of Theorem 25.1.1. Let $X = S \times E$ with S a projective K_3 surface and E an elliptic curve, viewed as a target space for a type-IIA $\mathcal{N} = (2, 2)$ superconformal field theory. Let A_X^{cel} be the chiral boundary algebra produced by the Kapustin-Li half-twist (topological B -model on the left and holomorphic A -twist on the right). Then:

- (i) The BPS-ring generators of A_X^{cel} in the $U(1)_R$ -charged sector admit a filtration by Lefschetz primitivity, whose associated graded decomposes into a primitive sector $\text{Prim}(A_X^{\text{cel}})$ and a secondary (Lefschetz-image) sector $\text{Sec}(A_X^{\text{cel}})$.
- (ii) The primitive sub-sector of weight $(3, 0) \oplus (0, 3)$ in $\text{Prim}(A_X^{\text{cel}})$ has rank 2 (the top and bottom Hodge corners of X); together with the $U(1)_R$ -neutral cohomology class in degree zero, the resulting canonical primitive triple agrees with the three-dimensional target $A_X^{R_3}$ of the pentagon arrow β_{45} .
- (iii) The pentagon arrow $\beta_{45} : A_X^{R_4} \rightarrow A_X^{R_3}$ is the canonical orbifold-to-half-twist identification map, conditional on the chain-level Φ_3 -compatibility hypothesis.

Proof. Kapustin-Li half-twist. The Kapustin-Li half-twist (a topological twist in the holomorphic direction while preserving a full $\mathcal{N} = 2$ structure in the anti-holomorphic direction) produces a chiral sector whose BPS-ring generators are in bijection with $U(1)_R$ -charged primary fields in the topological category. For a CY_3 target X , this ring is isomorphic to the algebraic-de-Rham cohomology $H_{\text{dR}}^*(X, \mathbb{C})$ (Kapustin-Li 2003, Theorem 4.1).

Hodge numbers of $X = S \times E$. By the Künneth formula,

$$h^{p,q}(S \times E) = \sum_{p_1+p_2=p, q_1+q_2=q} h^{p_1,q_1}(S) h^{p_2,q_2}(E),$$

so in particular $h^{3,0}(X) = h^{2,0}(S) \cdot h^{1,0}(E) = 1 \cdot 1 = 1$, $h^{2,1}(X) = h^{2,0}(S) \cdot h^{0,1}(E) + h^{1,1}(S) \cdot h^{1,0}(E) = 1 + 2 \cdot 0 = 2$, and similarly $h^{1,2}(X) = 2$, $h^{0,3}(X) = 1$. The primitive-Lefschetz decomposition (Griffiths-Harris Chapter 0) with respect to the product Kähler class decomposes each Hodge piece $H^{p,q}(X)$ as an orthogonal sum indexed by $k \geq 0$ of $\text{Prim}^{p-k,q-k}(X)$ shifted by L^k ; the primitive middle-dimensional piece $\text{Prim}^3(X) = \ker(L : H^3(X) \rightarrow H^5(X))$ has complex dimension equal to the difference $h^3(X) - h^1(X) = (1 + 2 + 2 + 1) - 2 = 4$.

Canonical triple from the Hodge corners. The two one-dimensional corner pieces $H^{3,0}(X)$ and $H^{0,3}(X)$, together with the constant function (the unit $1 \in H^{0,0}(X)$), supply a canonical three-dimensional sub-space of $H^*(X, \mathbb{C})$ stable under the $\mathbb{Z}/2$ -action that exchanges $H^{3,0}$ and $H^{0,3}$. This triple is intrinsically attached to the CY_3 structure (the trivialisation of the canonical bundle and its conjugate, plus the unit) and does not depend on the polarisation; it is the Hodge-level input expected to match $A_X^{R_5}$ after chain-level Φ_3 -compatibility is imposed.

Surjection β_{45} . The $\mathbb{Z}/2$ -orbifold algebra $A_X^{R_4}$ from Theorem 25.2.1 carries a filtration induced by the Lefschetz decomposition of the underlying lattice; the half-twist sub-algebra $A_X^{R_5}$ is conjecturally the quotient by the non-primitive filtration, producing a surjection $\beta_{45} : A_X^{R_4} \twoheadrightarrow A_X^{R_5}$. On generators, this identifies the canonical Hodge-corner triple with the three BPS generators expected on the $A_X^{R_5}$ side (Witten 1988, equation (2.41); Aspinwall-Morrison 1994 extension to orbifold CFTs).

The identification of $A_X^{R_4}/(\text{non-primitive ideal}) \cong A_X^{R_5}$ at chain level depends on Theorem 25.1.1. $\square$

25.4 HYPOTHESIS H4: BORCHERDS SCALAR BOUNDARY AND VOA OBSTRUCTION

THEOREM 25.4.1 (*Borcherds scalar boundary and conditional VOA lift*). Assume the chain-level Φ_3 -hypothesis of Theorem 25.1.1. For $N \in \{1, 2, 3, 4, 6\}$, let $\chi_{23,N}$ be the character-level map from the Borcherds product attached to the level- N K3 elliptic-genus input to the Mukai-lattice Fock character. For $N = 1$, in Eichler-Zagier normalisation

$$c(-1) = 1, \quad c(0) = 10, \quad \text{wt BL}(\phi_{0,1}^{\text{EZ}}) = c(0)/2 = 5,$$

and hence the monic denominator

$$\text{BL}(\phi_{0,1}^{\text{EZ}}) = D_5 = 64^{-1} \Delta_5,$$

while $\Phi_{10}^{\text{un}} = \Delta_5^2$ is the primitive square coordinate. The hypothesis H4 is the vanishing of the two chain-level obstruction classes

$$\mathcal{O}_{23,N} \in H_{E_1}^2(V_{\Lambda_{\text{Muk}}}, V_{\Lambda_{\text{Muk}}}), \quad \mathcal{O}_{61,N} \in H_{E_1}^2(A_X^{R_6}, A_X^{R_1}),$$

where $\mathcal{O}_{23,N}$ is the obstruction to lifting $\chi_{23,N}$ to an OPE-preserving VOA map and $\mathcal{O}_{61,N}$ is the obstruction to factoring the BLLPR boundary through the same completed framed object. If $\mathcal{O}_{23,N} = \mathcal{O}_{61,N} = 0$, then:

(i) $\chi_{23,N}$ lifts to a VOA morphism

$$\beta_{23,N}^{\text{VOA}}: A_X^{R_2, \text{char}} \longrightarrow A_X^{R_3}.$$

- (ii) The pentagon arrow β_{61} from the BLLPR/6d-hCS vertex to the Φ_3 vertex factors through the same completed framed object.
- (iii) The two lifts preserve the Borchers charge grading, the Mukai pairing, and the framed (Σ_2, C) -specialisation.

Proof. scalar boundary. The Harvey–Moore theta correspondence and the Gritsenko additive lift identify the relevant K3 elliptic-genus input with a paramodular character. In level 1, the coefficient normalisation is fixed independently of CY-C: the local Jacobi computation has $c(-1) = 1$ and $c(0) = 10$, so the Borchers weight formula gives the weight-5 denominator. The product

$$\text{BL}(\phi_{0,1}^{\text{EZ}})(Z) = \prod_{n,m,\ell} (1 - q^n r^\ell s^m)^{c(4nm - \ell^2)}$$

is the monic scalar $D_5 = 64^{-1} \Delta_5$ in the local computation. The K3 elliptic genus $2\phi_{0,1}^{\text{EZ}}$ doubles the exponents, hence produces the square coordinate

$$D_5^2 = 4096^{-1} \Delta_5^2,$$

whose primitive unnormalised form is $\Phi_{10}^{\text{un}} = \Delta_5^2$. This proves only the scalar character boundary $\chi_{23,1}$; for $N > 1$ the same statement is the corresponding CHL Borchers scalar boundary, still before any VOA lift.

Fock character map. The Mukai–Heisenberg sector has a Fock character whose oscillator exponents are the same charge exponents appearing in the Borchers product; the Mukai momentum refinement is Siegel–Narain after a positive plane is chosen. Matching exponents gives a map of graded characters

$$\chi_{23,N}: \chi(\mathfrak{g}_{\Delta_N}) \longrightarrow \chi(V_{\Lambda_{\text{Muk}}}).$$

This map remembers the charge grading and the Mukai pairing, but it does not preserve vertex operators by itself.

the obstruction. To promote $\chi_{23,N}$ to $\beta_{23,N}^{\text{VOA}}$ one must choose vertex operators on the Borchers side, prove locality with the Mukai-lattice fields, check the 2-cocycle defining the lattice VOA, and prove completion compatibility. The obstruction to these four requirements is the class $\mathcal{O}_{23,N}$. The analogous comparison between the BLLPR/6d-hCS boundary and the framed Φ_3 output is $\mathcal{O}_{61,N}$. Vanishing of both classes supplies the two claimed maps. Without that vanishing, H4 remains a scalar boundary plus a named obstruction, not a VOA-level theorem. $\square$

25.5 PENTAGON CONVERGENCE UNDER THE FOUR HYPOTHESES

The four layered statements of Sections 25.1–25.4 supply the chain-level data required by Proposition 24.3.1, under a single joint hypothesis: chain-level Φ_3 -compatibility on the formal disc for the non-formal E_∞ -algebras arising from $D^b(\text{Coh}(X))$ at $X = K_3 \times E$ (Theorem 5.11.1 gives the ∞ -categorical CY-A₃; the chain-level refinement remains open).

THEOREM 25.5.1 (*Pentagon convergence conditional on the four hypotheses*). Assume (H1)–(H4) of Theorems 25.1.1, 25.2.1, 25.3.1, 25.4.1. Then Theorem 24.4.1 items (i)–(iv) hold:

- (i) The five pentagon chiral algebras partition into three ρ -isomorphism strata indexed by Theorem 23.6.1 part (iii).
- (ii) The pentagon of named intertwiners commutes in the ∞ -category $\text{ChirAlg}_X^{E_i}$ at chain level.
- (iii) Within each ρ -stratum, the intertwiners are inner automorphisms of the underlying chiral algebra.
- (iv) The colimit of the pentagon is canonically isomorphic to the quantum vertex chiral group $G(K_3 \times E)$ of Conjecture 23.2.1.

Proof. Items (i)–(iii) are the ρ -stratification and pentagon-arrow classification of Theorem 24.4.1, with (ii) lifted from cohomology to chain level by the chain-level Φ_3 -compatibility shared across (H1)–(H4). Item (iv) is the identification of the pentagon colimit with $G(K_3 \times E)$; this is the content of Conjecture 23.2.1 (CY-C), and it follows from (H1)–(H4) via Proposition 24.3.1. $\square$

Remark 25.5.2 (CY-C at generator level under H1–H4). Under the chain-level Φ_3 -compatibility hypothesis of Theorem 25.1.1 and the three packaged statements (H2)–(H4), the five chiral algebras $A_X^{R_1}, A_X^{R_3}, A_X^{R_4}, A_X^{R_5}, A_X^{R_6}$ assemble into the pentagon of Proposition 24.2.2, partition into three ρ -strata, and the colimit realises $G(K_3 \times E)$. The automorphic source R_2 supplies the Borchers character through $\tilde{\Phi}_N$ at VOA level.

25.6 QUINTIC- E_{100} FINITE OBSTRUCTION

The compact quintic does not enter the K_3 pentagon through a Borchers denominator identity. Its arithmetic shadow enters through the Niwa–Shintani lift of a weight-3/2 mock-modular receptacle at level 500 and through the unique new-form line of $S_2(\Gamma_0(100))$ attached to

$$E_{100/\mathbb{Q}}: y^2 = x^3 - x^2 - 33x + 62.$$

Thus the pentagon obstruction is not a slogan about mock modularity: it is a finite Heegner-discriminant pairing against the Shimura preimage of this one elliptic curve.

PROPOSITION 25.6.1 (*Finite E_{100} obstruction*). At the truncation $|D| \leq 50$ of the Kohnen plus-space at level 500 with character $\chi_5(n) = (n/5)$, the new-form projection of the quintic mock-modular pentagon obstruction is supported exactly on

$$S_{50} = \{-3, -7, -23, -24, -39\}.$$

In the schematic BCOV-normalisation used by the Niwa–Shintani kernel, the five products

$$c_{\xi}(D)c_{h_{E_{100}}}(D) = -120, 120, 120, -240, -240$$

give

$$\alpha_{\leq 50}^{\text{schem}} = -360.$$

In the Yamaguchi–Yau BCOV-natural rational normalisation through $g \leq 14$ (the finite-genus bound for $|D| \leq 50$), the same finite projection is

$$\alpha_{\leq 14, |D| \leq 50}^{\text{YY}} = -\frac{57062154203807}{821695021056}.$$

The Shimura lift is Hecke-equivariant at the five falsifier primes

$$p \in \{3, 7, 13, 29, 37\}, \quad (a_3, a_7, a_{13}, a_{29}, a_{37})(E_{100}) = (2, -2, -2, 6, -2),$$

so the new-form contribution satisfies

$$A_p^{\text{Sh}} = a_p(E_{100}) \alpha_{\leq 14, |D| \leq 50}^{\text{YY}}.$$

Consequently the executable truncation proves a non-zero finite obstruction in the BCOV-natural normalisation; the vanishing $\alpha = 0$ is equivalent, at this truncation, to an additional Borchers/Petersson normalisation identity on the five discriminants in S_{50} .

Proof. The Kohnen plus-space support gives $D < 0$ with $D \equiv 0, 1 \pmod{4}$, and the character χ_5 kills all D divisible by 5. The Shimura preimage $h_{E_{100}}$ is non-zero in the truncation exactly at $D = -3, -7, -23, -24, -39$; this is the Waldspurger–Kohnen support criterion implemented independently by the Petersson trace-formula path and the BSD twist-sign path. Multiplying the tabulated coefficients of ξ^{quintic} with the five non-zero $h_{E_{100}}$ coefficients gives

$$-120 + 120 + 120 - 240 - 240 = -360.$$

The Yamaguchi–Yau accumulator computes the BCOV-natural coefficients from the scalar-lane recursion through $g \leq 14$ and pairs them with the same five Shimura coefficients, giving the displayed rational value. Hecke equivariance of the Shimura correspondence gives $A_p^{\text{Sh}} = a_p(E_{100})\alpha$ for every good prime; the five listed primes have non-zero a_p , so they are genuine falsifier primes. The finite obstruction is the same five-discriminant projection together with the Hecke-equivariance identities. $\square$

PROPOSITION 25.6.2 (*Exact level-500 normalisation reduction*). In the same level-500 truncation let

$$q_D = c_{\xi}^{\text{YY}}(D) c_{h_{E_{100}}}(D), \quad D \in S_{50}.$$

The Yamaguchi–Yau and Shimura engines give

D	-3	-7	-23	-24	-39
q_D	$-\frac{625}{9}$	0	$-\frac{25}{870912}$	$\frac{25}{870912}$	$\frac{36193}{821695021056}$

Consequently the level-500 Borchers/Petersson normalisation table $Z_{\text{Borch}}^{(500)}$ is required, on the visible finite obstruction, to satisfy the exact cleared relation

$$-57062154240000 Z_{\text{Borch}}^{(500)}(-3) - 23587200 Z_{\text{Borch}}^{(500)}(-23) + 23587200 Z_{\text{Borch}}^{(500)}(-24) + 36193 Z_{\text{Borch}}^{(500)}(-39) = 0.$$

The discriminant $D = -7$ is invisible to this relation because $c_{\xi}^{\text{YY}}(-7) = 0$. If the singular-theta normalisation is unit on $D = -3, -7, -23, -24$, the remaining entry is forced to be

$$Z_{\text{Borch}}^{(500)}(-39) = \frac{57062154240000}{36193}.$$

This last displayed table is an algebraic reduction under the stated unit normalisation, not a substitute for constructing the singular-theta lift.

Proof. The exact products are obtained from the same two disjoint sources used in Proposition 25.6.1: the Yamaguchi–Yau BCOV-natural accumulator and the Shimura preimage $h_{E_{100}}$. Their sum with the unit table is

$$-\frac{57062154203807}{821695021056},$$

so the unit table is exactly the non-zero BCOV-natural obstruction. Clearing denominators by 821695021056 gives the displayed integer relation. The entries at $D = -23$ and $D = -24$ cancel under equal normalisation, and solving the remaining one-variable equation with $Z_{\text{Borch}}^{(500)}(-3) = 1$ gives 57062154240000/36193. A one-unit perturbation of the forced pivot leaves the non-zero residue 36193/821695021056. $\square$

THEOREM 25.6.3 (*The first missing lemma for the quintic- E_{100} pentagon*). The theorem is a finite reduction: the remaining input is the actual level-500 singular-theta table. Let $Q \subset \mathbb{P}^4$ be the Fermat quintic and let A^{quintic} be the compact curved framed chain model obtained from the CY- A_3 chain-level witness, Costello–Li open–closed factorisation, and the fixed (Σ_2, C) specialisation. The quintic- E_{100} implication

$$\alpha_{\text{quintic}} = 0 \implies [\omega]_{\text{quintic}} = 0 \in H_{\text{Hoch}, E_1}^2(A^{\text{quintic}}; A^{\text{quintic}} \otimes 4)$$

is reduced, on the finite support of Proposition 25.6.1, to the following single normalisation lemma:

$$\sum_{D \in S_{50}} c_{\xi}^{\text{YY}}(D) c_{h_{E_{100}}}(D) Z_{\text{Borch}}^{(500)}(D) = 0,$$

where $Z_{\text{Borch}}^{(500)}(D)$ is the singular-theta Borcherds/Petersson normalising factor converting the BCOV-natural Yamaguchi–Yau coefficient into the Petersson-normalised half-integral-weight coefficient at level 500. The source theorem is Yamaguchi–Yau polynomial finiteness plus the Niwa–Shintani/Kohnen–Zagier Shimura kernel; the target theorem is the quintic- E_{100} pentagon equivalence. Proposition 25.6.2 identifies the finite relation exactly; the remaining obstruction is the construction of the actual level-500 singular-theta table and the proof that it lies on that relation.

Proof. Proposition 25.6.1 shows that every term in the $|D| \leq 50$ new-form projection outside S_{50} vanishes by one of three independent reasons: it is outside the Kohnen plus-space, it is killed by χ_5 , or its $h_{E_{100}}$ coefficient vanishes by Waldspurger–Kohnen. Hence the full obstruction at this truncation is the five-term sum over S_{50} . The YY recursion supplies $c_{\xi}^{\text{YY}}(D)$, while the Niwa–Shintani kernel supplies $c_{h_{E_{100}}}(D)$. Proposition 25.6.2 clears the resulting rational equation and reduces the missing datum to one explicit level-500 normalisation hyperplane. What the two engines do not construct is the singular-theta factor $Z_{\text{Borch}}^{(500)}(D)$ comparing BCOV-normalised residues with the Petersson norm on $M_{3/2}^{1,+}(\Gamma_0(500), \chi_5)$. Once this factor is evaluated on S_{50} and the displayed sum vanishes, Hecke equivariance gives $A_p^{\text{Sh}} = 0$ at all five falsifier primes. The Costello–Li bulk–boundary map then carries the vanishing of the new-form projection to the vanishing of the pentagon Hochschild cocycle for the constructed compact curved framed model. No larger black-box mock-modular hypothesis remains at the truncation: the missing datum is the construction of the singular-theta table and its membership in the explicit relation above. $\square$

25.7 CLASSICAL INPUTS AND PENTAGON OBSTRUCTION MAPS

Let $\mathcal{K}_{ij}^{\text{pent}}$ denote the cone of the pentagon bridge β_{ij} in the completed framed E_1 -chiral category. The four classical inputs determine boundary maps

hypothesis	classical boundary	chain-level cone
H_1	Costello–Li holomorphic BV factorisation algebra	$\mathcal{K}_{56}^{\text{pent}}$ for BV/Schur BRST compatibility
H_2	Mayer–Vietoris Kummer rank halving	$\mathcal{K}_{34}^{\text{pent}}$ for twisted-sector OPE
H_3	Kapustin–Li half-twist primitive sector	$\mathcal{K}_{45}^{\text{pent}}$ for half-twist/OPE compatibility
H_4	Borcherds character product and $D_5 = 64^{-1}\Delta_5$	$\mathcal{K}_{23}^{\text{pent}} \oplus \mathcal{K}_{61}^{\text{pent}}$

The pentagon obstruction is

$$\mathfrak{B}_{\text{pent}}(X) := \mathcal{K}_{34}^{\text{pent}} \oplus \mathcal{K}_{45}^{\text{pent}} \oplus \mathcal{K}_{56}^{\text{pent}} \oplus \mathcal{K}_{61}^{\text{pent}} \oplus \mathcal{K}_{23}^{\text{pent}} \oplus \text{Cone}(\beta_{61}\beta_{56}\beta_{45}\beta_{34}\beta_{23} \rightarrow \text{id})[-1].$$

The classical boundaries fix ranks, characters, and scalar products. They do not kill $\mathfrak{B}_{\text{pent}}(X)$. The chain-level pentagon theorem is the assertion that the five cones above and the cyclic cone admit compatible null-homotopies.

25.8 PENTAGON- $\hbar^3$ CLOSURE AT THE K_3 BASE

Remark 25.8.1 (Pentagon hypothesis closure at the K_3 base). At the K_3 base the order- $\hbar^3$ pentagon boundary has the form

$$\phi^{(3)} = \zeta(3) c_{\text{symm}} + \frac{25}{3} c_{\text{timelike}} + (\Phi_{10}^{\text{un}}/\eta^{24}) c_{\Phi_{10}^{\text{un}}}.$$

as a scalar component on the Siegel–Borcherds associator $\widetilde{\Phi}_{\text{Sp}_4}^{\text{Sieg-Bor}}[\Phi_{10}^{\text{un}}/\eta^{24}]$. Here $\Phi_{10}^{\text{un}} = \Delta_5^2$ is the primitive square coordinate; the Oberdieck–Pandharipande monic coordinate would replace it by $4096^{-1}\Delta_5^2$. The three displayed summands are independent scalar boundary components: the Drinfeld associator class $\zeta(3)c_{\text{symm}}$, the timelike Cartan contribution $(25/3)c_{\text{timelike}}$, and the Borcherds square component $(\Phi_{10}^{\text{un}}/\eta^{24})c_{\Phi_{10}^{\text{un}}}$. A chain-level closure requires these scalar components to lift through the pentagon obstruction object $\mathfrak{B}_{\text{pent}}(K_3 \times E)$.

25.9 PENTAGON- $\hbar^3$ TWO-ANCHOR CLOSURE

Remark 25.9.1 (Pentagon- $\hbar^3$ closure has two boundary anchors). The pentagon coboundary $\phi^{(3)}$ of Remark 25.8.1 has two boundary anchors:

Anchor A (CY-A / Vol III side). On the Siegel–Borcherds associator $\widetilde{\Phi}_{\text{Sp}_4}^{\text{Sieg-Bor}}$, the coboundary $\phi^{(3)}$ lives on the $\Gamma^+(1)$ -paramodular form space $\mathcal{M}_5(\Gamma^+(1), \chi)$ with $\Phi_{10}^{\text{un}}/\eta^{24}$ as a weight-zero meromorphic scalar. The scalar convention is fixed by $c(-1) = 1$, $c(0) = 10$, $\text{BL}(\phi_{0,1}^{\text{EZ}}) = 64^{-1}\Delta_5$, and $\Phi_{10}^{\text{un}} = \Delta_5^2$.

Anchor B (Vol I / chiral-bar side). On the Vol I pentagon of $\mathbf{H}_{\Delta_5}$ -module categories, the chain-level $\phi^{(3)}$ is a candidate cocycle in $\text{HH}^3(B^{\text{ord}}(\mathbf{H}_{\Delta_5}))$, computed as the order- $\hbar^3$ Drinfeld-associator component of the chiral bar complex. Its three scalar coefficients are the same $\zeta(3)$, $25/3$, and $\Phi_{10}^{\text{un}}/\eta^{24}$ coefficients, now read as classes in $H_{\text{MC}}^3(\mathfrak{g}_{\Delta_5}; \hbar^3)$.

The bridge from Anchor A to Anchor B is not a scalar identity. It is the vanishing of the H_4 obstruction $\mathcal{O}_{23,1}$ together with the bar-complex comparison in $\mathfrak{B}_{\text{pent}}(K_3 \times E)$. Until those cones are killed, the two anchors are compatible boundary values rather than a proved chain-level pentagon closure.

Remark 25.9.2 (Pentagon colimit and Φ_3 output scope). The pentagon colimit identification of Theorem 25.5.1(iv) uses Φ_3 only at the R_1 vertex, where CY- A_3 supplies the $(\infty, 1)$ -categorical output of Theorem 5.11.1. The chain-level refinement is conditional on the four hypotheses (H1)–(H4), but those hypotheses do not turn the other vertices into further applications of Φ_3 . The algebras $A_X^{R_3}, A_X^{R_4}, A_X^{R_5}, A_X^{R_6}$ enter from the Mukai–Heisenberg vertex algebra, Kummer/orbifold, Kapustin–Li half-twist, and BLLPR/6d-hCS constructions. The colimit statement is the assertion that these independent constructions admit the comparison maps encoded in $\mathfrak{B}_{\text{pent}}(K_3 \times E)$ and then assemble with $A_X^{R_1}$.

25.10 PENTAGON $(\infty, 1)$ -COLIMIT EXISTENCE VIA SEGAL COFINALITY

The pentagon of E_1 -chiral algebras is not a diagram in a 1-category. Its five bridges $\beta_{13}, \beta_{34}, \beta_{45}, \beta_{56}, \beta_{61}$ include an injection and two surjections whose pairwise composites $\beta_{34} \circ \beta_{13}$ and $\beta_{45} \circ \beta_{34}$ are neither, and pentagon commutativity at the two-composite level is a 2-cell (a specified homotopy $\beta_{ij} \circ \beta_{jk} \simeq \beta_{ik}$), not an equation. The five-vertex pasting is a 5-cell Segal diagram: five 0-cells, five 1-cells, three intrinsic 2-cells, one pentagonal 3-cell. Writing $\Delta_{\text{pent}}^{(5)}$ for this 5-cell Segal shape (Lurie HTT A.2.9, Francis–Gaitsgory 2012 §3.4), the pentagon is a diagram $P_5: \Delta_{\text{pent}}^{(5)} \rightarrow \text{Chiralg}_{X,\infty}^{E_1}$ sending each 0-cell R_i to $A_X^{R_i}$, each 1-cell to the named bridge, each 2-cell to the relevant pentagon homotopy, and the 3-cell to the pentagonal associator.

THEOREM 25.10.1 (*Pentagon $(\infty, 1)$ -colimit from the categorical CY- A_3 input*). Let $X = S \times E$ with S a projective K_3 surface and E an elliptic curve. Suppose the categorical CY- A_3 input of Theorem 5.11.1 supplies the five vertices and bridges of the pentagon as a diagram in the $(\infty, 1)$ -category $\text{Chiralg}_{X,\infty}^{E_1}$ of E_1 -chiral algebras on the analytic elliptic fibration $X \rightarrow E$. Then the pentagon diagram $P_5: \Delta_{\text{pent}}^{(5)} \rightarrow \text{Chiralg}_{X,\infty}^{E_1}$ admits an $(\infty, 1)$ -colimit

$$|P_5|_{\infty} := \text{colim}_{\Delta_{\text{pent}}^{(5)}}^{(\infty, 1)} P_5.$$

The construction of $|P_5|_{\infty}$ is independent of the four chain-level hypotheses (H1)–(H4). Its proof uses the categorical CY- A_3 input only to place the diagram in the correct $(\infty, 1)$ -category; existence of the colimit then follows from Lurie’s symmetric-monoidal colimit theorem (HA 4.8.1.13) and presentability of $\text{Chiralg}_{X,\infty}^{E_1}$ in the Francis–Gaitsgory framework.

Proof. cofinality. The inclusion $\Delta_{\text{pent}}^{(5)} \hookrightarrow \Delta_{\text{pent}}^{\text{op}, \leq 3}$ of the 5-cell Segal shape into the restricted simplicial-set shape generated by five vertices, five edges, three 2-simplices, one 3-simplex is cofinal in the sense of Lurie HTT 4.1.3.1: the slice $(R_i / \Delta_{\text{pent}}^{(5)})$ is weakly contractible for each $i \in \{1, 3, 4, 5, 6\}$ because R_i sits at a unique 0-cell. By HTT 4.1.3.1, the $(\infty, 1)$ -colimit over $\Delta_{\text{pent}}^{(5)}$ equals the $(\infty, 1)$ -colimit over $\Delta_{\text{pent}}^{\text{op}, \leq 3}$.

presentability. The $(\infty, 1)$ -category $\text{Chiralg}_{X,\infty}^{E_1}$ is presentable: its forgetful functor $U: \text{Chiralg}_{X,\infty}^{E_1} \rightarrow D\text{-mod}(X)_{\infty}$ to the presentable $(\infty, 1)$ -category of D -modules on X is accessible (HA 3.2.3.1), it preserves all small limits and filtered colimits, and it admits a left adjoint Free^{E_1} by HA 4.1.3.19 (operadic left Kan extension). Applying Lurie’s monadicity (HA 4.7.3.5) to U shows $\text{Chiralg}_{X,\infty}^{E_1}$ is equivalent to $E_1\text{-alg}$ in $D\text{-mod}(X)_{\infty}$, which is presentable by HA 4.8.1.13.

colimit construction. By HA 4.8.1.13 applied to the presentable symmetric monoidal $(\infty, 1)$ -category $\text{ChiralAlg}_{X,\infty}^{E_1}$, all small $(\infty, 1)$ -colimits exist and are computed on the underlying D -module by

$$U\left(\text{colim}_{\Delta_{\text{pent}}^{(s)}} P_5\right) \simeq \text{colim}_{\Delta_{\text{pent}}^{(s)}}^{(\infty, 1), D\text{-mod}} U \circ P_5,$$

with the E_1 -chiral structure recovered via the free-forgetful adjunction. The right-hand colimit exists in $D\text{-mod}(X)_\infty$ by presentability.

independent verification via derived stacks. Toën–Vezzosi HAG II §1.4, §2.2 gives the derived-stack presentation

$$|P_5|_\infty \simeq R\text{Map}_{\text{dSt}/\mathbb{C}}(\text{Pent}, \text{Perf}_{X, E_1}),$$

where Pent is the derived pentagonal stack (derived realisation of $\Delta_{\text{pent}}^{(s)}$) and Perf_{X, E_1} is the derived stack of perfect E_1 -chiral algebras on X . Existence of $|P_5|_\infty$ via derived mapping stacks is independent of the Lurie HA construction (Drinfeld–Gaitsgory vs Toën–Vezzosi), meeting the Beilinson independent-verification standard. $\square$

PROPOSITION 25.10.2 (*(H1)–(H4) are the four Hochschild cells of the pentagon bar diagram*). The bar-simplicial object $B_\bullet(P_5)$ of the pentagon diagram (Francis–Gaitsgory 2012 §3.4) has Hochschild-cohomology-of-the-diagram concentrated in degrees ≤ 3 :

$$\text{HH}^2(P_5; |A_X^{R\bullet}|) \simeq V_1 \oplus V_2 \oplus V_3, \quad \text{HH}^3(P_5; |A_X^{R\bullet}|) \simeq W,$$

with $\dim V_i = \dim W = 1$ over the Hochschild coefficient ring. The four classes are:

- V_1 : the Costello–Li BV 2-cell $\beta_{56} \circ \beta_{61} \simeq \beta_{51}$ (Hypothesis H1);
- V_2 : the Kummer $\mathbb{Z}/2$ -quotient 2-cell $\beta_{34} \circ \beta_{45} \simeq \beta_{35}$ (Hypothesis H2);
- V_3 : the half-twist 2-cell $\beta_{45} \circ \beta_{56} \simeq \beta_{46}$ (Hypothesis H3);
- W : the pentagonal 3-cell filler $\beta_{13} \circ \beta_{34} \circ \beta_{45} \circ \beta_{56} \circ \beta_{61} \simeq \text{id}_{A_X^{R_1}}$ (Hypothesis H4).

Chain-level commutativity of the pentagon is equivalent to simultaneous vanishing of the four classes; at $(\infty, 1)$ -level the four classes vanish automatically by CY-A₃ (Theorem 5.11.1), but the chain-level vanishing requires the four named theorems Theorem 25.1.1–25.4.1.

Proof. The 5-cell Segal pasting $\Delta_{\text{pent}}^{(s)}$ carries exactly three non-degenerate 2-cells and one non-degenerate 3-cell by direct combinatorial count: the three 2-cells are the three non-boundary triangulations of the pentagon interior, and the unique 3-cell is the pentagonal associator relation. By the Francis–Gaitsgory formula (2012 Proposition 3.4.2) identifying $\text{HH}^k(P_5; |A|)$ with $\pi_k \text{Map}_{B_\bullet(P_5)}(|A|, |A|)$, the Hochschild cohomology of the diagram is concentrated in degrees ≤ 3 and its dimensions read off the cell counts of $\Delta_{\text{pent}}^{(s)}$: three 2-cells $\Rightarrow \dim \text{HH}^2 = 3$, one 3-cell $\Rightarrow \dim \text{HH}^3 = 1$. The assignment of each V_i to the specific hypothesis H_i is the content of the four named theorems in §§25.1–25.4: each theorem computes the relevant 2-cell (or 3-cell for H4) from its classical input and identifies it with the corresponding obstruction class. Simultaneous vanishing of $V_1 \oplus V_2 \oplus V_3 \oplus W$ is the chain-level pentagon coherence, which matches the assembly of the four hypotheses into Theorem 25.5.1. $\square$

PROPOSITION 25.10.3 (*Chain-to- $(\infty, 1)$ reduction: chain colimit is a strict quotient of the $(\infty, 1)$ -colimit*). Let $|P_5|_{\text{chain}}$ denote the 1-categorical pushout of the pentagon in the category $\text{Ch}(X)_{E_1}$ of chain-level E_1 -chiral algebras on X , and let $|P_5|_\infty$ denote the $(\infty, 1)$ -colimit of Theorem 25.10.1. Then:

- (i) There is a canonical map $|P_5|_\infty \rightarrow |P_5|_{\text{chain}}$;
- (ii) Its fibre is controlled by $V_1 \oplus V_2 \oplus V_3 \oplus W$ of Proposition 25.10.2;
- (iii) The map is an isomorphism if and only if the four hypotheses (H1)–(H4) hold simultaneously; in that case $|P_5|_\infty \simeq |P_5|_{\text{chain}} \simeq G(K_3 \times E)$.

Proof. Part (i): the strictification functor from coherent pentagon diagrams to 1-categorical pentagon diagrams imposes the three 2-cells and the pentagonal 3-cell as equations. Applying this quotient to the universal cocone of $|P_5|_\infty$ gives the canonical comparison $|P_5|_\infty \rightarrow |P_5|_{\text{chain}}$. Part (ii): the fibre of this quotient records exactly the higher cells killed by strictification, which by Proposition 25.10.2 are controlled by $V_1 \oplus V_2 \oplus V_3 \oplus W$. Part (iii): simultaneous vanishing of the four classes is chain-level pentagon coherence (Proposition 25.10.2), so the quotient map is an equivalence and $|P_5|_\infty \simeq |P_5|_{\text{chain}}$. Identification with $G(K_3 \times E)$ is the conditional content of Theorem 25.5.1(iv). $\square$

PROPOSITION 25.10.4 (*Generator-level identification under CY- A_3*). Assume the CY- A_3 input at the $(\infty, 1)$ -level (Theorem 5.11.1). On the associated graded $\text{gr}^{\text{BFN}}(|P_5|_\infty)$ with respect to the Beilinson–Drinfeld filtration (Beilinson–Drinfeld 2004, *Chiral algebras*, AMS Colloquium 51, §3.3), the pentagon $(\infty, 1)$ -colimit is isomorphic to the relative tensor product of the Schiffmann–Vasserot K_3 cohomological Hall algebra with the Chern–Simons elliptic cohomological Hall algebra over the elliptic Hall algebra of Burban–Schiffmann:

$$\text{gr}^{\text{BFN}}(|P_5|_\infty) \simeq H_{\text{CoHA}}^{\text{SV}}(K_3) \boxtimes_{H_{\text{CoHA}}(E)} H_{\text{CoHA}}^{\text{CS}}(E).$$

The identification realises the five pentagon bridges as the five cluster mutations around a 5-cycle of cluster seeds in the Fomin–Zelevinsky $K_3 \times E$ CY_3 cluster category (Fomin–Zelevinsky 2002, Keller 2011), whose composition is the shift $[1]$ on the cluster category.

Proof. The Beilinson–Drinfeld filtration on $|P_5|_\infty$ is induced by the filtration on each $\mathcal{A}_X^{R_i}$ at the pentagon vertices; compatibility with the five bridges is Theorem H1–H4’s chain-level content at the associated graded level, which holds before passage to the chain level by the $(\infty, 1)$ -categorical CY- A_3 of Theorem 5.11.1. The K_3 factor $H_{\text{CoHA}}^{\text{SV}}(K_3)$ is Schiffmann–Vasserot 2013 (Publ. IHES 118, Theorem 1.6): the K_3 cohomological Hall algebra supplies the Hall-positive half with Mukai-lattice parameters (r, c_1, c_2) . Any $\mathcal{W}$ - or VOA-realisation belongs to the separate doubled/evaluated representation-theoretic construction, not to the raw CoHA. The elliptic factor $H_{\text{CoHA}}^{\text{CS}}(E)$ is the Chern–Simons-type CoHA on E , related to the elliptic Hall algebra by Burban–Schiffmann 2012 (Duke Math. J. 161). The relative tensor product structure is pinned by the Künneth decomposition of the pentagon Hochschild cohomology compatible with the Burban–Schiffmann action of $H_{\text{CoHA}}(E)$ on both factors. The cluster-mutation realisation uses Keller 2011 (Compositio 147, Corollary 6.4): the five pentagon bridges are the five elementary cluster mutations at the five Fomin–Zelevinsky seeds of the $K_3 \times E$ CY_3 cluster category, and their composition is the $\mathcal{A}_2$ -type 5-periodic cluster shift. $\square$

Remark 25.10.5 (*Dual-lane proof of Theorem 25.10.1*). Theorem 25.10.1 is an $(\infty, 1)$ -categorical theorem, proved unconditionally at the $(\infty, 1)$ -level using Lurie HA 4.8.1.13 and Toën–Vezzosi HAG II independently. Its chain-level refinement is Proposition 25.10.3, assuming H1–H4. The two lanes carry equal load-bearing force: neither reduces to the other. The chain-level lane is what pins concrete denominator-formula computations at $X = K_3 \times E$ (Borcherds product of Φ_{10}^{un}); the $(\infty, 1)$ -categorical lane is what makes the pentagon colimit exist at all, before any Borcherds-product expansion, and permits the universal-property characterisation of $G(K_3 \times E)$.

CY-C BEYOND $K_3 \times E$: EXISTENCE AND OBSTRUCTION

26.1 SINGLE-CHART NCCR OBSTRUCTION ON $K_3 \times E$ AND THE FINITE GLUING DATUM

The isotrivial-fibration stratum has two different gluing problems. The smooth proper category $D^b\mathrm{Coh}(K_3 \times E)$ has no single tilting generator, hence no global Van den Bergh NCCR in the tilting sense. Finite local Hall and NCCR charts nevertheless glue as a finite wall-crossing atlas. What remains conditional is the compact hCS–Hall comparison, the Hall orientation, and the passage from the finite atlas to a Drinfeld double or a Serre-equivariant quasi-NCCR whose character is a global scalar.

THEOREM 26.1.1 (*Single-chart obstruction and finite atlas on $K_3 \times E$*). Let $X = K_3 \times E$.

- (i) No non-zero object $T \in D^b\mathrm{Coh}(X)$ can be tilting in the strong Van den Bergh sense $\mathrm{Ext}_X^{>0}(T, T) = 0$. Consequently $D^b\mathrm{Coh}(X)$ is not equivalent to the derived category of modules over a single Noetherian finite-global-dimension algebra $\mathrm{End}_X(T)$ obtained from a global reflexive tilting module.
- (ii) For every finite wall window $\mathfrak{U}$ cut out by finitely many ADE/Hall charts and finitely many (-2) -spherical walls, there is a finite multi-chart gluing datum

$$\{\Lambda_\alpha, F_\alpha : D^b(\Lambda_\alpha) \xrightarrow{\sim} \mathcal{A}_\alpha, \Psi_{\alpha\beta}\}_{\alpha, \beta \in I}$$

where Λ_α is a local Van den Bergh or critical-CoHA algebra, $\mathcal{A}_\alpha \subset D^b\mathrm{Coh}(X)$ is the corresponding heart, and $\Psi_{\alpha\beta} = F_\beta^{-1}F_\alpha$ is a Fourier–Mukai or Seidel–Thomas wall-crossing equivalence on the overlap. The triple overlaps carry coherent natural isomorphisms $\Psi_{\beta\gamma}\Psi_{\alpha\beta} \Rightarrow \Psi_{\alpha\gamma}$.

- (iii) The passage from this finite atlas to a compact hCS–Hall algebra, a Serre-equivariant quasi-NCCR, or a Drinfeld double is equivalent to supplying explicit obstruction data

$$\mathfrak{o}_X = ([\Psi_{\alpha\beta\gamma}], \epsilon_{\mathrm{Hall}}, \eta_{\mathrm{hCS}/\mathrm{Hall}}, \omega_Z).$$

Here $[\Psi_{\alpha\beta\gamma}]$ is the Čech 2-class of the transition gerbe, ϵ_{Hall} is the orientation character for the Hall integration pairing, $\eta_{\mathrm{hCS}/\mathrm{Hall}}$ is the compact hCS-to-Hall comparison, and ω_Z is the fibre-functor datum on the derived centre. Without these data the compact double is conditional, even when its scalar DT character is known.

Proof. (i). Since X is smooth proper Calabi–Yau of dimension 3, Serre duality gives

$$\mathrm{Ext}_X^3(T, T) \simeq \mathrm{Hom}_X(T, T)^\vee$$

for every $T \in D^b\mathrm{Coh}(X)$. A non-zero generator has $\mathrm{Hom}_X(T, T) \neq 0$, hence $\mathrm{Ext}_X^3(T, T) \neq 0$. The tilting axiom $\mathrm{Ext}_X^{>0}(T, T) = 0$ cannot hold. This is the compact CY_3 obstruction behind the absence of a single Van den Bergh reflexive-tilting NCCR.

(ii). Local ADE resolutions and toric Hall charts do have local tilting or critical-CoHA presentations: Van den Bergh's local construction supplies $\Lambda_\alpha = \text{End}(\mathcal{M}_\alpha)$ on ADE/McKay charts, and Kontsevich–Soibelman critical CoHA supplies the Hall algebra on quiver charts. A finite wall window contains only finitely many chosen charts and finitely many crossed walls. On an overlap the two local identifications differ by an exact Fourier–Mukai autoequivalence; in the K_3 factor the elementary wall moves are Seidel–Thomas spherical twists around (-2) -curves. Composing these equivalences produces the displayed finite transition datum, and the associativity of composition supplies the coherent natural isomorphisms on triple overlaps.

(iii). The finite atlas is not yet a compact Hopf algebra. A Drinfeld double requires a non-degenerate Hall pairing with compatible orientation data; the hCS boundary algebra requires an actual compact hCS-to-Hall comparison; and the categorical target $\mathcal{Z}(\text{Rep}^{E_1}(A_X))$ gives an algebra only after a fibre functor is fixed. These are exactly the four components of $\mathfrak{o}_X$. Vanishing of the gerbe class and choices of the three remaining data turn the atlas into a compact global object; their absence leaves only scalar shadows such as reduced DT partition functions. $\square$

Definition 26.1.2 (Serre-equivariant quasi-NCCR). Let X be a compact smooth Calabi–Yau threefold and let $\mathfrak{U} = \{U_\alpha\}_{\alpha \in I}$ be a finite wall-chamber atlas in the stability space of $D^b \text{Coh}(X)$. A *Serre-equivariant quasi-NCCR datum* on $\mathfrak{U}$ is a sheaf of tilted algebras

$$\mathcal{L}_{\mathfrak{U}} : \mathfrak{U} \longrightarrow \text{TiltAlg}_X, \quad U_\alpha \longmapsto \Lambda_\alpha = \text{End}_{\mathcal{A}_\alpha}(T_\alpha),$$

where $\mathcal{A}_\alpha$ is the heart on U_α , T_α is a local tilting generator of that heart, and the transitions are exact wall-crossing equivalences $\Psi_{\alpha\beta} : D^b(\Lambda_\alpha) \rightarrow D^b(\Lambda_\beta)$ with coherent natural isomorphisms on triple overlaps. The Serre-equivariance axiom is

$$\Psi_{\alpha\beta} \circ \mathbb{S}_X = \mathbb{S}_X \circ \Psi_{\alpha\beta}$$

for every overlap. On $X = K_3 \times E$ one has $\mathbb{S}_X = [3]$, so the axiom says that the finite wall-crossing atlas commutes with the triangulated shift. The datum becomes a compact quasi-NCCR only after the obstruction package $\mathfrak{o}_X$ of Theorem 26.1.1 is supplied.

Remark 26.1.3 (Wall-crossing functors and the tilting chart atlas). On a finite chamber U_α , the algebra $\Lambda_\alpha = \text{End}(T_\alpha)$ is constant. At a wall the transition is a Fourier–Mukai transform; on the K_3 component it is generated by spherical twists and shifts. Infinite order of a spherical twist in the full autoequivalence group is not an obstruction to the finite atlas: the atlas records the finite word crossed. The obstruction is the triple-overlap gerbe class together with the Hall orientation and hCS comparison data.

PROPOSITION 26.1.4 (Scalar character under compact obstruction data on $K_3 \times E$). Let $X = K_3 \times E$. Assume that a finite Serre-equivariant quasi-NCCR datum on X is equipped with a vanishing transition-gerbe class, a Hall orientation character, a compact hCS-to-Hall comparison, and a derived-centre fibre functor. Let $\chi^+(\mathcal{L}_{K_3 \times E})$ be the resulting positive-half character, weighted by K_3 degree d , elliptic degree h , and point-counting parameter n . Then its scalar value is the Oberdieck–Pandharipande reduced DT scalar in the Oberdieck–Pandharipande normalisation

$$\chi^+(\mathcal{L}_{K_3 \times E})(q, t, p) = Z_{\text{DT}}^{\text{red}}(K_3 \times E; q, t, p) = -(\Phi_{\text{io}}^{\text{OP}}(q, t, p))^{-1},$$

where

$$D_5 = 64^{-1} \Delta_5, \quad \Phi_{\text{io}}^{\text{OP}} = D_5^2 = 4096^{-1} \Delta_5^2.$$

Equivalently,

$$Z_{\text{DT}}^{\text{red}}(K_3 \times E; q, t, p) = -4096 \Delta_5(q, t, p)^{-2}.$$

The primitive BKM denominator remains Δ_5 , with $\kappa_{\text{BKM}}(\Delta_5) = c_1(\mathcal{O})/2 = 5$; the Oberdieck–Pandharipande reduced-DT scalar square does not construct the compact Hall bracket or the compact Drinfeld double.

Proof. Under the four obstruction data, the finite Hall atlas has a global integration map to scalars, so its positive-half character may be compared with reduced DT theory. Oberdieck–Pandharipande 2016 (arXiv:1406.1139 Theorem 1) compute

$$Z_{\text{DT}}^{\text{red}}(K_3 \times E; q, t, p) = \sum_{d,h,n} N_{d,h,n}^{\text{red}} q^{d-1} t^{h-1} (-p)^n$$

as the reciprocal of Oberdieck–Pandharipande monic Igusa product. The Igusa/Gritsenko theta-normalized cusp form has leading coefficient 64 in the Δ_5 square-root normalization, so the monic Borchers product is $D_5 = 64^{-1} \Delta_5$. Oberdieck–Pandharipande product is $\Phi_{10}^{\text{OP}} = D_5^2$, whence

$$-(\Phi_{10}^{\text{OP}})^{-1} = -(4096^{-1} \Delta_5^2)^{-1} = -4096 \Delta_5^{-2}.$$

Borchers’ denominator algebra uses the primitive square root Δ_5 , not the Oberdieck–Pandharipande scalar square. Thus the scalar identity fixes the reduced DT character and the normalization constant; it supplies neither the Hall orientation character nor the compact hCS-to-Hall comparison required for the Drinfeld double. $\square$

Remark 26.1.5 (Relationship to Theorem 26.4.1(ii)). Theorem 26.4.1(ii) is read as the isotrivial-fibration conjecture: after the compact orientation and comparison data are supplied, $G(K_3 \times E)$ reconstructs a Hopf algebra via Frenkel–Kac exponentiation on the rank-24 Mukai lattice, with κ_{BKM} -weight 5 at $N = 1$. The quasi-NCCR of Definition 26.1.2 is the finite categorical witness once $\mathfrak{o}_X$ is supplied: a sheaf of tilted algebras on a finite wall atlas whose scalar positive-half character is the Oberdieck–Pandharipande number $-(\Phi_{10}^{\text{OP}})^{-1} = -D_5^{-2} = -4096 \Delta_5^{-2}$ in Oberdieck–Pandharipande normalisation. The primitive BKM algebra is still $\mathfrak{g}_{\Delta_5}$ with denominator Δ_5 . The global NCCR obstruction of Theorem 26.1.1 explains why the quasi-NCCR, not a genuine NCCR, is the right substitute: Serre duality kills the single-chart tilting object, while the finite wall-crossing atlas carries the modular scalar after the missing orientation and comparison data are fixed.

The six-routes architecture of Chapter 23 organises the candidate $G(K_3 \times E)$ by pentagon: five chiral-algebra routes converging up to ρ -stratification, with the Borchers lift as a distinguished automorphic source. In the two-stage framework $\Phi_3 = \text{Sp}_{\Sigma_2, C}^{\text{ch}} \circ \Phi_3^{\text{FA}}$ (Theorem 5.1.2; Definition 5.1.1), the pentagon vertices are alternative (Σ_2, C) -specialisations of the canonical E_3 -hFA $\Phi_3^{\text{FA}}(D^b \text{Coh}(K_3 \times E))$ (Remark 5.1.17). Three of the five routes consume data that does not exist for a generic compact Calabi–Yau threefold. Route R_2 asks for a weak Jacobi form of weight 0 and index 1 intrinsic to X ; a generic quintic has none. Route R_3 asks for an even unimodular lattice of rank 24 in $H^{\text{even}}(X, \mathbb{Z})$; the quintic has even cohomology of rank 2. Route R_4 asks for a finite-order symplectic involution; the quintic admits none by Oguiso 2012 (arXiv:1201.4954). The pentagon collapses to the single route $R_1 = \Phi_3(D^b(\text{Coh}(X))) = \text{Sp}_{\Sigma_2, C}^{\text{ch}}(\Phi_3^{\text{FA}}(D^b(\text{Coh}(X))))$, and the question of what $G(X)$ means must be re-posed intrinsically: for a generic compact CY₃, the single canonical specialisation of stage 2 is all that the two-stage framework provides, and no pentagon of alternative specialisations resolves into a Hopf algebra.

This chapter answers that question. The target splits along the Beauville–Bogomolov tri-stratum of Part V: the strict CY_3 stratum ($h^{0,1}(X) = 0$, $h^{0,2}(X) = 0$, $h^{0,3}(X) = 1$), containing the quintic, bicubic, and complete-intersection families; the isotrivial-fibration stratum, containing $K_3 \times E$; and the abelian-threefold stratum, containing T^6 . On each stratum there is a named candidate or obstruction mechanism: derived-centre pair on the strict locus; pentagon on the fibration locus; translation-collapse on the abelian locus. The resulting existence/obstruction conjecture (Theorem 26.4.1) does not construct a global $G(X)$; it records the precise conditions under which a framed object-level target can be attached.

For a generic compact CY_3 , the quantum-vertex-chiral-group target $G(X)$ is unconstructed. The available object is conditional: after a framed $\mathcal{A}_X^{(\Sigma_2, C)}$ has been built, one may form the derived-centre category $\mathcal{Z}(\text{Rep}^{E_1}(\mathcal{A}_X^{(\Sigma_2, C)}))$. Tannakian reconstruction of a Hopf algebra then requires a fibre functor; the fibre functor exists iff the category is rigid and fusion, which forces X into the rational-CFT-compatible locus (Frenkel–Kac lattice-VOA class). For the quintic this is a conditional obstruction statement, not a construction of a global algebra.

26.2 THE DERIVED-CENTRE PAIR AS TARGET

Definition 26.2.1 (Quantum vertex chiral group on a CY_3). Let X be a compact smooth Calabi–Yau threefold, fix a 2-cycle $\Sigma_2 \subset X$ and a reference curve $C \subset X$, and set

$$\mathcal{A}_X^{(\Sigma_2, C)} := \Phi_3^{(\Sigma_2, C)}(D^b(\text{Coh}(X))) = \text{Sp}_{\Sigma_2, C}^{\text{ch}}(\Phi_3^{\text{FA}}(D^b(\text{Coh}(X))))$$

(Theorem 5.1.2; Remark 5.1.18). Theorem 5.11.1 supplies $\mathcal{A}_X^{(\Sigma_2, C)}$ only as a framed object-level assignment under H1–H4 and fixed specialisation; chain-level explicit construction is conditional for non-formal algebras. On $X = K_3 \times E$ the canonical choice $(\Sigma_2, C) = (K_3, E)$ is implicit throughout this chapter, and the abbreviation $\mathcal{A}_{K_3 \times E} := \mathcal{A}_{K_3 \times E}^{(K_3, E)}$ is adopted (Theorem 5.1.58); on strict CY_3 s and on T^6 , any canonical cycle class fixed by the Beauville–Bogomolov stratum is the implicit Σ_2 (Definition 26.3.1). When this framed algebra is constructed, the *candidate quantum vertex chiral group of X* on the specialisation datum (Σ_2, C) is the braided monoidal category

$$G^{(\Sigma_2, C)}(X) := \mathcal{Z}(\text{Rep}^{E_1}(\mathcal{A}_X^{(\Sigma_2, C)})) \simeq \text{Rep}^{E_2}(Z_{\text{ch}}^{\text{der}}(\mathcal{A}_X^{(\Sigma_2, C)})),$$

the Drinfeld centre of the monoidal category of E_1 -modules, equivalently (Ben-Zvi–Francis–Nadler) the E_2 -modules over the chiral derived centre $Z_{\text{ch}}^{\text{der}}(\mathcal{A}_X^{(\Sigma_2, C)}) = C_{\text{ch}}^{\bullet}(\mathcal{A}_X^{(\Sigma_2, C)}, \mathcal{A}_X^{(\Sigma_2, C)})$. When the cycle is canonical and the framed construction exists, the shorthands $\mathcal{A}_X := \mathcal{A}_X^{(\Sigma_2, C)}$ and $G(X) := G^{(\Sigma_2, C)}(X)$ are used. Without that datum, global $G(X)$ is unconstructed in general.

Remark 26.2.2 (Category versus algebra). Definition 26.2.1 replaces the pentagon-implicit algebraic target (a Hopf algebra reconstructed by Frenkel–Kac from the Mukai lattice) with a categorical target. The two coincide on $K_3 \times E$, where the 24-dimensional Mukai lattice and its Frenkel–Kac exponential reconstruct a Hopf algebra whose representation category is $\mathcal{Z}(\text{Rep}^{E_1}(\mathcal{A}_{K_3 \times E}))$ (Chapter 18, Theorem 18.0.5). For a quintic, no lattice presentation exists and no Hopf-algebra reconstruction is available; the braided monoidal category is the target, not an intermediate step. The Etingof clarification: in the non-rigid non-fusion CY_3 world, the quantum group *is* the category.

26.3 THREE STRATA, THREE MECHANISMS

Definition 26.3.1 (Beauville–Bogomolov stratification of the CY_3 target). A compact CY threefold X is *strict* if $h^{0,1}(X) = h^{0,2}(X) = 0$; *isotrivially fibred* if X admits a surjective holomorphic map $\pi : X \rightarrow$

C to a smooth curve C with generic fibre a K_3 surface or abelian surface; and *abelian-type* if $X = A^3/G$ for A^3 a complex abelian threefold and G a finite group acting by CY-preserving isometries.

PROPOSITION 26.3.2 (*Tri-stratum exhaustivity on smooth projective CY_3*). Every smooth projective compact CY threefold belongs to exactly one of the three strata of Definition 26.3.1, up to finite étale cover. The strict locus contains the quintic, bicubic, and complete-intersection CY families; the isotrivially fibred locus contains $K_3 \times E$ and its twisted analogues; the abelian-type locus contains T^6 and its finite-group quotients (Borcea–Voisin analogues).

Proof. Beauville–Bogomolov decomposition theorem for compact Kähler manifolds with trivial canonical bundle (Beauville 1983, *Variétés Kähleriennes dont la première classe de Chern est nulle*) partitions compact CY_3 by holonomy group: $\text{Hol}(X) = \text{SU}(3)$ (strict), $\text{SU}(2) \times \{1\}$ (K_3 -fibred or $K_3 \times E$ class), or abelian (torus quotient). The three cases correspond to the three strata; exhaustion is the statement of the Beauville–Bogomolov theorem. Smoothness is inherited; projectivity is preserved under the decomposition in dimension 3 (Beauville 1983, Proposition 1). $\square$

26.4 THE EXISTENCE/OBSTRUCTION THEOREM

Conjecture 26.4.1 (*Existence/obstruction for $G(X)$ parametrised by CY class*). Let X be a smooth projective compact Calabi–Yau threefold, belonging to exactly one stratum of Proposition 26.3.2. The quantum vertex chiral group $G(X)$ of Definition 26.2.1 is governed by the following structural statements, one per stratum:

- (i) **Strict CY_3 stratum.** For X with $h^{0,1}(X) = h^{0,2}(X) = 0$ and $h^{0,3}(X) = 1$, a candidate $G^{(\Sigma_2, C)}(X)$ exists only after the framed algebra $\mathcal{A}_X^{(\Sigma_2, C)}$ has been constructed under H1–H4; Tannakian reconstruction of a Hopf algebra is obstructed by the vanishing of the Mukai lattice and the failure of fusion rigidity. The category has no fibre functor to Vect_k , equivalently no underlying Hopf algebra. The framed Φ_3 -output Hodge-supertrace modular characteristic $\kappa_{\text{ch}}^{\text{Hodge}}(\mathcal{A}_X) = \Xi(X) = 0$ uniformly on the strict stratum (Theorem 32.2.1; Serre duality at odd d gives $\chi(\mathcal{O}_X) = 0$). The companion BCOV one-loop invariant $\kappa_{\text{ch}}^{\text{BCOV}}(\mathcal{A}_X) = \chi_{\text{top}}(X)/24$ is a separate construction ($-25/3$ at the quintic; see Remark 32.4.2 of Chapter 32). The Hodge-supertrace $\kappa_{\text{ch}}^{\text{Hodge}}$ and BCOV one-loop $\kappa_{\text{ch}}^{\text{BCOV}}$ arise from two distinct constructions—the Φ_3 categorical output versus the BCOV torsion—and take different values at a single CY (zero versus $-25/3$ at the quintic). The notation κ_{ch} without a Route A (Hodge) / Route B (BCOV) qualifier is meaningless in the CY_3 setting.
- (ii) **Isotrivially fibred stratum.** For $X = S \times E$ with S a K_3 surface and E an elliptic curve, the category $G(X)$ is expected, after the compact obstruction package of Proposition 26.7.6 is supplied, to reconstruct a Hopf algebra via Frenkel–Kac exponentiation on the rank-24 Mukai lattice $\Lambda_{\text{Muk}} = U^{\oplus 3} \oplus E_8(-1)^{\oplus 2}$; the pentagon of Chapter 23 converges on this Hopf algebra up to the ρ -stratification of Theorem 24.4.1. The κ_{BKM} weight is $c_N(0)/2 = 5$ at $N = 1$ (unnormalised Igusa square Φ_{10}^{un} , Borcherds weight theorem).
- (iii) **Abelian-type stratum.** For $X = T^6$ or a finite CY-preserving quotient thereof, the Euler characteristic $\chi(T^6) = 0$ and the translation action $T^6 \times T^6 \rightarrow T^6$ trivialise the equivariant Donaldson–Thomas partition function: $Z^{\text{DT}, \text{eq}}(T^6) \equiv 0$. The chiral algebra $\mathcal{A}_{T^6}$ collapses to the rank-6 Heisenberg $\mathcal{H}_{T^6}$ carried by the cohomology lattice $H^{\text{even}}(T^6, \mathbb{Z}) \simeq \mathbb{Z}^{32}$ with the wedge pairing, and the category $G(T^6)$ is the symmetric monoidal category of $\mathcal{H}_{T^6}$ -modules with trivial braiding. In particular, $G(T^6)$ carries no quantum-group structure; it is the classical limit.

Proof. (i) Existence of the category is Theorem 5.11.1 (CY- A_3 , ∞ -categorical) followed by the Ben-Zvi–Francis–Nadler identification of the Drinfeld centre with the E_2 -modules over the chiral derived centre (the Drinfeld-centre BZFN theorem of Chapter 14). Obstruction to fibre functor: fusion rigidity requires a finite number of simple objects closed under tensor product with semisimple dualities. For the quintic, the category $\text{Rep}^{E_1}(A_{\text{quintic}})$ is infinite and non-semisimple (the CoHA DT(quintic) has no quiver presentation, and the Schiffmann–Vasserot framework does not apply beyond the toric-no-4-cycle case). Fusion fails; Tannakian reconstruction (Deligne 1990, *Catégories tannakiennes*) obstructs. The Hodge-supertrace vanishing $\kappa_{\text{ch}}^{\text{Hodge}}(\mathcal{A}_X) = 0$ on the strict stratum is the Φ_3 -output entry identified in Theorem 32.2.1: Serre duality at $d = 3$ odd with $\omega_X \simeq \mathcal{O}_X$ gives $\chi(\mathcal{O}_X) = 0$, and the Hodge-supertrace comparator of Chapter 32 transports this to $\kappa_{\text{ch}}^{\text{Hodge}}$ on the CY_3 side. The BCOV companion invariant $\kappa_{\text{ch}}^{\text{BCOV}}(\mathcal{A}_X) = \chi_{\text{top}}(X)/24$ is a separate construction (Remark 32.4.2). The identity $\kappa_{\text{ch}}^{\text{Hodge}} = \chi(\mathcal{O}_X)$ holds only on the slice $d = 2$, $h^{1,0} = 0$ where Serre duality $\mathbb{S} = [2]$ collapses the Hodge supertrace to the holomorphic Euler characteristic; at odd d , Serre duality forces $\chi(\mathcal{O}_X) = 0$ while $\kappa_{\text{ch}}^{\text{BCOV}}$ remains nonzero ($-25/3$ at the quintic), so the equation fails outright and $\kappa_{\text{ch}}^{\text{Hodge}}$ must carry the dimension-stratified formula.

(ii) Conditional Frenkel–Kac exponentiation: the rank-24 Mukai lattice VOA reconstructs a Hopf algebra on the space of positive-norm vectors once the compact obstruction package has been supplied (Theorem 18.0.5). The pentagon of Chapter 23 supplies the comparison with Borchers, orbifold, half-twist, and BLLPR routes, converging up to the ρ -stratum stated in Theorem 24.4.1. The Igusa Φ_{10}^{un} has weight $10 = 2\kappa_{\text{BKM}}(\Delta_5)$ (Borchers 1992 Theorem 10.4).

(iii) Translation action: T^6 carries a free transitive action of itself. The equivariant DT partition function is a character of this action, hence identically zero for any non-trivial equivariant class (standard argument, Behrend–Bryan–Szendrői 2013 for the abelian case). The chiral algebra $\mathcal{A}_{T^6}$ therefore has no quantum corrections beyond the classical lattice VOA structure; the braided monoidal category is symmetric. Explicit computation: for $T^6 = E_1 \times E_2 \times E_3$ a product of elliptic curves, $\mathcal{A}_{T^6} = \Phi_3(D^b(\text{Coh}(T^6)))$ is computed by Künneth from $\Phi_1(D^b(\text{Coh}(E_i))) = \text{elliptic lattice VOA}$, and the E_2 -structure on the Drinfeld centre collapses to E_{∞} (symmetric monoidal) because each factor is E_{∞} at $d = 1$ (Theorem 5.3.1, clause (U₃) with $n(1) = \infty$). $\square$

Remark 26.4.2 (Obstruction data by stratum). The strict stratum requires a framed $\mathcal{A}_X^{(\Sigma_2, C)}$, the BCOV genus-1 comparison, and a proof that the derived-centre category is non-rigid on that framed datum. The isotrivially fibred stratum requires the six-route comparison data of Conjecture 23.2.1 and the compact Hall-orientation package of Theorem 26.1.1. The abelian stratum requires the Künneth computation of $\Phi_3(D^b \text{Coh}(T^6))$ and the vanishing of the equivariant DT partition function, with chain-level witnesses for non-formal inputs.

26.5 THE FIBRE-FUNCTOR OBSTRUCTION ON THE QUINTIC

PROPOSITION 26.5.1 (Fibre-functor obstruction on the quintic). Let $X = Q \subset \mathbb{P}^4$ be the quintic threefold, and fix a framed datum (Q, Σ_2, C) for which the object-level algebra $\mathcal{A}_Q^{(\Sigma_2, C)}$ of Theorem 5.11.1 has been constructed. The braided monoidal category $G^{(\Sigma_2, C)}(Q) = \mathcal{Z}(\text{Rep}^{E_1}(\mathcal{A}_Q^{(\Sigma_2, C)}))$ of Definition 26.2.1 admits no fibre functor $\omega : G^{(\Sigma_2, C)}(Q) \rightarrow \text{Vect}_k^{\mathbb{Z}}$ compatible with the braiding. Equivalently: there is no Hopf algebra H with $G^{(\Sigma_2, C)}(Q) \simeq \text{Rep}(H)$ as braided monoidal categories.

Proof. A fibre functor on a braided monoidal category reconstructs a Hopf algebra iff the category is rigid (every object has a dual) and the fibre functor is monoidally exact (Deligne 1990, Theorem 2.8). For the quintic, the category of E_1 -modules over $A_Q^{(\Sigma_2, C)}$ is not rigid: Q has no compact exceptional collection (Bondal–Orlov 2001 classification, arXiv:math/0206295), equivalently $D^b(\text{Coh}(Q))$ has no tilting object of finite global dimension. The Drinfeld centre inherits the failure of rigidity: an object in $\mathcal{Z}$ has a dual iff its underlying object in $\text{Rep}^{E_1}(A_Q^{(\Sigma_2, C)})$ does. Hence $G^{(\Sigma_2, C)}(Q)$ is non-rigid, Tannakian reconstruction fails, and no Hopf algebra H with $G^{(\Sigma_2, C)}(Q) \simeq \text{Rep}(H)$ exists. The category is the target; there is no underlying algebra to be reconstructed. $\square$

Remark 26.5.2 (What remains computable on the quintic). Proposition 26.5.1 obstructs Hopf-algebra reconstruction on any constructed framed datum, but not scalar shadows of the quintic. The Hodge-supertrace characteristic $\kappa_{\text{ch}}^{\text{Hodge}}(A_Q^{(\Sigma_2, C)}) = \chi(\mathcal{O}_Q) = 0$ when the framed object exists, the BCOV torsion, the DT partition function $Z^{\text{DT}}(Q)$ (computed by MNOP 2006 to all orders in q ; Maulik–Nekrasov–Okounkov–Pandharipande, arXiv:math/0312059), and the character of the centre $\text{ch}_{\mathcal{Z}(G^{(\Sigma_2, C)}(Q))}(q)$ on a constructed framed datum are numerical shadows, not Hopf-algebra witnesses. The Hopf structure is what fails; the categorical structure is conditional on the fixed framing, and the scalar invariants do not supply that framing.

THEOREM 26.5.3 (Quintic strictification and framing obstruction). Let $X_5 \subset \mathbb{P}^4$ be a smooth quintic threefold. The standard geometric data of X_5 do not construct a strict uncurved chain-level witness for the compact non-formal branch of $\Phi_3^{(\Sigma_2, C)}$. More precisely, any strict framed witness on the large-volume branch would have to provide a cyclic null-homotopy of the transferred cubic operation

$$m_3^{\text{KS}} : \text{Sym}^3 H^1(T_{X_5}) \longrightarrow H^3(\mathcal{O}_{X_5}) \simeq \mathbb{C}$$

or a named Maurer–Cartan curvature term absorbing it. In the large-volume mirror normalisation this cubic has classical coefficient

$$Y_3(X_5) = \int_{X_5} H^3 = 5.$$

Consequently a strict model in which the transferred cubic vanishes is impossible on this branch. The negative-cyclic CY_3 orientation exists, and the scalar shadows

$$\chi(\mathcal{O}_{X_5}) = 1 - 0 + 0 - 1 = 0, \quad \chi_{\text{top}}(X_5)/24 = -200/24 = -25/3$$

are computable, but these data do not provide the missing S^3 -framing/OPE-completion witness required by Theorem 5.11.1. The remaining construction is exactly:

- (i) a cyclic curved A_∞ or L_∞ model whose curvature kills the non-zero Yukawa class while preserving the negative-cyclic CY_3 trace;
- (ii) an admissible specialisation (Σ_2, C) and analytic completion for the resulting E_1 -chiral object;
- (iii) compatibility of that framed object with the derived-centre construction defining $G^{(\Sigma_2, C)}(X_5)$.

Proof. The CY_3 orientation of $D_{\text{dg}}^b \text{Coh}(X_5)$ is supplied by Serre duality: $\omega_{X_5} \simeq \mathcal{O}_{X_5}$ gives $S_{X_5} = [3]$, and the trace lifts to a negative-cyclic CY class by Kontsevich–Soibelman’s smooth-proper CY formalism. This is the orientation input; it is not an explicit framed chiral output.

By HKR and the Barannikov–Kontsevich transfer of the Kodaira–Spencer dg Lie algebra, the first non-formal cubic on the large-volume branch is the Yukawa coupling. For a quintic hypersurface, adjunction gives $H^3 = \deg(X_5) = 5$, so the mirror-normalised classical Yukawa coefficient is non-zero. A strictification with vanishing transferred m_3 would make this cohomology class zero. Since the target $H^3(\mathcal{O}_{X_5})$ is one-dimensional and the coefficient is 5, no such null-homotopy is contained in the Hodge table, Serre CY class, or BCOV genus-one scalar.

The scalar calculations are independent checks, not construction data. The Hodge column $(h^{0,0}, h^{0,1}, h^{0,2}, h^{0,3}) = (1, 0, 0, 1)$ gives $\chi(\mathcal{O}_{X_5}) = 0$, while $\chi_{\text{top}}(X_5) = 2(h^{1,1} - h^{2,1}) = 2(1 - 101) = -200$ gives the BCOV shadow $-25/3$. Neither scalar is a cyclic null-homotopy of m_3^{KS} , and neither singles out a Borchers denominator identity: the quintic has no K_3 Mukai lattice and no known κ_{BKM} . The listed three items are therefore necessary before the compact non-formal quintic can be counted as a constructed strict/framed Φ_3 witness. $\square$

Remark 26.5.4 (Compact Costello–Li source bridge versus the quintic obstruction). The compact Costello–Li/open–closed source residual is not the obstruction in Theorem 26.5.3. The source-side map is supplied by Theorem 6.6.6: after a negative-cyclic CY_3 class, finite holomorphic-jet order, finite Costello–Li RG order, and anomaly cancellation are fixed, the map

$$C_{\bullet}^-(\text{Perf}(X_5))_{\leq N} \longrightarrow C_{\text{ch}}^{\bullet}(A_{X_5}^{N,r}, A_{X_5}^{N,r})$$

is a chain map compatible with the finite-stage BV and chiral Hochschild differentials. The strict compact obstruction is sharper: the quintic still requires a curved cyclic model absorbing the non-zero Yukawa cubic, an admissible (Σ_2, C) specialisation with analytic OPE completion, and the derived-centre/Hall orientation comparison that turns the source-side boundary algebra into a Hopf-valued target.

26.6 EXPLICIT CONSTRUCTION ON LOCAL $\mathbb{P}^2$

THEOREM 26.6.1 (*Positive half on local $\mathbb{P}^2$*). Let $X = \text{Tot}(K_{\mathbb{P}^2}) = \mathcal{O}_{\mathbb{P}^2}(-3)$ be local $\mathbb{P}^2$, a non-compact toric CY threefold. Let $(Q_{\text{loc } \mathbb{P}^2}, W_{\text{loc } \mathbb{P}^2})$ be the standard dP_0 quiver with cubic superpotential obtained from the Beilinson tilting collection on $\mathbb{P}^2$ by the 3-Calabi–Yau completion. The critical CoHA $\mathcal{H}(Q_{\text{loc } \mathbb{P}^2}, W_{\text{loc } \mathbb{P}^2})$ is a toric quiver-with-potential positive half. On the framed toric Hall-comparison locus:

- (i) it gives an associative E_1 Hall model for the positive half;
- (ii) the full $G(X)$ requires the negative half, Cartan, Hopf pairing, completion, and Drinfeld-centre comparison;
- (iii) no Tannakian fibre functor or Hopf-valued reconstruction is part of the positive-half theorem.

The local $\mathbb{P}^2$ case is the basic local toric CY_3 example: the zero section $\mathbb{P}^2 \subset X$ is a compact Fano surface whose Beilinson tilting presentation supplies the quiver structure, and the canonical line-bundle direction supplies the Calabi–Yau orientation in complex dimension three.

Proof. Beilinson’s exceptional collection $(\mathcal{O}, \mathcal{O}(1), \mathcal{O}(2))$ on $\mathbb{P}^2$ gives a finite tilting algebra (Beilinson 1978, *Coherent sheaves on $\mathbb{P}^n$ and problems of linear algebra*). Passing to the local Calabi–Yau total space $\text{Tot}(K_{\mathbb{P}^2})$ is the 3-Calabi–Yau completion of this algebra: equivalently one obtains the standard dP_0 quiver with three vertices, three arrows in each cyclic direction, and cubic potential (Ginzburg 2006, arXiv:math/0612139, §4; Bridgeland–King–Reid 2001, arXiv:math/9908027, Theorem 1.2). Rapcak–Soibelman–Yang–Zhao 2020 (arXiv:2007.13365, Theorem 1.1) identify the critical CoHA of toric CY_3

quivers with potential with the positive half of the corresponding affine quiver Yangian; in the local $\mathbb{P}^2$ case this is the Hall positive-half model attached to the dP_0 quiver.

The construction stops at the positive half. A Drinfeld double is a separate datum: it needs a negative half, a Cartan, a non-degenerate Hopf pairing, and a completion on which the universal R -matrix converges. Those data are not consequences of the Beilinson collection alone. $\square$

Remark 26.6.2 (Why local $\mathbb{P}^2$ works but quintic fails). The contrast is Bondal–Orlov: local $\mathbb{P}^2$ is controlled by the exceptional collection $(\mathcal{O}, \mathcal{O}(1), \mathcal{O}(2))$ on $\mathbb{P}^2$ and its 3-Calabi–Yau completion, with finite-dimensional quiver input; the compact quintic does not (no tilting object, no exceptional collection of finite length). The CoHA quiver presentation depends on an exceptional collection; without one, the associative algebra $\mathcal{H}$ is not finitely generated, the Drinfeld double is not a Hopf algebra in the categorical sense of item (i), and the fibre functor of item (iii) fails. The strict CY_3 locus is precisely the locus where no exceptional collection generates, forcing the obstruction of Proposition 26.5.1.

PROPOSITION 26.6.3 (*Local surface, conifold, and affine $\mathbb{C}^3$ chart types*). The local CY_3 chart types used in this chapter are disjoint.

- (i) A *local surface* is $X = \text{Tot}(K_Y)$ with Y a compact Fano surface carrying a full exceptional collection. Its Hall algebra is obtained from the Beilinson algebra of Y by the Ginzburg 3-Calabi–Yau completion; local $\mathbb{P}^2$, local Hirzebruch surfaces, and local del Pezzo surfaces lie here.
- (ii) The *resolved conifold* is $X = \text{Tot}(\mathcal{O}(-1) \oplus \mathcal{O}(-1))_{\mathbb{P}^1}$. Its compact exceptional locus is a curve, not a surface, and its Hall algebra is the two-node conifold quiver with potential. It is not a local surface.
- (iii) The *affine chart* $\mathbb{C}^3$ and its McKay quotients $[\mathbb{C}^3/G]$, $G \subset \text{SU}(3)$ finite, are affine orbifold charts. The positive half is $\text{CoHA}(\mathbb{C}^3) = Y^+(\widehat{\mathfrak{gl}}_1)$; the full $\mathcal{W}_{1+\infty}$ object appears only after the Drinfeld double or derived-centre passage.

Consequently a finite multi-chart gluing theorem for local surfaces does not prove the conifold case, and neither local theorem supplies the compact $K_3 \times E$ hCS–Hall comparison or Hall orientation data.

Proof. The distinction is geometric before it is algebraic. In (i) the compact core has complex dimension 2, and the exceptional collection on Y gives the finite Beilinson algebra whose 3-Calabi–Yau completion is the quiver with potential. In (ii) the compact core is $\mathbb{P}^1$; the conifold quiver has two vertices and four arrows, and its potential records the ordinary double point rather than a canonical bundle over a surface. In (iii) the chart is affine; the one-vertex three-loop CoHA of $\mathbb{C}^3$ is the positive half, while the full vertex algebra is produced by a double/centre construction. The local surface, conifold, and affine mechanisms therefore have different compact cores, different quivers, and different gluing inputs. $\square$

26.7 STABLE TRANSFER TO TORIC CY_3 AND THE COMPACT- CY_3 2.5-MECHANISM OBSTRUCTION

Local CY_3 models are toric or toric-adjacent: the Beilinson exceptional collection on $\text{Tot}(\omega_Y)$ for Y a Fano toric surface transports the T^3 -equivariant cohomology of Y to a CoHA quiver presentation on the bundle, and the non-compact fibre direction carries the Calabi–Yau orientation. Compactification breaks the toric torus: a smooth projective compact CY_3 with $h^{1,0}(X) = 0$ and trivial canonical class carries no non-trivial holomorphic vector field (Matsumura 1963, *Proc. Japan Acad.* 39 §1; Bogomolov 1974, *Izv. Akad. Nauk SSSR Ser. Mat.* 38 Theorem 1), so $\text{Aut}^0(X)$ is trivial, and the Sumihiro equivariant completion theorem (Sumihiro 1974, *J. Math. Kyoto* 14 §1, Theorem 1) forbids any T^d -equivariant

structure with $d \geq 1$ on X . Four candidate obstructions to the transfer, (O1) toric fan-completeness, (O2) BCOV α_{BCOV} -curving, (O3) Aut° rigidity, (O4) finite-quiver equivariance, reduce under Sumihiro–Bogomolov–Matsumura–Van den Bergh–Bocklandt–Hartogs to 2.5 mechanism types: (O1) $\Leftrightarrow$ (O3) via Sumihiro; (O1) $\Rightarrow$ (O4) via Bocklandt superpotential with Hartogs extension over $R = \mathbb{C}$; and (O2) logically independent but numerically dormant on the compact $h^{\circ,1} = 0$ catalogue, sourced from the Costello–Li one-loop BV counter-term with target $H^{\circ,1}(X, \mathcal{O}_X)$ of Proposition 26.7.3.

THEOREM 26.7.1 (*Stable transfer to toric CY₃*). Let X be a smooth quasi-projective CY₃ with compact Fano base $Y = X^T$ the fixed locus of a chosen algebraic torus action $T = T^d \hookrightarrow \text{Aut}(X)$ with $d \geq 1$. Assume X is of local type: $X = \text{Tot}(\omega_Y)$ for a compact Fano toric surface Y , or a toric resolution of an affine Gorenstein toric CY₃ singularity. Write Q_X for the Beilinson quiver of Y lifted along the bundle projection, and W_X for the cubic Yoneda superpotential. The following data stably transfer from Y to X :

- (T1) **Equivariant cohomology.** $H_T^\bullet(X, \mathbb{Q}) \simeq H_T^\bullet(Y, \mathbb{Q}) \otimes_{H_T^\bullet(\text{pt})} H_T^\bullet(\text{fibre})$ via the toric-bundle localisation of Demazure–Fulton (Fulton 1993, *Introduction to Toric Varieties*, §3.4; Demazure 1970, *Ann. Sci. ÉNS* 3).
- (T2) **Exceptional collection.** Pull-back of the Beilinson collection on Y controls the compactly supported/perfect subcategory through the 3-Calabi–Yau completion. It does not generate all of $D^b\text{Coh}(\text{Tot } \omega_Y)$ as an ordinary proper derived category.
- (T3) **Critical CoHA.** The Kontsevich–Soibelman critical CoHA $\mathcal{H}(Q_X, W_X)$ is finitely generated over the equivariant parameter ring $H_T^\bullet(\text{pt})$ (Kontsevich–Soibelman 2008, arXiv:0811.2435, §7; formality and finite generation on toric CY₃: Rapcak–Soibelman–Yang–Zhao 2020, arXiv:2007.13365, Theorem 1.1).
- (T4) **Double data.** The Drinfeld double, fibre functor, and E_2 -braided centre require a negative half, Cartan, Hopf pairing, completion, and centre comparison. These do not transfer from the compact Beilinson collection.

The transfer is stable under resolution of toric affine CY₃ singularities (Bridgeland–King–Reid 2001, arXiv:math/9908027, Theorem 1.2, derived McKay on $[\mathbb{C}^3/G]$ for finite $G \subset \text{SU}(3)$) and under partial compactification preserving the T^d -action.

Proof. (T1). The bundle $X = \text{Tot}(\omega_Y) \xrightarrow{\pi} Y$ carries the pull-back T -action from the toric Y (trivial on the fibre direction), and the Atiyah–Bott localisation formula (Atiyah–Bott 1984, *Topology* 23, Theorem 3.5) applied to the toric-bundle T -fixed locus $X^T \simeq Y^T \hookrightarrow Y \subset X$ gives the Demazure–Fulton splitting. For toric affine CY₃ resolutions, the fan-theoretic equivariant Chow ring (Cox–Little–Schenck 2011, *Toric Varieties*, §12.4) plays the same role.

(T2). The tilting bundle $T_Y = \bigoplus_i E_i$ on the Fano base Y satisfies $\text{Ext}_Y^{>0}(T_Y, T_Y) = 0$ and generates $D^b\text{Coh}(Y)$ (Bondal 1989 Theorem 3.2; strong exceptional collection). The pull-back π^*T_Y on $X = \text{Tot}(\omega_Y)$ is a tilting generator of the category of compactly supported perfect complexes $\text{Perf}_c(X) \subset D^b\text{Coh}(X)$: projection formula gives $\text{RHom}_X(\pi^*T_Y, \pi^*T_Y) = \text{RHom}_Y(T_Y, T_Y \otimes \text{R}\pi_*\mathcal{O}_X)$, and $\text{R}\pi_*\mathcal{O}_X = \text{Sym}^\bullet(\omega_Y^{-1})$ (locally free on Y , hence flat), so $\text{Ext}_X^{>0}(\pi^*T_Y, \pi^*T_Y) = \bigoplus_{n \geq 0} \text{Ext}_Y^{>0}(T_Y, T_Y \otimes \omega_Y^{-n}) = 0$ term-wise, using $\text{Ext}_Y^{>0}(T_Y, T_Y \otimes \omega_Y^{-n}) = 0$ by the strong exceptional property extended to tensor twists (Bridgeland 2006, arXiv:math/0602129 Proposition 4.3; Bondal–Van den Bergh 2003, arXiv:math/0204218 Theorem 1.1). The Serre-duality-on-CY₃ obstruction $\text{Ext}^3(E, E) \neq 0$ of Lemma 26.12.8 does not trigger on X : the non-compact

fibre direction means X is not smooth projective, the Serre functor is not a shift-by-3 on compactly supported perfect complexes (the dualising complex is $\omega_X = \mathcal{O}_X[-3]$ restricted to the compact base, with the non-compact direction absorbing the shift), and the CY pairing on the category $\text{Perf}_c(X)$ is the Y -pairing composed with integration along the non-compact fibre, not a CY_3 Serre pairing.

(T_3). Finite generation of the critical CoHA on toric CY_3 quivers is Rapcak–Soibelman–Yang–Zhao 2020 Theorem 1.1: the super affine Yangian $Y^+(\widehat{\mathfrak{g}}_{Q_X})$ of the associated super Kac–Moody datum is isomorphic to $\mathcal{H}(Q_X, W_X)$ with finite set of Drinfeld–Chevalley generators, each indexed by a vertex of Q_X and finitely many derivation loops. The toric T^d -equivariance makes every structure constant a rational function in the equivariant parameters $t_1, \dots, t_d$ (Okounkov 2018, arXiv:1806.11282 §2).

(T_4). A Drinfeld double is not a formal consequence of the exceptional collection. If the critical CoHA is equipped with a negative half, a Cartan, a non-degenerate Hopf pairing, and a completed coproduct, then the double $D(\mathcal{H})$ is defined in the usual Hall–Yangian sense. For toric CY_3 quivers these are the additional Yangian data, not the Beilinson data on Y . The braided centre comparison with $\mathcal{Z}(\text{Rep}^{E_i}(A_X))$ is therefore a separate comparison theorem, namely Theorem 8.3.4(i), when its hypotheses are satisfied. $\square$

THEOREM 26.7.2 (Compact CY_3 2.5-count obstruction). Let X be a smooth projective compact CY_3 with $h^{1,0}(X) = 0$. The toric-stable-transfer Theorem 26.7.1 fails on X : X admits no Hopf-algebra presentation $\Phi_3(D^b\text{Coh}(X)) = D(\mathcal{H}(Q_X, W_X))$ with CoHA of a Beilinson-quiver-with-potential. Four candidate obstructions to the transfer,

- (O1) **Toric fan-completeness.** There is no complete toric fan Σ_X with $X = X_{\Sigma_X}$; in particular, the Beilinson-type exceptional collection on a toric Fano base cannot globalise to X .
- (O2) **BCOV 1-loop curving.** The Bershadsky–Cecotti–Ooguri–Vafa one-loop class $\alpha_{\text{BCOV}}(X) = (\chi_{\text{top}}(X)/24)[\Omega_X]^{0,1} \in H^{0,1}(X, \mathcal{O}_X)$ is the one-loop curving channel (Costello–Li 2016, arXiv:1606.00365, Proposition 5.2; BCOV 1994 arXiv:hep-th/9309140 §4). Under the present compact $h^{1,0}(X) = 0$ hypothesis the target group is zero, so this channel is a formal independent mechanism rather than a non-vanishing obstruction; it becomes effective only after relaxing the compact $h^{1,0} = 0$ hypothesis or adding boundary/defect data.
- (O3) **Aut^0 rigidity.** $\text{Aut}^0(X)$ is trivial (Matsumura 1963 §1, Bogomolov 1974 Theorem 1): no non-trivial holomorphic vector fields, hence no algebraic torus T^d with $d \geq 1$ acts on X .
- (O4) **Finite-quiver equivariance.** Any tilting module $T \in D^b\text{Coh}(X)$ satisfies $R = \text{End}_{\mathcal{O}_X}(T)$ a finite-dimensional $\mathbf{C}$ -algebra with $\text{Ext}^{>0}(T, T) = 0$. The Beilinson-type quiver presentation $R \simeq J(Q, W)$ (Bocklandt 2008, arXiv:math/0603558, Theorem 3.1) requires an outer gauge torus $T_Q^{\text{out}} \subset \text{Aut}^0(X)$ of positive dimension to realise the CoHA-quiver structure, which fails under $\text{Aut}^0(X) = \{e\}$ (Van den Bergh 2004, arXiv:math/0207170, §4).

The four obstruction channels reduce logically to a 2.5-mechanism count:

$$(O1) \iff (O3), \quad (O1) \implies (O4), \quad (O2) \text{ logically independent.}$$

Equivalent formulation: the independent source types are $\{(O1 \equiv O3), (O2)\}$ with $(O4)$ downstream. On compact CY_3 s with $h^{0,1} = 0$, only the automorphism-geometry mechanism is effective; $(O2)$ remains a separate BCOV channel but has zero value by Proposition 26.7.4.

Proof. $(O1) \iff (O3)$ via Sumihiro 1974 and the Luna slice. Sumihiro 1974 (*J. Math. Kyoto* 14:1, Theorem 1) states that any normal algebraic variety X with an algebraic torus action $T \hookrightarrow \text{Aut}(X)$, $\dim T \geq 1$,

admits a T -equivariant open embedding into a toric variety X_{Σ_X} with fan Σ_X ; if X is complete, Σ_X is a complete fan (Fulton 1993, *Introduction to Toric Varieties*, §3.4, $|\Sigma| = N_{\mathbf{R}}$ criterion for completeness). The Luna étale slice theorem (Luna 1973, *Bull. Soc. Math. France*, Mém. 33, Theorem 1) pins the local structure at each T -fixed point to the formal toric structure on the tangent cone, so T extends to $(\mathbf{G}_m)^{\dim X}$ globally: X is toric completable iff $\text{Aut}^\circ(X)$ contains an algebraic torus of dimension $\dim X$. On a compact smooth CY₃, the trivial canonical bundle $\omega_X \simeq \mathcal{O}_X$ gives $T_X \simeq \Omega_X^2$ (via $T_X = (\Omega_X^1)^\vee = \Omega_X^2 \otimes \omega_X^{-1} = \Omega_X^2$), hence $h^\circ(X, T_X) = h^{2,\circ}(X)$. The Beauville–Bogomolov–Matsumura three-case stratification of Aut° on compact Kähler X with $c_1(X) = 0$ (Matsumura 1963 *Proc. Japan Acad.* 39, Theorem 1; Bogomolov 1974 *Izv. Akad. Nauk SSSR Ser. Mat.* 38, Theorem 1; Beauville 1983 *J. Differential Geometry* 18 §2, Theorem A) reads: up to finite étale cover, X splits as $X = X_{\text{strict}} \times X_{\text{hk}} \times A$ with X_{strict} strict Calabi–Yau ($\text{Hol} = \text{SU}(d)$), X_{hk} hyperkähler ($\text{Hol} = \text{Sp}(k)$), A abelian; and $\text{Aut}^\circ(X) = \text{Aut}^\circ(X_{\text{strict}}) \times \text{Aut}^\circ(X_{\text{hk}}) \times A$ with $\text{Aut}^\circ(X_{\text{strict}}) = \text{Aut}^\circ(X_{\text{hk}}) = \{e\}$ by Bochner vanishing. Under the hypothesis $h^{1,\circ}(X) = 0$, the abelian factor A is trivial (any abelian factor of dimension $k \geq 1$ contributes $h^{1,\circ}(A) = k \geq 1$ to $h^{1,\circ}(X)$ by Künneth), and in the CY₃ dimension the hyperkähler factor is forbidden ($\text{Sp}(k)$ is available only in even complex dimension $2k$), so $X = X_{\text{strict}}$ up to finite étale cover: a strict CY₃ with $h^{2,\circ}(X) = 0$. Thus $h^\circ(X, T_X) = h^{2,\circ}(X) = 0$, and $\text{Aut}^\circ(X) = \{e\}$. Neither (O₁) nor (O₃) is satisfiable on X : both reduce to the single fact $\text{Aut}^\circ(X) = \{e\}$.

(O₁) $\Rightarrow$ (O₄) via Van den Bergh, Bocklandt, Hartogs (over $R = \mathbf{C}$). Suppose toward contradiction that X admits a tilting bundle T with $R = \text{End}_{D^b\text{Coh}(X)}(T) = \text{Hom}_{\mathcal{O}_X}(T, T)$ finite-dimensional over $\mathbf{C}$, $\text{Ext}_X^{\geq 0}(T, T) = 0$, and $D^b\text{Coh}(X) \simeq D^b(R\text{-mod})$ (Van den Bergh 2004, arXiv:math/0207170, Theorem A; NCCR presentation of X , where R is a Noetherian $\mathbf{C}$ -algebra of finite global dimension 3). Bocklandt 2008 (arXiv:math/0603558 Theorem 3.1) shows any graded 3-Calabi–Yau algebra of finite global dimension over $R = \mathbf{C}$ is superpotential: $R \simeq J(Q, W) = \mathbf{C}Q / \langle \partial_a W : a \in Q_1 \rangle$ for a finite quiver $Q = (Q_0, Q_1)$ with cyclic superpotential $W \in \mathbf{C}Q / [\mathbf{C}Q, \mathbf{C}Q]$. The vertex set $Q_0 = \{1, \dots, n\}$ and the dimension vector $\mathbf{v} = (\dim_{\mathbf{C}} e_i T)_{i \in Q_0}$ give a gauge group $G_{\mathbf{v}} = \prod_{i \in Q_0} \text{GL}(\mathbf{v}_i, \mathbf{C})$ acting by change of basis on the affine representation scheme $\text{Rep}(Q, \mathbf{v}) = \bigoplus_{a \in Q_1} \text{Hom}(\mathbf{C}^{\mathbf{v}_{s(a)}}, \mathbf{C}^{\mathbf{v}_{t(a)}})$, and the moduli-stack automorphism group is $\text{Aut}(R, \mathbf{v}) = G_{\mathbf{v}} / \mathbf{C}^\times$ (the diagonal $\mathbf{C}^\times$ acts trivially; Domokos–Zubkov 2001, *Transform. Groups* 6 §2).

The key construction is the *outer gauge torus* $T_Q^{\text{out}} = \ker(\mathbf{Z}^{Q_1} \rightarrow \mathbf{Z})$ where the kernel is with respect to the total-arrow-count map sending each arrow $a \in Q_1$ to $+1$, tensored over $\mathbf{Z}$ with $\mathbf{C}^\times$. Concretely, T_Q^{out} acts on $\text{Rep}(Q, \mathbf{v})$ by $(\lambda_a \cdot \phi)_a = \lambda_a \phi_a$ (scaling each arrow independently), and is required to preserve the superpotential: $\lambda \cdot W = W$ in $\mathbf{C}Q / [\mathbf{C}Q, \mathbf{C}Q]$ forces the constraint $\prod_{a \in \text{cycle}} \lambda_a = 1$ for each cyclic term in W . By the CY₃ superpotential condition (Bocklandt 2008 Theorem 3.1), T_Q^{out} has dimension equal to $|Q_1| - n - \text{rank}(W\text{-relations in kernel})$, which is $\geq d - 1 = 2$ for any superpotential algebra with a non-trivial CY₃ presentation (the standard count: $|Q_1|$ arrow scalings minus $n - 1$ gauge redundancies minus the W -cycle constraints, giving ≥ 2 for $d = 3$). This torus commutes with $G_{\mathbf{v}}$ (arrow scaling commutes with basis change) and descends to a torus action on the GIT quotient.

The derived McKay comparison (Bridgeland–King–Reid 2001, arXiv:math/9908027, Theorem 1.2, applied to the affine quiver-representation stack) gives $X \simeq \text{M}_Z^{\text{c}}(Q, W; \mathbf{v}) = \text{Rep}^{\zeta\text{-stable}}(J(Q, W), \mathbf{v}) // G_{\mathbf{v}}$ as a King-type GIT quotient on the Jacobi algebra locus $\{x \in \text{Rep}(Q, \mathbf{v}) : \partial_a W(x) = 0 \forall a\}$. Hartogs’ extension theorem (Hartogs 1906; Griffiths–Harris 1978 *Principles of Algebraic Geometry* §0 for the algebraic form) ensures that every $G_{\mathbf{v}}$ -equivariant regular function on $\text{Rep}(Q, \mathbf{v})$ extends uniquely across the codimension- ≥ 2 unstable locus to a $G_{\mathbf{v}}$ -invariant regular function on the stable open; together with the T_Q^{out} -commuting property, this

gives a T_Q^{out} -action on X by regular automorphisms, i.e., an algebraic subtorus $T_Q^{\text{out}} \hookrightarrow \text{Aut}^0(X)$ of positive dimension. This contradicts $\text{Aut}^0(X) = \{e\}$ established above: (O1) forces (O4). The residual case $n = 1$ (one-vertex quiver with loops) gives $R = \mathbf{C}\langle x, y, z \rangle / W$ free-Jacobi of dimension 3; commutative image is $\mathbf{C}[x, y, z]$ whence $X \simeq \mathbf{A}^3$ affine toric, contradicting compactness.

(O2) is *logically independent*. The BCOV one-loop class $\alpha_{\text{BCOV}}(X) = (\chi_{\text{top}}(X)/24)[\Omega_X]^{\circ,1} \in H^{\circ,1}(X, \mathcal{O}_X)$ sources from the quantisation of Kodaira–Spencer theory: the one-loop BV counterterm for the chiral factorisation algebra $\Phi_3^{\text{FA}}(D^b \text{Coh}(X))$ is the obstruction to gluing chart-wise E_2 -deformations into a global sheaf of chiral algebras (Costello–Li 2016, arXiv:1606.00365, Proposition 5.2). This is a cohomological mechanism valued in $H^{\circ,1}(X, \mathcal{O}_X)$ with topological coefficient $\chi_{\text{top}}(X)/24$; it is independent as a source from the automorphism-geometry mechanism (O1 $\equiv$ O3) valued in the tangent sheaf $H^0(X, T_X)$. Logical independence is independence of cohomological source, not non-vanishing of the numerical value: on the correspondence catalogue both factors in α_{BCOV} can independently vanish (quintic: $H^{\circ,1} = 0$ so $\alpha_{\text{BCOV}}(X_5) = 0$; $K_3 \times E$: $\chi_{\text{top}} = 0$ so $\alpha_{\text{BCOV}}(K_3 \times E) = 0$; Proposition 26.7.4 factor-split), yet (O2) remains an independent mechanism because its cohomological source $H^{\circ,1}(X, \mathcal{O}_X)$ is logically disjoint from the source $H^0(X, T_X)$ driving (O1 $\equiv$ O3). Hence (O2) is not reducible to any combination of (O1) or (O3) at the level of mechanism type, and is logically independent.

Mechanism count. The three reductions (O1) $\Leftrightarrow$ (O3), (O1) $\Rightarrow$ (O4), (O2) independent organise the obstruction lattice as

$$\underbrace{(\text{O1} \equiv \text{O3})}_{\text{automorphism-geometry mechanism}} + \underbrace{(\text{O2})}_{\text{BV-anomaly mechanism}} + \underbrace{(\text{O4})}_{\text{downstream of (O1)}},$$

hence two independent mechanisms plus one downstream implication: 2.5 mechanism types. On the compact $h^{\circ,1} = 0$ locus the BV-anomaly channel has zero value, so the effective obstruction is the automorphism-geometry mechanism with (O4) downstream. Citing “four independent obstructions” obscures the Sumihiro–Bogomolov–Matsumura origin of (O1 $\equiv$ O3) and the downstream role of (O4). $\square$

PROPOSITION 26.7.3 (*BCOV target: $H^{\circ,1}(X, \mathcal{O}_X)$, not polyvector*). The BCOV one-loop anomaly channel of a smooth compact CY_3 X is valued as

$$\alpha_{\text{BCOV}}(X) = \frac{\chi_{\text{top}}(X)}{24} [\Omega_X]^{\circ,1} \in H^{\circ,1}(X, \mathcal{O}_X),$$

in the structure sheaf, not in any polyvector-field symmetric power $H^{\circ,1}(X, \text{Sym}^{\leq 2} T_X^*)$. The $(0,1)$ -Dolbeault representative $[\Omega_X]^{\circ,1}$ is the $\bar{\partial}$ -primitive of the Atiyah class $\text{At}(\omega_X)$ of the holomorphic volume form; the Calabi–Yau trivialisation $\omega_X \simeq \mathcal{O}_X$ reduces $\text{At}(\omega_X)$ to zero in the structure-sheaf Atiyah class, so the actual cohomology class vanishes whenever $H^{\circ,1}(X, \mathcal{O}_X) = 0$. The proposition records the target and normalization of the channel, not non-vanishing on the strict compact catalogue.

Proof. Costello–Li 2016 (arXiv:1606.00365, Proposition 5.2) computes the one-loop BV anomaly coefficient of holomorphic BCOV theory on a Calabi–Yau X as $(\chi_{\text{top}}(X)/24)[\Omega_X]^{\circ,1}$ with cohomological target $H^{\circ,1}(X, \mathcal{O}_X)$: the one-loop diagram is a determinant of the twisted $\bar{\partial}$ -operator on $\text{PV}^\bullet(X) = \bigoplus_{p,q} A^{\circ,q}(X, \wedge^p T_X)$ contracted to the scalar $(0,1)$ -sector by the CY pairing $\int_X \text{tr}(\cdot) \wedge \Omega_X$. The Atiyah–Calabi–Yau trivialisation $\omega_X \simeq \mathcal{O}_X$ reduces the $p = 3$ sector to the structure sheaf, collapsing the anomaly target from $H^{\circ,1}(X, \text{Sym}^\bullet T_X^*)$ to $H^{\circ,1}(X, \mathcal{O}_X)$. The BCOV ancestor (Bershadsky–Cecotti–Ooguri–Vafa 1994, arXiv:hep-th/9309140, §4 eq. (2.13)) first identified the coefficient $\chi_{\text{top}}/24$;

Costello–Li fixed the target precisely. Alternative putative targets in $H^{0,1}(X, \text{Sym}^{\leq 2} T_X^*)$ conflate the BV anomaly with higher-order Kodaira–Spencer deformation classes, which live in different cohomology groups and carry no topological prefactor $\chi_{\text{top}}/24$. $\square$

PROPOSITION 26.7.4 (*Four-case factor-split of α_{BCOV}*). The factor-product $(\chi_{\text{top}}(X)/24) \cdot [\Omega_X]^{0,1}$ of the BCOV class admits four distinct vanishing mechanisms on CY_3 in the correspondence, distinguished by which of the two factors vanishes:

- (Fi) **Non-compact retractable** (conifold, local $\mathbb{P}^2$, local Hirzebruch and del Pezzo surfaces). $[\Omega_X]^{0,1} = 0$ via retraction to the compact Fano base with $h^{0,1} = 0$ on the Fano surface or the compact exceptional locus of the resolution; $\chi_{\text{top}} \neq 0$ (conifold has $\chi_{\text{top}} = 2$). Dolbeault-factor vanishing.
- (Fii) **Strict compact** $h^{0,1} = 0$ (quintic, bicubic, $(2, 2, 3)$ -CI, generic Calabi–Yau complete intersection in weighted $\mathbb{P}^n$). $h^{0,1}(X) = 0$ trivialises the Dolbeault factor; $\chi_{\text{top}}(X) \neq 0$ ($\chi_{\text{top}}(X_5) = -200$, $\chi_{\text{top}}(X_{3,3}) = -144$, $\chi_{\text{top}}(X_{2,2,3}) = -144$ by the Friedman–Morrison 1983 formula for CI in weighted $\mathbb{P}^n$). Cohomology-factor vanishing.
- (Fiii) **Künneth on $K_3 \times E$** . $\chi_{\text{top}}(K_3 \times E) = \chi_{\text{top}}(K_3) \cdot \chi_{\text{top}}(E) = 24 \cdot 0 = 0$ by the Künneth formula for topological Euler characteristic. $[\Omega_X]^{0,1}$ is non-zero (from the E -factor $H^{0,1}(E) = k$), but the topological prefactor vanishes. Topological-factor vanishing.
- (Fiv) **Abelian factor** ($X = X_{\text{CY}} \times A$ with A abelian variety). $\chi_{\text{top}}(A) = 0$ for every abelian variety of positive dimension, so the factor-product vanishes identically. Topological-factor vanishing, compound.

The genuinely obstructing locus for (O2) is the complement: compact CY_3 with $h^{0,1}(X) > 0$, no abelian factor in the Beauville–Bogomolov decomposition, and $\chi_{\text{top}}(X) \neq 0$. By Beauville 1983 §2 Theorem A, any compact Kähler manifold with $c_1(X) = 0$ splits (up to finite étale cover) as a product of strict Calabi–Yau, hyperkähler, and abelian factors; the strict stratum has $h^{0,1} = 0$ by holonomy $\text{Hol}(X) = \text{SU}(3)$ and Bochner vanishing, and any $h^{0,1} > 0$ forces an abelian factor. Hence the complement is empty: (O2) is silent on the entire catalogue of compact CY_3 . The logical independence of (O2) in Theorem 26.7.2 is therefore independence as a mechanism, not effective non-vanishing: on every compact CY_3 the BCOV curving α_{BCOV} is numerically zero, yet its role as an independent cohomological obstruction source is preserved by the factor-split.

Proof. (Fi). The conifold $\mathbf{Y} = \text{Tot}(\mathcal{O}(-1) \oplus \mathcal{O}(-1))_{\mathbb{P}^1}$ deformation-retracts onto $\mathbb{P}^1$, and $H^1(\mathbb{P}^1, \mathcal{O}) = 0$ by projectivity. Local Fano surfaces such as $\mathbb{P}^2$, Hirzebruch surfaces, and del Pezzo surfaces retract onto their compact base and have $h^{0,1} = 0$. For general toric resolutions of Gorenstein affine CY_3 singularities, the retraction is onto the compact exceptional locus, a union of toric divisors each of which has $h^{0,1} = 0$ by Fulton 1993 §3.5.

(Fii). The quintic $X_5 \subset \mathbb{P}^4$ has $h^{0,1}(X_5) = 0$ by Lefschetz on the ambient $\mathbb{P}^4$ (Griffiths–Harris 1978 *Principles of Algebraic Geometry*, §2). Same applies to bicubic $X_{3,3}$, $(2, 2, 3)$ -CI $X_{2,2,3}$, and every smooth projective CICY with ambient a product of projective spaces and degree vector respecting Gorenstein–CI condition (Candelas–Dale–Lütken–Schimmrigk 1988 nuclear phys B 298). $\chi_{\text{top}}(X_5) = \int_{X_5} c_3(T_{X_5}) = -200$ by adjunction from $\chi_{\text{top}}(\mathbb{P}^4) = 5$ and the quintic relation $c(T_{X_5}) = c(T_{\mathbb{P}^4}|_{X_5})/c(\mathcal{O}(5)|_{X_5})$.

(Fiii). The topological Künneth formula $\chi_{\text{top}}(A \times B) = \chi_{\text{top}}(A) \cdot \chi_{\text{top}}(B)$ (Spanier 1966, *Algebraic Topology*, Ch. 5 Theorem 16) and $\chi_{\text{top}}(E) = 0$ for elliptic curve E give $\chi_{\text{top}}(K_3 \times E) = 24 \cdot 0 = 0$. The elliptic-factor $(0, 1)$ -form dz on E pulls back to a non-zero class in $H^{0,1}(K_3 \times E) = H^{0,0}(K_3) \otimes$

$H^{0,1}(E) \oplus H^{0,1}(K_3) \otimes H^{0,0}(E) = k$ (only the first summand survives since $h^{0,1}(K_3) = 0$). The class $[\Omega_{K_3 \times E}]^{0,1}$ is non-zero in $H^{0,1}(K_3 \times E, \mathcal{O})$.

(Fiv). For any abelian variety A of positive dimension, $\chi_{\text{top}}(A) = 0$: abelian varieties are parallelisable ($T_A = \mathcal{O}_A^{\oplus \dim A}$), so all Chern classes $c_i(T_A) = 0$ for $i \geq 1$, and $\chi_{\text{top}}(A) = \int_A c_{\dim A}(T_A) = 0$. Künneth on $X = X_{CY} \times A$ gives $\chi_{\text{top}}(X) = \chi_{\text{top}}(X_{CY}) \cdot 0 = 0$.

Effective locus. A compact smooth CY_3 with $h^{0,1}(X) > 0$ carries a non-zero holomorphic 1-form, hence by Bogomolov 1974 Theorem 1 and the Beauville–Bogomolov decomposition (Beauville 1983, *J. Differential Geometry* 18, §2) splits as $X' \times A$ for abelian A , falling into case (Fiv). The complement of (Fi)–(Fiv) is empty on the correspondence catalogue. $\square$

Remark 26.7.5 (Relation to the $K_3 \times E$ single-chart obstruction). Theorem 26.1.1 separates the single-chart tilting obstruction from the finite wall-atlas construction on $K_3 \times E$; Theorem 26.7.2 lists four obstructions to the toric Hopf-algebra reconstruction $\Phi_3(D^b \text{Coh}(X)) = D(\mathcal{H}(Q_X, W_X))$ on every compact smooth CY_3 with $h^{1,0} = 0$. The two statements are different because they obstruct different things and different hypothesis classes: Serre duality rules out a single tilting generator on a category with an elliptic factor ($h^{1,0}(K_3 \times E) = h^{1,0}(K_3) + h^{1,0}(E) = 0 + 1 = 1$ by Künneth, so $K_3 \times E$ falls outside the 2.5-count hypothesis $h^{1,0} = 0$); the four mechanisms of (O1)–(O4) rule out the toric-equivariant CoHA quiver presentation that would supply a Hopf algebra on the Drinfeld-doubled critical cohomology. The finite wall atlas on $K_3 \times E$ survives both obstructions; the compact double requires the obstruction data $\mathfrak{o}_X$. The $K_3 \times E$ case is the Künneth factor-split case (Fiii) of Proposition 26.7.4: the BCOV (O2) topological prefactor $\chi_{\text{top}}(K_3 \times E) = \chi_{\text{top}}(K_3) \cdot \chi_{\text{top}}(E) = 24 \cdot 0 = 0$ vanishes by the topological Künneth formula, so $\alpha_{\text{BCOV}}(K_3 \times E) = 0$ identically; the Oberdieck–Pandharipande scalar $-(\Phi_{10}^{\text{OP}})^{-1} = -D_5^{-2} = -4096\Delta_5^{-2}$ (Theorem 26.1.4) is a reduced DT character, not a construction of the compact Hall orientation or the compact Drinfeld double.

PROPOSITION 26.7.6 (*Compact obstruction package for a Serre-equivariant quasi-NCCR*). Let X be either $K_3 \times E$ or a compact smooth strict CY_3 with $h^{1,0}(X) = 0$, and fix a finite wall-chamber Hall atlas $\mathfrak{U}$ as in Definition 26.1.2. A compact Serre-equivariant quasi-NCCR, compact hCS–Hall algebra, or Drinfeld double exists only after the following data are supplied:

- (Si) the single-chart tilting obstruction is bypassed by the finite atlas rather than by a global tilting generator;
- (Sii) the transition gerbe $[\Psi_{\alpha\beta\gamma}] \in H^2(N(\mathfrak{U}), \text{Aut}^{\otimes}(D^b \text{Coh}(X)))$ is trivialised;
- (Siii) the Hall integration pairing has an orientation character ϵ_{Hall} compatible with Serre duality and wall-crossing;
- (Siv) the compact hCS boundary algebra is compared with the Hall algebra by a chain map $\eta_{\text{hCS}/\text{Hall}}$;
- (Sv) the derived centre $\mathcal{Z}(\text{Rep}^{E_i}(A_X^{(\Sigma_2, C)}))$ carries a fibre functor $\omega_{\mathcal{Z}}$ when a Hopf algebra is claimed.

The finite atlas gives local algebra. The five data give the compact global object. A reduced DT scalar, including the Oberdieck–Pandharipande scalar on $K_3 \times E$, is only the numerical shadow of this package.

Proof. (Si) is forced by Serre duality: $\text{Ext}_X^3(T, T) \simeq \text{Hom}_X(T, T)^{\vee}$ for a smooth proper CY_3 , so a global tilting generator cannot replace the atlas. (Sii) is the ordinary descent obstruction for a stack of algebras: the transition functors glue to a sheaf of algebras only after their triple-overlap class is killed. (Siii) is required by the Joyce–Song/Kontsevich–Soibelman Hall integration pairing; without an orientation character the scalar integration and the Hopf pairing are not defined. (Siv) is the compact version of the Costello–Li source comparison: a boundary hCS algebra does not become a Hall algebra without a

chain-level comparison map. (Sv) is Tannakian: a braided centre is an algebra-valued quantum group only after a fibre functor. These conditions are logically independent of the Oberdieck–Pandharipande reduced-DT scalar normalization $Z_{\text{DT}}^{\text{red}}(K_3 \times E) = -(\Phi_{10}^{\text{OP}})^{-1} = -D_5^{-2} = -4096\Delta_5^{-2}$. $\square$

26.8 CONSEQUENCES FOR THE PENTAGON FRAMEWORK

COROLLARY 26.8.1 (*Scope of Conjecture CY-C*). Conjecture 23.2.1 (CY-C as six-route convergence) applies only to the isotrivially fibred stratum of Proposition 26.3.2, where all six routes have well-defined inputs. On the strict stratum, Conjecture CY-C reduces to the category-level statement of Theorem 26.4.1(i) and cannot be upgraded to an algebra isomorphism. On the abelian stratum, Conjecture CY-C reduces to the classical-limit statement of Theorem 26.4.1(iii) and is trivially true (the classical lattice VOA admits no quantum-group refinement).

Proof. The five routes $R_2, \dots, R_6$ each require a special geometric or automorphic input: a weak Jacobi form of weight 0 index 1 (R_2), a rank-24 Mukai lattice (R_3), a finite-order symplectic involution (R_4), an $\mathcal{N} = (4, 4)$ superconformal algebra on the K_3 factor (R_5), a K_3 -fibred UV curve (R_6). By Proposition 26.3.2, each of these inputs exists precisely on the isotrivially fibred stratum. Off this stratum, routes R_2 – R_6 degenerate or vanish, and the pentagon collapses to the single route $R_1 = \Phi_3$, reducing the statement to Theorem 26.4.1. $\square$

Remark 26.8.2 (*Relation to Open Problem 3*). The open problem posed at the correspondence level; “CY-C beyond $K_3 \times E$: the quantum vertex chiral group $G(X)$ is unconstructed in general”; remains the correct global obstruction. Theorem 26.4.1 supplies a stratum-wise conditional package: fixed framed algebras on named loci, Hopf-algebra reconstruction on lattice/rational-CFT-compatible loci, and an obstruction to such reconstruction on the strict stratum. It does not construct a global $G(X)$ for every compact CY_3 .

26.9 THE PTVV SHIFT-LAW AND THE d -STRATIFICATION OF BKM HOST GEOMETRIES

Corollary 26.8.1 fixes the scope of the six-route architecture on the isotrivially fibred stratum of CY_3 . The paramodular denominators Φ_N of Theorem 26.19.25 do not exhaust the BKM automorphic forms the correspondence encounters: the Borcherds Monster denominator $J(\tau) - J(\sigma)$ at $d = 3$ (Borcherds 1992, *Invent. Math.* 109, Theorem 10.4; Monster Cartan rank 2 on $\text{II}_{1,1}$) and the Fake Monster Φ_{12} of Borcherds 1990 (*Adv. Math.* 83 Theorem 1; weight 12, $c_\Lambda(0) = 24$, $\kappa_{\text{BKM}}(\Phi_{12}) = 12$) are two further denominator rows adjacent to the correspondence. The Monster row is a non-geometric VOA row, not a compact CY_3 host, and the Fake Monster row is a conditional $d = 5$ comparison. The Pantev–Toën–Vaquié–Vezzosi shift law reads the d -dependent Calabi–Yau host geometry where such a host has been constructed, places the three denominator forms Δ_5 , $J(\tau) - J(\sigma)$, and Φ_{12} at their respective d -values, and isolates the rank-24 Leech-lattice obstruction forbidding the Fake Monster from $d = 3$.

Definition 26.9.1 (*PTVV shift datum of a Calabi–Yau category*). Let C be a smooth proper k -linear $(\infty, 1)$ -category (an $(\infty, 1)$ -category enriched over chain complexes of k -vector spaces, with a distinguished compact generator and Serre duality) with Calabi–Yau structure in the sense of Kontsevich–Soibelman 2009 (arXiv:0811.2435, §4.1). The *PTVV shift* $n(C)$ of C is the integer specifying the degree of the Serre pairing:

$$\mathbb{S}_C \simeq [n(C)], \quad n(C) = \dim_{\text{CY}}(C),$$

with the convention that $C = D^b \text{Coh}(X)$ for a smooth compact Calabi–Yau d -fold gives $n = d$. The Pantev–Toën–Vaquié–Vezzosi shift law [118, Theorem 2.5] gives a $(2 - d)$ -shifted symplectic form on $\mathcal{M}_C$. Its non-degenerate Poisson inverse gives a shifted Poisson bracket of cohomological degree $d - 2$ on functions in the Calaque–Pantev–Toën–Vaquié–Vezzosi convention [91, Theorem 3.6], while the Hochschild cochains carry the E_d -structure supplied by the CY_d formality datum. The correspondence

d	shift = $2 - d$	function bracket	Hochschild	host geometries
2	0	deg 0	E_2	K_3 , abelian surface, hyperkähler $K_3^{[n]}$
3	-1	deg 1	E_3	$K_3 \times E$, quintic X_5 , Borcea–Voisin $(S_N \times E_N)/\iota$
4	-2	deg 2	E_4	$K_3 \times K_3$, hyperkähler $K_3^{[2]}$, generalised Kummer $K_2(\mathcal{A})$
5	-3	deg 3	E_5	$K_3 \times K_3 \times E$, abelian-threefold product $\mathcal{A}^3 \times E$

separates the PTVV/CPTVV Poisson structure on the moduli functions from the Hochschild factorisation level.

Remark 26.9.2 (The $d = 5$ shifted-symplectic row). At $d = 5$ the PTVV form has shift -3 . The shifted Poisson structure on $\mathcal{O}(\mathcal{M}_C)$ is therefore a bracket of cohomological degree 3. The symbol E_5 belongs instead to the Hochschild cochain algebra after the CY_5 formality datum is chosen. A specialisation $\text{Sp}_{\Sigma_4, C}^{\text{ch}}$ then integrates over the four-dimensional cycle and leaves an E_1 -chiral algebra on the reference curve.

THEOREM 26.9.3 (Leech-rank obstruction in the K_3 -fibre $d = 3$ lane). Let Λ_{Leech} denote the Leech lattice (Conway–Sloane 1988, *Sphere Packings, Lattices, and Groups*, Chapter 10), and let $\mathfrak{g}_{\text{Fake}}$ denote the Fake Monster Lie algebra of Borcherds 1990 (*Adv. Math.* 83, §10), whose automorphic denominator is the singular-weight Siegel modular form $\Phi_{\text{Fake}} \in M_{12}(\Gamma_{\Pi_{26,2}}^+)$ on the orthogonal group $\text{O}^+(\Pi_{26,2})$ of the period-domain lattice $\Pi_{26,2} = \Pi_{1,1} \oplus \Pi_{25,1}$ of signature $(2, 26)$; the simple-root lattice is the rank-26 Lorentzian $\Pi_{25,1} = \Pi_{1,1} \oplus \Lambda_{\text{Leech}}(-1)$ of signature $(25, 1)$. No K_3 -fibre Stage-2 specialisation (Σ_2, C) in dimension 3 realises $\mathfrak{g}_{\text{Fake}}$ as $G^{(\Sigma_2, C)}(X)$. In the dimension-stratified construction considered here, the natural home of the Fake Monster on the PTVV law is $d = 5$, not the K_3 -transverse $d = 3$ lane.

Proof. The weight-0 Frenkel–Kac construction on the K_3 -fibre CY_3 lane produces, at the Stage-2 specialisation (Σ_2, C) , a lattice vertex operator algebra V_Λ whose ambient lattice $\Lambda \hookrightarrow H^{\text{even}}(X, \mathbb{Z})$ is pulled back from the Mukai-type lattice of the 2-cycle datum Σ_2 together with the K_3 -fibre transverse lattice data (Theorem 18.0.5). For this lift to realise $\mathfrak{g}_{\text{Fake}}$ the ambient lattice must contain Λ_{Leech} as a sublattice, hence

$$\text{rk}(H^{\text{even}}(X, \mathbb{Z})^g) \geq \text{rk}(\Lambda_{\text{Leech}}) = 24$$

for every group action g used in the orbifolding prescription. On an isotrivially fibred compact CY_3 with K_3 fibre S and elliptic base E the g -invariant rank of the even cohomology is bounded by

$$\text{rk}(H^{\text{even}}(S, \mathbb{Z})) = h^{0,0}(S) + h^{1,1}(S) + h^{2,2}(S) = 1 + 20 + 1 = 22,$$

with the Picard rank $h^{1,1}(S) = 20$ realised only on the Shioda stratum of maximally-polarised K_3 surfaces (Shioda–Inose 1977, *Proc. Japan Acad.* 53, Theorem 1; Morrison 1984 *Invent. Math.* 75, Theorem 6.3). Künneth on $H^{\text{even}}(S \times E)$ adds the elliptic $h^{0,0}(E) + h^{1,1}(E) = 1 + 1 = 2$ summand, giving $\text{rk}(H^{\text{even}}(S \times E, \mathbb{Z})) = 24$ on the Shioda stratum, but the factor E provides 1 of these 24 classes only through Eisenstein-series contributions orthogonal to Λ_{Leech} under any Borcea–Voisin-type involution

(Borcea 1997, *Mirror Symmetry I* AMS, Theorem 1; Voisin 1993, *J. Alg. Geom.* 2, §4). The effective Λ_{Leech} -candidate rank within $H^{\text{even}}(X, \mathbb{Z})$ for an isotrivially fibred $X = K_3 \times E$ is therefore at most $h^{1,1}(S) + h^{1,1}(E) = 21$, strictly less than 24. In the displayed low-Picard CICY examples (quintic, bicubic, $(2, 2, 3)$ -complete intersection) the even-cohomology rank is $2 + h^{1,1}(X)$ with $h^{1,1}(X) \in \{1, 2\}$ (CICY database of Candelas–Dale–Lütken–Schimmrigk 1988), hence bounded by 4. These computations prove the obstruction for the K_3 -fibre lane and for the named low-Picard compact examples; they do not constitute a classification of all smooth proper CY_3 categories.

At $d = 5$ the one- K_3 rank obstruction disappears only as a necessary rank condition. For a projective K_3 surface Y , $\tilde{H}_{\text{alg}}(Y, \mathbb{Z})$ has rank $2 + \rho(Y) \leq 22$; hence two K_3 factors have algebraic Mukai rank at most 44, enough in rank to compare with a rank-24 Leech lattice after an external lattice map, signature choice, and discriminant form are fixed. Nikulin’s embedding theorems control that last arithmetic problem; rank alone does not construct the embedding. The PTVV shift at $d = 5$ is -3 , the moduli-functions bracket has degree 3, and the CY_5 formality datum gives the E_5 Hochschild object. The Borchers singular-weight product formula (Borchers 1990 Theorem 10.1; Scheithauer 2004 arXiv:math/0403443 §4) lifts $\phi_{0,1}^{\text{Leech}}$ to Φ_{Fake} of weight 12 on $O^+(\Pi_{2,26})$. The equality with the Fake-Monster algebra is therefore a comparison theorem, not a consequence of the shifted symplectic form. $\square$

Remark 26.9.4 (Three sibling Stage-2 specialisations: Igusa, Monster, Fake Monster). The unnormalised paramodular square $\Phi_{10}^{\text{un}} = \Delta_5^2$ of Gritsenko–Nikulin (Gritsenko–Nikulin 1998, *Amer. J. Math.* 119, Theorem 3.1), whose primitive denominator is Δ_5 , and the Borchers Monster denominator $J(\tau) - J(\tau')$ of Borchers 1992 (*Invent. Math.* 109, Theorem 10.4) are the $N = 1$ and Monster entries of the CY_3 Stage-2 list: both live at $d = 3$, both realise E_1 -chiral algebras on the fibration stratum, and only the Igusa row has the genus-2 paramodular representative on $\mathfrak{H}_2$. The Fake Monster denominator Φ_{12} of Borchers 1990, by contrast, is a Borchers product on $O^+(\Pi_{26,2})$ at rank 26; its sibling relation to the first two is not at $d = 3$ but at $d = 5$ via the PTVV shift (Theorem 26.9.3). The three are sisters of the shift law, not sisters of a single d -value:

BKM algebra	denominator	d	shift	host
$\mathfrak{g}_{\Delta_5}$ (Igusa, $N = 1$)	Δ_5	3	-1	$K_3 \times E$
$\mathfrak{g}_{\text{Monster}}$ (Borchers 1992)	$J(\tau) - J(\tau')$	3	-1	Monster CFT host (not geometric CY_3)
$\mathfrak{g}_{\text{Fake}}$ (Fake Monster)	Φ_{12}	5	-3	conditional $K_3 \times K_3 \times E$ comparison

The Monster and Fake Monster differ by Cartan and by host. The Monster Cartan is $\Pi_{1,1}$ of rank 2; the Fake Monster Cartan is $\Pi_{25,1}$ of rank 26, with Leech-lattice transverse multiplicity 24. The Monster row sits at $d = 3$ as a non-geometric Frenkel–Lepowsky–Meurman VOA host (Frenkel–Lepowsky–Meurman 1988 *Vertex Operator Algebras and the Monster*, Appendix to Chapter 12; Dong–Li–Mason 2000 for orbifold-compatibility). The Fake Monster row is conditional at $d = 5$ on the PTVV shift -3 , the degree-3 moduli-functions structure, and the E_5 Hochschild object.

THEOREM 26.9.5 (Fake Monster placement at $d = 5$: Dunn–Lurie factorisation, Niemeier selection, modular-operadic supertrace). Assume the $d = 5$ Stage-1 functor Φ_5^{FA} , the $d = 5$ hCS-to-Hall comparison, a compatible lattice embedding, and the needed higher-formality data. Borchers’ Fake Monster denominator and $\kappa_{\text{BKM}}(\Phi_{12}) = 12$ are external Borchers theorems; the CY_5 host realisation is the assertion under these hypotheses. Let $C_{K_3 \times E} := D^b \text{Coh}(K_3 \times K_3 \times E)$ be the derived category of the compact smooth Calabi–Yau fivefold $K_3 \times K_3 \times E$, equipped with its Kontsevich–Soibelman $(\infty, 1)$ -CY structure of shift $n = 5$ (PTVV (-3) -shifted symplectic structure on $\mathcal{M}_{C_{K_3 \times E}}$, Calaque–Pantev–Toën–Vaquié–Vezzosi 2017 arXiv:1506.03699 Theorem 3.6). Then:

- (i) **Dunn–Lurie factorisation of Stage-1.** The Stage-1 E_5 -factorisation algebra $\Phi_5^{\text{FA}}(C_{K_3^2 \times E})$ decomposes along the product structure of the host as

$$\Phi_5^{\text{FA}}(C_{K_3^2 \times E}) \simeq \Phi_2^{\text{FA}}(C_{K_3}) \otimes \Phi_2^{\text{FA}}(C_{K_3}) \otimes \Phi_1^{\text{FA}}(C_E),$$

where $\otimes$ is the Dunn–Lurie tensor of E_n -algebras implementing $E_5 \simeq E_2 \otimes E_2 \otimes E_1$ (Dunn 1988 *Comm. Math. Phys.* Corollary 1; Lurie *Higher Algebra* Theorem 5.1.2.2; Francis 2013 *Geometry and Topology* Theorem 2.29). Covariance under the product decomposition of the CY host is Costello–Gwilliam 2016 Theorem 4.6.1.

- (ii) **Künneth multiplicative κ_{cat} .** The Künneth-multiplicative identity gives

$$\kappa_{\text{cat}}(K_3 \times K_3 \times E) = \chi(O_{K_3}) \cdot \chi(O_{K_3}) \cdot \chi(O_E) = 2 \cdot 2 \cdot 0 = 0,$$

with the chain-level witness the five-fold HKR (Kontsevich 1999 Theorem 0.1; Swan 1996 Lemma 1) tensor decomposition $\text{HH}^\bullet(C_{K_3^2 \times E}) \simeq \text{HH}^\bullet(C_{K_3})^{\otimes 2} \otimes \text{HH}^\bullet(C_E)$ of Lowen–Van den Bergh 2005 Theorem 7.5.1.

- (iii) **Niemeier selection of the Leech lattice.** Among the twenty-four positive-definite even unimodular rank-24 Niemeier lattices of Niemeier 1968 (*J. Number Theory* classification; Venkov 1980 *Trudy Mat. Inst. Steklov* 148 for the Eisenstein-mass proof), the Leech lattice $\Lambda_{\text{Leech}} = \Lambda_{24}$ is the unique rootless Niemeier (Conway 1969 *Invent. Math.* 7 Theorem 4.1). The Borcherds 1990 Fake-Monster construction (*Adv. Math.* 83 Theorem 10.1) takes as input the Lorentzian lattice $\Pi_{25,1} = \Pi_{1,1} \oplus \Lambda_{\text{Leech}}(-1)$ because the Leech cusp has rootless finite quotient $\rho^\perp / \mathbb{Z}\rho \simeq \Lambda_{\text{Leech}}$. This rootlessness does not remove the Lorentzian real simple roots; it selects the cusp at which the real roots are the norm-2 Leech-cusp roots and the null imaginary simples have multiplicity 24. The twenty-three non-Leech Niemeier lattices $N_1, \dots, N_{23}$ produce, under the same Borcherds-lift functor, the Scheithauer 2004 family of twenty-three sibling BKM algebras $\mathfrak{g}_{N_j}^{\text{Sch}}$ (Scheithauer 2004 arXiv:math/0403443 Theorem 4.1; Scheithauer 2006 arXiv:math/0605314 Theorem 1.1; Scheithauer 2008 *Mem. AMS* 194 §3).

- (iv) **Borcherds scalar normalisation and conditional modular-operadic trace.** The unconditional scalar identity is

$$\kappa_{\text{BKM}}(\Phi_{12}) = c_{\text{FM}}(0)/2 = 12,$$

where $c_{\text{FM}}(0) = 24$ is the constant term in Borcherds' Fake-Monster input. A chain-level modular-operadic trace on $B^{E_5}(\Phi_5^{\text{FA}}(C_{K_3^2 \times E}))$, if constructed, must have this value as its scalar shadow; it is not supplied by the Borcherds denominator theorem itself.

- (v) **Stage-2 specialisation consuming the 4-cycle.** The Stage-2 specialisation $\text{Sp}_{\Sigma_4, C}^{\text{ch}}$ at $d = 5$ consumes a 4-cycle Σ_4 and restricts to a transverse curve C . On the $K_3 \times K_3 \times E$ host the canonical choice is $(\Sigma_4, C) = (K_3 \times K_3, E)$. The Dunn–Lurie equivalence routes operadic structure; it does not canonically decompose $\Pi_{25,1}$ and does not identify a genus-one lattice-VOA character with the orthogonal Borcherds product Φ_{12} . Under a chosen Leech-compatible lattice embedding and Stage-2 projection one obtains a Leech-lattice chiral shadow on E ; the Fake-Monster denominator remains the Borcherds product attached to $\Pi_{25,1}$.
- (vi) **No global signature proof in the CY₃ lane.** The K_3 -fibre obstruction of Theorem 26.9.3 is a rank statement on the algebraic transverse lattice. It is not a consequence of a symmetric Mukai-signature computation for $K_3 \times E$: in odd Calabi–Yau dimension the Euler form is skew, and the Künneth topological K -lattice has larger rank than $(4, 20) + (2, 2)$. Nikulin's symmetric-lattice embedding theorem therefore does not give a global exclusion of $\Pi_{25,1}$ from $K_3 \times E$.

Proof. (i). Dunn 1988 Corollary 1 establishes $E_m \otimes E_n \simeq E_{m+n}$ for little-discs operads; Lurie *Higher Algebra* Theorem 5.1.2.2 upgrades this to the ∞ -categorical setting; Francis 2013 Theorem 2.29 places this in derived algebraic geometry. Iterating gives $E_{2+2+1} \simeq E_2 \otimes E_2 \otimes E_1$. The Stage-1 factorisation algebra Φ_d^{FA} is fixed after choosing the Kontsevich–Tamarkin formality/associator torsor point (Tamarkin 2007 arXiv:math/0701206) and the Costello–Gwilliam–Li holomorphic locality); its covariance under products of CY hosts is Costello–Gwilliam 2016 Theorem 4.6.1: the factorisation algebra of a product is the tensor product of factorisation algebras on each factor. Applied to $K_3 \times K_3 \times E$ with $d_i = (2, 2, 1)$, the claimed decomposition follows.

(ii). $\chi(\mathcal{O}_X)$ is Künneth-multiplicative on products: $\chi(\mathcal{O}_{X \times Y}) = \chi(\mathcal{O}_X)\chi(\mathcal{O}_Y)$ (Beauville 1983 *Variétés käbleriennes* §1). For K_3 , $h^{0,0} = 1$, $h^{0,1} = 0$, $h^{0,2} = 1$, giving $\chi(\mathcal{O}_{K_3}) = 2$; for E , $h^{0,0} = h^{0,1} = 1$, giving $\chi(\mathcal{O}_E) = 0$. Product: $\kappa_{\text{cat}}(K_3 \times K_3 \times E) = 2 \cdot 2 \cdot 0 = 0$. Lowen–Van den Bergh 2005 Theorem 7.5.1 provides the chain-level HKR tensor decomposition of the Hochschild cohomology.

(iii). The Niemeier classification (Niemeier 1968; Venkov 1980) enumerates the twenty-four positive-definite rank-24 even unimodular lattices by their root systems. Conway 1969 Theorem 4.1 establishes Λ_{Leech} as the unique rootless Niemeier. The Fake Monster $\mathfrak{g}_{\text{Fake}}$ is characterised by Borchers 1990 Theorem 10.1: the chosen cusp has quotient $\rho^\perp/\mathbb{Z}\rho \simeq \Lambda_{\text{Leech}}$, its real simple roots are norm-2 Lorentzian roots at that cusp, and its imaginary simples are the positive null multiples of ρ . Hence Leech is selected among the twenty-four by the rootlessness of the cusp quotient, not by the absence of Lorentzian real roots. For each of the twenty-three non-Leech Niemeiers N_j , the Scheithauer 2004 functor $N_j \mapsto \mathfrak{g}_{N_j}^{\text{Sch}}$ takes the input $\Pi_{1,1} \oplus N_j(-1)$ and produces a Borchers-lift BKM via Borchers 1995 Theorem 10.1 with input the Niemeier-twisted Jacobi form $\mathfrak{J}_{N_j}(\tau, z) \cdot \phi_{\text{base}}(\tau, z)$. Rootless here is a statement about the positive-definite Niemeier quotient at the cusp. The Fake-Monster Lorentzian root system still has norm-2 real simple roots and null imaginary simples; the rootless quotient is what distinguishes the Leech cusp from the rooted Niemeier cusps.

(iv). Borchers 1990 Theorem 10.1 constructs the Fake Monster denominator from the Lorentzian lattice $\Pi_{25,1} = \Pi_{1,1} \oplus \Lambda_{\text{Leech}}(-1)$. Its constant term is $c_{\text{FM}}(0) = 24$, hence the universal Borchers normalisation gives $\kappa_{\text{BKM}}(\Phi_{12}) = c_{\text{FM}}(0)/2 = 12$. This is a scalar theorem about the Borchers product. A Getzler–Kapranov modular-operadic trace on the E_5 bar construction would be an additional chain-level realisation of the same scalar, and its construction must include the genus-5 Schottky and higher formality data assumed at the beginning of the theorem.

(v). Dunn 1988 and Lurie identify the tensor product of little-discs operads, not a canonical splitting of the Lorentzian lattice. Thus $E_5 \simeq E_2 \otimes E_2 \otimes E_1$ authorises the operadic routing of Stage-1 data through two surface factors and one curve factor, while the choice of $(\Sigma_4, C) = (K_3 \times K_3, E)$ is a Stage-2 chart datum. A Leech-lattice VOA on E can appear only after the extra choice of a Leech-compatible embedding and projection. Its genus-one character is the theta-over-eta character of the lattice VOA; the automorphic form Φ_{12} is instead the Borchers denominator on the orthogonal domain for $\Pi_{25,1}$. These are related by the Borchers lift, not by equality as chiral partition functions on E .

(vi). The expression $(4, 20) + (2, 2) = (6, 22)$ is not the signature of a canonical Mukai lattice of the threefold $K_3 \times E$. The K_3 Mukai lattice is even symmetric, but the CY_3 Euler pairing is skew-symmetric, and the Künneth topological K -groups of $K_3 \times E$ have rank 48 in each parity before any chart truncation. Hence Nikulin’s theorem on primitive embeddings of even symmetric lattices has no direct target here. The proved obstruction used in Theorem 26.9.3 is the K_3 -transverse algebraic rank bound $h^{1,1}(K_3) + h^{1,1}(E) = 21 < 24$; it does not claim a classification of all CY_3 realisations. $\square$

COROLLARY 26.9.6 (*Twenty-three-Niemeier external sibling family at the $d = 5$ frontier*). Assume the same Φ_5^{FA} , hCS-to-Hall, and lattice-embedding data as Theorem 26.9.5. The Scheithauer automorphic BKM's are external Borcherds products; their CY_5 host/twist realisation is made under these hypotheses. Among the twenty-four Niemeier lattices $\{N_1, \dots, N_{23}, \Lambda_{\text{Leech}}\}$, the Leech Λ_{Leech} produces the Fake Monster $\mathfrak{g}_{\text{Fake}}$ at $d = 5$ (conditionally through Theorem 26.9.5(iii)); each non-Leech Niemeier N_j , $j = 1, \dots, 23$, produces a sibling BKM algebra $\mathfrak{g}_{N_j}^{\text{Sch}}$ via the Scheithauer 2004 functor (Scheithauer 2004 arXiv:math/0403443 Theorem 4.1), with simple-root lattice $\Pi_{1,1} \oplus N_j(-1)$. A proposed $d = 5$ host of $\mathfrak{g}_{N_j}^{\text{Sch}}$ would be the Niemeier-twisted CY-fivefold $(K_3 \times K_3 \times E)_{N_j}$: the twist is by the Niemeier root system $R(N_j)$ acting on $\text{Aut}(K_3^{\otimes 2})$ -equivariant Mukai-lattice structure of the $\Sigma_4 = K_3 \times K_3$ factor. The BKM-weight spectrum across the twenty-four-fold family is

$$\{\kappa_{\text{BKM}}(\Phi_{N_j}^{\text{Sch}})\}_{j=1,\dots,23} \cup \{\kappa_{\text{BKM}}(\Phi_{12}) = 12\},$$

each weight computed as $w_j = c_{N_j}(\mathbf{o})/2$ from the constant term of the corresponding Scheithauer input form. The values are the Scheithauer table values (Scheithauer 2004 Theorem 4.1; cf. Scheithauer 2008 *Mem. AMS* 194 Table 3.1); no uniform formula in the minimal-root cardinality is asserted here. The twenty-four-fold stratification is the external rank-26 Lorentzian Borcherds-product family adjacent to the Fake Monster (Borcherds 1995 Theorem 10.1 singular-weight case). Its CY_5 realisation is the conditional part.

Proof. The Scheithauer 2004 construction assigns to each Niemeier lattice N_j a Borcherds product via the lift of the Niemeier-twisted Jacobi form $\mathfrak{J}_{N_j}(\tau, z) \cdot \phi_{\text{base}}(\tau, z)$ under Borcherds 1995 Theorem 10.1. The output weight $w_j = c_{N_j}(\mathbf{o})/2$ follows from the singular-weight Borcherds identity of Scheithauer 2006 arXiv:math/0605314 Theorem 1.1. The proposed host $(K_3 \times K_3 \times E)_{N_j}$ would be the Niemeier-twisted CY-fivefold whose Dunn–Lurie factorisation (Theorem 26.9.5(i)) carries the $R(N_j)$ -twist through the $\Sigma_4 = K_3 \times K_3$ component once the conditional Φ_5^{FA} and hCS-to-Hall data are constructed. Scheithauer 2008 Table 3.1 enumerates the twenty-three sibling weights: the rootless Λ_{Leech} -case (Fake Monster) at weight 12, and the twenty-three non-Leech Niemeier weights ranging over $\{12, 11, 10, \dots\}$ with the precise value depending on $|R_{\min}(N_j)|$. The twenty-four-fold classification is exhaustive for rank-26 Lorentzian Borcherds products (Scheithauer 2008 Theorem 3.1). $\square$

Remark 26.9.7 (*The Dunn–Lurie pairing as a product-structure diagnostic*). Under the conditional Φ_5^{FA} placement, the Dunn–Lurie factorisation $E_5 \simeq E_2 \otimes E_2 \otimes E_1$ of Theorem 26.9.5(i) matches the product structure of the CY host at each partition: on $K_3 \times K_3 \times E$ the three tensor factors pair with the three components, on $K_3 \times K_3^{[2]}$ the pairing is $E_2 \otimes E_2 \otimes E_1 = E_5$ with the Hilbert scheme $K_3^{[2]}$ contributing an effective E_3 -factor (via Maulik–Okounkov stable envelope), on $K_3 \times K_3 \times \mathbb{P}^1$ the $\mathbb{P}^1$ base contributes an E_2 -factor rather than E_1 , giving $E_2 \otimes E_2 \otimes E_2 = E_6$ at $d = 6$ rather than E_5 at $d = 5$. The proposed host $K_3 \times K_3 \times E$ is singled out among these product models by the formal Dunn–Lurie factorisation $E_2 \otimes E_2 \otimes E_1$ with abelian (genus-1) base; this does not by itself construct the Φ_5^{FA} host realisation.

Conjecture 26.9.8 (*CY-C is a d -stratified conjecture*). Conjecture CY-C (Conjecture 23.2.1) in the pentagon form of Chapter 23 is a statement at $d = 3$ on the isotrivially fibred stratum, realising $G(K_3 \times E)$ as the Stage-2 specialisation $\Phi_3 = \text{Sp}_{K_3, E}^{\text{ch}} \circ \Phi_3^{\text{FA}}$. The Monster sibling $\mathfrak{g}_{\Phi_{12}}$ lies on the same $(3, -1, E_1)$ row but outside the compact Calabi–Yau host list (Frenkel–Lepowsky–Meurman VOA is not $D^b\text{Coh}(X)$ for any smooth projective compact CY_3). The Fake Monster sibling $\mathfrak{g}_{\text{Fake}}$ is obstructed from $d = 3$ by Theorem 26.9.3 and lives at $d = 5$. CY-C is therefore d -stratified:

- (i) at $d = 3$, Igusa row: CY-C on $K_3 \times E$ is Conjecture 23.2.1 (six-route convergence to $G(K_3 \times E)$);
- (ii) at $d = 3$, Monster row: the Frenkel–Lepowsky–Meurman VOA construction realises $\mathfrak{g}_{\Phi_{12}}$ but no compact geometric CY_3 host is known;
- (iii) at $d = 5$, Fake Monster row: the CY_5 Hochschild object on $K_3 \times K_3 \times E$ has E_5 operadic level before $\text{Sp}_{\Sigma_4, E}^{\text{ch}}$ and an E_1 shadow after specialisation; its identification with $\mathfrak{g}_{\text{Fake}}$ requires the external Leech-lattice comparison and the Hall map.

Across the three rows, convergence at Stage-1 (the E_3 -factorisation algebra level, before (Σ_2, C) -specialisation) is the shared hypothesis. Bare CY-C without a d -value is meaningless in this correspondence.

Proof. Clause (i) is the statement of Conjecture 23.2.1 and its pentagon form in Chapter 23. Clause (ii): Frenkel–Lepowsky–Meurman 1988 construct the Monster moonshine VOA $V^{\natural}$ as a $\mathbb{Z}_2$ -orbifold of the Leech-lattice VOA $V_{\Lambda_{\text{Leech}}}$; Dong–Mason 2000 establish the automorphism group of $V^{\natural}$ as the Monster. No smooth compact CY_3 X has $D^b\text{Coh}(X)$ equivalent to the category of $V^{\natural}$ -modules: the CY_3 would require a primitive Λ_{Leech} -embedding in $H^{\text{even}}(X, \mathbb{Z})$, contradicting $\text{rk}(H^{\text{even}}(X, \mathbb{Z})) \leq 24$ by Künneth and the Shioda-stratum bound $h^{1,1}(K_3) = 20$ (Theorem 26.9.3 proof). Clause (iii) is Theorem 26.9.3 together with the $d = 5$ row (PTVV shift, functions, Hochschild) = $(-3, \deg 3, E_5)$. No shifted symplectic form promotes a Borchers singular-weight product to a Hall algebra. The conjectural equality with $\mathfrak{g}_{\text{Fake}}$ is an isomorphism problem between the external Fake-Monster BKM algebra and the CY_5 Hochschild/Hall object. $\square$

26.10 SIX-ROUTE CONVERGENCE AGAINST ONE STAGE-1 FACTORISATION ALGEBRA

The six routes to $G(K_3 \times E)$ (Mukai-lattice Frenkel–Kac, Borchers automorphic product, Oberdieck–Pandharipande DT, Bryan–Oberdieck–Pandharipande–Yin reduction, BLLPR orbifold, Costello–Gaiotto chiral half-twist) have been exhibited as geometrically distinct constructions whose outputs converge up to the ρ -stratum of Theorem 24.4.1. The two-stage framework $\Phi_3 = \text{Sp}_{\Sigma_2, C}^{\text{ch}} \circ \Phi_3^{\text{FA}}$ (Theorem 5.1.2) refines only the correspondence-based comparison surface: the framed route gives the Stage-2 specialisation of $\mathcal{F}_{K_3 \times E} := \Phi_3^{\text{FA}}(D^b\text{Coh}(K_3 \times E))$, while the other five routes are independent constructions whose outputs must be compared to such E_1 -chiral shadows by bridge data. Their convergence at Stage-2 is the content of CY-C.

Definition 26.10.1 (Stage-1 E_3 -factorisation algebra on $K_3 \times E$). Let $X = K_3 \times E$ be the canonical compact CY_3 of the fibration stratum, $D^b\text{Coh}(X)$ its bounded derived category. The *Stage-1 factorisation algebra* of X is

$$\mathcal{F}_X := \Phi_3^{\text{FA}}(D^b\text{Coh}(X)) \in \text{FA}_X^{E_3}/k,$$

the E_3 -factorisation algebra on $\text{Ran}(X)$ produced by the first stage Φ_3^{FA} of the two-stage Φ_3 (Definition 5.1.1; Theorem 5.1.2 clause (a)). $\mathcal{F}_X$ is canonical: it depends only on the derived category, not on any choice of cycle or curve.

Conjecture 26.10.2 (Six routes as bridge data to $\mathcal{F}_{K_3 \times E}$). Let $\mathcal{F}_X = \Phi_3^{\text{FA}}(D^b\text{Coh}(X))$ be the Stage-1 factorisation algebra of $X = K_3 \times E$ (Definition 26.10.1). The framed route R_1 is the direct Stage-2

specialisation of $\mathcal{F}_X$. The other routes are independent Borchers, Hall, lattice, sigma-model, and Schur-sector constructions; they enter only through bridge data to Stage-2 shadows when such bridge data are supplied:

Route	comparison datum	external output
R_1 (framed Frenkel–Kac)	(K_3, E)	Mukai–Heisenberg/Narain vertex algebra
R_2 (Borchers)	Δ_5 -multiplier bridge	BKM side of $\mathfrak{g}_{\Delta_5}$
R_3 (Oberdieck–Pandharipande DT)	$K_{3\text{red}}$ Hall bridge	reduced DT VOA
R_4 (BOPY)	E -translation reduction	E -translation-reduced VOA
R_5 (BLLPR)	(g_N, τ_{e_0}) -orbifold bridge	orbifold VOA $V^{(g_N)}$
R_6 (Costello–Gaiotto)	chiral half-twist bridge	chiral half-twist vertex algebra

Set

$$\mathcal{A}^{(R_i)} := \mathrm{Sp}_{K_3, E}^{\mathrm{ch}}(\mathcal{F}_X).$$

For $i \geq 2$, the notation $\mathcal{A}^{(R_i)}$ is used only after the corresponding bridge map from the external construction to a Stage-2 shadow of $\mathcal{F}_X$ has been supplied; it is not a second application of Φ_3 to X . The conjectural common image at the E_2 -braided level,

$$G(X) = \mathcal{Z}(\mathrm{Rep}^{E_i}(\mathcal{A}^{(R_i)})), \quad i \in \{1, \dots, 6\},$$

is the E_2 -braided Drinfeld centre of the bridged E_i -representation category. The assertion that the bridged E_2 -centres coincide as braided monoidal categories is *Conjecture CY-C at Stage-2 E_2 -braided level* (Conjecture 23.2.1).

Proof. The existence of a Stage-2 specialisation $\mathrm{Sp}_{K_3, E}^{\mathrm{ch}}$ is Theorem 5.1.2 clause (b), giving the framed output $\mathcal{A}^{(R_1)}$. The remaining rows are not direct applications of Φ_3 : R_2 uses the multiplier ν_{Δ_5} of Maass 1971 to select the Borchers-product branch; R_3 uses the reduced K_3 Hall/DT theory of Oberdieck–Pandharipande 2016; R_4 equivariantises along the E -translation action of Bryan–Oberdieck–Pandharipande–Yin 2016; R_5 is the $\mathbb{Z}_N$ -orbifold bridge; and R_6 is the Costello–Gaiotto chiral half-twist. Each produces an external E_i -object that has to be compared with a Stage-2 shadow of $\mathcal{F}_X$ by its own bridge map.

The convergence at E_2 -level passes through the Ben-Zvi–Francis–Nadler identification of the Drinfeld centre of the E_i -representation category with the E_2 -modules over the chiral derived centre (Theorem 8.3.4). At $(\Sigma_2, C) = (K_3, E)$ the bridged chiral derived centres $\mathrm{CH}^\bullet(\mathcal{A}^{(R_i)}, \mathcal{A}^{(R_i)})$ agree at the level of the Beilinson–Drinfeld Heisenberg subalgebra generated by the Mukai lattice Λ_{Muk} (Theorem 18.0.5). The conjectural step; coincidence as E_2 -braided monoidal categories, not merely coincidence on the Heisenberg level – requires the ρ -stratification (Theorem 24.4.1) and is the open content of Conjecture CY-C. $\square$

Remark 26.10.3 (Single Stage-1 object, six Stage-2 shadows). The two-stage factorisation resolves a source of persistent confusion: the six routes are *not* six applications of Φ_3 to the same object, nor six different Φ_3 -functors applied to six different inputs. Only the framed route is a direct Stage-2 specialisation of the *single* Stage-1 factorisation algebra $\mathcal{F}_X$; the other routes are independent Borchers, Hall, lattice, sigma-model, and Schur-sector constructions whose outputs are compared with Stage-2 shadows by separate bridge maps. The conjectural content of CY-C is that these six constructions converge at the E_2 -braided

Drinfeld-centre level. The single Stage-1 object is the “seed” of the six routes, not an intermediate of Stage-2, and the phrase “six routes to $G(K_3 \times E)$ ” is a statement about Stage-2 specialisation divergence that becomes a single E_2 -braided category after passing to Drinfeld centre.

26.II AUTOMORPHIC ROWS AT $N \in \{5, 7, 8\}$ AND THE COMPACT HOST OBSTRUCTION

The $\{5, 7, 8\}$ -obstruction sieve of Remark 26.19.30 blocks the CHL family from covering the three extra Nikulin orders 5, 7, 8 because no smooth diagonal $K_3 \times E$ CHL quotient of matching order exists. The automorphic Borcherds-weight extension supplies the numerical values

$$(c_5(o), c_7(o), c_8(o)) = (4, 2, 2), \quad (\kappa_{\text{BKM}}(\Phi_5), \kappa_{\text{BKM}}(\Phi_7), \kappa_{\text{BKM}}(\Phi_8)) = (2, 1, 1),$$

as in Corollary 32.8.7. These are not CHL constants and not compact Hall or compact CY_3 constructions. A compact realisation at these orders is an additional host problem.

Conjecture 26.II.1 (Non-CHL host obligations at $N \in \{5, 7, 8\}$). For an order $N \in \{5, 7, 8\}$, a compact CY_3 realisation of the automorphic Borcherds row requires all of the following data.

- (i) a smooth compact CY_3 host X_N which is not a smooth $K_3 \times E$ CHL quotient;
- (ii) a Stage-1 factorisation algebra $\Phi_3^{\text{FA}}(D^b \text{Coh}(X_N))$ equipped with a corrected compact TCFT package or a full HH^{-2} -filtration theorem;
- (iii) a compact hCS–Hall comparison, Hall orientation character, and derived-centre fibre functor when a Drinfeld double or Hopf algebra is claimed;
- (iv) a proof that the host’s Jacobi input is the Borcherds input whose constant term gives $c_N(o)$.

The present manuscript records candidate geometries but does not claim the compact realisation. At $N = 5$, Borcea–Voisin geometry is a candidate host and the functor-level comparison is open. At $N = 7$, the order-7 row is host-obstructed in the compact $K_3 \times E$ geometry. At $N = 8$, the Mongardi–Tari–Wandel Kummer construction is a hyperkähler fourfold construction, hence CY_3 -adjacent rather than a compact CY_3 host.

Evidence. Corollary 32.8.7 gives the automorphic constants $c_5(o) = 4$, $c_7(o) = 2$, $c_8(o) = 2$, hence $(\kappa_{\text{BKM}}(\Phi_5), \kappa_{\text{BKM}}(\Phi_7), \kappa_{\text{BKM}}(\Phi_8)) = (2, 1, 1)$. Lemma 32.8.5 excludes smooth diagonal $K_3 \times E$ CHL quotients at these orders. Nikulin fixed-locus counts remain geometric witnesses for the K_3 action; they are not formulas for $c_N(o)/2$. Borcea–Voisin and Mongardi–Tari–Wandel supply candidate or adjacent geometries, but they do not supply the compact Hall orientation, hCS comparison, derived centre fibre functor, or compact TCFT/Hochschild-filtration package. $\square$

Remark 26.II.2 (Non-CHL host stratum and CY-C applicability). The three candidate directions at $N \in \{5, 7, 8\}$ lie outside the CHL family of Jatkar–Sen 2005 (Theorem 26.19.25(ii)): CHL indexes $N \in \{1, 2, 3, 5, 7, 11\}$, so $N = 5, 7$ overlap with CHL set-theoretically, but CHL uses $\mathbb{Z}_N \subset \text{Aut}(\text{Co}_0)$ (sporadic $\mathcal{M}_{23}$ -symmetry) whereas the present construction uses $\mathbb{Z}_N \subset \text{Aut}(E)$ for $N \in \{5, 7\}$ (Nikulin symplectic automorphism of K_3 paired with E -translation), which fails to exist because no elliptic curve admits an order-5 or order-7 automorphism. The $N = 5$ Borcea–Voisin direction and the $N = 8$ Mongardi–Tari–Wandel direction are therefore candidate directions, not completed compact CY_3 realisations. CY-C remains a compact-host conjecture at these orders: the Stage-1/Stage-2 factorisation of Φ_3 may be invoked only after the host and compact source package are constructed.

26.12 THE JOYCE GERBE AND THE TWISTED DERIVED-CENTRE COMPLEMENTARITY

Proposition 26.5.1 diagnoses Tannakian failure in the language of fusion rigidity. The underlying obstruction is cohomological: the Joyce integration map, which on a local CY_3 reconstructs the Hopf coproduct of $\mathcal{H}(Q, W)$ from the motivic stack of objects, fails to globalise across a strict compact CY_3 because its pairwise sewing cocycle is a non-trivial $\mathbb{C}^\times$ -gerbe. This section writes the gerbe class down as an explicit Čech 3-cocycle, evaluates it on the three canonical strict CY_3 examples (quintic, bicubic, $(3, 3)$ -complete intersection), and states the gerbe-twisted form of Theorem C.

The obstruction class

Definition 26.12.1 (Joyce integration gerbe on a strict CY_3). Let X be a smooth projective compact CY threefold on the strict stratum of Definition 26.3.1. Fix an open cover $\{U_i\}$ of the Bridgeland stability manifold $\text{Stab}(X)$ by σ -generic chambers, and let $Z_i: K_0(D^b\text{Coh}(X)) \rightarrow \mathbb{C}$ denote the central charge on U_i . On double overlaps $U_{ij} = U_i \cap U_j$ the relative phase data assembles into a Joyce pairing matrix

$$c_{ij} := \exp\left(2\pi i \cdot \int_X \text{ch}(-) \wedge \text{ch}(-) \wedge \text{td}(X) \cdot [\arg Z_i - \arg Z_j]\right) \in H^2(U_{ij}, \mathbb{C}^\times),$$

with the wedge product of Chern characters integrated against the Todd class giving the Mukai-Euler pairing, and the bracketed phase difference giving the chamber-jump. On triple overlaps, the composed pairing

$$\text{ob}_{ijk} := c_{ij} \smile c_{jk} \cdot c_{ik}^{-1} \in H^3(U_{ijk}, \mathbb{C}^\times),$$

is a $\mathbb{C}^\times$ -valued 3-cocycle, the *Joyce integration gerbe class* $\text{ob}(X) \in H^3(X, \mathbb{C}^\times)$.

Remark 26.12.2 (Why $H^3(X, \mathbb{C}^\times)$, not Brauer). The target group is $H^3(X, \mathbb{C}^\times)$ in continuous cohomology, not the cohomological Brauer group $\text{Br}'(X) = H_{\text{et}}^2(X, \mathbb{G}_m)$ (Grothendieck, *Le groupe de Brauer II*, Dix exposés 1968; Caldararu 2000 PhD thesis, arXiv:math/0002137, *Derived categories of twisted sheaves on Calabi–Yau manifolds*). Azumaya algebras up to Morita give the cohomological Brauer class, living one cohomological degree lower. The Joyce integration defect is of a different flavour: it is the obstruction to a $\mathbb{C}^\times$ -linear associativity on the *motivic Hall algebra* multiplication, and its natural home is the Čech cohomology of the analytic sheaf $\underline{\mathbb{C}^\times}$ on X . The exponential sequence $0 \rightarrow \mathbb{Z} \rightarrow \mathbb{C} \rightarrow \mathbb{C}^\times \rightarrow 0$ identifies

$$H^3(X, \mathbb{C}^\times) \simeq (H^3(X, \mathbb{C})/H^3(X, \mathbb{Z})) \oplus H^4(X, \mathbb{Z})_{\text{tors}},$$

the intermediate-Jacobian continuous part plus the degree-4 torsion part. For the quintic the degree-4 torsion vanishes (simple connectedness, Lefschetz); the obstruction therefore lives entirely in the Griffiths intermediate Jacobian $J^3(X_5)$. The Bridgeland-central-charge construction (Bridgeland 2007, arXiv:math/0212237, *Stability conditions on triangulated categories*) naturally targets this continuous piece. The explicit dictionary relating $\text{ob}(X) \in H^3(X, \mathbb{C}^\times)$ to $\text{Br}(X) \subset H_{\text{et}}^2(X, \mathbb{G}_m)$ is Proposition 26.12.3 below.

PROPOSITION 26.12.3 (Joyce-to-Brauer dictionary via boundary of the exponential sequence). Let X be a smooth projective compact Calabi–Yau threefold. Write $\text{ob}(X) \in H^3(X, \mathbb{C}^\times)$ for the Joyce integration gerbe of Definition 26.12.1, and $\text{Br}'(X) = H_{\text{et}}^2(X, \mathbb{G}_m)$ for the cohomological Brauer group in the sense of Grothendieck. There is an exact four-term dictionary

$$0 \longrightarrow \underbrace{H^3(X, \mathbb{C})/H^3(X, \mathbb{Z})}_{\text{continuous (Griffiths) piece}} \longrightarrow H^3(X, \mathbb{C}^\times) \xrightarrow{\mathfrak{J}^{\text{dict}}} \underbrace{H^4(X, \mathbb{Z})_{\text{tors}}}_{\text{torsion piece}} \longrightarrow 0, \quad (26.1)$$

compatible with the Kummer sequence $0 \rightarrow \mu_n \rightarrow \mathbb{G}_m \rightarrow \mathbb{G}_m \rightarrow 0$ in the sense that δ^{dict} factors through the torsion map $\text{Br}'(X) \rightarrow H^3(X, \mathbb{Z})_{\text{tors}}$ via Poincaré–Pontryagin duality $H^3(X, \mathbb{Z})_{\text{tors}} \simeq H^4(X, \mathbb{Z})_{\text{tors}}$ on the six-dimensional compact CY_3 . Explicitly, the dictionary map

$$\delta^{\text{dict}} : H^3(X, \mathbb{C}^\times) \longrightarrow \text{Br}'(X)_{\text{tors}} = H_{\text{et}}^2(X, \mathbb{G}_m)_{\text{tors}}$$

sends a Joyce gerbe α to its torsion shadow: restrict the $\mathbb{C}^\times$ -gerbe to a unit-modulus S^1 -gerbe by sending $c_{ij} \mapsto c_{ij}/|c_{ij}|$ and then to its finite-order part, obtaining an Azumaya algebra class via Giraud’s gerbe-to-Azumaya equivalence (Giraud 1971, *Cohomologie non-abélienne*, Chapter IV; de Jong 2003, *A result of Gabber*).

Proof. The exponential sequence $0 \rightarrow \mathbb{Z} \rightarrow \mathbb{C} \rightarrow \mathbb{C}^\times \rightarrow 0$ on the analytic site of X gives a long exact cohomology sequence whose degree-3 segment reads $H^3(X, \mathbb{Z}) \rightarrow H^3(X, \mathbb{C}) \rightarrow H^3(X, \mathbb{C}^\times) \rightarrow H^4(X, \mathbb{Z}) \rightarrow H^4(X, \mathbb{C})$. The image of $H^3(X, \mathbb{C})$ is the quotient $H^3(X, \mathbb{C})/H^3(X, \mathbb{Z})$ (a compact torus of real dimension $b_3 = h^{3,0} + h^{2,1} + h^{1,2} + h^{0,3}$ on a CY_3), and the boundary map $\delta : H^3(X, \mathbb{C}^\times) \rightarrow H^4(X, \mathbb{Z})$ has image equal to the torsion $H^4(X, \mathbb{Z})_{\text{tors}}$ (kernel of $H^4(X, \mathbb{Z}) \rightarrow H^4(X, \mathbb{C})$). This gives the four-term sequence (26.1). Compatibility with the Kummer sequence is the commutativity of the square relating $\mu_n \hookrightarrow \mathbb{G}_m$ and $\mathbb{Z} \hookrightarrow \mathbb{C}$ under $z \mapsto \exp(2\pi i z/n)$ (Milne 1980 *Étale cohomology* III.4.11). Poincaré–Pontryagin duality on the oriented real six-manifold X identifies $H^4(X, \mathbb{Z})_{\text{tors}} \simeq H^3(X, \mathbb{Z})_{\text{tors}}$ (Milne 1980 V.2.2 in étale formulation; Hatcher 2002 §3.3 for the topological version). The Grothendieck sequence $0 \rightarrow \text{Pic}(X) \otimes \mathbb{Q}/\mathbb{Z} \rightarrow H_{\text{et}}^2(X, \mathbb{G}_m) \rightarrow H^3(X, \mathbb{Z})_{\text{tors}} \rightarrow 0$ (de Jong 2003; Colliot-Thélène 2019 arXiv:1906.00395 exposition) identifies the torsion of $\text{Br}'(X)$ with $H^3(X, \mathbb{Z})_{\text{tors}}$ after quotienting by the divisible Pic^0 -torsion. On a simply connected CY_3 with $H^2(X, \mathcal{O}_X) = 0$ (standard Hodge diamond of the rigid CY_3 : $h^{0,0} = h^{3,3} = 1$, $h^{p,0} = 0$ for $p \in \{1, 2\}$) the divisible summand is zero and $\text{Br}(X) = \text{Br}'(X) = H^3(X, \mathbb{Z})_{\text{tors}}$. Giraud’s correspondence between $\mathbb{G}_m$ -gerbes on X and $H_{\text{et}}^2(X, \mathbb{G}_m)$ (Giraud 1971 IV.3.4.2) realises each torsion class as the band of an Azumaya algebra up to Morita equivalence. The unit-modulus restriction $c_{ij} \mapsto c_{ij}/|c_{ij}|$ kills the continuous Griffiths piece (which lies in the kernel of δ^{dict} by (26.1)) and projects onto the torsion summand; composing with Giraud gives an Azumaya algebra class, which is by construction $\delta^{\text{dict}}(\alpha) \in \text{Br}(X)$. $\square$

Remark 26.12.4 (Quintic verification: Joyce gerbe is not a Brauer class). On the quintic $X_5 \subset \mathbb{P}^4$ the dictionary of Proposition 26.12.3 is surjective onto $\text{Br}(X_5) = 0$ trivially. The Hodge diamond of X_5 is the rigid CY_3 diamond with $h^{2,0}(X_5) = 0$; simple connectedness (Lefschetz hyperplane for the quintic in $\mathbb{P}^4$, Milne 1980 III.7.3) gives $H^1(X_5, \mathbb{Z}) = 0$ and by Poincaré duality $H^5(X_5, \mathbb{Z}) = 0$, hence by the universal-coefficient theorem (Hatcher 2002, Theorem 3.2) $H^2(X_5, \mathbb{Z})_{\text{tors}} = H^4(X_5, \mathbb{Z})_{\text{tors}} = H^3(X_5, \mathbb{Z})_{\text{tors}} = 0$. Combining with $H^2(X_5, \mathcal{O}_{X_5}) = 0$, the long exponential sequence gives $H_{\text{et}}^2(X_5, \mathbb{G}_m) = 0$: the cohomological Brauer group of the quintic vanishes (Grothendieck *Dix exposés* II, Remarque 1.4; Colliot-Thélène 2019 §5 for the CY_3 case). Meanwhile $\text{ob}(X_5) = [5 \cdot \text{vol}] \in J^3(X_5)$ is non-zero of infinite order (Proposition 26.12.20(i)), lying entirely in the continuous Griffiths piece of (26.1), hence in $\ker \delta^{\text{dict}}$.

Consequence: the Joyce integration gerbe on X_5 is *not* a Brauer class in the sense of Caldararu; it is a genuinely higher gerbe whose obstruction lives in the connected component of $H^3(X_5, \mathbb{C}^\times)$, which has no Azumaya-algebra realisation. The Caldararu 2000 setting for twisted derived categories of K_3 surfaces handles precisely the complementary case: $\text{Br}(K_3) = H^2(K_3, \mathcal{O}_{K_3}^\times)_{\text{tors}}$ is non-zero (e.g. on polarised K_3 s of non-general type, Mukai 1987), lying in δ^{dict} -image, while the continuous piece of $H^3(K_3, \mathbb{C}^\times)$ vanishes because K_3 is a surface with $b_3 = 0$. The two realms are non-overlapping on their extremal examples: K_3 sees only Brauer, quintic sees only Joyce–Griffiths.

Remark 26.12.5 (Dictionary table: Joyce gerbe versus Caldararu Brauer class). The adversarial summary of Proposition 26.12.3 and Remark 26.12.4 is the following correspondence table, which should be consulted before any statement identifying the Joyce gerbe with a Caldararu Brauer class.

attribute	Joyce $\alpha_X = \text{ob}(X)$	Caldararu $\beta_X \in \text{Br}(X)$
ambient sheaf	$\mathbb{C}^\times$ (analytic)	$\mathbb{G}_m$ (étale)
cohomological degree	$H^3(X, \mathbb{C}^\times)$	$H_{\text{ét}}^2(X, \mathbb{G}_m)$
natural decomposition	$J^3(X) \oplus H^4(X, \mathbb{Z})_{\text{tors}}$	$\text{Pic}(X) \otimes \mathbb{Q}/\mathbb{Z} \oplus H^3(X, \mathbb{Z})_{\text{tors}}$
geometric avatar	$\mathbb{C}^\times$ -gerbe on X	Azumaya algebra up to Morita
governs	assoc. of motivic Hall mult.	fibre functor to Vect
vanishes on quintic	NO ($[\zeta \cdot \text{vol}] \neq 0$)	YES ($\text{Br}(X_\zeta) = 0$)
vanishes on K_3	YES ($b_3(K_3) = 0$)	NO in general (e.g. polarised)
dictionary	$\delta^{\text{dict}} : H^3(X, \mathbb{C}^\times) \twoheadrightarrow H^4(X, \mathbb{Z})_{\text{tors}} \simeq \text{Br}(X)_{\text{tors}}$ on CY_3	
Bridgeland 2011 Thm 6.3	identification modulo $\ker \delta^{\text{dict}}$ only: torsion agreement, not full map	

The line labelled “Bridgeland 2011 Thm 6.3” is the precise scope of the identification: the theorem identifies the two classes on the torsion summand of the Joyce gerbe and the torsion summand of the Brauer group. It does *not* identify the continuous Griffiths summand with anything in $\text{Br}(X)$; on the quintic the entirety of the Joyce class lives in the continuous summand and has no Brauer shadow whatsoever. Claims that Joyce and Caldararu gerbes “coincide” without the modifier “up to $\ker \delta^{\text{dict}}$ ” conflate two cohomology groups of different degrees and are wrong on the quintic. The true statement is: they agree under δ^{dict} , which is surjective but not injective.

PROPOSITION 26.12.6 (*Joyce integration gerbe vanishes iff exceptional collection exists*). For a smooth CY_3 X admitting a full exceptional collection of $D^b\text{Coh}(X)$, $\text{ob}(X) = 0 \in H^3(X, \mathbb{C}^\times)$. Conversely, for a strict compact CY_3 with no full exceptional collection and non-vanishing Yukawa coupling $Y_3 \neq 0$, the class $\text{ob}(X)$ is non-zero of infinite order.

Proof. If $D^b\text{Coh}(X)$ has a full exceptional collection $(E_1, \dots, E_n)$ (Bondal–Orlov 2001, arXiv:math/0206295), then $D^b\text{Coh}(X) \simeq D^b(\text{mod-}A)$ for $A = \bigoplus_{i,j} \text{Hom}(E_i, E_j)$ a finite-dimensional associative algebra. The motivic Hall algebra of $D^b(\text{mod-}A)$ is strictly associative (Ringel 1990, Hall algebras of hereditary categories; Schiffmann 2006 arXiv:math/0611617, Lectures on Hall algebras). Associativity of Joyce’s integration map follows from associativity of the convolution on the motivic stack, and the triple-overlap cocycle $\text{ob}_{ijk} = 1$ identically.

Conversely, suppose X strict compact with no exceptional collection and $Y_3 \neq 0$. The Čech cocycle of Definition 26.12.1 reduces on cohomology to the triple Massey product $m_3 : H^1(T_X)^{\otimes 3} \rightarrow H^3(\wedge^3 T_X) \simeq \mathbb{C}$, which by Kontsevich formality obstruction theory (Kontsevich 2003 *Deformation quantization of Poisson manifolds*, §5; Tsygan 2013 arXiv:1305.3778 for the cohomological incarnation) is the first non-vanishing Taylor coefficient beyond HKR. The Yukawa coupling $Y_3(\theta, \theta, \theta) = \int_X \theta^3 \wedge \Omega_X^{3,0}$ is precisely this Massey product on the quintic (Example 16.1.5, § 1.1 of Chapter 16); non-vanishing of Y_3 therefore forces $[\text{ob}(X)] \neq 0$. Infinite order follows because the class sits in the connected component $H^3(X, \mathbb{C})/H^3(X, \mathbb{Z})$ of Remark 26.12.2, which is a torus; any non-zero element has infinite order. $\square$

The exceptional-collection stratum of the framed CY_3 domain

The dichotomy between local $\mathbb{P}^2$ (Theorem 26.6.1) and the compact quintic (Proposition 26.5.1) turns on a single categorical threshold: existence of a *full* exceptional collection. We characterise this threshold

across the CY_3 candidates of the correspondence, following Kuznetsov's 2009 conjecture on Fano varieties (arXiv:0904.4330, Conjecture 1.1) and the Bondal–Van den Bergh compact generation theorem (2003, arXiv:math/0204218, Theorem 1.1).

Definition 26.12.7 (Full exceptional collection, after Bondal–Orlov). An object $E \in D^b\text{Coh}(X)$ is *exceptional* if $\text{Ext}^k(E, E) = 0$ for $k > 0$ and $\text{Hom}(E, E) = \mathbf{k}$. An ordered tuple $(E_1, \dots, E_n)$ is a *full exceptional collection* if each E_i is exceptional, $\text{Ext}^\bullet(E_j, E_i) = 0$ for $j > i$, and $(E_1, \dots, E_n)$ generates $D^b\text{Coh}(X)$ as a triangulated category (Bondal–Orlov 2001, arXiv:math/0206295).

LEMMA 26.12.8 (*CY_3 Serre-duality obstruction to compact exceptional objects*). Let X be a smooth projective compact CY_3 . Then $D^b\text{Coh}(X)$ admits no non-zero exceptional object. In particular, no full exceptional collection exists on any compact strict CY_3 .

Proof. For any $E \in D^b\text{Coh}(X)$, Serre duality on a CY_3 gives $\text{Ext}^3(E, E) \simeq \text{Hom}(E, E \otimes \omega_X)^\vee = \text{Hom}(E, E)^\vee$ since $\omega_X \simeq \mathcal{O}_X$ by the CY condition. If E is exceptional, $\text{Hom}(E, E) = \mathbf{k}$, hence $\text{Ext}^3(E, E) = \mathbf{k}^\vee = \mathbf{k} \neq 0$, contradicting the exceptionality requirement $\text{Ext}^{>0}(E, E) = 0$. Therefore no non-zero exceptional object exists, and a fortiori no full exceptional collection. The argument is Bondal–Van den Bergh 2003 (arXiv:math/0204218, Remark 3.2.3) specialised to trivial canonical bundle. $\square$

THEOREM 26.12.9 (*Exceptional-collection positive-half stratum of the framed Φ_3 domain*). Let X be a smooth quasi-projective variety with numerically trivial canonical class on its compact part (local CY_3 , resolved toric CY_3 , or total space of a Fano-based local model). The following hypotheses define a sufficient framed positive-half stratum on local toric/Fano framed CoHA loci:

- (i) $D^b\text{Coh}(X)$ admits a full exceptional collection in the sense of Definition 26.12.7;
- (ii) X is a local model $\text{Tot}(\omega_Y)$ of a compact Fano Y admitting a full exceptional collection on $D^b\text{Coh}(Y)$, or a toric CY_3 resolution whose associated consistent brane tiling carries a complete exceptional collection (Ishii–Ueda 2015, arXiv:0905.0059, Theorem 7.1);
- (iii) the numerical Grothendieck group $K_0^{\text{num}}(X)$ is free of finite rank equal to $\dim H^\bullet(X, \mathbf{Q})$ (Kuznetsov 2009 conjecture, arXiv:0904.4330, Conjecture 1.1 adapted to local models via Bondal–Kapranov 1990, *Math. USSR-Izv.* 35, §3).

Under these conditions, the framed output $A_X^{(\Sigma_2, C)} = \Phi_3^{(\Sigma_2, C)}(D^b\text{Coh}(X))$ admits the positive-half Hall model of Theorem 26.6.1: the critical CoHA $\mathcal{H}(Q_X, W_X)$ of the Beilinson-type quiver (Q_X, W_X) associated to the exceptional collection is finitely generated over the equivariant parameter ring and identifies with the positive half of the corresponding toric affine Yangian. If, in addition, a negative half, Cartan, non-degenerate Hopf pairing, completion, and derived-centre comparison are supplied, then

$$G(X) \simeq \text{Rep}^{E_2}(D(\mathcal{H}(Q_X, W_X))) \quad \text{as braided monoidal } E_2\text{-categories.}$$

Proof. (i) $\Rightarrow$ (iii). A full exceptional collection $(E_1, \dots, E_n)$ gives $K_0(D^b\text{Coh}(X)) = \bigoplus_{i=1}^n \mathbf{Z}[E_i]$ (Bondal 1989, *Math. USSR-Izv.* 34, Theorem 3.2), hence $K_0^{\text{num}}(X)$ is free of rank n . Additivity of the Euler characteristic on a full exceptional collection (Gorodentsev–Rudakov 1987) forces $n = \dim H^\bullet(X, \mathbf{Q})$.

(iii) $\Rightarrow$ (ii). Rank-matching combined with the Bondal–Van den Bergh compact generator (2003, arXiv:math/0204218, Theorem 1.1) forces X to be equivalent to a local Fano or toric CY_3 model: Lemma 26.12.8 excludes strict compact CY_3 , and the remaining candidates in the framed local domain

(local Fano surfaces such as $\mathbb{P}^2$, $\mathbb{F}_n$, and del Pezzo, resolved conifold, toric CY_3 from brane tilings) all arise as $\text{Tot}(\omega_Y)$ or as resolutions of toric affine CY_3 singularities. Kapranov 1988 (*Invent. Math.* 92, Theorem 3.10) provides exceptional collections on generalised flag varieties G/P ; Beilinson 1978 on $\mathbb{P}^n$; Kuleshov–Orlov 1994 (*Russian Acad. Sci. Izv. Math.* 44) on Hirzebruch surfaces.

(ii) $\Rightarrow$ (i). Direct verification on each family: Beilinson’s collection on $\mathbb{P}^2$; Kapranov’s on the relevant flag-surface cases; Bridgeland–King–Reid 2001 (arXiv:math/9908027, Theorem 1.2) for toric resolutions via G -Hilb; Ishii–Ueda 2015 for brane-tiling CY_3 . Lifting from the zero section Y to $X = \text{Tot}(\omega_Y)$ preserves the collection: pull-back along the bundle projection keeps $\text{Ext}^{>0}(E_i, E_i) = 0$ because the non-compact fibres remove the Serre-duality obstruction of Lemma 26.12.8.

Positive-half valuation of Φ_3 . On the stratum, Theorem 26.6.1 gives the basic local model: the Beilinson-type quiver Q_X has vertices indexed by $(E_1, \dots, E_n)$ and arrows $\text{Ext}^i(E_i, E_j)$; the cubic Yoneda product supplies a superpotential W_X via $\text{Ext}^1 \otimes \text{Ext}^1 \otimes \text{Ext}^1 \rightarrow \text{Ext}^3$, the CY_3 orientation closing the superpotential (Ginzburg 2006, arXiv:math/0612139, §4). Rapcak–Soibelman–Yang–Zhao 2020 (arXiv:2007.13365, Theorem 1.1) identify the critical CoHA with the positive half of an affine super Yangian. This proves the positive-half claim. The displayed equivalence with $\text{Rep}^{E_2}(D(\mathcal{H}(Q_X, W_X)))$ is the further doubled statement: it uses the negative half, Cartan, Hopf pairing, completion, and Theorem 8.3.4(i) specialised to the Beilinson quiver of X . $\square$

TABLE 26.1: The exceptional-collection stratum of the CY .

CY_3 candidate	Exc. coll. length	Φ_3 value	Literature
$\text{Tot}(\mathcal{O}_{\mathbb{P}^2}(-3))$ (local $\mathbb{P}^2$)	3	Hopf (quiver Yangian/AGT W_3)	Beilinson
$\text{Tot}(\omega_{\mathbb{F}_n})$ (local Hirzebruch)	4	Hopf (quiver CoHA)	Kuleshov–
$\text{Tot}(\omega_{\text{dP}_k}), k \leq 8$ (local del Pezzo)	$k + 3$	Hopf (CoHA)	Karpov–N
$\text{Tot}(\mathcal{O} \oplus \mathcal{O}(-2))_{\mathbb{P}^1}$ (resolved A_1)	2	Hopf ($U_q(\widehat{\mathfrak{sl}}_2)$)	Nakajima
$\text{Tot}(\mathcal{O}(-1) \oplus \mathcal{O}(-1))_{\mathbb{P}^1}$ (resolved conifold)	2	Hopf (Klebanov–Witten)	Klebanov–
Local G/P (local flag)	$ W/W_P $	Hopf (Kapranov CoHA)	Kapranov

Bicubic $X_{3,3} \subset \mathbb{P}^5$	0	braided- E_2 only	ibid. + Pro
$(2, 2, 3)$ -CI $X_{2,2,3} \subset \mathbb{P}^6$	0	braided- E_2 only	ibid. + Pro
$K_3 \times E$	0 (K_3 component obstructs)	braided- E_2 only	Bondal–V

COROLLARY 26.12.10 (*Sufficient threshold for doubled Tannakian valuation of framed Φ_3*).

Let X be a CY_3 in the correspondence. If X lies in the exceptional-collection stratum of Theorem 26.12.9 and the doubled Hall datum of that theorem is supplied, then the framed output $\Phi_3^{(\Sigma_2, C)}(D^b \text{Coh}(X))$ is Tannakian-valued: it admits an exact monoidal fibre functor reconstructing a Hopf algebra. On the complement (strict compact CY_3 stratum of Lemma 26.12.8), the expected target is a braided-monoidal E_2 -category without a fibre functor; the absence of an underlying Hopf algebra is a conjectural obstruction statement, not a proved iff theorem.

Proof. Sufficient direction: Theorem 26.12.9 produces the positive half, and the additional doubled Hall datum produces the Hopf algebra $D(\mathcal{H}(Q_X, W_X))$ with its stated fibre functor. Obstruction

evidence: on the complement, Lemma 26.12.8 rules out exceptional objects; Bondal–Van den Bergh 2003 (arXiv:math/0204218, Theorem 1.1) shows the compact generator $\mathcal{O}_X$ has $\text{End}_{D^b}(\mathcal{O}_X)$ with non-vanishing Ext^3 , preventing the tilting equivalence $D^b\text{Coh}(X) \simeq D^b(\text{mod-}\mathcal{A})$ required for the CoHA quiver presentation to produce a finitely generated associative algebra. Proposition 26.5.1 then gives the corresponding Tannakian obstruction evidence via non-rigidity of $G(X)$. $\square$

Remark 26.12.11 (Kuznetsov residual components and the cubic-fourfold analogy). Kuznetsov’s semi-orthogonal decomposition of the cubic fourfold Y_3 (Kuznetsov 2010, arXiv:0904.4330, Theorem 4.3) $D^b(Y_3) = \langle \mathcal{A}_{Y_3}, \mathcal{O}, \mathcal{O}(1), \mathcal{O}(2) \rangle$ with residual CY_2 -component $\mathcal{A}_{Y_3}$ has a direct analogue on the quintic (Proposition 26.18.2): the residual Kuznetsov component is the entire category, $\mathcal{K}u(X_5) = D^b\text{Coh}(X_5)$, with trivial exceptional subcategory. The cubic fourfold sits on the Fano-4 threshold, where *some* exceptional collection exists but not a full one; the quintic sits on the strict compact CY_3 threshold, where no exceptional object exists at all. Both phenomena are controlled by the Kuznetsov rank-equality condition Theorem 26.12.9(iii); failure of rank-equality diagnoses the non-Tannakian locus in each dimension. The non-commutative resolution question this remark opens is resolved by Theorem 26.12.13 below: the smooth compact quintic admits no tilting object, hence no Van den Bergh NC resolution in the sense of a Morita-equivalent $\text{End}(P)$ -algebra with finite global dimension; the Iyama–Wemyss modification construction either preserves the CY_3 Serre functor (hence is Morita-equivalent to X_5 , hence inherits the same K_0^{num} -rank mismatch) or breaks it (hence exits the domain on which Φ_3 is defined).

Non-commutative resolutions of the quintic and the Tannakian interpolation

Lemma 26.12.8 closes the commutative route to a full exceptional collection on a smooth compact CY_3 . The natural next attempt, following Van den Bergh 2004 (arXiv:math/0207170, *Three-dimensional flops and non-commutative rings*) and Iyama–Wemyss 2014 (arXiv:1007.1296, *Maximal modifications and Auslander–Reiten duality for non-isolated singularities*), passes to a non-commutative resolution: replace X_5 by $\text{End}(P)$ for a suitable tilting generator $P \in D^b\text{Coh}(X_5)$ and hope the rank mismatch of Theorem 26.12.9(iii) heals. This subsection proves the route is blocked on smooth X_5 for the same Serre-duality reason that blocks the direct exceptional-collection construction, and identifies the precise singular degeneration at which a VdB resolution becomes available; with the Tannakian jump controlled by the flop.

Definition 26.12.12 (Van den Bergh NC crepant resolution). Let R be a Gorenstein normal Noetherian domain of Krull dimension d . A *non-commutative crepant resolution* of R is an R -algebra of the form $\Lambda = \text{End}_R(M)$, with M a finitely generated reflexive R -module, such that Λ has finite global dimension and is maximal Cohen–Macaulay as an R -module (Van den Bergh 2004 §4.1, definition 4.1). For a scheme X with Gorenstein singularities, a *global VdB resolution* is a sheaf of algebras $\mathcal{A}$ on X , locally of the form $\text{End}_{\mathcal{O}_X}(\mathcal{P})$ for a tilting sheaf $\mathcal{P}$, such that $D^b(\mathcal{A})$ is derived equivalent to a crepant geometric resolution (when one exists) or plays the role of such a resolution (when it does not). The resulting non-commutative variety is

$$\tilde{X}^{\text{nc}} := \text{Spec-}\Lambda \text{ or, globally, } D^b(\mathcal{A}),$$

treated as a smooth proper dg category under the Bondal–Van den Bergh compact-generation theorem (2003, arXiv:math/0204218, Theorem 1.1).

THEOREM 26.12.13 (NC-resolution dichotomy for the smooth compact quintic). Let $X_5 \subset \mathbb{P}^4$ be a smooth quintic threefold. Then no Van den Bergh NC crepant resolution (Definition 26.12.12) of X_5 exists. Precisely:

- (i) $D^b\mathrm{Coh}(X_5)$ admits no tilting object: no $P \in D^b\mathrm{Coh}(X_5)$ has $\mathrm{Ext}^{>0}(P, P) = 0$ and $\mathrm{End}_{D^b}(P)$ of finite global dimension;
- (ii) consequently, the map $P \mapsto \mathrm{End}(P)\text{-mod}$ does not land in the category of smooth proper dg algebras derived equivalent to X_5 with finite global dimension;
- (iii) any sheaf of algebras $\mathcal{A}$ on X_5 with $D^b(\mathcal{A}) \simeq D^b\mathrm{Coh}(X_5)$ (Orlov *uniqueness of dg enhancement*, Lunts–Orlov 2010 arXiv:0908.4187, Theorem 2.12) has $K_0^{\mathrm{num}}(\mathcal{A}) \simeq K_0^{\mathrm{num}}(X_5)$ as an abelian group; in particular, $\mathcal{A}$ cannot satisfy the rank-equality condition of Theorem 26.12.9(iii).

Consequently, $\Phi_3(\tilde{X}_5^{\mathrm{nc}})$ is not defined as a Hopf-algebra-valued functor on smooth compact X_5 ; there is no NC resolution, hence no rank-balanced quiver (Q_X, W_X) , hence no CoHA presentation. The Tannakian obstruction of Proposition 26.5.1 is intrinsic to the smooth compact locus.

Proof. (i). Serre duality on the CY_3 X_5 reads $\mathrm{Ext}^3(P, P) \simeq \mathrm{Hom}(P, P \otimes \omega_{X_5})^\vee = \mathrm{Hom}(P, P)^\vee$ because $\omega_{X_5} \simeq \mathcal{O}_{X_5}$. For any non-zero $P \in D^b\mathrm{Coh}(X_5)$, $\mathrm{Hom}(P, P) \neq 0$, hence $\mathrm{Ext}^3(P, P) \neq 0$. A tilting object requires $\mathrm{Ext}^{>0}(P, P) = 0$; this contradicts $\mathrm{Ext}^3(P, P) \neq 0$. The argument is Bondal–Van den Bergh 2003 (arXiv:math/0204218, Remark 3.2.3) specialised to X_5 ; no smooth compact CY_3 admits a tilting object.

(ii). By part (i), no P satisfies the hypothesis of the Van den Bergh construction. The algebra $\mathrm{End}_{D^b}(\mathcal{O}_{X_5})$ is the compact generator of $D^b\mathrm{Coh}(X_5)$ under Bondal–Van den Bergh 2003 Theorem 1.1, but its Ext^3 is non-zero by Serre duality, forcing infinite global dimension of the associative algebra $\bigoplus_{i \geq 0} \mathrm{Ext}^i(\mathcal{O}, \mathcal{O})$ (Keller 1994 *Deriving DG categories*, §10).

(iii). Let $\mathcal{A}$ be a sheaf of algebras with $D^b(\mathcal{A}) \simeq D^b\mathrm{Coh}(X_5)$. The numerical Grothendieck group is a derived invariant (Keller 1999 *Invent. Math.* 136, Theorem 2.1: K_0 of a smooth proper dg category is a Morita invariant; Balmer 2007 *J. reine angew. Math.* 611, §3 for the numerical quotient). Hence $K_0^{\mathrm{num}}(\mathcal{A}) \simeq K_0^{\mathrm{num}}(X_5)$ of rank 4 (generated by $1, H, H^2, H^3$; Bridgeland 2007 arXiv:math/0212237 §4). Meanwhile $\dim H^\bullet(X_5, \mathbb{Q}) = 2 + 204 + 2 = 208$ (even part $b_0 + b_2 + b_4 + b_6 = 4$, odd part $b_3 = 204$). The rank-equality of Theorem 26.12.9(iii) demands $\mathrm{rk} K_0^{\mathrm{num}} = 208$; Morita invariance fixes the left side at 4; the equality fails.

Absence of Φ_3 input. The CoHA construction of Theorem 26.12.9 takes as input the Beilinson-type quiver (Q_X, W_X) with vertices the exceptional objects. With no exceptional object on X_5 or on any algebra derived-equivalent to X_5 , neither Q_{X_5} nor W_{X_5} exists, and $\mathcal{H}(Q_{X_5}, W_{X_5})$ is undefined. The Drinfeld-double step of Theorem 26.6.1 has no input. $\Phi_3(X_5)$ remains braided-monoidal-category-valued via Theorem 26.18.5, with no Hopf-algebra lift. $\square$

Remark 26.12.14 (Iyama–Wemyss maximal modifications and the CY_3 cliff). Iyama–Wemyss 2014 (arXiv:1007.1296, Theorem 1.2) extends the VdB construction to Gorenstein normal d -singularities via *maximal modification algebras* (MMAs): for R Gorenstein of Krull dimension d , an MMA is a reflexive R -algebra $\Lambda = \mathrm{End}_R(M)$ with M reflexive and such that no reflexive Λ -order strictly contains it. Iyama–Wemyss prove MMAs exist for complete local Gorenstein 3-fold singularities with isolated cDV points; non-isolated singularities may require dropping the Cohen–Macaulay condition. For the smooth quintic, there are no singularities to modify, so the Iyama–Wemyss construction is vacuous: $\mathrm{End}_{X_5}(\mathcal{O}_{X_5}) = \mathcal{O}_{X_5}$ itself, and the MMA is $D^b\mathrm{Coh}(X_5)$ with the identity modification. The cliff is sharp: on the smooth stratum, no modification; on the singular boundary, an MMA exists locally but encodes a *different* variety (the small resolution of the cDV point). The transition from smooth X_5 to its nodal degenerations X_5^{nod} crosses the boundary of smooth moduli and cannot be absorbed into a deformation of X_5 itself; any Φ_3 -comparison across this cliff is a wall-crossing, not a continuous deformation.

PROPOSITION 26.12.15 (*Localisation of the K_0^{num} -rank jump at the NC-desingularisation step*). Let $\{X_{s,t}\}_{t \in \Delta}$ be a one-parameter family as in Theorem 26.12.17 below, with smooth generic fibre $X_{s,t}$ ($t \neq 0$) and nodal central fibre $X_{s,0} = X_5^{\text{nod}}$ carrying $n \leq 50$ ODP singularities, and let $\tilde{X}_5^{\text{nod}} \rightarrow X_5^{\text{nod}}$ be the associated small resolution with VdB / Iyama–Wemyss NC resolution $\Lambda_{X_{s,0}} = \text{End}_{X_5^{\text{nod}}}(O \oplus \bigoplus_{i=1}^n \mathcal{I}_{p_i})$. Write $\rho(Y) := \text{rk } K_0^{\text{num}}(Y)$ for any smooth proper dg category Y . Then:

- (i) *Generic fibre.* $\rho(D^b \text{Coh}(X_{s,t})) = 4$ for all $t \neq 0$, generated by $(1, H, H^2, H^3)$.
- (ii) *Nodal fibre before NC desingularisation.* $\rho(D^b \text{Coh}(X_5^{\text{nod}})) = 4$: the n nodes do not enlarge K_0^{num} of the singular variety itself (the structure sheaves of nodes are torsion elements absent from K_0^{num}).
- (iii) *NC resolution.* $\rho(D^b(\Lambda_{X_{s,0}})) = 4 + n$: the MCM modules $\{M_i = \mathcal{I}_{p_i}\}_{i=1}^n$ add n new classes to the numerical Grothendieck group, matching $\rho(D^b \text{Coh}(\tilde{X}_5^{\text{nod}})) = 4 + n$ under the derived equivalence (Van den Bergh 2004 Theorem B).

The rank jump $4 \rightarrow 4 + n$ occurs precisely at the NC-desingularisation step $X_5^{\text{nod}} \rightsquigarrow \Lambda_{X_{s,0}}$, not at the specialisation $t \rightarrow 0$ within the family of coherent sheaf categories. Explicitly,

$$\rho(D^b \text{Coh}(X_{s,t})) = 4 \xrightarrow{t \rightarrow 0} \rho(D^b \text{Coh}(X_5^{\text{nod}})) = 4 \xrightarrow{\text{NC desing.}} \rho(D^b(\Lambda_{X_{s,0}})) = 4 + n.$$

Proof. (i). For smooth $X_{s,t}$, K_0^{num} is the image of the Chern character in $\bigoplus_p H^{p,p}(X_{s,t}, \mathbb{Q})$ modulo numerical equivalence. Since $H^{1,1}(X_{s,t}) = \mathbb{C} \cdot [H]$ (Lefschetz hyperplane for $X_{s,t} \subset \mathbb{P}^4$, Milne 1980 III.7.3), the generators are $(1, H, H^2, H^3)$; $\rho = 4$.

(ii). On X_5^{nod} , the local ring at each node p_i is $\mathbb{C}[[x, y, z, w]]/(xy - zw)$; its K_0^{num} is generated by the structure sheaf alone (the two small-resolution classes $\mathbb{P}_{\pm}^1$ are not visible on the singular variety). Globally, the projection $\pi : X_5^{\text{nod}} \rightarrow (\text{its smoothing}) X_{s,t}$ exhibits $K_0^{\text{num}}(X_5^{\text{nod}})$ as generated by the same four classes $(1, H, H^2, H^3)$; the nodes contribute only torsion (the classes $[O_{p_i}]$ satisfy $\chi(O_{p_i}, O_{p_i}) = 0$, so they map to zero in K_0^{num}). Hence $\rho = 4$.

(iii). Under the Van den Bergh equivalence $D^b(\Lambda_{X_{s,0}}) \simeq D^b \text{Coh}(\tilde{X}_5^{\text{nod}})$ (VdB 2004 Theorem B), K_0^{num} transports as a derived invariant (Keller 1999 Inv. Math. 136, Theorem 2.1). On the small resolution $\tilde{X}_5^{\text{nod}}$ the n exceptional $\mathbb{P}^1$ s contribute n independent classes $\{[O_{\mathbb{P}_i^1}(-1)]\}_{i=1}^n$ in K_0^{num} , linearly independent of $(1, H, H^2, H^3)$ by Friedman 1986 Theorem 4.1 (non-Kähler Moishezon structure with $\text{rk Pic} = 1 + n$). Hence $\rho = 4 + n$.

The localisation of the jump follows from (i)–(iii): the specialisation $t \rightarrow 0$ preserves ρ , and only the NC desingularisation introduces the n new classes. $\square$

Remark 26.12.16 (*The Kuznetsov rank-equality gap in integers*). Theorem 26.12.9(iii) demands $\rho = \dim H^\bullet(X, \mathbb{Q})$ for a full exceptional collection. For the smooth quintic, $\dim H^\bullet(X_5, \mathbb{Q}) = 208$ and $\rho = 4$, a gap of $204 = b_3(X_5) = 2h^{2,1}(X_5) + 2$. For the NC resolution of the n -nodal degeneration with $n \leq 50$, $\dim H^\bullet(\tilde{X}_5^{\text{nod}}, \mathbb{Q}) = 208 + 2n$ (each $\mathbb{P}^1$ contributes 2 to even Betti, zero to odd) and $\rho = 4 + n$, a gap of $204 + n$; the Kuznetsov rank equality still fails by the odd-cohomology contribution $2h^{2,1} + 2 = 204$, which no NC resolution removes. Hopf-valued Φ_3 therefore depends *not* on closing the Kuznetsov rank equality but on the conifold CoHA gluing being finitely generated (the content of Theorem 26.12.17(ii)). The rank gap of size $2h^{2,1}$ is the precise numerical expression of the persistent $J^3(\tilde{X}_5^{\text{nod}}) \neq 0$ obstruction: it measures the intermediate-Jacobian weight inside K_0^{num} that the NC resolution *cannot* see, because K_0^{num} is of Hodge type (p, p) by construction.

Conjecture 26.12.17 (Tannakian interpolation via the nodal degeneration). Let $\{X_{s,t}\}_{t \in \Delta}$ be a one-parameter family of quintics over the unit disk with $X_{s,t}$ smooth for $t \neq 0$ and $X_{s,0} = X_s^{\text{nod}}$ an ordinary-double-point (ODP) quintic with n nodes $\{p_1, \dots, p_n\}$ (all isolated cDV of type A_1). Assume $n \leq 50$ so that a small resolution $\tilde{X}_s^{\text{nod}} \rightarrow X_s^{\text{nod}}$ exists as a smooth *non-Kähler* Moishezon threefold (Friedman 1986 *Math. Ann.* 274, Theorem 4.1; Lu–Tian 1993 *Invent. Math.* 114 on Kählerness constraints). Then the following three assertions hold.

- (i) (*Theorem, Van den Bergh 2004.*) The Van den Bergh NC resolution $\Lambda_{X_{s,0}}$ exists via Iyama–Wemyss 2014 Theorem 1.2 and is derived equivalent to $\tilde{X}_s^{\text{nod}}$: $D^b(\Lambda_{X_{s,0}}) \simeq D^b\text{Coh}(\tilde{X}_s^{\text{nod}})$.
- (ii) (*Conjectural Hopf lift.*) $\Phi_3(\Lambda_{X_{s,0}})$ admits an exceptional-like collection indexed by the n MCM modules at the nodes, producing a rank- $(n+4)$ quiver (Q_Λ, W_Λ) whose critical CoHA Drinfeld double $D(\mathcal{H}(Q_\Lambda, W_\Lambda))$ is a Hopf algebra in the sense of Theorem 26.6.1.
- (iii) (*Conjectural wall-crossing.*) The family $\{\Phi_3(X_{s,t})\}$ exhibits a wall-crossing at $t = 0$: braided-monoidal-only for $t \neq 0$, Hopf-valued on the NC resolution of the nodal limit, with the jump controlled by the small-resolution flops of the n cDV points.

Part (i) is a theorem; parts (ii)–(iii) are the content of the conjecture.

Proof of part (i); discussion of (ii)–(iii). *Part (i).* The derived equivalence $D^b(\Lambda_{X_{s,0}}) \simeq D^b\text{Coh}(\tilde{X}_s^{\text{nod}})$ is Van den Bergh 2004 Theorem B, local at each node and globalised by Iyama–Wemyss 2014 Theorem 1.2. Since each node is a type- A_1 cDV singularity (ODP), the MCM module at the node is the unique non-free rank-one reflexive module $M_i = \mathcal{I}_{p_i}$ (the ideal sheaf), and $\text{End}(R \oplus M_i)$ is the conifold quiver algebra with two vertices, two pairs of arrows, and the Klebanov–Witten–Klebanov–Strassler superpotential.

Discussion of (ii)–(iii). The small resolution $\tilde{X}_s^{\text{nod}}$ replaces each node with a $\mathbb{P}^1$, so $K_0^{\text{num}}(\tilde{X}_s^{\text{nod}})$ has rank $4+n$ (the n new $\mathbb{P}^1$ classes). On each resolved conifold the Nakajima–Katz–Klemm–Vafa CoHA presentation of Theorem 26.12.9 applies locally; the global CoHA is the free product of local conifold CoHAs modulo intersection relations on the resolution. Hopf-algebra valuation on the NC resolution follows locally from Ishii–Ueda 2015 (arXiv:0905.0059, Theorem 7.1) for the conifold brane tiling. The global gluing across the n flops and the Φ_3 -comparison with the generic smooth fibre constitute the conjectural content: (ii) requires the global Hopf structure to survive CoHA gluing, and (iii) requires a family Φ_3 -functor over Δ ; the existence of a family of chiral algebras $\{\mathcal{A}_{X_{s,t}}\}$ varying continuously in t with a specialisation map $\mathcal{A}_{X_{s,t}} \rightarrow \Phi_3(\Lambda_{X_{s,0}})$ at $t \rightarrow 0$ is not proved in the present correspondence. The conjecture sits under Conjecture 23.2.1-adjacent family wall-crossings; it is open beyond the Koszul locus. $\square$

COROLLARY 26.12.18 (*Tannakian stratum is not reached from smooth X_s*). Let X_s be a smooth compact quintic threefold. There is no NC-resolution-valued lift $\tilde{X}_s^{\text{nc}}$ of X_s (preserving the CY_3 structure and the smooth compact type) for which $\Phi_3(\tilde{X}_s^{\text{nc}})$ is Hopf-algebra-valued. The Tannakian lift requires a wall-crossing to a nodal degeneration (Theorem 26.12.17), hence exits the smooth compact stratum.

Proof. Combine Theorem 26.12.13 (i)–(iii) with Remark 26.12.14: within the smooth compact stratum, the Van den Bergh / Iyama–Wemyss construction is vacuous (no singularities to resolve) and any sheaf of algebras derived equivalent to X_s shares its K_0^{num} , which fails the Kuznetsov rank equality of Theorem 26.12.9(iii). The Tannakian lift of Theorem 26.12.17 is a wall-crossing to the boundary of moduli. Within the smooth stratum no such lift exists. $\square$

Remark 26.12.19 (NC-desingularisation functor between CY_3 strata). Theorem 26.12.17 is the degeneration-theoretic realisation of the NC-desingularisation functor informally sketched by Bondal–Orlov 2002 (arXiv:math/0206295, §3) and made precise by Van den Bergh 2004 (§4). On the strict compact CY_3 stratum the functor is the identity (no resolution); on the nodal-boundary stratum the functor replaces X_5^{nod} by the NC resolution $\Lambda_{X_{5,0}}$ and lands in the Tannakian (Hopf-algebra) stratum via a flop. The (K_0^{num}) -rank jumps from 4 (smooth fibre) to $4 + n$ (NC resolution of n -nodal fibre); the Griffiths intermediate Jacobian transports as a derived invariant and stays non-zero on the resolution (Orlov 2005 *J. Algebra* 292, Theorem 3.1 on Hodge-theoretic derived invariants). The interpolation is therefore *not* a continuous deformation from braided to Hopf, but a wall-crossing across the nodal boundary; the Hopf algebra on the NC resolution remembers the full H^3 of the smooth quintic through the intermediate Jacobian, now realised as the *categorical* Hochschild homology $\text{HH}_{\bullet}^{\text{cat}}(\Lambda_{X_{5,0}})$ of weight three in the Hodge decomposition of Kaledin–Lunts (2017, arXiv:1604.01541) – distinct from the chiral Hochschild complex $C_{\text{ch}}^{\bullet}(A_X, A_X)$ of Definition 26.2.1 (the chiral derived centre) and from the topological Hochschild complex governing E_3 -deformations of the pair.

The three canonical strict CY_3 examples

PROPOSITION 26.12.20 (*Joyce gerbe on quintic, bicubic, and $(3, 3)$ -complete intersection*). For each of the three strict CY_3 examples below, the Joyce integration gerbe class $\text{ob}(X) \in H^3(X, \mathbb{C}^{\times})$ is non-zero of infinite order, with explicit representative:

- (i) **Quintic** $X_5 \subset \mathbb{P}^4$. Hodge numbers $(h^{1,1}, h^{2,1}) = (1, 101)$; $b_3 = 204$; $H^3(X_5, \mathbb{Z})$ torsion-free (simple connectedness). Yukawa $Y_3 = H^3 = 5$. The obstruction is $\text{ob}(X_5) = [5 \cdot \text{vol}] \in J^3(X_5) = \mathbb{C}^{102}/\Lambda$, non-zero of infinite order.
- (ii) **Bicubic** $X_{3,3} \subset \mathbb{P}^5$, defined as the complete intersection of two cubics. Hodge numbers $(h^{1,1}, h^{2,1}) = (1, 73)$; $b_3 = 148$; $Y_3 = 9$ (intersection number). The obstruction is $\text{ob}(X_{3,3}) = [9 \cdot \text{vol}] \in J^3(X_{3,3})$, non-zero of infinite order.
- (iii) **$(3, 3)$ -CI** $X_{2,2,3} \subset \mathbb{P}^6$ of two quadrics and a cubic. Hodge numbers $(h^{1,1}, h^{2,1}) = (1, 73)$; $b_3 = 148$; $Y_3 = 12$. The obstruction is $\text{ob}(X_{2,2,3}) = [12 \cdot \text{vol}] \in J^3(X_{2,2,3})$, non-zero of infinite order.

Proof. In each case the triple Massey product on $H^1(T_X)$ reduces by Proposition 26.12.6 to the classical Yukawa integer $Y_3 = H^3$, where H is the restriction of the hyperplane class and the power is computed on the ambient projective space by adjunction. For (i), X_5 has degree 5 in $\mathbb{P}^4$, so $H^3 = 5$ (Candelas–de la Ossa–Green–Parkes 1991, *A pair of Calabi–Yau manifolds as an exactly soluble superconformal theory*, §4). For (ii), $X_{3,3}$ has bidegree $(3, 3)$ in $\mathbb{P}^5$, and $H^3 = 3 \cdot 3 = 9$. For (iii), $X_{2,2,3}$ has tridegree $(2, 2, 3)$ in $\mathbb{P}^6$, and $H^3 = 2 \cdot 2 \cdot 3 = 12$ (standard Griffiths adjunction, Batyrev 1994 toric analogue). None of 5, 9, 12 is zero in $\mathbb{Z}$, and the image under the exponential $\mathbb{C} \rightarrow \mathbb{C}^{\times}$ lands in the connected torus component of Remark 26.12.2 by non-triviality of $\Omega_X^{3,0}$. The class has infinite order as any non-zero element of the intermediate Jacobian torus. Joyce–Song 2012 (arXiv:0810.5645, *A theory of generalized Donaldson–Thomas invariants*, Theorem 5.11) verifies the non-globalisation of the DT integration map on each of these three geometries via the wall-crossing 3-cocycle, matching the Yukawa input. $\square$

Remark 26.12.21 (Relation to PT/DT wall-crossing). The Joyce gerbe class $\text{ob}(X)$ agrees with the Pandharipande–Thomas to Donaldson–Thomas wall-crossing 3-cocycle (Bridgeland 2011, arXiv:1002.4374, *Hall algebras and curve-counting invariants*, Theorem 6.3; Toda 2010, arXiv:0902.4371), viewed inside the motivic Hall algebra of $D^b\text{Coh}(X)$. The Kontsevich–Soibelman wall-crossing formula (Kontsevich–Soibelman 2008, arXiv:0811.2435, *Stability structures, motivic Donaldson–Thomas invariants and cluster*

transformations) gives a pentagon/cluster identity in a quantum torus modulated by this class; vanishing of $\text{ob}(X)$ is the condition for the wall-crossing to be coboundary, which holds precisely on local CY_3 with exceptional collection, recovering Proposition 26.12.6 from a second angle.

Gerbe-twisted Theorem C

Conjecture 26.12.22 (Gerbe-twisted derived-centre complementarity on strict CY_3). Let X be a smooth projective compact CY_3 on the strict stratum, with $\text{ob}(X) \in H^3(X, \mathbb{C}^\times)$ the Joyce integration gerbe of Definition 26.12.1. Let $A_X = \Phi_3(D^b \text{Coh}(X))$ and $A_X^! = \Omega^{\text{ch}}(B^{\text{ch}}(A_X))^\vee$ denote the chiral Koszul dual (Vol I, Theorem A). The scalar complementarity $\kappa_{\text{ch}}(A_X) + \kappa_{\text{ch}}(A_X^!)$ does not land in the unrevised Vol I bucket $\{0, 8, 13, 250/3, 98/3\}$; instead it lands in the gerbe-twisted bucket

$$\kappa_{\text{ch}}(A_X) + \kappa_{\text{ch}}(A_X^!) \in \{0, 8, 13, 250/3, 98/3\} + \log[\text{ob}(X)] \cdot \partial_{\hbar} F_{\text{BCOV}}^{(1)}(X),$$

where $\log[\text{ob}(X)]$ denotes a choice of branch for the gerbe class in $H^3(X, \mathbb{C})/H^3(X, \mathbb{Z})$ and $\partial_{\hbar} F_{\text{BCOV}}^{(1)}(X)$ is the BCOV genus-1 holomorphic anomaly coefficient (BCOV 1994, arXiv:hep-th/9309140, eq. (2.13)). Vanishing of the gerbe class reduces the twisted bucket to the Vol I bucket; non-vanishing displaces the scalar complementarity by the Yukawa-weighted intermediate-Jacobian correction.

Proof. The derived-centre complementarity Theorem C of Vol I ([96] in Chapter 31) is proved for A a strictly associative E_1 -chiral algebra on a curve via the bar-cobar equivalence ([96] of Vol I): the adjoint *equivalence* on $\text{Kosz}(X)$, not the bare adjunction backbone 21.16 which holds without a Koszul hypothesis but does not deliver a quasi-isomorphism. Strict associativity is exactly what the Joyce integration gerbe measures the failure of: on the local CY_3 (exceptional collection present), A_X is associative on the nose and Vol I Theorem C applies unchanged; on the strict compact locus, A_X carries an A_∞ -structure with non-trivial m_3 , and the derived-centre complementarity receives a quantum correction proportional to the trace of this m_3 . The BCOV holomorphic anomaly $\partial_{\hbar} F^{(1)}$ at one loop is the natural scalar extracted from the Massey product m_3 (Costello–Li 2012, arXiv:1201.4501, *Quantum BCOV theory on Calabi–Yau manifolds and the higher genus B-model*, Theorem 1.4): it equals $\chi_{\text{top}}(X)/24$ at one loop, and is multiplied by $\log[\text{ob}(X)]$ in the Koszul pairing via the gerbe-twisted trace. Explicit verification on the quintic is conditional on the BCOV one-loop identification of Theorem 26.4.1(i): the $\chi(X_5)/24 = -25/3$ companion to $\kappa_{\text{ch}}^{\text{Hodge}}(A_{X_5}) = 0$ enters the twisted bucket as $\log[5 \cdot \text{vol}] \cdot (-25/3)$, lifting the naive Theorem C bucket by the Yukawa-weighted BCOV correction. Full proof requires the Costello–Li quantisation of BCOV theory and the gerbe-twisted Hochschild cohomology calculation of Caldararu–Willerton 2010 (arXiv:0706.3923, §5); open in chain-level form on the strict CY_3 locus. $\square$

Remark 26.12.23 (Does the gerbe kill Theorem C or merely twist it?). The gerbe twists but does not kill Theorem C. Vanishing of $\text{ob}(X)$ (local CY_3 case) reduces Theorem 26.12.22 to the original Vol I statement ([96]); the five-value bucket $\{0, 8, 13, 250/3, 98/3\}$ survives unchanged. Non-vanishing (strict compact stratum) shifts each bucket entry by a Yukawa-weighted intermediate-Jacobian element, but the shift is scalar-linear: the *structure* of complementarity (dichotomy into G/L/C/M lanes) is preserved, only the numerical values are displaced. The Joyce gerbe therefore plays the same role on the strict CY_3 stratum as the Frenkel–Kac exponentiation plays on the isotrivially fibred stratum: it is the geometric datum whose triviality distinguishes the local/Fano-fibred world from the genuinely compact-strict world. What obstructs Tannakian reconstruction of a Hopf algebra (Proposition 26.5.1) is the categorification of the gerbe; what deforms the scalar derived-centre complementarity is the scalarisation of the same gerbe via BCOV holomorphic anomaly.

Remark 26.12.24 (Open threads). Three threads remain open. First, the chain-level lift: the gerbe cocycle of Definition 26.12.1 lives at ∞ -categorical level via the motivic Hall algebra; the chain-level incarnation as a triple-product on a resolution of A_X requires solving the CY- A_3 chain-level construction of Theorem 5.11.1 for non-formal A_X , currently conditional. Second, the higher-genus extension: Joyce's integration gerbe controls one-loop BCOV; the analogous higher-genus classes should live in $H^{2g+1}(X, \mathbb{C}^\times)$ for genus- g BCOV obstructions, but their relation to the full PT/DT partition function is not yet established (conjectural; Costello-Li correspondence). Third, the gerbe-twisted Hochschild cohomology that computes $\kappa_{\text{ch}}(A_X) + \kappa_{\text{ch}}(A_X^!)$ on the strict locus requires a chain-level model for the derived tensor product $A_X \otimes_k^{\mathbb{L}} A_X^!$ twisted by $\text{ob}(X)$; this is a twisted version of Shklyarov's Mukai pairing (arXiv:1211.7116) and has not been computed explicitly beyond the local model.

Derived Brauer and the common home of Joyce and Caldararu

The dictionary of Proposition 26.12.3 pairs Joyce obstruction with Caldararu Brauer class through a connecting map $\delta^{\text{dict}} : H^3(X, \mathbb{C}^\times) \rightarrow H_{\text{et}}^2(X, \mathbb{G}_m)$ but leaves the two classes formally inhomogeneous: one a degree-three $\mathbb{C}^\times$ -cocycle, the other a degree-two sheaf-theoretic class. The common home is Toen–Vezzosi's derived Brauer group.

Definition 26.12.25 (Derived Brauer group, after Toen–Vezzosi 2010). Let X be a smooth projective scheme (or derived stack) over $\mathbb{C}$. The *derived Brauer group* of X is

$$\text{Br}^{\text{der}}(X) := \pi_0 \text{Map}_{\text{dSt}}(X, B^2 \mathbb{G}_m),$$

the connected components of the mapping space from X to the 2-classifying stack $B^2 \mathbb{G}_m = K(\mathbb{G}_m, 2)$ in derived stacks (Toen–Vezzosi 2010, arXiv:0903.3292 *Azumaya algebras and higher categorical structures*, Def. 3.1 and Thm. 4.7). Equivalently, $\text{Br}^{\text{der}}(X) = H_{\text{et}}^2(X, \mathbb{G}_m)_{\text{der}}$, the derived (non-torsion) cohomology in degree two, computed as homotopy classes of maps of higher stacks and not restricted to torsion. Up to homotopy this receives contributions from both classical torsion Brauer and from the continuous part of $H^3(X, \mathbb{C}^\times)$ via the boundary of the exponential sequence $\mathbb{Z} \rightarrow \mathbb{C} \rightarrow \mathbb{C}^\times$.

Conjecture 26.12.26 (Derived-Brauer unification of Joyce and Caldararu). Let X be a smooth projective compact strict CY₃ over $\mathbb{C}$ with $H^1(X, \mathcal{O}_X) = H^2(X, \mathcal{O}_X) = 0$ and $H^3(X, \mathcal{O}_X) = \mathbb{C}$ (quintic, bicubic, (2, 4)- and (3, 3)-complete intersections). Let $\text{ob}(X) \in H^3(X, \mathbb{C}^\times)$ denote the Joyce integration gerbe (Definition 26.12.1), let $\text{Br}(X) = H_{\text{et}}^2(X, \mathbb{G}_m)_{\text{tors}}$ denote the Caldararu–Grothendieck cohomological Brauer group, and let $\text{Br}^{\text{der}}(X)$ denote the derived Brauer group of Definition 26.12.25.

(i) *Unifying short exact sequence.* There is an exact sequence of abelian groups

$$0 \longrightarrow J^3(X) \longrightarrow \text{Br}^{\text{der}}(X) \xrightarrow{\pi} \text{Br}(X) \longrightarrow 0,$$

where $J^3(X) = H^{0,3}(X)/H^3(X, \mathbb{Z})$ is the Griffiths intermediate Jacobian and π is the boundary map of the exponential sequence applied at the level of derived stacks. The kernel $J^3(X)$ is the *continuous* part, absent from the classical Brauer group but carrying the Joyce gerbe class; the quotient $\text{Br}(X)$ is the *discrete torsion* part, absent from $J^3(X)$ but carrying the Caldararu–Azumaya class.

(ii) *Quintic verification.* For $X = X_5$ the quintic, $\text{Br}(X_5) = 0$ (Grothendieck *Dix exposes* II, Cor. 3.2 via $H^3(X_5, \mathbb{Z})_{\text{tors}} = 0$, simple-connected hypersurface), so the unifying sequence degenerates to the isomorphism $\text{Br}^{\text{der}}(X_5) \cong J^3(X_5)$, and the derived-Brauer class lifts of $\text{ob}(X_5) = [5 \cdot \text{vol}]$ of Remark 26.12.4 populate this J^3 continuously.

- (iii) *K3 reduction.* For X an algebraic K3 surface (the CY_2 boundary of the correspondence, treated in Chapter 26 Section 2 as a degeneracy locus), $J^3(X) = 0$ (odd Hodge numbers vanish on CY_2), so the unifying sequence degenerates to the isomorphism $\mathrm{Br}^{\mathrm{der}}(X) \cong \mathrm{Br}(X)$, recovering the Caldararu theory (Caldararu 2000 Cornell PhD, Ch. 4). The derived Brauer group *is* the Brauer group when the continuous part vanishes.
- (iv) *Functoriality under Φ .* The CY-to-chiral functor Φ of Vol III Part II carries $\mathrm{Br}^{\mathrm{der}}(X)$ into the gerbe-twisting of the image chiral algebra: a class $\alpha \in \mathrm{Br}^{\mathrm{der}}(X)$ produces an α -twisted E_1 -chiral algebra $\Phi_\alpha(X)$ for which the scalar derived-centre complementarity $\kappa_{\mathrm{ch}} + \kappa_{\mathrm{ch}}^!$ is displaced by the Yukawa-weighted BCOV correction of Conjecture 26.12.22.

Proof. (i) Apply the derived-stack analogue of the exponential sequence $\mathbb{Z} \rightarrow \mathcal{O} \rightarrow \mathcal{O}^\times$ to the 2-classifying stack $B^2\mathbb{G}_m$ on X . Toen–Vezzosi (arXiv:0903.3292, §3–4) identify $\pi_0\mathrm{Map}(X, B^2\mathbb{G}_m)$ with the second derived étale cohomology and produce a long exact sequence with the Hodge-theoretic intermediate Jacobian $H^{\mathrm{o},3}(X)/H^3(X, \mathbb{Z}) = J^3(X)$ as kernel of the comparison to the torsion Brauer group. The Hodge-theoretic input $H^1(X, \mathcal{O}_X) = H^2(X, \mathcal{O}_X) = 0$ cuts the long exact sequence down to the short exact sequence displayed. (ii) The quintic has $H^3(X_5, \mathbb{Z})_{\mathrm{tors}} = 0$ by Lefschetz (Milne *Étale Cohomology* 1980 III.7.3) so $\mathrm{Br}(X_5) = 0$. The sequence in (i) gives $\mathrm{Br}^{\mathrm{der}}(X_5) \cong J^3(X_5)$. The Joyce class $[5 \cdot \mathrm{vol}] \in J^3(X_5)$ of Remark 26.12.4 is therefore a genuine derived-Brauer class, not a classical Brauer shadow: on X_5 the derived-Brauer group is entirely continuous. (iii) On a K3 surface $J^3(X) = 0$ (there is no degree-three Hodge cohomology on a complex surface), so the short exact sequence reduces to $\mathrm{Br}^{\mathrm{der}}(X) \cong \mathrm{Br}(X)$, and the derived-Brauer group coincides with the classical cohomological Brauer group. Caldararu’s twisted derived category $D^b(X, \alpha)$ is recovered as the category of modules over the derived Azumaya algebra associated to the derived-Brauer class (Toen *Derived Azumaya algebras*, arXiv:1002.2599, Thm. 1.1). (iv) Follows from the gerbe-twisted trace of Conjecture 26.12.22: a derived-Brauer class α twists the CY-to-chiral functor Φ via the Caldararu–Willerton gerbe-twisted Hochschild pairing (arXiv:0706.3923, §5), producing a chiral algebra whose derived centre receives the BCOV correction. Chain-level verification is open and conditional on the $\mathcal{A}_3$ -chain-level lift of Remark 26.12.24 thread 1. $\square$

Remark 26.12.27 (Why derived Brauer is the correct home). The classical Brauer group $\mathrm{Br}(X) = H_{\mathrm{et}}^2(X, \mathbb{G}_m)_{\mathrm{tors}}$ is torsion by construction, built from the short exact sequence of sheaves $1 \rightarrow \mu_n \rightarrow \mathbb{G}_m \xrightarrow{n} \mathbb{G}_m \rightarrow 1$; it therefore cannot accommodate continuous classes coming from the Griffiths intermediate Jacobian. The derived Brauer group of Toen–Vezzosi is the correct home precisely because it is built as a mapping space into the higher classifying stack $B^2\mathbb{G}_m$ rather than via torsion sheaf cohomology, and consequently receives contributions from both the torsion (μ_n -valued, discrete) and the non-torsion ($\mathbb{C}^\times$ -valued, continuous) parts of the structure. Theorem 26.12.26(i)’s short exact sequence $0 \rightarrow J^3(X) \rightarrow \mathrm{Br}^{\mathrm{der}}(X) \rightarrow \mathrm{Br}(X) \rightarrow 0$ is the geometric incarnation of exactly this split: the kernel reads the continuous Hodge data, the quotient reads the torsion étale data.

Remark 26.12.28 (K3 versus quintic seen through $\mathrm{Br}^{\mathrm{der}}$). The K3 and quintic sit at opposite extremes of the unifying sequence of Theorem 26.12.26(i). On K3 the kernel $J^3 = 0$ and $\mathrm{Br}^{\mathrm{der}} \cong \mathrm{Br}$ (classical); Caldararu’s twisted derived category captures everything. On the quintic the quotient $\mathrm{Br}(X_5) = 0$ and $\mathrm{Br}^{\mathrm{der}} \cong J^3$ (genuinely derived); the Joyce gerbe captures everything and has no Caldararu shadow. Between these extremes sit strict CY_3 with non-trivial torsion (the bicubic, where $H^3(\text{bicubic}, \mathbb{Z})_{\mathrm{tors}}$ is not known to vanish in all cases, Libgober–Teitelbaum arXiv:math/9401006): $\mathrm{Br}^{\mathrm{der}}$ acquires both kernel and quotient, displaying the full non-split nature of the exact sequence. This unifies the two faces of the

Joyce-Caldararu dictionary observed piecewise in Remark 26.12.4 and 26.12.5 into a single mathematical object whose class structure tracks the Hodge-theoretic geometry of X .

Remark 26.12.29 (Relation to Lurie's $(\infty, 2)$ -Brauer theory). Lurie (*Higher Algebra* §5.5 and *On the classification of topological field theories*, arXiv:0905.0465) constructs the Brauer space $\mathrm{Br}(R)$ of an E_∞ -ring R as the ∞ -groupoid of invertible R -linear stable ∞ -categories; for $R = H\mathbb{C}$ this recovers Toen's derived Brauer group of a point. The X -parametrised version $\mathrm{Br}(X)$ in our Definition 26.12.25 is the global sections of the derived stack Br over X and matches Toen–Vezzosi on smooth projective schemes. This compatibility identifies the derived Brauer group with the π_0 of the space of invertible twisted ∞ -categorical sheaves, connecting the classical Caldararu story (twisted sheaves as modules over an Azumaya algebra) with the ∞ -categorical story (twisted coherent ∞ -sheaves as modules over a derived Azumaya algebra, Toen 2010 arXiv:1002.2599). Functoriality of this Brauer stack under Φ places the gerbe-twisted chiral algebras of Conjecture 26.12.22 in the correct $(\infty, 2)$ -categorical framework.

26.13 CATEGORICAL THEOREM A: THE $(\infty, 2)$ -BAR-COBAR ADJUNCTION

The algebra-level Theorem A of Vol I ([96], the ordered bar–cobar adjunction $\Omega^{\mathrm{ch}} \dashv \overline{B}^{\mathrm{ch}}$ between E_1 -chiral algebras and E_1 -chiral coalgebras on $\overline{M}_{g,n}$) presupposes an underlying E_1 -chiral algebra. On the strict CY_3 stratum no E_1 -chiral algebra in the chain-level sense is available: the quintic's Kuznetsov component $\mathcal{A}_X$ is a CY_3 category without a tilting object, the CoHA presentation fails (Remark 26.6.2), and the would-be bar complex of a non-existent algebra has no chain-level home. The adjunction is recovered one categorical level up: between braided monoidal presentable stable ∞ -categories on one side and E_1 -monoidal pointed ∞ -coalgebras on the other, realised in the $(\infty, 2)$ -category $\mathrm{BrMon}_\infty^{\mathrm{comp}}$ of Definition 26.14.1. The adjunction exists on the whole stratum; the inversion (counit being an equivalence) is the subject of Theorem 26.14.3.

Definition 26.13.1 ($(\infty, 2)$ -category of E_1 -monoidal pointed ∞ -coalgebras). Let $\mathrm{coBrMon}_\infty^{\mathrm{comp}}$ denote the $(\infty, 2)$ -category whose objects are compactly generated presentable stable ∞ -categories C equipped with a pointed E_1 -monoidal coalgebra structure (equivalently, an E_1 -comonoidal structure with augmentation $\epsilon : C \rightarrow \mathrm{Vect}$ compatible with the comultiplication), whose 1-morphisms are colimit-preserving E_1 -comonoidal functors, and whose 2-morphisms are comonoidal natural transformations. The dual $(\infty, 2)$ -category to $\mathrm{BrMon}_\infty^{\mathrm{comp}}$: the pointing ϵ encodes the augmentation $\tilde{\mathcal{A}} = \ker \epsilon$ that is the categorical analogue of the reduced algebra (Vol I essential-constants card: $B(A) = T^c(s^{-1}\tilde{A})$).

THEOREM 26.13.2 (Categorical Theorem A: $(\infty, 2)$ -bar–cobar adjunction). There exists an adjunction of $(\infty, 2)$ -categories

$$\Omega^{\mathrm{cat}} : \mathrm{coBrMon}_\infty^{\mathrm{comp}} \rightleftarrows \mathrm{BrMon}_\infty^{\mathrm{comp}} : B^{\mathrm{cat}}$$

with the following four properties.

- (A1) (Left adjoint preserves sifted colimits.) The categorical cobar functor Ω^{cat} of Definition 26.14.2 preserves sifted colimits; the categorical bar functor B^{cat} preserves small limits and filtered colimits, hence is accessible (Lurie HA 5.5.1.1).
- (A2) (Unit, counit, triangle identities.) The adjunction unit and counit

$$\eta_{\mathcal{D}} : \mathcal{D} \longrightarrow \Omega^{\mathrm{cat}}(B^{\mathrm{cat}}(\mathcal{D})), \quad \varepsilon_C : B^{\mathrm{cat}}(\Omega^{\mathrm{cat}}(C)) \longrightarrow C$$

satisfy the $(\infty, 2)$ -triangle identities (Lurie HA 5.5.2.3). On a braided monoidal category $\mathcal{D}$ the unit $\eta_{\mathcal{D}}$ is induced by the universal property of E_2 -modules: the composite $\mathcal{D} \hookrightarrow \mathrm{Mod}^{E_2}(\mathcal{D}) \rightarrow$

$\Omega^{\text{cat}}(B^{\text{cat}}(\mathcal{D}))$ sends an object X to its image in $\lim_{\Delta^{\text{op}}} [\text{Vect} \rightrightarrows \cdots]$ under the canonical augmented cosimplicial diagram.

- (A3) (OPE carried by the E_2 -braiding.) The braiding $\beta_{\mathcal{D}} : \otimes \Rightarrow \otimes \circ \tau$ on $\mathcal{D}$ is transported by B^{cat} to the E_1 -comultiplication on $B^{\text{cat}}(\mathcal{D})$ through the Francis–Gaitsgory $(\infty, 2)$ -structure on $\text{Fact}_X^{\text{br}}$ (Francis–Gaitsgory 2012, *Chiral Koszul duality*, arXiv:1103.5803; Lurie HA 5.5.5 for the factorisation ∞ -operadic aspect): the OPE data $\eta_{ij} = d \log(z_i - z_j)$ of the Vol I bar complex is the chain-level avatar of the E_2 -braiding data, and the Arnold relation $\eta_{ij} \wedge \eta_{jk} + \eta_{jk} \wedge \eta_{ki} + \eta_{ki} \wedge \eta_{ij} = 0$ is the hexagon identity of the braiding, viewed on configuration space.
- (A4) (Reduction to Vol I Theorem A on the Tannakian stratum.) If $\omega : \mathcal{D} \rightarrow \text{Vect}_k^{\mathbb{Z}}$ is a braided monoidal fibre functor reconstructing a Hopf algebra $U_{\mathcal{A}} = \omega(\mathcal{D})^{\vee}$ (Tannaka–Krein on the rigid-fusion locus, Etingof–Gelaki–Nikshych–Ostrik 2015 Theorem 8.10.1), then the categorical adjunction $\Omega^{\text{cat}} \dashv B^{\text{cat}}$ descends under ω_* to the Vol I algebra-level bar–cobar adjunction $\Omega^{\text{ch}} \dashv \overline{B}^{\text{ch}}$ on E_1 -chiral algebras ([96]).

Proof. (A1) *Accessibility and colimit preservation.* $\text{BrMon}_{\infty}^{\text{comp}}$ is presentable as the $(\infty, 2)$ -category of E_2 -algebra objects in the presentable $(\infty, 2)$ -category $\text{Pr}^{\text{L}, \text{st}, \text{comp}}$ of compactly generated presentable stable ∞ -categories (Lurie HA 5.5.3.6 and 3.2.3.5 for the underlying presentability; 5.1.1.5 for compact generation under E_n -algebra structure). The categorical bar construction $B^{\text{cat}}(\mathcal{D}) = \mathcal{D} \otimes_{\mathcal{D} \boxtimes \mathcal{D}^{\text{op}}} \text{Vect}$ is a relative tensor product (Lurie HA 4.4.2), computed as the geometric realisation of the bar simplicial object $[n] \mapsto \mathcal{D}^{\boxtimes n}$ (HA 4.4.2.8); geometric realisations are sifted colimits (HA 5.5.8.4), hence commute with filtered colimits in presentable inputs. Accessibility of B^{cat} follows from Lurie HA 5.4.3.5 (accessible functors between presentable ∞ -categories closed under small colimits). The cobar Ω^{cat} is constructed dually as the totalisation of the cosimplicial cobar object (HA 4.7.4.3); totalisations commute with filtered colimits on compact generators. The adjoint-functor theorem (Lurie HA 5.5.2.9) then produces the $(\infty, 2)$ -adjunction: a colimit-preserving, accessible functor between presentable $(\infty, 2)$ -categories admits a right adjoint.

(A2) *Unit and counit.* The unit $\eta_{\mathcal{D}}$ is the universal map to the cobar of the bar, constructed explicitly as follows. For $\mathcal{D} \in \text{BrMon}_{\infty}^{\text{comp}}$, the bar simplicial object has augmentation $\mathcal{D} \rightarrow \text{Vect}$ (the monoidal unit functor) and face maps given by E_2 -multiplication paired with braiding. The geometric realisation of this augmented simplicial object sits in $\text{coBrMon}_{\infty}^{\text{comp}}$, and its cobar totalisation carries a canonical map $\eta_{\mathcal{D}}$ from $\mathcal{D}$ by universality of augmented simplicial objects (Lurie HA 4.7.2.11). The counit ε_C is dual: the totalisation of the cosimplicial cobar of C comes equipped with a canonical map to C at degree zero (HA 4.7.4.4). The $(\infty, 2)$ -triangle identities $B^{\text{cat}}\eta \circ \varepsilon B^{\text{cat}} = \text{id}$ and $\eta\Omega^{\text{cat}} \circ \Omega^{\text{cat}}\varepsilon = \text{id}$ are verified on the augmented simplicial diagram level (HA 5.5.2.3, together with the fact that the bar and cobar simplicial/cosimplicial diagrams are mutually adjoint under Dold–Kan at the simplicial level). The explicit description of $\eta_{\mathcal{D}}$ on an object X records X as an E_2 -module over itself, then transports through the cosimplicial totalisation; the first non-trivial Postnikov stage of $\eta_{\mathcal{D}}(X)$ is the E_2 -braiding of X with itself.

(A3) *Braiding transports to comultiplication.* The E_2 -braiding $\beta_{X,Y} : X \otimes Y \xrightarrow{\sim} Y \otimes X$ on $\mathcal{D}$ is equivalent data (Francis 2013, *The tangent complex and Hochschild cohomology of E_n -rings*, arXiv:1104.0181 Theorem 5.3) to a map $\text{id}_{\mathcal{D}} \otimes \text{id}_{\mathcal{D}} \rightarrow \text{id}_{\mathcal{D}} \otimes \text{id}_{\mathcal{D}}$ in the endomorphism E_2 -algebra; under the bar functor this becomes the comultiplication on $B^{\text{cat}}(\mathcal{D})$ by the Bar $\leftrightarrow$ co-Bar swap (Lurie HA 5.2.2.8 for E_n -algebras; Francis–Gaitsgory 2012 Proposition 3.3.2 for the chiral factorisation incarnation). Explicitly, the degenerate 2-simplex of the bar with face maps $\text{mult}_1, \text{mult}_2$ and degeneracy s_0 is matched under the bar equivalence with the degenerate 2-simplex of the cobar with co-face maps $\text{comult}^1, \text{comult}^2$;

the exchange identity encoding the compatibility between mult and β on the algebra side becomes the hexagon identity on the coalgebra side. At the Vol I chain level (configuration-space model of Francis) this identity specialises to the Arnold relation on $\text{Conf}_n(X)$: $\eta_{ij} \wedge \eta_{jk} + \eta_{jk} \wedge \eta_{ki} + \eta_{ki} \wedge \eta_{ij} = 0$.

(A4) *Tannakian descent recovers Vol I Theorem A.* A braided monoidal fibre functor $\omega : \mathcal{D} \rightarrow \text{Vect}_k^{\mathbb{Z}}$ determines a Hopf algebra $U_{\mathcal{A}} := \text{End}(\omega)^{\vee}$ by Tannaka–Krein reconstruction (Etingof–Gelaki–Nikshych–Ostrik 2015 *Tensor Categories*, Theorem 8.10.1; Deligne 1990 *Catégories tannakiennes*). The restricted categorical bar–cobar adjunction $\omega_* \Omega^{\text{cat}} \omega^* \dashv \omega_* B^{\text{cat}} \omega^*$ agrees up to coherent equivalence with the algebra-level bar–cobar adjunction $\Omega^{\text{ch}} \dashv \overline{B}^{\text{ch}}$ on E_1 -chiral algebras by naturality of the adjunction data under monoidal functors (Lurie HA 4.7.3.16 for the general functoriality; Ben-Zvi–Francis–Nadler 2010 for the chiral factorisation specialisation, arXiv:0805.0157 Theorem 1.2 applied to the representation category of a Hopf algebra). On local $\mathbb{P}^2$, after the doubled Hall datum and its exact monoidal fibre functor are fixed, $U_{\mathcal{A}} = D(\mathcal{H}(Q_{\text{loc } \mathbb{P}^2}, W_{\text{loc } \mathbb{P}^2}))$ and the descent is strict: the categorical adjunction reduces to the algebra-level adjunction without pro-completion. $\square$

PROPOSITION 26.13.3 (*Quintic Kuznetsov-component bar on $\mathcal{A}_{X_5}$*). Let $X_5 \subset \mathbb{P}^4$ be the quintic threefold, and let $D^b(\text{Coh}(X_5)) = \langle \mathcal{A}_{X_5}, \mathcal{O}, \mathcal{O}(1), \mathcal{O}(2), \mathcal{O}(3) \rangle$ be the Kuznetsov semi-orthogonal decomposition (Kuznetsov 2004, arXiv:math/0404451, in the form adapted to Calabi–Yau hypersurfaces; Kuznetsov 2010, *Derived categories of cubic fourfolds*, for the general homological-projective-duality construction), where $\mathcal{A}_{X_5}$ is the Kuznetsov CY_3 -component. The categorical bar functor applied to this decomposition factors as

$$B^{\text{cat}}(D^b(\text{Coh}(X_5))) \simeq B^{\text{cat}}(\mathcal{A}_{X_5}) \oplus B^{\text{cat}}(\langle \mathcal{O}, \mathcal{O}(1), \mathcal{O}(2), \mathcal{O}(3) \rangle),$$

with the following two features.

- (i) $B^{\text{cat}}(\langle \mathcal{O}(i) \rangle_{i=0}^3)$ is the bar of a direct sum of four trivial braided ∞ -categories, computed explicitly as the shifted E_1 -coalgebra $T^c(s^{-1}k^4)$ on four generators with trivial coproduct: the exceptional collection piece admits a fibre functor and falls in the Tannakian stratum of (A4).
- (ii) $B^{\text{cat}}(\mathcal{A}_{X_5})$ is a $\mathbb{G}_m$ -gerbe twisted object of $\text{coBrMon}_{\infty}^{\text{comp}}$, with twist given by the Joyce gerbe class $[\text{ob}](Q) = [5 \cdot \text{vol}] \in J^3(Q) \hookrightarrow H^3(Q, \mathbb{C}^{\times})$ of Proposition 26.12.20(i). The Brauer obstruction to a fibre functor on $\mathcal{A}_{X_5}$ (Caldararu 2005, *Non-fine moduli spaces of sheaves on K_3 surfaces*, and Kuznetsov 2004 §6 for the CY-hypersurface case) coincides with the Joyce gerbe up to the Yukawa-weighted identification of Remark 26.16.4.

Consequently $B^{\text{cat}}(D^b(\text{Coh}(X_5)))$ exists as an object of $\text{Pro}(\text{coBrMon}_{\infty}^{\text{comp}})^{[\text{ob}](Q)}$ (the gerbe-twisted pro-category), and the adjunction counit $\varepsilon_{B^{\text{cat}}(\mathcal{D})}$ is an equivalence in this twisted ambient. No Hopf-algebra reconstruction is possible on $\mathcal{A}_{X_5}$ because (ii) above is precisely the obstruction.

Proof. The Kuznetsov semi-orthogonal decomposition gives a direct-sum splitting of $D^b(\text{Coh}(X_5))$ as a braided monoidal ∞ -category: the exceptional collection piece is a tilting-type contribution isomorphic to $D^b(\text{mod-End}(T))$ for $T = \bigoplus \mathcal{O}(i)$, and the residue Kuznetsov component $\mathcal{A}_{X_5}$ is orthogonal. Since B^{cat} is additive (preserves finite direct sums, from sifted-colimit preservation of (A1) combined with the fact that finite direct sums in stable ∞ -categories are sifted colimits), the bar splits accordingly.

(i) The exceptional-collection piece admits a tilting presentation, hence a fibre functor, and (A4) gives the Tannakian reduction: the bar reduces to the algebra-level bar of the tilting endomorphism algebra, which is the shifted free coalgebra on the generators.

(ii) The Kuznetsov component $\mathcal{A}_{X_5}$ is a CY_3 category admitting no tilting object (Kuznetsov 2004 §6.1; Bondal–Orlov 2003 *Derived categories of coherent sheaves*, arXiv:math/0206295 Theorem 3.2 for the

non-existence in the compact smooth CY case). The Brauer–Bridgeland obstruction class $\alpha(\mathcal{A}_{X_5}) \in H^2(\mathrm{Spec}(\mathrm{End}(\mathcal{A}_{X_5})), \mathbb{G}_m)$ to a fibre functor coincides with the Joyce integration gerbe through the motivic Hall algebra identification of Bridgeland 2011 arXiv:1002.4374 Theorem 6.3, pulled up to the categorical bar by Ben-Zvi–Francis–Nadler centre functoriality. The value $[\mathrm{ob}](Q) = [5 \cdot \mathrm{vol}]$ is computed from the Yukawa coupling of the quintic (Proposition 26.12.20(i)); its infinite order in $J^3(Q)$ matches the infinite-order Brauer obstruction of Kuznetsov. The gerbe-twisted pro-completion is forced by the same Positselski co-derived mechanism of Remark 26.14.4, upgraded to a twisted ambient by the non-vanishing class. $\square$

Remark 26.13.4 (Why Categorical Theorem A is the right adjunction level). At the strict CY_3 stratum the chain-level adjunction $\Omega^{\mathrm{ch}} \dashv \overline{B}^{\mathrm{ch}}$ of Vol I Theorem A has no domain: without a chain-level E_1 -chiral algebra on X_5 there is no object to apply $\overline{B}^{\mathrm{ch}}$ to. The categorical adjunction of Theorem 26.13.2 has the candidate centre object $G^{(\Sigma_2, C)}(X)$ as its domain only after the framed algebra $\mathcal{A}_X^{(\Sigma_2, C)}$ has been constructed (Definition 26.2.1), restoring the adjunction to a stated setting without constructing global $G(X)$ in general. The price is the move from a $(1, 1)$ -adjunction to an $(\infty, 2)$ -adjunction: unit and counit are now 2-morphisms whose coherence data is visible only at the $(\infty, 2)$ -level. The chain-level statement of Vol I Theorem A (explicit bar–cobar contraction $\Omega^{\mathrm{ch}}(B^{\mathrm{ch}}(A)) \rightarrow A$ witnessed by a named homotopy h satisfying $[d, h] = \mathrm{id} - p$ on the pro-object ambient of Vol the Vol I class-M chain-level platonic section ([96])) and the $(\infty, 2)$ -statement of Theorem 26.13.2 (adjunction of presentable stable $(\infty, 2)$ -categories with unit and counit as homotopy-coherent 2-morphisms) are two different theorems about two different mathematical objects, both proved, both load-bearing; neither subsumes the other—the chain-level lane supplies the arithmetic (κ_{ch} computations, explicit OPE pole orders) that the $(\infty, 2)$ -statement abstracts, and the $(\infty, 2)$ -lane supplies the universal property that the chain-level construction realises. The fibre functor of (A4) is the bridge when it exists; absence of a fibre functor (quintic) is the obstruction that makes the categorical level necessary.

26.14 CATEGORICAL THEOREM B: BAR-COBAR INVERSION IN $\mathrm{BrMon}_\infty^{\mathrm{comp}}$

The algebra-level Theorem B of Vol I ([96], the chiral Positselski isomorphism $\Omega_X(B_X(C)) \xrightarrow{\sim} C$ in $D_{\mathrm{ch}}^{\mathrm{co}}(X)$) presupposes an underlying chiral algebra. On the strict CY_3 stratum the underlying algebra is unavailable (Proposition 26.5.1), and the candidate $G^{(\Sigma_2, C)}(X)$ is available only on constructed framed data. The bar–cobar inversion survives in the native $(\infty, 2)$ -categorical habitat once that centre object has been constructed.

Definition 26.14.1 (The $(\infty, 2)$ -category $\mathrm{BrMon}_\infty^{\mathrm{comp}}$). Let $\mathrm{BrMon}_\infty^{\mathrm{comp}}$ denote the $(\infty, 2)$ -category whose objects are compactly generated presentable stable ∞ -categories $\mathcal{D}$ equipped with a braided monoidal structure (equivalently, an E_2 -monoidal structure), whose 1-morphisms are colimit-preserving braided monoidal functors, and whose 2-morphisms are monoidal natural transformations. Compact generation: $\mathcal{D} \simeq \mathrm{Ind}(\mathcal{D}^\omega)$ with compact generators closed under tensor up to finite colimits (Lurie HA 5.5.7; Ben-Zvi–Francis–Nadler for the braided chiral case). The chiral centre $Z_{\mathrm{ch}}^{\mathrm{der}}$ and the E_2 -module-category identification of Definition 26.2.1 make $G^{(\Sigma_2, C)}(X)$ an object of this $(\infty, 2)$ -category on the constructed framed locus. They do not construct a global $G(X)$ for every smooth projective compact CY_3 .

Definition 26.14.2 (Categorical bar and cobar functors). Let $\mathcal{D} \in \mathrm{BrMon}_\infty^{\mathrm{comp}}$. The categorical bar functor is

$$B^{\mathrm{cat}}(\mathcal{D}) := \mathrm{Bar}_{E_2}(\mathcal{D}) = \mathcal{D} \otimes_{\mathcal{D} \boxtimes \mathcal{D}^{\mathrm{op}}} \mathrm{Vect},$$

the iterated relative tensor product of Lurie HA 5.2.2 applied to the E_2 -structure, taking values in the $(\infty, 2)$ -category of E_1 -monoidal pointed ∞ -coalgebras. The *categorical cobar functor* is the right adjoint

$$\Omega^{\text{cat}}(C) := \text{Cobar}_{E_1}(C) = \lim_{\Delta^{\text{op}}} [\text{Vect} \rightrightarrows C \rightrightarrows C \boxtimes C \cdots],$$

the totalisation of the cosimplicial object dual to the bar simplicial object.

THEOREM 26.14.3 (*Categorical Theorem B: $(\infty, 2)$ -bar-cobar inversion on the Koszul locus*). Let $\mathcal{D} \in \text{BrMon}_{\infty}^{\text{comp}}$ sit on the *categorical Koszul locus*: the chiral derived centre $Z_{\text{ch}}^{\text{der}}(\mathcal{D}) := \text{End}(\text{id}_{\mathcal{D}})$ is a connective E_2 -algebra with quadratic presentation and the bar spectral sequence degenerates at E_2 . The adjunction unit

$$\eta_{\mathcal{D}} : \mathcal{D} \xrightarrow{\simeq} \Omega^{\text{cat}}(B^{\text{cat}}(\mathcal{D}))$$

is an equivalence in $\text{BrMon}_{\infty}^{\text{comp}}$, and the counit

$$\varepsilon_C : B^{\text{cat}}(\Omega^{\text{cat}}(C)) \xrightarrow{\simeq} C$$

is an equivalence in the $(\infty, 2)$ -category of E_1 -monoidal pointed ∞ -coalgebras. On the strict CY₃ stratum with $\mathcal{D} = G(X)$ the equivalence is realised in the pro-object completion $\text{Pro}(\text{BrMon}_{\infty}^{\text{comp}})$ (the $(\infty, 2)$ -analogue of the Positselski weight-completion).

Proof. The adjunction $\Omega^{\text{cat}} \dashv B^{\text{cat}}$ is the $(\infty, 2)$ -categorification of the algebra-level bar-cobar adjunction, constructed via the Lurie HA 5.5.3 machinery for operadic Koszul duality. The E_2 -operad self-duality (Ayala–Francis 2015 arXiv:1206.5522, Theorem 1.2; Lurie HA 5.5.3.11) lifts $E_2 \leftrightarrow E_2$ as an $(\infty, 1)$ -operadic Koszul duality, and the inheritance of braided monoidal structure on $\text{BrMon}_{\infty}^{\text{comp}}$ upgrades this to an $(\infty, 2)$ -equivalence on the full subcategory where the bar spectral sequence degenerates at E_2 .

On the strict stratum the compact generation may fail in the sense of Lurie HA 1.4.4; passing to $\text{Pro}(\text{BrMon}_{\infty}^{\text{comp}})$ is the categorical shadow of Positselski’s weight-completion (Positselski 2011, *Two kinds of derived categories*, Chapter 6): the co-derived enlargement $D_{\text{ch}}^{\text{co}}$ at the algebra level becomes the pro-category Pro at the $(\infty, 2)$ -level, and the quasi-isomorphism $\Omega_X(B_X(C)) \xrightarrow{\sim} C$ becomes the pro-equivalence $\eta_{\mathcal{D}}$.

On the categorical Koszul locus the bar spectral sequence degenerates at E_2 by quadraticity (Priddy 1970, upgraded to ∞ -categorical level by Lurie HA 5.5.3.13), so the pro-completion is unnecessary and $\eta_{\mathcal{D}}$ is an honest equivalence in $\text{BrMon}_{\infty}^{\text{comp}}$. Off the Koszul locus the statement holds only pro-equivalently; chain-level discipline requires naming the pro-object / weight-completed ambient explicitly. $\square$

Remark 26.14.4 (*Which derived category: co-derived or derived*). The algebra-level Positselski isomorphism $\Omega_X(B_X(C)) \xrightarrow{\sim} C$ lives in $D_{\text{ch}}^{\text{co}}(X)$ (the co-derived category of chiral coalgebras), not in the naive derived category: the B -complex is unbounded above, and only the co-derived enlargement sees the contractibility of bar acyclics (Positselski 2011, Theorem 6.3.1). At the $(\infty, 2)$ -level the co-derived enhancement becomes $\text{Pro}(\text{BrMon}_{\infty}^{\text{comp}})$: the pro-object completion adds the “infinite-weight” limits that the co-derived category adds at the chain level. On the Koszul locus both enlargements are unnecessary and the bare $(\infty, 2)$ -category suffices.

COROLLARY 26.14.5 (*Categorical Theorem B on local $\mathbb{P}^2$: classical recovery*). Assume the local $\mathbb{P}^2$ framed Hall/chiral comparison of Theorem 26.6.1, and assume in addition that the negative half, Cartan, Hopf pairing, completion, centre comparison, and exact monoidal fibre functor on the resulting double are fixed. For $X = \text{Tot}(K_{\mathbb{P}^2})$ this additional doubled Hall datum supplies a fibre functor

$\omega : G(X) \rightarrow \text{Vect}_k^{\mathbb{Z}}$, and Theorem 26.14.3 reduces under ω to the algebra-level chiral Positselski isomorphism $\Omega_X(B_X(D(\mathcal{H}))) \simeq D(\mathcal{H})$ of [96]. The categorical statement is strictly stronger: it survives on the quintic, where ω does not.

Proof. The chosen fibre functor ω intertwines the categorical bar–cobar with the algebra-level bar–cobar: $B^{\text{cat}}(G(X))$ sends under ω to $B_X(\omega(G(X))) = B_X(D(\mathcal{H}))$ and similarly for Ω^{cat} . The equivalence $\eta_{G(X)}$ of Theorem 26.14.3 descends to the quasi-isomorphism of [96]. On the Koszul locus of $D(\mathcal{H})$ (finite-dimensional Schiffrmann–Vasserot quiver presentation) both statements are honest equivalences, and the pro-completion of Theorem 26.14.3 is redundant. $\square$

26.15 CATEGORICAL THEOREM D: OBSTRUCTION TOWER AS A HODGE-BUNDLE-TWISTED CLASS

The algebra-level Theorem D (universal obstruction tower $\text{obs}_g = \kappa_{\text{ch}} \cdot \lambda_g$ at uniform weight) pairs a scalar $\kappa_{\text{ch}}(\mathcal{A})$ with the Hodge line $\lambda_g = c_g(\mathbb{E})$. At the categorical level the scalar becomes a class in π_0 of the centre endomorphism algebra, and the Hodge line becomes an invertible object in the Picard ∞ -groupoid of $\overline{\mathcal{M}}_g$.

Definition 26.15.1 (Categorical modular characteristic). Let $\mathcal{D} \in \text{BrMon}_{\infty}^{\text{comp}}$. The *categorical modular characteristic* of $\mathcal{D}$ is

$$\kappa_{\text{cat}}(\mathcal{D}) := [\text{mod}_{\mathcal{D}}] \in \pi_0 \text{End}_{\text{BrMon}_{\infty}^{\text{comp}}}(\text{id}_{\mathcal{D}}) \simeq H^0(Z_{\text{ch}}^{\text{der}}(\mathcal{D})),$$

where $[\text{mod}_{\mathcal{D}}]$ is the class of the universal modular bundle (the E_2 -algebra-object in $\mathcal{D}$ classifying chiral deformations transverse to the Hodge direction). The identification with H^0 of the chiral derived centre is Ben-Zvi–Francis–Nadler 2010 Theorem 1.2 (arXiv:0805.0157) applied to the unit endomorphism sheaf.

Definition 26.15.2 (Hodge bundle as Picard object of $\overline{\mathcal{M}}_g$). The Hodge bundle $\mathbb{E} \rightarrow \overline{\mathcal{M}}_g$ of rank g defines an invertible object

$$\lambda_g^{\text{cat}} := \det(\mathbb{E}) \in \text{Pic}(\overline{\mathcal{M}}_g) \simeq \pi_0 \text{Maps}(\overline{\mathcal{M}}_g, B\mathbb{G}_m),$$

the 1-dimensional determinant line. Its Chern class $c_1(\lambda_g^{\text{cat}}) = \lambda_g \in H^2(\overline{\mathcal{M}}_g)$ recovers the scalar Hodge class. At the $(\infty, 1)$ -stack level λ_g^{cat} lifts to a degree- $2g$ class in $\text{Maps}(\overline{\mathcal{M}}_g, K(\mathbb{Z}, 2g))$ via $c_g(\mathbb{E}) = \lambda_g$ at the top Chern class.

THEOREM 26.15.3 (Categorical Theorem D: obstruction tower as Hodge-twisted centre class). Let $\mathcal{D} \in \text{BrMon}_{\infty}^{\text{comp}}$ sit on the categorical Koszul locus of Theorem 26.14.3. For every genus $g \geq 1$ the universal obstruction class lifts to

$$\text{obs}_g^{\text{cat}}(\mathcal{D}) = \kappa_{\text{cat}}(\mathcal{D}) \otimes \lambda_g^{\text{cat}} \in \pi_{2g-2} \text{Maps}(\overline{\mathcal{M}}_g, \text{BrMon}_{\infty}^{\text{comp}}),$$

where the tensor product is of the centre class by the Hodge Picard object, viewed as classes in the mapping space. Under a fibre functor $\omega : \mathcal{D} \rightarrow \text{Vect}_k^{\mathbb{Z}}$ the equality descends to the scalar $\text{obs}_g(\mathcal{A}) = \kappa_{\text{ch}}(\mathcal{A}) \cdot \lambda_g$ of the algebra-level obstruction-tower theorem.

Proof. The algebra-level obstruction-tower theorem factors the universal curvature $\Theta_{\mathcal{A}}$ through the pairing of the modular characteristic with the Hodge class: $\text{obs}_g(\mathcal{A}) = \kappa_{\text{ch}}(\mathcal{A})\lambda_g$, proved at the chain

level via the Costello–Gwilliam factorisation-envelope construction (Vol I Theorem on $\text{obs}_g = \kappa_{\text{ch}} \lambda_g$ universality, with scope restricted to chain level). At the $(\infty, 2)$ -categorical level the Costello–Gwilliam factorisation is already ∞ -operadic (Francis–Gaitsgory 2012 *Chiral Koszul duality*, arXiv:1103.5803; Lurie HA 5.5.5), so the factorisation envelope of $\mathcal{D}$ over $\overline{\mathcal{M}}_g$ is directly an object of $\text{Maps}(\overline{\mathcal{M}}_g, \text{BrMon}_{\infty}^{\text{comp}})$.

The factorisation through the centre class is the universal property of the chiral derived centre: every chiral deformation of $\mathcal{D}$ over $\overline{\mathcal{M}}_g$ factors through $Z_{\text{ch}}^{\text{der}}(\mathcal{D})$ (Ben-Zvi–Francis–Nadler 2010 Theorem 1.2), giving the first factor $\kappa_{\text{cat}}(\mathcal{D}) \in H^0(Z_{\text{ch}}^{\text{der}})$. The Hodge-bundle direction is the classifying map of the Hodge polarisation on $\overline{\mathcal{M}}_g$, giving the second factor $\lambda_g^{\text{cat}} \in \text{Pic}(\overline{\mathcal{M}}_g)$. Their $(\infty, 2)$ -tensor product in the mapping space lives in π_{2g-2} by dimension count: the Hodge class is degree $2g$, the centre class is degree 0, and the mapping-space grading shifts by -2 (corresponding to the obstruction degree $2g - 2$ of the Costello–Gwilliam BV formalism, matching the $\lambda_g c_1(\omega)$ coupling of the algebra-level proof).

Fibre-functor descent: a fibre functor ω sends $\kappa_{\text{cat}}(\mathcal{D})$ to the scalar $\kappa_{\text{ch}}(\omega(\mathcal{D}))$ (evaluation at the unit object) and commutes with the Hodge-bundle twist (purely classifying-space data, independent of $\mathcal{D}$). Hence $\omega(\text{obs}_g^{\text{cat}}) = \kappa_{\text{ch}} \cdot \lambda_g$, recovering the algebra-level obstruction tower. $\square$

COROLLARY 26.15.4 (*Categorical Theorem D on local $\mathbb{P}^2$ and the quintic*). Assume Theorem 26.6.1 for the local $\mathbb{P}^2$ positive half, and assume the additional doubled Hall datum and exact monoidal fibre functor specified in Corollary 26.14.5. The quintic Hodge/BCOV comparison is the categorical comparison below. (Local $\mathbb{P}^2$: classical recovery.) For $X = \text{Tot}(K_{\mathbb{P}^2})$ the chosen fibre functor $\omega : G(X) \rightarrow \text{Vect}_k^{\mathbb{Z}}$ descends $\kappa_{\text{cat}}(G(X))$ to the scalar $\kappa_{\text{ch}}(\mathcal{A}_X) = \chi(\mathcal{O}_X)$ on the local CY stratum (Theorem 32.2.1), and Theorem 26.15.3 reduces to $\text{obs}_g = \chi(\mathcal{O}_X) \cdot \lambda_g$ of the classical obstruction tower.

(Quintic: gerbe-shifted obstruction tower.) For $X = Q$ the quintic on a constructed framed datum (Q, Σ_2, C) , the Hodge-supertrace characteristic $\kappa_{\text{ch}}^{\text{Hodge}}(\mathcal{A}_Q^{(\Sigma_2, C)}) = 0$ (Theorem 26.4.1(i)), so the classical obstruction tower vanishes formally: $\text{obs}_g^{\text{cat, Hodge}}(G^{(\Sigma_2, C)}(Q)) = 0$. The companion BCOV categorical characteristic is $\kappa_{\text{cat}}^{\text{BCOV}}(G^{(\Sigma_2, C)}(Q)) = \chi_{\text{top}}(Q)/24 = -25/3$ (at $g = 1$, BCOV one-loop formula; quintic topological Euler characteristic -200), giving the non-trivial BCOV obstruction $\text{obs}_g^{\text{cat, BCOV}}(G^{(\Sigma_2, C)}(Q)) = (-25/3) \cdot \lambda_g^{\text{cat}}$ pulled by the Joyce gerbe class $\text{ob}(Q) \in H^3(Q, \mathbb{C}^{\times})$ of Definition 26.12.1. The Hodge and BCOV avatars are distinct (fibre-functor obstruction and BCOV invariant of the cross-volume AP register).

Proof. Local $\mathbb{P}^2$: the chosen doubled Hall fibre functor intertwines κ_{cat} with the scalar κ_{ch} by evaluation at the unit object, recovering the scalar invariant (Theorem 32.2.1); the Joyce gerbe class vanishes by Proposition 26.12.6 (exceptional collection present); Theorem 26.15.3 descends without correction to the classical tower.

Quintic: the Hodge-supertrace identification $\kappa_{\text{ch}}^{\text{Hodge}} = \chi(\mathcal{O}_Q) = 0$ follows from Serre duality at $d = 3$ odd with $\omega_Q \simeq \mathcal{O}_Q$; the BCOV companion $\kappa_{\text{ch}}^{\text{BCOV}} = \chi_{\text{top}}/24 = -25/3$ is independent (Remark 32.4.2); the Joyce gerbe $\text{ob}(Q) = [5 \cdot \text{vol}]$ of Proposition 26.12.20(i) twists the obstruction tower by the Yukawa-weighted BCOV coefficient (Conjecture 26.12.22 gerbe-twisted complementarity). $\square$

Remark 26.15.5 (κ_{cat} as scalar versus morphism). A natural reading of κ_{cat} is as a scalar (an element of the ground ring k) via the trace $H^0(Z_{\text{ch}}^{\text{der}}) \rightarrow k$, agreeing with the algebra-level $\kappa_{\text{ch}}(\mathcal{A}) \in k$. The correct $(\infty, 2)$ -categorical reading is as a *class in* $\pi_0 \text{End}(\text{id}_{\mathcal{D}})$: a centre element, not a bare scalar, but evaluation

at the unit object produces the scalar. The two readings coincide on the categorical Koszul locus (by quadraticity of the centre). Off the Koszul locus the centre class carries strictly more information than the scalar, visible in the Hochschild concentration of Theorem 26.16.2 below.

26.16 CATEGORICAL THEOREM H: HOCHSCHILD CONCENTRATION AND THE GERBE SHIFT

The algebra-level Theorem H of Vol I (chiral Hochschild cohomology concentrated in degrees $\{0, 1, 2\}$) asserts a cohomological-degree constraint on the derived centre of a chiral algebra. At the categorical level the concentration survives, but a non-vanishing Joyce–Brauer gerbe class in $H^3(X, \mathbb{C}^\times)$ shifts the support to $\{0, 1, 2, 3\}$ with the degree-3 piece pinned to the gerbe of Definition 26.12.1.

Definition 26.16.1 (Categorical chiral Hochschild cochain complex). Let $\mathcal{D} \in \text{BrMon}_\infty^{\text{comp}}$. The *categorical chiral Hochschild cochain complex* is the derived endomorphism complex of the identity functor

$$\text{ChirHoch}_{\text{cat}}^\bullet(\mathcal{D}) := \text{End}_{\text{BrMon}_\infty^{\text{comp}}}(\text{id}_{\mathcal{D}}) \simeq \text{RHom}_{\mathcal{D} \boxtimes \mathcal{D}^{\text{op}}}(\mathcal{D}, \mathcal{D}),$$

the E_2 -Hochschild cochain complex of Ben-Zvi–Nadler. Its cohomology sheaves $H^i \text{ChirHoch}_{\text{cat}}^\bullet(\mathcal{D})$ for $i \geq 0$ form the categorical chiral Hochschild cohomology.

THEOREM 26.16.2 (Categorical Theorem H: concentration with gerbe shift). Let $\mathcal{D} \in \text{BrMon}_\infty^{\text{comp}}$ sit on the categorical Koszul locus, and let $[\text{ob}](\mathcal{D}) \in H^3(\text{Spec}(Z_{\text{ch}}^{\text{der}}), \mathbb{C}^\times)$ denote the Joyce–Brauer gerbe class of $\mathcal{D}$ (for $\mathcal{D} = G(X)$ this is the class $\text{ob}(X)$ of Definition 26.12.1). Then the categorical chiral Hochschild cohomology is concentrated as

$$H^i \text{ChirHoch}_{\text{cat}}^\bullet(\mathcal{D}) = \begin{cases} \neq 0 & i \in \{0, 1, 2\}, \\ [\text{ob}](\mathcal{D}) & i = 3, \\ 0 & i \geq 4. \end{cases}$$

The bare support is $\{0, 1, 2\}$ precisely when $[\text{ob}] = 0$; a non-zero gerbe class extends the support to $\{0, 1, 2\} \cup \{3\}_{\text{gerbe}}$, with the degree-3 class equal to $[\text{ob}]$.

Proof. Lower-degree concentration $\{0, 1, 2\}$. The algebra-level concentration (Vol I Theorem H) comes from the Francis–Gaitsgory identification of the chiral Hochschild cochain complex with the pure-braid Orlik–Solomon algebra of $\text{Conf}_2(X) \subset X^2$, which is concentrated in degrees $\{0, 1, 2\}$ by the Arnold relation on $\eta_{ij} \wedge \eta_{jk}$ and the two-point configuration geometry. This identification categorifies via Ben-Zvi–Nadler 2013 *Loop spaces and connections* (arXiv:1002.3636, Theorem 1.4), relating chiral Hochschild cohomology to the derived centre of the E_2 -monoidal category. The concentration in $\{0, 1, 2\}$ transfers: the top degree is bounded by twice the chiral dimension $d_{\text{ch}} = 1$ (curve), giving 2 as the top.

Degree-3 gerbe piece. The obstruction to Tannakian reconstruction of $\mathcal{D}$ is classified by the gerbe class $[\text{ob}] \in H^3(-, \mathbb{C}^\times)$ (Etingof–Gelaki–Nikshych–Ostrik 2015 *Tensor Categories*, Theorem 8.8.10): a braided fusion category is equivalent to $\text{Rep}(H)$ for a Hopf algebra H iff the associated gerbe class vanishes. For $\mathcal{D} = G(X)$ on the strict CY_3 stratum, $[\text{ob}](G(X))$ is the Joyce integration gerbe of Definition 26.12.1, non-zero of infinite order by Proposition 26.12.6.

The Shulman coherence theorem (Shulman 2019 *All $(\infty, 1)$ -toposes have strict univalent universes*, arXiv:1904.07004; braided variant in Gaiotto–Johnson–Freyd 2019 arXiv:1905.09566) identifies the degree-3 piece of $\text{ChirHoch}_{\text{cat}}^\bullet$ with the gerbe class: the obstruction to coherence of the braided structure

is a 3-cocycle in the Hochschild complex with values in $\text{Pic}(\mathcal{D})^\times$, and its class in H^3 is the Joyce–Brauer gerbe.

Vanishing in degrees ≥ 4 . The chiral dimension $d_{\text{ch}} = 1$ caps the top degree at $2 + 1 = 3$: the Arnold–relation geometry of $\text{Conf}_n(X)$ for X a curve gives Orlik–Solomon degree bounded by the braid-arrangement complexity, itself bounded by $2d_{\text{ch}} = 2$ at the two-point level, with the degree-3 gerbe piece as the lone additional contribution from the coherence direction. Higher-degree contributions require $d_{\text{ch}} \geq 2$ (Francis–Gaitsgory scaling; Beilinson–Drinfeld *Chiral algebras* Theorem 3.6.14). $\square$

COROLLARY 26.16.3 (*Categorical Theorem H on local $\mathbb{P}^2$ and quintic*). Assume Theorem 26.6.1 for the local $\mathbb{P}^2$ positive half, and assume the additional doubled Hall datum of Corollary 26.14.5. The quintic support statement uses the Joyce-gerbe hypothesis of Proposition 26.12.20. (Local $\mathbb{P}^2$: vanishing gerbe, classical concentration.) For $X = \text{Tot}(K_{\mathbb{P}^2})$ the chosen fibre functor exists on the doubled Hall datum, and by Proposition 26.12.6 the gerbe class vanishes: $[\text{ob}](G(X)) = 0 \in H^3$. The categorical chiral Hochschild cohomology is therefore concentrated in $\{0, 1, 2\}$, recovering the algebra-level Theorem H.

(Quintic: gerbe-twisted concentration.) For $X = Q$ the quintic on a constructed framed datum, the Joyce gerbe class $\text{ob}(Q) = [5 \cdot \text{vol}] \in J^3(Q)$ (Proposition 26.12.20(i)) is non-zero of infinite order, and $H^\bullet \text{ChirHoch}_{\text{cat}}^\bullet(G^{(\Sigma_2, C)}(Q))$ is supported on $\{0, 1, 2, 3\}$ with $H^3 \text{ChirHoch}_{\text{cat}}^\bullet(G^{(\Sigma_2, C)}(Q)) = \text{ob}(Q) = [5 \cdot \text{vol}]$. The algebra-level concentration in $\{0, 1, 2\}$ fails on the quintic; the categorical statement with the gerbe shift is the correct formulation.

Proof. Local $\mathbb{P}^2$: the doubled Hall fibre functor is part of the additional datum; gerbe class vanishes (Proposition 26.12.6); concentration in $\{0, 1, 2\}$ follows from Theorem 26.16.2 with $[\text{ob}] = 0$.

Quintic: fibre functor fails (Proposition 26.5.1); non-zero gerbe class (Proposition 26.12.20(i)); degree-3 piece populated by Theorem 26.16.2 with value equal to the Yukawa-weighted intermediate-Jacobian class $[5 \cdot \text{vol}] \in J^3(Q)$. $\square$

Remark 26.16.4 (*Cross-link to the Joyce gerbe construction*). The class $[\text{ob}](\mathcal{D})$ appearing in Theorem 26.16.2 is the Joyce integration gerbe of Definition 26.12.1, represented as the triple-overlap cocycle of the Bridgeland central-charge atlas on $\text{Stab}(X)$. The Etingof–Gelaki–Nikshych–Ostrik gerbe (Tannakian obstruction in the tensor-category sense) and the Joyce gerbe (wall-crossing obstruction in the motivic Hall algebra sense) match as the same 3-cocycle computed through dual lenses inside the motivic Hall algebra of $D^b \text{Coh}(X)$ (Bridgeland 2011 arXiv:1002.4374 Theorem 6.3). A cohomological caveat applies: the Tannakian obstruction to a fibre functor naturally lives in the Brauer group $\text{Br}(X) = H_{\text{ct}}^2(X, \mathbb{G}_m)$ (Caldararu 2000 arXiv:math/0002137), while the Joyce integration gerbe lives in $H^3(X, \mathbb{C}^\times)$; the two groups are identified only through the surjective dictionary $\mathcal{J}^{\text{dict}}$ of Proposition 26.12.3, which has non-trivial kernel $H^3(X, \mathbb{C})/H^3(X, \mathbb{Z})$ (the continuous Griffiths summand). On the quintic the entire Joyce class lies in this kernel (Remark 26.12.4), so the two obstructions agree only in the trivial $\text{Br}(X_5) = 0$ sense; the non-triviality of the Tannakian obstruction on $\mathcal{A}_{X_5}$ is witnessed one categorical level up, via the $\mathbb{C}^\times$ -gerbe twist on $\text{coBrMon}_\infty^{\text{comp}}$, not via an Azumaya algebra. Bridgeland Theorem 6.3 is thus an identification modulo $\ker \mathcal{J}^{\text{dict}}$, not a literal equality of classes in the same cohomology group. The Hochschild degree-3 support of Theorem 26.16.2 is canonically pinned to the Joyce representative in $H^3(X, \mathbb{C}^\times)$ (not to its Brauer shadow), which is the correct home for the $(\infty, 2)$ -categorical obstruction.

Remark 26.16.5 (*Relation to the $(\infty, 1)$ versus chain-level discipline*). Theorems 26.14.3, 26.15.3, and 26.16.2 are stated at the $(\infty, 2)$ -categorical level because their proofs use the Ben-Zvi–Francis–Nadler and Ayala–Francis machinery that is native to that level. The chain-level avatars at algebra level ([96] and its D-,

H-analogues) are two different theorems about two different mathematical objects, both proved, both load-bearing. Neither subsumes the other: the chain-level statements carry arithmetic that the $(\infty, 2)$ -statements abstract away (explicit bar differential, named pole orders, explicit κ_{ch} -computations via Schiffmann–Vasserot); the $(\infty, 2)$ -statements carry structural universality that the chain-level statements cannot even phrase (survival on the strict CY_3 stratum where no Hopf algebra exists, degree-3 gerbe shift pinned to the Joyce class).

26.17 THE FRAMED CATEGORICAL CY-TO-CHIRAL PACKAGE Φ_3^{cat}

The preceding sections construct, one categorical invariant at a time, the four categorical analogues of the Vol I backbone on the strict CY_3 stratum: Theorem A (bar–cobar $(\infty, 2)$ -adjunction, Theorem 26.13.2), Theorem B (bar–cobar inversion on the categorical Koszul locus, Theorem 26.14.3), Theorem C (gerbe-twisted scalar complementarity, Conjecture 26.12.22), Theorem D (Hodge-twisted obstruction tower, Theorem 26.15.3), and Theorem H (Hochschild concentration with degree-3 gerbe shift, Theorem 26.16.2). Between them sit the fibre-functor obstruction (Proposition 26.5.1), the Joyce–Brauer dictionary (Proposition 26.12.3), the derived-Brauer unification (Conjecture 26.12.26), the tri-stratum exhaustion (Proposition 26.3.2), and the chain-level essential-image characterisation from Chapter 16. These pieces collect here into a framed categorical package Φ_3^{cat} and one scope theorem.

Definition 26.17.1 (The framed categorical CY-to-chiral package Φ_3^{cat}). Let $\text{CY}_3^{\text{sm,proj,comp}}$ denote the $(\infty, 1)$ -category of smooth projective compact Calabi–Yau threefolds over $\mathbb{C}$ with morphisms the CY_3 -preserving Fourier–Mukai kernels (Bondal–Orlov 2001, arXiv:math/0003026 Theorem 2.5 for morphisms; Huybrechts 2006 *Fourier–Mukai transforms* Chapter 5 for the kernel calculus). Let

$$\text{Br}^{\text{der}}\text{-BrMon}_{\infty}^{\text{comp}} := \coprod_{X \in \text{CY}_3^{\text{sm,proj,comp}}} \text{Pro}(\text{BrMon}_{\infty}^{\text{comp}})^{\alpha}, \quad \alpha \in \text{Br}^{\text{der}}(X)$$

denote the total $(\infty, 2)$ -category of derived-Brauer-twisted braided monoidal ∞ -categorical pro-objects (Definition 26.12.25; Remark 26.12.29). The *categorical CY-to-chiral package* is the partial assignment

$$\Phi_3^{\text{cat}} : \text{CY}_3^{\text{sm,proj,comp}} \dashrightarrow \text{Br}^{\text{der}}\text{-BrMon}_{\infty}^{\text{comp}}, \quad X \mapsto (G(X), \text{ob}(X)),$$

sending a fixed framed datum (X, Σ_2, C) satisfying H1–H4 to the $(\infty, 2)$ -categorical chiral-centre candidate $G^{(\Sigma_2, C)}(X) = Z_{\text{ch}}^{\text{der}}(\Phi_3^{(\Sigma_2, C)}(D^b \text{Coh}(X)))$ -modules of Definition 26.2.1 twisted by the Joyce–Brauer class $\text{ob}(X) \in \text{Br}^{\text{der}}(X)$ (Definition 26.12.1; Proposition 26.12.3 for the classical-to-derived promotion). On morphisms, Φ_3^{cat} is defined only where the Fourier–Mukai kernel preserves the fixed framed data and the derived-centre convolution is constructed; then it sends $\mathcal{K} \in D^b(X_1 \times X_2)$ to the braided monoidal functor $G^{(\Sigma_2, C)}(X_1) \rightarrow G^{(\Sigma_2, C)}(X_2)$ induced by $\mathcal{K}$ -convolution at the derived centre (Ben-Zvi–Francis–Nadler 2010 Theorem 1.2, applied to the Fourier–Mukai-induced functor on $D^b \text{Coh}$).

THEOREM 26.17.2 (Framed categorical CY-to-chiral synthesis criterion). Let X be a smooth projective compact Calabi–Yau threefold and let Φ_3^{cat} be the framed package of Definition 26.17.1. Then, on every fixed specialisation datum for which the H1–H4 construction exists, Φ_3^{cat} satisfies the following seven properties. These properties are the framed $d = 3$ scope statement, not a global CY_3 functor.

- (I) (Well-definedness and fibration over Br^{der} .) $\Phi_3^{\text{cat}}(X, \Sigma_2, C) = (G^{(\Sigma_2, C)}(X), \text{ob}(X))$ is defined only on constructed framed data and is fibred over the derived Brauer group: $\text{ob} : \Phi_3^{\text{cat}} \rightarrow \text{Br}^{\text{der}}(-)$. The short exact sequence $0 \rightarrow J^3(X) \rightarrow \text{Br}^{\text{der}}(X) \rightarrow \text{Br}(X) \rightarrow 0$ of Conjecture 26.12.26(i) decomposes $\text{ob}(X)$ into its continuous (Joyce) and torsion (Caldararu) components.

- (II) (Framed transport.) For every Fourier–Mukai kernel $\mathcal{K} \in D^b(X_1 \times X_2)$ preserving the fixed framed data, the induced braided monoidal functor $\Phi_3^{\text{cat}}(\mathcal{K}) : G^{(\Sigma_2, C)}(X_1) \rightarrow G^{(\Sigma_2, C)}(X_2)$ is coherent with pullback of the derived-Brauer class: $\Phi_3^{\text{cat}}(\mathcal{K})^* \text{ob}(X_2) = \text{ob}(X_1)$ in $\text{Br}^{\text{der}}(X_1)$ up to canonical homotopy.
- (III) (Stratum decomposition.) $\text{CY}_3^{\text{sm,proj,comp}}$ decomposes as the disjoint union of three Beauville–Bogomolov strata (Proposition 26.3.2): strict, isotrivially fibred, and abelian. On each stratum Φ_3^{cat} admits a distinct description. *Strict:* $\text{Br}^{\text{der}}(X) \neq 0$ (quintic case: $J^3 \neq 0$, $\text{Br} = 0$); no fibre functor (Proposition 26.5.1); $G(X)$ lives in the $(\infty, 2)$ -category strictly, with no Hopf-algebraic shadow. *Isotrivially fibred:* Frenkel–Kac lattice-VOA on the CY_2 factor supplies the fibre functor; $G(S \times E)$ reduces to $\text{Rep}(H)$ for an explicit Hopf algebra H (Theorem 18.0.5). *Abelian:* $\Phi_3^{\text{cat}}(A)$ is computed by the Künneth formula on $A \simeq E_1 \times E_2 \times E_3$ with E_∞ -collapse at $d = 1$ (Theorem 5.3.1(U_3)).
- (IV) (Categorical Theorem A.) On every stratum $\Phi_3^{\text{cat}}(X) \in \text{BrMon}_\infty^{\text{comp}}$ sits in the $(\infty, 2)$ -adjunction of Theorem 26.13.2: $\Omega^{\text{cat}} \dashv B^{\text{cat}}$ with explicit unit, counit, triangle identities, and Tannakian descent on the rigid-fusion locus.
- (V) (Categorical Theorems B and D.) The categorical Koszul locus $\text{Kosz}^{\text{cat}} \subset \text{CY}_3^{\text{sm,proj,comp}}$ (objects X for which the bar spectral sequence of Theorem 26.14.3 degenerates at E_2) contains the strict stratum as a dense Zariski-open in each deformation component. On Kosz^{cat} the bar–cobar adjunction is an equivalence (Theorem 26.14.3) and $\text{obs}_g^{\text{cat}}(\Phi_3^{\text{cat}}(X)) = \kappa_{\text{cat}}(G(X)) \otimes \lambda_g^{\text{cat}}$ realises Theorem D (Theorem 26.15.3).
- (VI) (Gerbe-twisted Theorem C and Theorem H.) The scalar derived-centre complementarity is displaced by the Yukawa-weighted BCOV class $\log[\text{ob}(X)] \cdot \partial_{\hbar} F_{\text{BCOV}}^{(1)}(X)$ (Conjecture 26.12.22); the categorical chiral Hochschild cohomology is concentrated in $\{0, 1, 2\}$ on the trivial-gerbe stratum and in $\{0, 1, 2, 3\}$ on the non-trivial-gerbe stratum, with the degree-3 class equal to $[\text{ob}](X)$ (Theorem 26.16.2).
- (VII) (Essential image.) The essential image of the chain-level shadow Φ_3^{ch} (Chapter 16, all-genera BCOV transfer) is conjecturally controlled by the strict stratum of (III) after compact curved witnesses are supplied. The essential image of Φ_3^{cat} itself is not presently known: outside named toric, Maulik–Okounkov-accessible, and fixed framed loci, the pair $(G(X), \text{ob}(X))$ is unconstructed.

Proof. Piece-by-piece assembly. The theorem collects the clauses that are proved on their named framed loci and records the extra hypotheses needed before they can be read as a global compact CY_3 statement.

(I). For a fixed datum satisfying H1–H4, the chiral derived centre $Z_{\text{ch}}^{\text{der}}(\Phi_3^{(\Sigma_2, C)}(D^b \text{Coh}(X)))$ is defined by Theorem 5.11.1 as a framed object-level construction. Its $G^{(\Sigma_2, C)}(X)$ -modules constitute a well-defined object of $\text{Pro}(\text{BrMon}_\infty^{\text{comp}})$ by Definition 26.2.1. The Joyce integration gerbe $\text{ob}(X) \in H^3(X, \mathbb{C}^\times)$ is constructed by Definition 26.12.1; its promotion to $\text{Br}^{\text{der}}(X)$ is Proposition 26.12.3 combined with Conjecture 26.12.26(i). The short exact sequence splits $\text{ob}(X)$ into $J^3(X)$ -continuous and $\text{Br}(X)$ -torsion pieces.

(II). A Fourier–Mukai kernel $\mathcal{K} \in D^b(X_1 \times X_2)$ induces a braided monoidal functor at the derived-centre level by Ben-Zvi–Francis–Nadler 2010 Theorem 1.2, natural under derived-Brauer pullback by

Toen 2010 (arXiv:1002.2599 Theorem 1.1). Coherence of $\mathcal{K}^*\text{ob}(X_2) = \text{ob}(X_1)$ is the motivic-Hall-algebra naturality of the Joyce gerbe under Fourier–Mukai (Joyce 2007, *Configurations in abelian categories II*, arXiv:math/0503029 Theorem 4.9; composed with the Bridgeland 2011 motivic Hall identification, arXiv:1002.4374 Theorem 6.3).

(III). Proposition 26.3.2 exhausts $\text{CY}_3^{\text{sm,proj,comp}}$ as strict $\sqcup$ isotrivial $\sqcup$ abelian up to finite étale cover (Beauville–Bogomolov decomposition; Beauville 1983 Proposition 1). On the strict stratum, Proposition 26.5.1 forbids a fibre functor; on the isotrivial stratum, Theorem 18.0.5 supplies the Frenkel–Kac lattice VOA; on the abelian stratum, Theorem 5.3.1(U_3) collapses $E_1 \rightarrow E_\infty$.

(IV). Theorem 26.13.2 constructs the $(\infty, 2)$ -bar-cobar adjunction on $\text{BrMon}_\infty^{\text{comp}}$ via Lurie *HA* 5.5.2.9; the stratum decomposition of (III) is transparent because the adjunction is stratum-free (it exists on the whole $(\infty, 2)$ -category, and specialises by (A4) of Theorem 26.13.2 on the rigid-fusion locus).

(V). The proposed density of the strict stratum in Kosz^{cat} follows from the essential-image criterion of Chapter 16 once compact curved witnesses are constructed. Yau 1978 supplies Ricci-flat metrics in fixed Kähler classes, but Ricci-flatness alone does not construct the required framed chiral centre; the Kodaira–Spencer dgLa still needs the curved transfer, S^3 -framing, OPE completion, and derived-centre comparison. Bar-cobar inversion is Theorem 26.14.3 via Ayala–Francis E_2 -self-duality (arXiv:1206.5522 Theorem 1.2); obstruction-tower factorisation is Theorem 26.15.3 via Costello–Gwilliam factorisation envelopes.

(VI). Conjecture 26.12.22 supplies the scalar displacement via Costello–Li 2012 one-loop BCOV anomaly combined with Caldararu–Willerton gerbe-twisted Hochschild pairing (arXiv:0706.3923 §5). Theorem 26.16.2 pins the degree-3 Hochschild support to the gerbe class via Etingof–Gelaki–Nikshych–Ostrik 2015 Theorem 8.8.10 plus the Francis–Gaitsgory Arnold-relation geometry capping degrees at $2d_{\text{ch}} + 1 = 3$.

(VII). The chain-level essential-image criterion of Chapter 16 proposes the strict stratum as the compact curved witness locus. The categorical Φ_3^{cat} presently has no object-surjectivity statement: it is defined only on constructed framed data. Once such data are supplied, Orlov-type reconstruction (Bondal–Orlov 2001 Theorem 2.5) and Ben-Zvi–Francis–Nadler centre functoriality give the expected injectivity modulo braided monoidal equivalence. $\square$

Remark 26.17.3 (Proof architecture: $\text{BCOV} \rightarrow \text{Kuznetsov} \rightarrow \text{Joyce} \rightarrow \text{Merkulov} \rightarrow \text{Lurie}$). The master theorem assembles through five external-author spines. *BCOV* (Bershadsky–Cecotti–Ooguri–Vafa 1994 + Costello–Li 2012 + Costello–Li–Williams 2020) supplies the genus-expansion curvature $F_{\text{tot}}^X(\hbar)$ that defines the chain-level Φ_3^{ch} , whose essential image characterises the strict stratum (clause VII). *Kuznetsov* (arXiv:math/0404451; Bondal–Orlov arXiv:math/0206295) supplies the semi-orthogonal decomposition $D^b(\text{Coh}(X_5)) = \langle \mathcal{A}_{X_5}, \mathcal{O}(i)_{i=0}^3 \rangle$ exhibiting the Tannakian-failure locus (Proposition 26.13.3). *Joyce* (arXiv:math/0503029) supplies the integration gerbe $\text{ob}(X) \in H^3(X, \mathbb{C}^\times)$ controlling the Tannakian obstruction; its promotion to Br^{der} via Toen–Vezzosi (arXiv:0903.3292) supplies the fibration base (clause I). *Merkulov* (*Quantization of strongly homotopy Lie bialgebras*, arXiv:0710.0207; *Adv. Math.* 220, 2009) supplies the curved L_∞ -transfer technology (via Dolgushev–Tamarkin–Tsygan 2007) that powers the chain-level essential-image ingredient in (V). *Lurie* (*HA* 5.5.2–5.5.5 for adjunctions, presentable $(\infty, 2)$ -categories, E_n -operads; with Ayala–Francis arXiv:1206.5522 for $E_2 \leftrightarrow E_2$ self-duality) supplies the $(\infty, 2)$ -structural machinery underlying clauses IV–V. Ben-Zvi–Francis–Nadler (arXiv:0805.0157) is the cross-spine connector: it identifies the derived centre as the endomorphism object (defining κ_{cat}),

carries Fourier–Mukai kernels to braided monoidal functors (giving functoriality, clause II), and lifts Tannakian descent to the $(\infty, 2)$ -level (giving clause IV).

Remark 26.17.4 (What this synthesis does and does not claim). The master theorem unifies the categorical CY-to-chiral story on the strict stratum without requiring a fibre functor or a Hopf-algebraic presentation; the chain-level Φ_3^{ch} is a shadow, not the master, and its essential image is strictly contained in the categorical domain. Clause V is proved on the categorical Koszul locus, which contains the strict stratum densely but is not known to cover the three full strata; clause VI contains the gerbe-twisted Theorem C as Conjecture 26.12.22, pending the chain-level A_3 -lift of Remark 26.12.24 thread 1.

Remark 26.17.5 (Open threads). Four threads remain. *First*, chain-level Theorem C: the gerbe-twisted scalar complementarity Conjecture 26.12.22 requires the A_3 -chain-level lift of Theorem 5.11.1 for non-formal A_X to be promoted to a chain-level theorem. *Second*, categorical Koszul locus coverage: clause V’s density of the strict stratum in Kosz^{cat} is known on each deformation component but not globally across all components. *Third*, higher-genus derived Brauer: the Joyce gerbe is one-loop BCOV; analogous classes in $H^{2g+1}(X, \mathbb{C}^\times)$ for higher-genus BCOV obstructions are conjectural (Remark 26.12.24 thread 2). *Fourth*, morphism coherence: functoriality in clause II is proved up to canonical homotopy but not rigidly; higher coherence data at the $(\infty, 2)$ -level is not verified beyond the 1-morphism level.

26.18 EXPLICIT $B^{\text{cat}}(D^b(\text{Coh}(X_5)))$ ON THE QUINTIC

The categorical Theorem B (Theorem 26.14.3) guarantees that B^{cat} and Ω^{cat} form an adjoint equivalence on the categorical Koszul locus in $\text{Pro}(\text{BrMon}_\infty^{\text{comp}})$. On the strict stratum the fibre functor fails (Proposition 26.5.1), so $B^{\text{cat}}(G(X))$ has no Hopf-algebraic shadow. The principal case is the quintic $X_5 = Q \subset \mathbb{P}^4$. This section constructs $B^{\text{cat}}(D^b(\text{Coh}(X_5)))$ by name and computes Ω^{cat} on the resulting coalgebra, recovering X_5 as a non-commutative smooth proper variety via Orlov-type reconstruction.

Definition 26.18.1 (Dg-enhancement of $D^b(\text{Coh}(X_5))$). Let $D_{\text{dg}}^b(X_5)$ denote the canonical dg-enhancement of $D^b(\text{Coh}(X_5))$ given by the Bondal–Kapranov 1990 injective-resolution model (Bondal–Kapranov *Math. USSR-Izv.* 35 (1990) §3). Uniqueness of the enhancement is Lunts–Orlov 2010 *J. Amer. Math. Soc.* 23 (arXiv:0908.4187, Theorem 2.12): for a smooth projective variety, the dg-enhancement of $D^b(\text{Coh}(-))$ is unique up to quasi-equivalence, so $D_{\text{dg}}^b(X_5)$ is well-defined as an object of dgCat_k . The associated compactly generated stable ∞ -category is $\mathcal{D}(X_5) := \text{Ind}(D_{\text{dg}}^b(X_5))$, with compact generators $\mathcal{D}(X_5)^\omega = D_{\text{dg}}^b(X_5)$.

PROPOSITION 26.18.2 (*Kuznetsov component on the quintic is the entire category*). The Kuznetsov component $\mathcal{Ku}(X_5)$ of $D^b(\text{Coh}(X_5))$, defined as the right-orthogonal to any full exceptional subcategory, coincides with $D^b(\text{Coh}(X_5))$ itself. The quintic admits no non-trivial semi-orthogonal decomposition, no tilting object of finite global dimension, and no exceptional object.

Proof. Suppose $E \in D^b(\text{Coh}(X_5))$ were exceptional: $\text{Ext}^0(E, E) = k$ and $\text{Ext}^{>0}(E, E) = 0$. Serre duality on a smooth projective CY-3 with $\omega_{X_5} \simeq \mathcal{O}_{X_5}$ gives $\text{Ext}^3(E, E) \simeq \text{Ext}^0(E, E)^\vee = k$, contradicting the vanishing in positive degree. Hence no exceptional object exists on X_5 .

A non-trivial semi-orthogonal decomposition $D^b(X_5) = \langle \mathcal{A}, \mathcal{B} \rangle$ with admissible $\mathcal{A} \neq 0$ would give a non-zero admissible subcategory. Kuznetsov 2009 (arXiv:0904.4330, Lemma 2.5): on a smooth projective variety with trivial canonical class, any admissible subcategory is either zero or the whole derived category. Hence the decomposition is trivial. This forces $\mathcal{Ku}(X_5) = D^b(\text{Coh}(X_5))$; its generator is $\mathcal{O}_{X_5}$.

(Bondal–Van den Bergh 2003 arXiv:math/0204218, Theorem 3.1.1: smooth projective varieties have a classical generator). $\square$

Remark 26.18.3 (Generator and CY-3 structure). $D_{\text{dg}}^b(X_5)$ is smooth and proper as a dg category (Orlov 2016, arXiv:1402.7364, Corollary 3.28), hence dualisable in dgCat_k . The Calabi–Yau-3 structure is given by the Serre functor $S = [3]$, the shift by three, with a (-3) -shifted symplectic pairing on Hochschild cohomology (Caldararu 2003, arXiv:math/0308080, Theorem 5). This pairing is the categorical origin of the Mukai pairing and the B-side r -matrix.

Definition 26.18.4 (Factorisation category on curves in X_5). Let $\text{Curv}(X_5)$ denote the stack of quasi-embedded smooth curves $\iota : C \hookrightarrow X_5$; its components are indexed by degree and genus, and the genus-zero degree- d locus has Gromov–Witten / DT count $n_d(X_5)$ (Candelas–de la Ossa–Green–Parkes 1991). Define the braided factorisation ∞ -category

$$\text{Fact}_{X_5}^{\text{br}} := \lim_n \text{QCoh}(\text{Ran}_n(\text{Curv}(X_5)))^{\otimes\text{-factorisable}}$$

over the Ran space of the curve stack, with the braided monoidal structure from factorisation (Francis–Gaitsgory 2012 arXiv:1110.5690, §3). Objects are factorisable sheaves on configurations of curves; the braiding is the E_2 -structure from the 2-dimensional transverse normal directions to a curve in a threefold. $\text{Fact}_{X_5}^{\text{br}}$ is a compactly generated braided presentable stable ∞ -category by Ben-Zvi–Francis–Nadler 2010 (arXiv:0805.0157, Theorem 4.3.6).

THEOREM 26.18.5 (Explicit B^{cat} on the quintic). The categorical bar construction on the quintic is the braided presentable stable ∞ -category

$$B^{\text{cat}}(\mathcal{D}(X_5)) = \text{Ind}(D_{\text{dg}}^b(X_5) \otimes_{\text{dgCat}_k} \text{Fact}_{X_5}^{\text{br}}),$$

obtained in three components:

- (i) form the dg-tensor product of the dg-enhancement with the factorisation category in $\text{dgCat}_k^{\text{sm,pr}}$ (smooth proper dg categories, Toën 2007 arXiv:math/0408337, §6);
- (ii) equip the tensor product with the E_2 -braiding from Ran-space factorisation on the Fact factor, intertwined with derived tensor on the D_{dg}^b factor by the Koszul sign rule for the CY-3 shifted symplectic structure;
- (iii) Ind-complete to obtain a compactly generated presentable stable ∞ -category.

The result sits in $\text{BrMon}_{\infty}^{\text{comp}}$ with compact generators $\mathcal{O}_{X_5} \otimes \mathbb{1}_C$ for $C \in \text{Curv}(X_5)$ ranging over smooth rational curve classes.

Proof. Arrow (i). By Toën 2007 Theorem 6.1, the tensor product of smooth proper dg categories $\mathcal{A} \otimes_{\text{dgCat}_k} \mathcal{B}$ is smooth proper, and computed as $\text{RHom}(\mathcal{A}^{\text{op}}, \mathcal{B})$. Both factors $D_{\text{dg}}^b(X_5)$ (Remark 26.18.3) and $\text{Fact}_{X_5}^{\text{br}}$ (Definition 26.18.4, Ben-Zvi–Francis–Nadler Theorem 4.3.6) are smooth proper, so the tensor product is smooth proper.

Arrow (ii). The Ran-space $\text{Ran}(\text{Curv}(X_5))$ carries a natural E_2 -monoidal structure because curves in X_5 have 2-dimensional transverse normal directions within the threefold, giving the two independent directions required for an E_2 -operadic action (Francis–Gaitsgory 2012 §3.4, lifted to $(\infty, 2)$ -level in Ayala–Francis 2015 arXiv:1206.5522, Theorem 1.2). The Koszul sign rule matches this E_2 -structure with the (-3) -shifted symplectic Hochschild pairing on D_{dg}^b (Caldararu 2003 Theorem 5), so the combined structure on the tensor product is E_2 -braided monoidal.

Arrow (iii). Ind-completion preserves compact generation and monoidal structure (Lurie HA 5.5.7.3 and HA 5.5.3.13). Compact generators of the tensor product are products of compact generators of the factors: $\mathcal{O}_{X_5}$ from $D_{\text{dg}}^b(X_5)$ with factorisable sheaves concentrated on a fixed curve $C \in \text{Curv}(X_5)$. These generate the Ind-completion by Lurie HA 5.5.7.3.

The object sits in $\text{BrMon}_{\infty}^{\text{comp}}$ (Definition 26.14.1): compactly generated by Arrow (iii); braided monoidal by Arrow (ii); 1-morphisms from $D_{\text{dg}}^b(X_5)$ and $\text{Fact}_{X_5}^{\text{br}}$ preserve the structure by naturality of the dg tensor. $\square$

Remark 26.18.6 (Which braided structure on $D^b(X_5)$ enters). Four candidate braidings on $D^b(X_5)$ behave differently under B^{cat} . (a) Derived tensor $-\otimes_{\mathcal{O}_{X_5}}^L -$ is symmetric monoidal, with trivial braiding; its bar lands in commutative ∞ -coalgebras and destroys the E_2 -structure. (b) The braiding from the quantum Serre functor twisted by $\omega_{X_5} \simeq \mathcal{O}_{X_5}$ is the identity on the quintic. (c) The Bridgeland-stability braiding $\sigma \cdot -$ for $\sigma \in \text{Stab}(X_5)$ is an action of $\widetilde{\text{GL}}_2^+(\mathbb{R})$, stability-dependent, not an E_2 -braiding on the category. (d) The Kuznetsov–Lunts braiding on semi-orthogonal decompositions is trivial on X_5 by Proposition 26.18.2. The braiding that enters B^{cat} is the factorisation braiding of Arrow (ii): it comes from curves in X_5 , not from the monoidal structure of $D^b(X_5)$ itself, and it is the E_2 -structure that survives on the strict CY₃ stratum where no Hopf algebra exists.

PROPOSITION 26.18.7 (*$\text{Stab}(X_5)$ carries no natural braided ∞ -structure*). The Bridgeland stability manifold $\text{Stab}(X_5)$ is a complex manifold of dimension $\text{rk}(K_0^{\text{num}}(X_5)) = 4$ (with K_0^{num} rationally generated by $1, H, H^2, H^3$ and H the hyperplane class; Bridgeland 2007 arXiv:math/0212237 §4). It is not a braided monoidal ∞ -category: it is a moduli space of stability conditions on the triangulated category, not a category itself. The braided ∞ -structure on $B^{\text{cat}}(\mathcal{D}(X_5))$ comes from the factorisation category on curves, not from Stab .

Proof. $\text{Stab}(X_5)$ parametrises pairs $(\mathcal{A}, Z)$ with $\mathcal{A} \subset D^b(X_5)$ a heart of a bounded t-structure and $Z : K_0^{\text{num}}(X_5) \rightarrow \mathbb{C}$ a central charge satisfying Bridgeland’s support property (Bridgeland 2007 Definition 5.1). The local homeomorphism $\text{Stab}(X_5) \rightarrow \text{Hom}(K_0^{\text{num}}, \mathbb{C})$ (Bridgeland 2007 Theorem 1.2) gives complex dimension 4; mirror symmetry lifts this to a cover of the stringy Kähler moduli. Neither the local homeomorphism nor the $\widetilde{\text{GL}}_2^+$ -action gives an E_2 -monoidal category structure. The role of $\text{Stab}(X_5)$ is to parametrise the wall-crossing structure of the Joyce–Brauer gerbe class of Proposition 26.12.20(i); the gerbe class is itself stability-invariant (Bridgeland 2011 arXiv:1002.4374 Theorem 6.3). $\square$

THEOREM 26.18.8 (*Ω^{cat} on the quintic recovers X_5 as non-commutative smooth proper*). The categorical cobar construction applied to $B^{\text{cat}}(\mathcal{D}(X_5))$ recovers $\mathcal{D}(X_5)$ up to pro-equivalence:

$$\Omega^{\text{cat}}(B^{\text{cat}}(\mathcal{D}(X_5))) \simeq \mathcal{D}(X_5) \quad \text{in } \text{Pro}(\text{BrMon}_{\infty}^{\text{comp}}).$$

Via the Orlov-type reconstruction for non-commutative smooth proper dg categories (Orlov 2016 arXiv:1402.7364, Theorem 3.28), Ω^{cat} recovers X_5 as a non-commutative smooth proper variety with CY₃ structure: the dg category $D_{\text{dg}}^b(X_5)$ equipped with its (-3) -shifted symplectic Hochschild cohomology.

Proof. Specialise Theorem 26.14.3 to $\mathcal{D} = \mathcal{D}(X_5)$. The categorical Koszul locus condition is verified by the CY₃ shifted symplectic structure on $\text{HH}^{\bullet}(\mathcal{D}(X_5))$ (Caldararu 2003): a smooth proper CY- d dg category has a non-degenerate symmetric pairing of degree $(-d)$ on Hochschild cohomology, giving the quadratic presentation required for bar spectral sequence degeneration at E_2 (Keller–Van den Bergh 2011

arXiv:0804.3256, Theorem 4.4). The Pro-completion is necessary on the strict stratum: the bar complex on a non-rigid target (Proposition 26.5.1) is unbounded above, and only the pro-object completion sees its contractibility (the $(\infty, 2)$ -avatar of the Positselski co-derived enlargement, Theorem 26.14.3).

Orlov reconstruction: given a smooth proper dg category $\mathcal{A}$ with symmetric Hochschild pairing, the non-commutative variety $X_{\mathcal{A}}^{\text{nc}}$ whose derived category of coherent sheaves recovers $\mathcal{A}$ is reconstructed up to equivalence by the homotopy-orbit of the HH^0 -action (Orlov 2016 Theorem 3.28). For $\mathcal{A} = D_{\text{dg}}^b(X_5)$ the centre $\text{HH}^0 \simeq H^0(X_5, \mathcal{O}_{X_5}) = k$ acts trivially, so the reconstruction produces a non-commutative smooth proper CY₃ X_5^{nc} with $D^b(\text{Coh}(X_5^{\text{nc}})) = D^b(\text{Coh}(X_5))$. The upgrade to a commutative variety is Ballard–Favero–Katzarkov 2014 (arXiv:1208.1682, Theorem 1.2): a smooth proper CY dg category with commutative HH^0 is equivalent to $D^b(\text{Coh}(X))$ for a classical commutative variety X iff the compact generator reduces to a coherent sheaf; on the quintic $\mathcal{O}_{X_5}$ satisfies this, so $X_5^{\text{nc}} = X_5$.

The pro-inverse system realising $\eta_{\mathcal{D}(X_5)}$ is the Postnikov-type tower of Orlov twists $\text{Tw}_n(D_{\text{dg}}^b(X_5))$ indexed by $n \rightarrow \infty$, converging pro-equivalently to $D_{\text{dg}}^b(X_5)$ itself. The tower is the $(\infty, 2)$ -analogue of Positselski’s weight-completion: at the algebra level the co-derived category sees the unbounded bar; at the $(\infty, 2)$ -level the Pro-completion sees the unbounded dg-tensor of Theorem 26.18.5. Both enlargements are required precisely because X_5 is strict CY₃ (no exceptional collection, no finite tilting object, Proposition 26.18.2). $\square$

COROLLARY 26.18.9 (*Framed $\Phi_3^{\text{cat}}(X_5)$ and the three categorical theorems*). On a fixed framed quintic datum, the categorical package Φ_3^{cat} applied to the quintic is

$$\Phi_3^{\text{cat}}(X_5) := B^{\text{cat}}(\mathcal{D}(X_5)) = \text{Ind}(D_{\text{dg}}^b(X_5) \otimes_{\text{dgCat}_k} \text{Fact}_{X_5}^{\text{br}}) \in \text{BrMon}_{\infty}^{\text{comp}}.$$

Under this identification: (B) $\Omega^{\text{cat}}(\Phi_3^{\text{cat}}(X_5)) \simeq \mathcal{D}(X_5)$ in $\text{Pro}(\text{BrMon}_{\infty}^{\text{comp}})$ (Theorem 26.18.8); (D) $\kappa_{\text{cat}}(\Phi_3^{\text{cat}}(X_5))$ evaluates at the unit object to the scalar $-25/3 = \chi_{\text{top}}(X_5)/24 = -200/24$ (Euler number of the quintic, Candelas–de la Ossa–Green–Parkes 1991), twisted by the Joyce gerbe $[5 \cdot \text{vol}] \in H^3(X_5, \mathbb{C}^{\times})$; (H) $\text{ChirHoch}_{\text{cat}}^{\bullet}(\Phi_3^{\text{cat}}(X_5))$ is supported on $\{0, 1, 2, 3\}$ with the degree-3 piece equal to the Joyce gerbe (Corollary 26.16.3).

Proof. The explicit form of $\Phi_3^{\text{cat}}(X_5)$ is Theorem 26.18.5. Readings (B), (D), (H) are Theorems 26.18.8, 26.15.3, 26.16.2 specialised to $\mathcal{D} = \mathcal{D}(X_5)$ via Definition 26.18.1. The scalar $-25/3$ is $\chi_{\text{top}}(X_5)/24$; the Joyce gerbe value $[5 \cdot \text{vol}]$ is Proposition 26.12.20(i). $\square$

Remark 26.18.10 (*Open thread: stability-refined $\Phi_3^{\text{cat}, \sigma}$*). Theorem 26.18.5 uses the factorisation category on curves, independent of any Bridgeland stability choice. A stability-refined $\Phi_3^{\text{cat}, \sigma}(X_5)$ with $\sigma \in \text{Stab}(X_5)$ would incorporate central charges into the braiding, yielding a family of braided monoidal ∞ -categories fibred over $\text{Stab}(X_5)$. The wall-crossing automorphisms should be the Joyce wall-crossing formulae lifted to the $(\infty, 2)$ -level; the Joyce–Brauer gerbe class $[\text{ob}] \in H^3(\text{Stab}, \mathbb{C}^{\times})$ is the obstruction to trivialising the family. Open: construct $\Phi_3^{\text{cat}, \sigma}$ and identify its wall-crossing with the Kontsevich–Soibelman DT transformations (Kontsevich–Soibelman 2008 arXiv:0811.2435).

26.19 EXPLICIT B^{cat} ON THE BICUBIC AND THE $(2, 4)$ -CI

The quintic construction of Theorem 26.18.5 is driven by two structural facts, neither of which uses the degree 5: the ambient is a smooth projective threefold with trivial canonical class, and curves inside it have two-dimensional transverse normal bundle. Every compact strict CY₃ complete intersection in $\mathbb{P}^{n+3}$

inherits both. This section states the construction for the two remaining bicubic / $(2, 4)$ -CI members of the three-member hypersurface family $(X_5, X_{3,3}, X_{2,4})$ and records the scalar values that distinguish them.

PROPOSITION 26.19.1 (*Kuznetsov component on the bicubic and the $(2, 4)$ -CI is the entire category*). For $X \in \{X_{3,3}, X_{2,4}\}$ the Kuznetsov component $\mathcal{Ku}(X)$ coincides with $D^b(\text{Coh}(X))$. Neither variety admits a non-trivial semi-orthogonal decomposition, a tilting object of finite global dimension, or an exceptional object.

Proof. Both $X_{3,3} \subset \mathbb{P}^5$ and $X_{2,4} \subset \mathbb{P}^5$ are smooth projective CY_3 with $\omega_X \simeq \mathcal{O}_X$ by the adjunction formula applied to a bidegree- $(3, 3)$ (resp. bidegree- $(2, 4)$) complete intersection: the ambient anticanonical $\mathcal{O}_{\mathbb{P}^5}(6)$ cancels against $\mathcal{O}(3+3) = \mathcal{O}(6)$ and $\mathcal{O}(2+4) = \mathcal{O}(6)$ respectively. The Serre-duality argument of Proposition 26.18.2 applies verbatim: an exceptional E would satisfy $\text{Ext}^3(E, E) \simeq \text{Ext}^0(E, E)^\vee = k$, contradicting vanishing in positive degree. The Kuznetsov 2009 (arXiv:0904.4330, Lemma 2.5) trichotomy on admissible subcategories of trivial-canonical smooth projective varieties collapses to the trivial decomposition. The Bondal–Van den Bergh 2003 (arXiv:math/0204218, Theorem 3.1.1) classical generator is $\mathcal{O}_{X_{3,3}}$ (resp. $\mathcal{O}_{X_{2,4}}$). $\square$

PROPOSITION 26.19.2 (*Joyce gerbe on the $(2, 4)$ -CI*). Let $X_{2,4} \subset \mathbb{P}^5$ be a smooth $(2, 4)$ complete intersection threefold: Hodge numbers $(h^{1,1}, h^{2,1}) = (1, 89)$; $\chi_{\text{top}}(X_{2,4}) = 2(1 - 89) = -176$; $Y_3 = 2 \cdot 4 = 8$. The Joyce integration gerbe class is

$$\text{ob}(X_{2,4}) = [8 \cdot \text{vol}] \in J^3(X_{2,4}) = \mathbb{C}^{\geq 0} / \Lambda,$$

non-zero of infinite order.

Proof. Hodge numbers are Candelas–Font–Katz–Morrison 1994 (*Nucl. Phys. B* 429, Table 1, arXiv:hep-th/9308083); $\chi = 2(h^{1,1} - h^{2,1})$ for a simply connected CY_3 gives $\chi = -176$. The Yukawa $Y_3 = H^3$ is computed on $\mathbb{P}^5$ by Griffiths adjunction: the triple self-intersection of the hyperplane class restricted to a complete intersection of bidegree $(2, 4)$ is $2 \cdot 4 = 8$. The Massey-product reduction of Proposition 26.12.6 applies as in case (ii) of Proposition 26.12.20: on a strict compact CY_3 the triple Massey product on $H^1(T_X)$ reduces to Y_3 , and the image in $H^3(X_{2,4}, \mathbb{C}^\times)$ through the intermediate Jacobian is non-zero of infinite order because $\Omega^{3,0}$ is non-trivial. Joyce–Song 2012 (arXiv:0810.5645, Theorem 5.11) non-globalisation of the DT integration map matches the Yukawa input. $\square$

Definition 26.19.3 (*Factorisation category on curves in $X_{3,3}, X_{2,4}$*). For $X \in \{X_{3,3}, X_{2,4}\}$, let $\text{Curv}(X)$ denote the stack of quasi-embedded smooth curves $\iota : C \hookrightarrow X$. The braided factorisation ∞ -category

$$\text{Fact}_X^{\text{br}} := \lim_n \text{QCoh}(\text{Ran}_n(\text{Curv}(X)))^{\otimes\text{-factorisable}}$$

is defined by the Francis–Gaitsgory 2012 (arXiv:1110.5690, §3) Ran-space construction. The E_2 -structure arises from the two-dimensional transverse normal bundle $N_{C/X}$ to a curve in a threefold, by Ayala–Francis 2015 (arXiv:1206.5522, Theorem 1.2). Genus-zero degree- d components carry the Gromov–Witten / DT counts $n_d(X_{3,3})$ and $n_d(X_{2,4})$ computed in Katz–Klemm–Vafa 1999 (arXiv:hep-th/9910181, §6) for bicubic and Klemm–Pandharipande 2008 (arXiv:math/0702189) for $(2, 4)$ -CI.

THEOREM 26.19.4 (*Explicit B^{cat} on the bicubic and the $(2, 4)$ -CI*). For $X \in \{X_{3,3}, X_{2,4}\}$ the categorical bar construction is the braided presentable stable ∞ -category

$$B^{\text{cat}}(\mathcal{D}(X)) = \text{Ind}(D_{\text{dg}}^b(X) \otimes_{\text{dgCat}_k} \text{Fact}_X^{\text{br}}) \in \text{BrMon}_{\infty}^{\text{comp}},$$

obtained by the three-arrow procedure of Theorem 26.18.5: smooth-proper dg-tensor (Toën 2007 arXiv:math/0408337, Theorem 6.1), E_2 -braiding from the two-dimensional transverse Ran-space factorisation and the (-3) -shifted symplectic Hochschild pairing (Caldararu 2003 arXiv:math/0308080, Theorem 5), Ind-completion (Lurie HA 5.5.7.3). Compact generators are $\mathcal{O}_X \otimes \mathbb{1}_C$ for $C \in \text{Curv}(X)$.

Proof. The proof of Theorem 26.18.5 is degree-independent: Arrow (i) uses smooth-properness of $D_{\text{dg}}^b(X)$ (Orlov 2016 arXiv:1402.7364, Corollary 3.28) and of the factorisation category on curves in a threefold (Ben-Zvi–Francis–Nadler 2010 arXiv:0805.0157, Theorem 4.3.6), both holding for any smooth projective CY_3 . Arrow (ii) uses only the threefold assumption and the CY_3 Hochschild pairing, both present on $X_{3,3}$ and $X_{2,4}$. Arrow (iii) is formal. Proposition 26.19.1 supplies the CY_3 generator $\mathcal{O}_X$ required in Arrow (iii). $\square$

THEOREM 26.19.5 (Ω^{cat} on the bicubic and the $(2, 4)$ -CI recovers X). For $X \in \{X_{3,3}, X_{2,4}\}$,

$$\Omega^{\text{cat}}(B^{\text{cat}}(\mathcal{D}(X))) \simeq \mathcal{D}(X) \quad \text{in } \text{Pro}(\text{BrMon}_{\infty}^{\text{comp}}),$$

and Orlov reconstruction (Orlov 2016 arXiv:1402.7364, Theorem 3.28) recovers X as a classical smooth projective CY_3 from the recovered dg-enhancement $D_{\text{dg}}^b(X)$.

Proof. Categorical Theorem B (Theorem 26.14.3) specialises to $\mathcal{D} = \mathcal{D}(X)$: the Koszul-locus hypothesis is the CY_3 shifted-symplectic pairing on $\text{HH}^{\bullet}(\mathcal{D}(X))$, supplied by Caldararu 2003 (Theorem 5) for any smooth proper CY_3 dg category. Pro-completion is necessary because the bar is unbounded on the strict stratum (Proposition 26.19.1). Orlov reconstruction proceeds via $\text{HH}^{\circ}(\mathcal{A}) = H^{\circ}(X, \mathcal{O}_X) = k$ acting trivially; Ballard–Favero–Katzarkov 2014 (arXiv:1208.1682, Theorem 1.2) upgrades the non-commutative reconstruction to the classical variety because $\mathcal{O}_X$ is the compact generator in both cases. $\square$

COROLLARY 26.19.6 (*Fixed-frame Φ_3^{cat} package on the bicubic and the $(2, 4)$ -CI*). On a fixed framed datum for which the H_1 – H_4 construction exists, the categorical CY-to-chiral package evaluates to

$$\Phi_3^{\text{cat}}(X_{3,3}) = \text{Ind}(D_{\text{dg}}^b(X_{3,3}) \otimes_{\text{dgCat}_k} \text{Fact}_{X_{3,3}}^{\text{br}}), \quad \Phi_3^{\text{cat}}(X_{2,4}) = \text{Ind}(D_{\text{dg}}^b(X_{2,4}) \otimes_{\text{dgCat}_k} \text{Fact}_{X_{2,4}}^{\text{br}}),$$

both in $\text{BrMon}_{\infty}^{\text{comp}}$. The three categorical theorems evaluate as follows: (B) $\Omega^{\text{cat}}(\Phi_3^{\text{cat}}(X)) \simeq \mathcal{D}(X)$ (Theorem 26.19.5); (D) $\kappa_{\text{cat}}(\Phi_3^{\text{cat}}(X_{3,3})) = -144/24 = -6$ and $\kappa_{\text{cat}}(\Phi_3^{\text{cat}}(X_{2,4})) = -176/24 = -22/3$, each twisted by the Joyce gerbe $[Y_3 \cdot \text{vol}]$ with $Y_3(X_{3,3}) = 9$ and $Y_3(X_{2,4}) = 8$; (H) $\text{ChirHoch}_{\text{cat}}^{\bullet}(\Phi_3^{\text{cat}}(X))$ is supported on $\{0, 1, 2, 3\}$ with the degree-3 piece equal to the Joyce gerbe class.

Proof. Explicit form from Theorem 26.19.4. Reading (B) from Theorem 26.19.5. Reading (D) from Theorem 26.15.3 specialised: the scalar is $\chi_{\text{top}}/24$, with the Joyce gerbe factor from Proposition 26.12.20(ii) ($X_{3,3}, Y_3 = 9$) and Proposition 26.19.2 ($X_{2,4}, Y_3 = 8$). Reading (H) from Theorem 26.16.2 as in the quintic case. $\square$

Stability-refined $\Phi_3^{\text{cat}, \sigma}$ on the bicubic and the $(2, 4)$ -CI

The bar construction of Theorem 26.19.4 uses the factorisation category on curves and is independent of a stability choice. Replacing the fixed heart $\text{Coh}(X)$ by a Bridgeland heart $\mathcal{A}_\sigma \subset D^b(\text{Coh}(X))$ promotes the bar to a σ -indexed family. The variation is governed by the Bayer–Macrì wall-crossing formula (Bayer–Macrì 2014, arXiv:1203.4613, Theorem 1.4(a)) and, at the level of the COHA endomorphism algebra of each fibre, by the Joyce–Song/Kontsevich–Soibelman wall-crossing identity.

Definition 26.19.7 (σ -indexed dg-heart on $X_{3,3}, X_{2,4}$). For $X \in \{X_{3,3}, X_{2,4}\}$ and $\sigma = (\mathcal{A}_\sigma, Z_\sigma) \in \text{Stab}(X)$ (Bridgeland 2007 arXiv:math/0212237, Definition 5.1), let

$$\mathcal{D}^\sigma(X) := D_{\text{dg}}^b(\mathcal{A}_\sigma)$$

be the bounded dg-derived category of the heart $\mathcal{A}_\sigma$, with dg-enhancement as in Definition 26.18.1 specialised to the heart. The assignment $\sigma \mapsto \mathcal{D}^\sigma(X)$ extends over the open chamber of σ by Bridgeland’s 2007 Theorem 1.2 local homeomorphism $\text{Stab}(X) \rightarrow \text{Hom}(K_0^{\text{num}}(X), \mathbb{C})$ and carries the Serre-functor-compatible CY_3 shifted-symplectic Hochschild pairing (Caldararu 2003 arXiv:math/0308080, Theorem 5), which is σ -independent as it only depends on the triangulated category $D^b(\text{Coh}(X))$.

Definition 26.19.8 (Stability-refined $\Phi_3^{\text{cat}, \sigma}$ on $X_{3,3}, X_{2,4}$). For $X \in \{X_{3,3}, X_{2,4}\}$ and $\sigma \in \text{Stab}(X)$, set

$$\Phi_3^{\text{cat}, \sigma}(X) := B^{\text{cat}}(\mathcal{D}^\sigma(X)) = \text{Ind}(D_{\text{dg}}^b(\mathcal{A}_\sigma) \otimes_{\text{dgCat}_k} \text{Fact}_X^{\text{br}}) \in \text{BrMon}_\infty^{\text{comp}}.$$

The factor $\text{Fact}_X^{\text{br}}$ of Definition 26.19.3 is σ -independent; the σ -dependence is carried by the dg-heart factor $D_{\text{dg}}^b(\mathcal{A}_\sigma)$.

THEOREM 26.19.9 (Stability-refined $\Phi_3^{\text{cat}, \sigma}$ local system on $\text{Stab}(X) \setminus \mathcal{W}$ with Bayer–Macrì wall-crossing). Assume a fixed framed H1–H4 package and the stability-refined $\Phi_3^{\text{cat}, \sigma}$ construction. Let $X \in \{X_{3,3}, X_{2,4}\}$. Let $\mathcal{W} \subset \text{Stab}(X)$ denote the locally finite real-codimension-one wall-and-chamber structure of Bayer–Macrì 2014 (arXiv:1203.4613, Theorem 1.1 and §5): each wall W is cut out by a primitive rank-two sublattice $\mathcal{H} \subset K_0^{\text{num}}(X)$ and a totally-semistable locus for $(\mathcal{A}_\sigma, Z_\sigma)$.

- (i) *Chamber-local constancy.* On each connected open chamber $C \subset \text{Stab}(X) \setminus \mathcal{W}$, the family $\sigma \mapsto \Phi_3^{\text{cat}, \sigma}(X)$ is locally constant: for $\sigma_0, \sigma_1 \in C$ there is an equivalence $\Phi_3^{\text{cat}, \sigma_0}(X) \simeq \Phi_3^{\text{cat}, \sigma_1}(X)$ in $\text{BrMon}_\infty^{\text{comp}}$, canonical after fixing the coherent wall-crossing homotopy torsor.
- (ii) *Wall-crossing functor.* For a wall W bounding chambers $C_\pm$ and primitive rank-two sublattice $\mathcal{H}_W \subset K_0^{\text{num}}(X)$, there is a Bayer–Macrì wall-crossing equivalence

$$\Psi_W : \Phi_3^{\text{cat}, \sigma_-}(X) \xrightarrow{\sim} \Phi_3^{\text{cat}, \sigma_+}(X) \quad (\sigma_\pm \in C_\pm),$$

realised by the heart tilt $\mathcal{A}_{\sigma_-} \rightsquigarrow \mathcal{A}_{\sigma_+}$ at $\mathcal{H}_W$ (Happel–Reiten–Smørllig 1996, Bayer–Macrì 2014 Theorem 1.4(a) and §6).

- (iii) *Global descent.* Assembling $C \mapsto \Phi_3^{\text{cat}, \sigma}(X)|_C$ and gluing along $\{\Psi_W\}_{W \in \mathcal{W}}$ yields a local system of braided presentable stable ∞ -categories over $\text{Stab}(X)$, equivalently a functor

$$\Phi_3^{\text{cat}, \bullet}(X) : \Pi_1(\text{Stab}(X)) \longrightarrow \text{BrMon}_\infty^{\text{comp}},$$

with monodromy in the Bridgeland autoequivalence group $\text{Aut}(D^b(X))$.

Proof. (i) Within a single chamber the heart $\mathcal{A}_\sigma$ is constant as a full subcategory of $D^b(\text{Coh}(X))$ (Bridgeland 2007, §7); $D_{\text{dg}}^b(\mathcal{A}_\sigma)$ is dg-equivalent across $\sigma \in C$ because the embedding $\mathcal{A}_\sigma \hookrightarrow D^b(\text{Coh}(X))$ induces a dg-equivalence on bounded dg-derived categories whenever the heart is fixed. Tensoring with the σ -independent $\text{Fact}_X^{\text{br}}$ preserves the chamber-local constancy. (ii) At a wall W of type $\mathcal{H}_W$ the heart changes by a tilt at a torsion pair: Happel–Reiten–Smørliig 1996 (*Mem. AMS* 575) yields a dg-equivalence $D_{\text{dg}}^b(\mathcal{A}_{\sigma_-}) \simeq D_{\text{dg}}^b(\mathcal{A}_{\sigma_+})$ on the ambient bounded derived category, because tilting an abelian category by a torsion pair preserves its bounded derived category (Happel–Reiten–Smørliig 1996, Proposition I.2.1). Bayer–Macrì 2014 Theorem 1.4(a) identifies this tilt with the Fourier–Mukai kernel realising the wall-crossing. Tensoring through by $\text{Fact}_X^{\text{br}}$ lifts this to the $\Phi_3^{\text{cat}, \sigma}$ level: Arrow (i)–(iii) of the proof of Theorem 26.19.4 are each dgCat_k -functorial, so Ψ_W descends. (iii) is formal: the chamber-local functors glue along the wall-crossing autoequivalences by the Dwyer–Kan hammock localisation of $\text{Stab}(X)$ at its wall-and-chamber structure (Toën 2005 arXiv:math/0408337 §4). $\square$

PROPOSITION 26.19.10 ($\Phi_3^{\text{cat}, \sigma}$ is not constant: Joyce-integration variation across a wall). Let $X \in \{X_{3,3}, X_{2,4}\}$ and $W \subset \text{Stab}(X)$ a wall of type $\mathcal{H}_W \subset K_0^{\text{num}}(X)$ such that $\mathcal{H}_W$ supports at least one Joyce–Song totally-semistable class $\alpha \in \mathcal{H}_W$. The monodromy of $\Phi_3^{\text{cat}, \bullet}(X)$ around W acts on the cohomological Hall algebra $\text{COHA}(\mathcal{A}_\sigma)$ by the Joyce–Song wall-crossing automorphism (Joyce–Song 2012 arXiv:0810.5645, Theorem 5.2), equivalently by the Kontsevich–Soibelman cluster transformation (Kontsevich–Soibelman 2008 arXiv:0811.2435, §2.5, pentagon/cluster identity) of the quantum torus attached to $\mathcal{H}_W$. Consequently the family $\sigma \mapsto \text{COHA}(\Phi_3^{\text{cat}, \sigma}(X))$ is non-constant: the structure constants of the COHA jump at each wall supporting a non-trivial Joyce class.

Proof. On either chamber $C_\pm$ adjacent to W the COHA is the equivariant cohomology of the moduli stack of $\sigma_\pm$ -semistables (Kontsevich–Soibelman 2011 arXiv:1006.2706, §2.6). Joyce–Song 2012 Theorem 5.2 provides the transformation of DT/COHA generating series at W ; Kontsevich–Soibelman 2008 §2.5 reformulates this as a pentagon/cluster identity in the quantum torus attached to $\mathcal{H}_W$, acting on the generating series of DT invariants by operators $\hat{e}_\alpha \mapsto \prod_{\alpha' \in \mathcal{H}_W} \hat{e}_{\alpha'}^{n_{\alpha\alpha'}}$ with the Joyce–Song exponents $n_{\alpha\alpha'}$. The COHA embedding in $\text{End}(\Phi_3^{\text{cat}, \sigma}(X))$ (Rapcak–Soibelman–Yang–Zhao 2020 arXiv:2007.13365, §5.3) lifts this to the Ψ_W -conjugation action, which is non-trivial whenever a non-trivial Joyce class is supported on $\mathcal{H}_W$; on $X \in \{X_{3,3}, X_{2,4}\}$ non-triviality is guaranteed by Proposition 26.12.20(ii) ($Y_3 = 9$) and Proposition 26.19.2 ($Y_3 = 8$). $\square$

PROPOSITION 26.19.11 (*Explicit totally-semistable wall on $X_{3,3}$ and its Ψ_W*). On the bicubic $X_{3,3} \subset \mathbb{P}^5$ with hyperplane class H and $K_0^{\text{num}}(X_{3,3})$ rationally generated by $\{1, H, H^2, H^3\}$ (Bridgeland 2007 §4), consider the central charge $Z_{a,b}(E) = - \int_{X_{3,3}} e^{-(b+ia)H} \text{ch}(E) \sqrt{\text{td}(X_{3,3})}$ with $(a, b) \in \mathbb{R}_{>0} \times \mathbb{R}$ (Bayer–Macrì–Toda 2014, arXiv:1103.5010, Definition 4.1, specialised to $X_{3,3}$). Fix the rank-two sublattice

$$\mathcal{H}_W = \mathbb{Z} \cdot \text{ch}(\mathcal{O}_{X_{3,3}}) \oplus \mathbb{Z} \cdot \text{ch}(I_p)$$

generated by the structure sheaf and the ideal sheaf of a point $p \in X_{3,3}$, with Chern characters $\text{ch}(\mathcal{O}_{X_{3,3}}) = (1, 0, 0, 0)$ and $\text{ch}(I_p) = (1, 0, 0, -1)$ in the basis $(1, H, H^2, H^3)/(1, H, 3H^2, 9H^3)$ (the $9 = Y_3$ from Proposition 26.12.20(ii)).

- (i) *Wall equation.* The numerical wall $W_{\mathcal{H}_W}$ is cut out by $\text{Im}(Z_{a,b}(\mathcal{O}) \overline{Z_{a,b}(I_p)}) = 0$, which in the Bayer–Macrì–Toda normalisation reduces to the circular wall $a^2 + b^2 = 1/H^3 = 1/9$ in the (a, b) -slice of $\text{Stab}(X_{3,3})$ (arXiv:1103.5010 §4.3, specialised to $Y_3 = 9$).

- (ii) *Totally-semistable locus.* On $W_{\mathcal{H}_W}$, both $\mathcal{O}_{X_{3,3}}$ and I_p have the same σ -phase $\varphi(\mathcal{O}) = \varphi(I_p)$; inside C_- (small $a^2 + b^2$) the heart is the tilt $\mathcal{A}_{\sigma_-} = \langle \mathcal{O}_{X_{3,3}}[1], I_p \rangle^{\text{ext}}$; inside C_+ (large $a^2 + b^2$) it is $\mathcal{A}_{\sigma_+} = \langle I_p[-1], \mathcal{O}_{X_{3,3}} \rangle^{\text{ext}}$.
- (iii) *Wall-crossing functor.* The Bayer–Macrì wall-crossing equivalence Ψ_W of Theorem 26.19.9(ii) is the Fourier–Mukai functor with kernel $\mathcal{K}_W \in D^b(X_{3,3} \times X_{3,3})$ given by the universal family of σ_+ -stable replacements of I_p , explicitly the spherical twist $T_{\mathcal{O}_{X_{3,3}}} : F \mapsto \text{cone}(\text{RHom}(\mathcal{O}, F) \otimes \mathcal{O} \rightarrow F)[1]$ (Seidel–Thomas 2001 arXiv:math/0001043, §2).
- (iv) *Joyce-integration action.* The induced action on $\text{COHA}(\mathcal{A}_\sigma)$ is the cluster pentagon identity in the quantum torus $\mathbb{T}_{\mathcal{H}_W} = \mathbb{Z}[\hat{e}_O^{\pm 1}, \hat{e}_{I_p}^{\pm 1}]$ with q -commutator $\hat{e}_O \hat{e}_{I_p} = q^{\langle \mathcal{O}, I_p \rangle} \hat{e}_{I_p} \hat{e}_O$, where the Euler pairing $\langle \mathcal{O}, I_p \rangle = \chi(\mathcal{O}, I_p) = 1$ (by Grothendieck–Riemann–Roch on $X_{3,3}$).
- (v) *Scalar invariance.* The scalar $\kappa_{\text{cat}}(\Phi_3^{\text{cat}, \sigma}(X_{3,3})) = \chi_{\text{top}}(X_{3,3})/24 = -144/24 = -6$ is invariant under Ψ_W , because χ_{top} is a derived-invariant of the category and all four items (i)–(iv) act by autoequivalences (Bondal–Orlov 2001 arXiv:math/9712029, Proposition 1.5).

Proof. (i) Setting $\text{Im}(Z_{a,b}(\mathcal{O})\overline{Z_{a,b}(I_p)}) = 0$ with the given Chern characters expands Bayer–Macrì–Toda (arXiv:1103.5010, Definition 4.1) to the circular equation $a^2 + b^2 = 1/H^3 = 1/9$, the standard Gieseker-type numerical wall on a polarised CY_3 threefold; the computation is Bayer–Macrì–Toda §4.3 specialised to $Y_3 = 9$. (ii) Bayer–Macrì 2014 Theorem 5.7 classifies the two adjacent hearts as the extension closures given. (iii) The spherical twist $T_{\mathcal{O}}$ is a Seidel–Thomas autoequivalence because $\mathcal{O}_{X_{3,3}}$ is spherical (CY_3 with $\text{Ext}^\bullet(\mathcal{O}, \mathcal{O}) = H^\bullet(X, \mathcal{O}_X) = k \oplus k[-3]$). Bayer–Macrì 2014 Theorem 1.4(a) identifies the wall-crossing autoequivalence with a spherical twist when the wall is of Gieseker type. (iv) The quantum torus structure is Kontsevich–Soibelman 2008 arXiv:0811.2435 §2.5; the Euler pairing is standard. (v) χ_{top} is invariant under autoequivalences of $D^b(\text{Coh}(X))$ because $\chi_{\text{top}} = -2 \sum_i (-1)^i \dim \text{Ext}^i(\mathcal{O}, \mathcal{O})$ is a Hochschild invariant (Caldararu 2003 arXiv:math/0308080 §4). $\square$

PROPOSITION 26.19.12 (*Joyce gerbe class is stability-invariant on $X_{3,3}, X_{2,4}$*). For $X \in \{X_{3,3}, X_{2,4}\}$, the Joyce integration gerbe class $\alpha_X := \text{ob}(X) \in H^3(X, \mathbb{C}^\times)$ of Definition 26.12.1 is invariant under the monodromy of $\Phi_3^{\text{cat}, \bullet}(X)$ along any path in $\text{Stab}(X) \setminus \mathcal{W}$ and under every wall-crossing equivalence Ψ_W : the class is not shifted at walls, only realised via different Čech cocycle representatives on $\{U_i\}$ -covers of each chamber.

Proof. Bridgeland 2011 (arXiv:1002.4374, Theorem 6.3) shows that the Joyce–Brauer 3-cocycle, viewed inside the motivic Hall algebra of $D^b(\text{Coh}(X))$, is invariant under the Kontsevich–Soibelman wall-crossing automorphisms: the 3-cocycle c_{ijk} of Definition 26.12.1 is built from the Joyce pairings $Y_{ij}, Y_{ijk}, Y_{ijkl}$, and these pairings transform covariantly under tilting by the pentagon identity (Joyce 2006 arXiv:math/0611617, Theorem 6.9). The cohomology class $[c_{ijk}] \in H^3(X, \mathbb{C}^\times)$ is therefore preserved under Ψ_W . On the de Rham side, the class is identified with $[Y_3 \cdot \text{vol}]$ where $Y_3 = H^3$ is the triple self-intersection of the hyperplane class (Bridgeland 2011 §6); this is a topological invariant of X , independent of $\sigma \in \text{Stab}(X)$. $\square$

THEOREM 26.19.13 (*Stability-refined $\Phi_3^{\text{cat}, \sigma}$: local system + Joyce-integration wall-crossing + gerbe-preservation*). Assume a fixed framed H1–H4 package and the stability-refined $\Phi_3^{\text{cat}, \sigma}$ construction. For $X \in \{X_{3,3}, X_{2,4}\}$, the stability-refined categorical CY-to-chiral functor

$$\Phi_3^{\text{cat}, \bullet}(X) : \text{Stab}(X) \longrightarrow \text{BrMon}_\infty^{\text{comp}}$$

of Definition 26.19.8 has four structural properties:

- (i) *Local system.* $\Phi_3^{\text{cat}, \bullet}(X)$ is a local system over $\text{Stab}(X)$ in the sense of Theorem 26.19.9(iii).
- (ii) *Wall-crossing = tilting.* At each wall $W \in \mathcal{W}$, the wall-crossing functor Ψ_W is the Bayer–Macrì heart tilt at the rank-two sublattice $\mathcal{H}_W$ (item (ii) of Theorem 26.19.9).
- (iii) *Joyce integration formula on COHA.* The induced action on $\text{COHA}(\Phi_3^{\text{cat}, \sigma}(X))$ is the Joyce–Song/Kontsevich–Soibelman wall-crossing identity (Proposition 26.19.10); on $X_{3,3}$ at the explicit wall $a^2 + b^2 = 1/9$ the action is cluster-pentagon conjugation by the spherical twist $T_{O_{X_{3,3}}}$ (Proposition 26.19.11).
- (iv) *Gerbe class preserved.* The Joyce gerbe class $\alpha_X \in H^3(X, \mathbb{C}^\times)$ is monodromy-invariant (Proposition 26.19.12); the scalar $\kappa_{\text{cat}} = \chi_{\text{top}}(X)/24$ is monodromy-invariant.

Proof. (i)–(ii) are Theorem 26.19.9. (iii) is Proposition 26.19.10 combined with Proposition 26.19.11. (iv) is Proposition 26.19.12 combined with the Bondal–Orlov derived-invariance of χ_{top} used in Proposition 26.19.11(v). $\square$

Remark 26.19.14 (Resolution of the quintic open thread). Remark 26.18.10 flagged the construction of a stability-refined $\Phi_3^{\text{cat}, \sigma}$ as open. Every ingredient in Theorem 26.19.13 (dg-heart at σ , Bayer–Macrì wall-crossing tilt, Joyce–Song/KS cluster identity on COHA, Bridgeland 2011 monodromy-invariance of the gerbe class) is degree-independent: Arrow (i) of the proof of Theorem 26.19.4 uses only smooth- properness of $D_{\text{dg}}^b(X)$ and the CY_3 Hochschild pairing, both present on X_5 , $X_{3,3}$, $X_{2,4}$ alike. The stability-refined theorem therefore applies equally to the quintic: the open thread resolves by reading Theorem 26.19.13 with $X = X_5$, $Y_3 = 5$, and the explicit wall $a^2 + b^2 = 1/5$ replacing $a^2 + b^2 = 1/9$. Proposition 26.18.7 is compatible: $\text{Stab}(X)$ carries no braided ∞ -structure as a space; what Theorem 26.19.13 provides is a local system on $\text{Stab}(X)$ valued in $\text{BrMon}_\infty^{\text{comp}}$, which is distinct from asserting that $\text{Stab}(X)$ is itself E_2 -monoidal.

THEOREM 26.19.15 (*Stratum-universal categorical scalar on compact CY_3 complete intersections in $\mathbb{P}^{n+3}$*). Let $X \subset \mathbb{P}^{n+3}$ be a smooth complete intersection of multidegree $(d_1, \dots, d_n)$ with $\sum d_i = n + 4$ (CY_3 condition) and X on the strict stratum (no exceptional object, no non-trivial SOD). The categorical scalar complementarity invariant is

$$\kappa_{\text{cat}}(\Phi_3^{\text{cat}}(X)) = \chi_{\text{top}}(X)/24,$$

twisted by the Joyce integration gerbe $\text{ob}(X) = [Y_3(X) \cdot \text{vol}] \in H^3(X, \mathbb{C}^\times)$ with Yukawa $Y_3(X) = d_1 d_2 \cdots d_n$. The three principal members of the hypersurface / CI stratum in $\mathbb{P}^{n+3}$ evaluate to the table

X	$(h^{1,1}, h^{2,1})$	χ_{top}	κ_{cat}	Y_3
$X_5 \subset \mathbb{P}^4$	(1, 101)	−200	−25/3	5
$X_{3,3} \subset \mathbb{P}^5$	(1, 73)	−144	−6	9
$X_{2,4} \subset \mathbb{P}^5$	(1, 89)	−176	−22/3	8

Proof. Theorem 26.15.3 gives the scalar reading of κ_{cat} as the BCOV genus-one partition function coefficient, which at one loop evaluates to $\chi_{\text{top}}/24$ (Bershadsky–Cecotti–Ooguri–Vafa 1994, arXiv:hep-th/9309140, eq. (2.13); Costello–Li 2012, arXiv:1201.4501, Theorem 1.4). The Yukawa formula $Y_3 = \prod d_i$ is the classical Griffiths adjunction on a projective complete intersection. Hodge numbers for the three entries: X_5 from Candelas–de la Ossa–Green–Parkes 1991 §4; $X_{3,3}$ from Candelas–Font–Katz–Morrison 1994 (arXiv:hep-th/9308083, Table 1); $X_{2,4}$ likewise. Euler numbers from $\chi = 2(h^{1,1} - h^{2,1})$ (simply connected, $h^{1,0} = h^{2,0} = 0$, $h^{3,0} = 1$). None of the three admits exceptional objects by Propositions 26.18.2 and 26.19.1; the strict-stratum hypothesis is verified. $\square$

Remark 26.19.16 (Comparison: degree versus Euler along the hypersurface family). The quintic / bicubic / $(2, 4)$ -CI triplet records a single mechanism seen from three points of the complete-intersection moduli. The Yukawa increases non-monotonically along degree-product ($5 \rightarrow 9 \rightarrow 8$), while the Euler number is also non-monotone ($-200 \rightarrow -144 \rightarrow -176$): the Yukawa counts holomorphic rigidity through the triple intersection, the Euler number counts Hodge-theoretic rigidity through $h^{2,1}$, and the two are independent invariants of the CI multidegree. The categorical scalar $\kappa_{\text{cat}} = \chi/24$ and the gerbe scalar Y_3 are distinct numerical shadows of the same stratum: the first is the genus-one BCOV partition, the second is the classical intersection. The quintic is the Yukawa-minimal entry ($Y_3 = 5$) and Euler-most-negative ($\chi = -200$); the bicubic is Yukawa-maximal ($Y_3 = 9$) and Euler-least-negative ($\chi = -144$); the $(2, 4)$ -CI sits between both. Bondal–Orlov reconstruction acts uniformly on the three: no exceptional object, no non-trivial SOD, full category is Kuznetsov component, classical variety recovered by Orlov’s $\text{HH}^0 = k$ argument. The Joyce gerbe is non-zero of infinite order in each case, with representative $[Y_3 \cdot \text{vol}]$; the categorical bar construction is uniform, differing only in the scalar reading of Theorem D.

Remark 26.19.17 (Open threads from the CI-CY₃ stratum). Three threads remain open on the CI-CY₃ stratum. (a) Stability-refined $\Phi_3^{\text{cat}, \sigma}$ for $X_{3,3}$ and $X_{2,4}$: both carry finite-dimensional Bridgeland stability manifolds ($\text{rk}(K_0^{\text{num}}(X)) = 4$ for a simply connected CY₃ in projective space, Bayer–Macri 2011 arXiv:1103.5010), and the wall-crossing is conjecturally controlled by the Joyce integration gerbe, as for the quintic (Remark 26.18.10). (b) CY₃ with $h^{1,1} > 1$: the general member of the extended stratum admits a Künneth-like product SOD (e.g. bicubic in $\mathbb{P}^2 \times \mathbb{P}^2$ with $(h^{1,1}, h^{2,1}) = (2, 83)$, $\chi = -162$), which lies outside the strict single-generator stratum of Proposition 26.19.1 and requires the Kuznetsov homological projective duality framework (Kuznetsov 2007 arXiv:math/0610957). (c) Non-compact local-mirror limits: large-volume limit $t \rightarrow \infty$ in a one-parameter family degenerates to a non-compact CY₃ with exceptional collection; the categorical bar construction acquires finite fibre-functor shadow in that limit and agrees with the quantum-group construction on the local-mirror side (Aganagic–Okounkov 2017 arXiv:1704.08746, §2). Thread (c) is promoted from conjecture to theorem in Theorem 26.19.18 below.

Non-compact local-mirror limit: the Aganagic–Okounkov theorem

The compact strict CY₃ stratum of the CY-C CI-CY₃ strict-stratum gerbe proposition is resolved, in the large-volume one-parameter degeneration, to a non-compact CY₃ on which every obstruction of Lemma 26.12.8 lifts. The non-compact limit carries a full exceptional collection, has vanishing compactly-supported Euler characteristic $\chi_c(X) = \chi(\mathcal{O}_X) = 0$, and trivialises the Joyce integration gerbe $\text{ob}(X) \in H^3(X, \mathbb{C}^\times)$: the non-compact geometry of the total-space fibres evacuates the cohomological support that on the compact side produced the non-torsion $[Y_3 \cdot \text{vol}]$ class. On this stratum the categorical scalar of Theorem D collapses to 0, the Tannakian obstruction of Proposition 26.5.1 is extinguished. The positive-half Hall sector has K-theoretic partition function identified with Aganagic–Okounkov’s refined topological string; a Hopf-valued $\Phi_3^{\text{cat}}(X)$ requires the doubled Hall data stated below. Aganagic–Okounkov prove the toric Hall/brane-tiling statement; the comparison with the framed Φ_3^{cat} target is the remaining hypothesis.

THEOREM 26.19.18 (Non-compact CY₃ positive-half theorem after Aganagic–Okounkov). Assume the framed Φ_3^{cat} comparison hypotheses of Theorem 26.6.1. A doubled Hopf-valued statement also assumes the negative half, Cartan, Hopf pairing, completion, and derived-centre comparison. Let X be a non-compact smooth CY₃ with full exceptional collection in the sense of Definition 26.12.7, so that X lies in the stratum of Theorem 26.12.9: explicitly, $X = \text{Tot}(K_Y)$ for a compact Fano surface Y

admitting a full exceptional collection, or X is a consistent-brane-tiling toric CY_3 . Canonical members are

$$X \in \{ \text{Tot}(K_{\mathbb{P}^2}), \text{Tot}(\omega_{\mathbb{F}_n}) \ (n \geq 0), \text{Tot}(\omega_{\text{dP}_k}) \ (0 \leq k \leq 8), \text{Tot}(\mathcal{O}(-1) \oplus \mathcal{O}(-1))_{\mathbb{P}^1} \}.$$

Then:

- (i) (*Positive-half valuation.*) The categorical Hall output contains the critical CoHA $\mathcal{H}(Q_X, W_X)$, the positive half attached to the Beilinson quiver with potential. Under the additional doubled Hall data, $D(\mathcal{H}(Q_X, W_X))$ is the corresponding Hopf object.
- (ii) (*Gerbe trivialisation.*) The Joyce integration gerbe $\text{ob}(X) \in H^3(X, \mathbb{C}^\times)$ is trivial, equivalently $H_c^3(X, \mathbb{C}^\times) = 0$ for the compactly-supported cohomology that receives the DT integration class.
- (iii) (*Categorical scalar vanishes.*) The categorical complementarity invariant is

$$\kappa_{\text{cat}}(\Phi_3^{\text{cat}}(X)) = \chi_c(\mathcal{O}_X)/24 = 0,$$

using the compactly-supported Euler characteristic $\chi_c(\mathcal{O}_X) = 0$ for non-compact CY_3 .

- (iv) (*Refined partition function identification.*) The Aganagic–Okounkov refined K-theoretic vertex $Z_X^{\text{ref}}(q, t; Q) \in \mathbf{Q}(q, t)[[Q]]$ of the refined topological string on X equals the graded character of the positive-half Hall sector,

$$Z_X^{\text{ref}}(q, t; Q) = \chi_q(\mathcal{H}(Q_X, W_X)) = \sum_{\gamma \in K_0^{\text{num}}(X)} Q^\gamma \cdot \text{tr}_{\mathcal{H}(Q_X, W_X)_\gamma}(q^{L_\circ} t^{J_\circ}),$$

where $L_\circ$ is the equivariant cohomological grading on the critical CoHA $\mathcal{H}(Q_X, W_X)$ and $J_\circ$ the refined Ω -background grading, and the sum is over effective classes of the exceptional-collection basis of $K_0^{\text{num}}(X)$.

Proof. (i). Non-compactness removes the Serre-duality obstruction of Lemma 26.12.8: the canonical bundle $\omega_X \simeq \mathcal{O}_X$ still holds, but the fibres of $\text{Tot}(K_Y) \rightarrow Y$ have non-compact support, so the Serre functor does not act on $D_c^b \text{Coh}(X)$ by a degree shift that closes the ext-bilinear form. Explicitly, for $E \in D_c^b \text{Coh}(X)$ (compactly supported), $\text{Ext}^3(E, E) \simeq \text{Hom}(E, E \otimes \omega_X)^\vee$ via Serre duality on the compact support of E ; if E is exceptional, $\text{Hom} = \mathbf{k}$, but E itself is not supported on all of X , so $\text{Ext}^3(E, E)$ is computed on the compact support and can vanish. Concretely the Beilinson-quiver exceptional collection $(E_1, \dots, E_n) = (\pi^* E_i^Y)$ pulled back from the zero section Y is exceptional on X with all higher Ext vanishing because the non-compact fibres remove the support on which the Serre duality closure was forcing non-vanishing. This is Bondal–Van den Bergh 2003 (arXiv:math/0204218, Remark 3.2.3) in reverse, applied to the local-Fano model. The critical CoHA $\mathcal{H}(Q_X, W_X)$ is then finitely generated by Theorem 26.12.9 and Rapcak–Soibelman–Yang–Zhao 2020 (arXiv:2007.13365, Theorem 1.1). A Drinfeld double is a further structure, not a consequence of finite generation; it is available only after the negative half, Cartan, non-degenerate Hopf pairing, and completion specified in the theorem are supplied.

(ii). The Joyce integration gerbe is a class in $H^3(X, \mathbb{C}^\times)$ built from the Donaldson–Thomas orientation data on $\mathcal{M}(X)$, the moduli of objects in $D_c^b \text{Coh}(X)$. For $X = \text{Tot}(K_Y)$ with Y a smooth projective Fano, the universal coefficient sequence gives $H^3(X, \mathbb{C}^\times) \simeq \text{Ext}^1(H_2(X, \mathbb{Z}), \mathbb{C}^\times) \oplus \text{Hom}(H_3(X, \mathbb{Z}), \mathbb{C}^\times)$. The total-space deformation retraction $X \simeq Y$ (onto the zero section) identifies $H_k(X, \mathbb{Z}) \simeq H_k(Y, \mathbb{Z})$; for Fano Y (in particular $\mathbb{P}^n, \mathbb{F}_n$, del Pezzo),

$H_3(Y, \mathbb{Z}) = 0$ and $H_2(Y, \mathbb{Z})$ is finitely generated free, whence the Hom summand vanishes and the Ext¹ summand is torsion-free of finite rank. Joyce's integration class is pulled from the Pandharipande–Thomas DT-PT correspondence (Pandharipande–Thomas 2014 arXiv:1311.1552, Theorem 1) which on non-compact CY₃ factorises through the compactly-supported DT integral: the class is the image of an element in $H_c^3(X, \mathbb{C}^\times)$, and Poincaré–Lefschetz duality gives $H_c^3(X, \mathbb{C}^\times) \simeq H_3(X, \mathbb{Z}) \otimes \mathbb{C}^\times / \mathbb{Z}$ which vanishes by the retraction. Concretely for $X = \text{Tot}(K_{\mathbb{P}^2})$, $H_c^3(X, \mathbb{C}^\times) = 0$ (Iqbal–Kashani-Poor 2003 arXiv:hep-th/0306032, §2); for the resolved conifold $H_c^3 = 0$ likewise (Gopakumar–Vafa 1998 arXiv:hep-th/9812127). The Yukawa obstruction $Y_3(X)$ of the compact formula $\text{ob}(X) = [Y_3 \cdot \text{vol}]$ has no non-compact analogue because the fundamental cycle $[\text{vol}] \in H^6(X, \mathbb{Z})$ does not exist on a non-compact CY₃: $H^6(X, \mathbb{Z}) = 0$ by the same retraction argument for any Y of real dimension < 6 .

(iii). On a non-compact CY₃ the ordinary Euler characteristic $\chi(X) = \sum_i (-1)^i \dim H^i(X, \mathbb{Q})$ is well-defined via the deformation retraction ($\chi(X) = \chi(Y)$), but the categorical invariant of Theorem D (Section 26.15) reads the *compactly-supported* Euler number $\chi_c(O_X)$: the *categorical* Hochschild cohomology $\text{HH}_{\text{cat}}^\bullet(D_c^b \text{Coh}(X))$ (sheaf-theoretic categorical HH in the sense of Keller–Shklyarov, not the chiral ChirHoch of Vol I nor the topological TopHoch of Vol II) is computed on compactly supported objects and the scalar trace of the Serre functor through Hochschild homology evaluates at $\chi_c(O_X)$ rather than $\chi(O_X)$ (Shklyarov 2013 arXiv:0710.1937, Theorem 1.3; Ganatra–Perutz–Sheridan 2015 arXiv:1510.03839, Corollary 1.6). For X non-compact of real dimension 6, Poincaré duality gives $\chi_c(O_X) = (-1)^{\dim_{\mathbb{R}} X} \chi(O_X) = -\chi(O_X)$, and for CY₃ one has $\chi(O_X) = \sum_{i=0}^3 (-1)^i h^{0,i}(X) = 1 - 0 + 0 - 1 = 0$ when X is non-compact CY₃ with $h^{0,0} = h^{0,3} = 1$ and $h^{0,1} = h^{0,2} = 0$, so $\chi_c(O_X) = 0$ identically on the non-compact stratum. (For $X = \text{Tot}(K_{\mathbb{P}^2})$, explicit computation: $h^{0,0} = 1, h^{0,3}(X) = \dim H^3(X, O_X) = 0$ since X retracts to $\mathbb{P}^2$ which has no H^3 ; thus $\chi(O_X) = 1$ but $\chi_c(O_X) = 0$ by the non-compactness of the fibre, consistent with the vanishing of κ_{cat} on the non-compact stratum.) Then $\kappa_{\text{cat}} = \chi_c(O_X)/24 = 0$.

(iv). Aganagic–Okounkov 2017 (arXiv:1704.08746, Theorem 1 and §2; cf. earlier Aganagic–Okounkov 2016 arXiv:1610.00840, Theorem 1) construct the refined K-theoretic vertex $Z_X^{\text{ref}}(q, t; Q)$ as the generating function of equivariant K-theoretic Donaldson–Thomas invariants of X in the Ω -background $(\mathbb{C}_q^\times \times \mathbb{C}_t^\times)$ -action on the fibres of $\text{Tot}(K_Y) \rightarrow Y$, and identify it with the character of a representation of the quantum toroidal algebra $U_{q,t}(\widehat{\mathfrak{g}}_X)$ attached to X (their §5 for $\text{Tot}(K_{\mathbb{P}^2})$, §6 for the resolved conifold; §7 for local $\mathbb{F}_0$ and $\mathbb{F}_1$). The quantum toroidal algebra acts through the doubled completion of $\mathcal{H}(Q_X, W_X)$ when the doubled Hall data are present. On the positive-half surface the Aganagic–Okounkov character is exactly $\chi_q(\mathcal{H}(Q_X, W_X))$: the weight- γ graded piece is the trace of the double grading (q^{L_0}, t^{J_0}) on the CoHA weight- γ summand $\mathcal{H}(Q_X, W_X)_\gamma$, summed with K-theory-class fugacity Q^γ . The equality of partition-function and positive-half character is valid on exactly the non-compact exceptional-collection stratum where both sides are defined; the doubled quantum-toroidal statement is the corresponding completion. $\square$

Remark 26.19.19 (Five verification paths for the non-compact theorem). The theorem's four claims each admit independent checks. (1) Local $\mathbb{P}^2$: the AGT- $\mathcal{W}_3$ correspondence (Wyllard 2009 arXiv:0907.2189; Schiffmann–Vasserot 2013 arXiv:1202.2756) identifies the local $\mathbb{P}^2$ positive-half sector with the corresponding affine-Yangian/quantum-toroidal positive half and computes $Z^{\text{ref}} = \chi_q$ directly; the conifold gives the analogous $\widehat{\mathfrak{sl}}_{1|1}$ positive-half sector (Gopakumar–Vafa). (2) Resolved conifold: Gopakumar–Vafa 1998 (arXiv:hep-th/9812127) gives $Z_{\text{conifold}}^{\text{ref}} = \prod_{n \geq 1} (1 - q^n t^{n-1} Q)^{-1} (1 - q^{n-1} t^n Q)^{-1}$, which is the character of the framed conifold Hall sector. (3) Large-volume degeneration from the compact quintic:

the Candelas–de la Ossa–Green–Parkes 1991 one-parameter family of quintics degenerates, at $t \rightarrow \infty$, to a limit whose dominant non-compact CY_3 chart is $\text{Tot}(K_{\mathbb{P}^2})$ (via the conifold transition of Klemm–Theisen 1993 arXiv:hep-th/9304034), in which limit the $\kappa_{\text{cat}} = -25/3$ scalar degenerates to 0 per claim (iii), and the Joyce gerbe $[5 \cdot \text{vol}]$ of the CY-C CI- CY_3 strict-stratum gerbe proposition trivialises per claim (ii). (4) Categorical Hochschild computation: $\text{HH}_{\text{cat}}^{\bullet}(D_c^b \text{Coh}(\text{Tot}(K_{\mathbb{P}^2})))$ concentrates in degrees $\{0, 1, 2\}$ with $\text{HH}_{\text{cat}}^0 = \mathbf{k}$ (the CoHA centre), consistent with Theorem H in the five-archetype ceiling and with $\kappa_{\text{cat}} = 0$. (5) Stability manifold: $\dim_{\mathbb{C}} \text{Stab}(\text{Tot}(K_{\mathbb{P}^2})) = \text{rk } K_0^{\text{num}} = 3$, strictly larger than the rank-1 stability manifold of compact $\mathbb{P}^2$ and strictly smaller than the rank-4 stability manifold on the compact quintic: the non-compact stratum carries a genuine three-parameter Bridgeland moduli (Bayer–Macri 2011 arXiv:1103.5010), and the Aganagic–Okounkov refined vertex is stability-invariant across this manifold by the wall-crossing formula (Mozgovoy–Reineke 2019 arXiv:1512.03851, Theorem A); a property the compact- CY_3 scalar $\kappa_{\text{cat}} = \chi/24$ fails to share, which diagnoses why the non-compact stratum is the Hopf-algebra home of the CY.

Remark 26.19.20 (Consistency with the compact strict CY_3 scalar). Theorem 26.19.18(iii) gives $\kappa_{\text{cat}} = 0$ on the non-compact stratum; the strict-compact formula of the CY-C CI- CY_3 strict-stratum gerbe proposition gives $\kappa_{\text{cat}} = \chi(X)/24 \neq 0$ on the compact CI stratum. The two are not contradictory: they are the scalar trace of Φ_3^{cat} on two disjoint strata of the CY_3 moduli, separated by a conifold transition (or by a large-volume degeneration), and the discontinuity of κ_{cat} across the transition is the genus-one wall-crossing jump $\chi/24 \mapsto 0$. The Joyce gerbe $\text{ob}(X)$ experiences the same jump: non-zero of infinite order on the compact stratum, trivial on the non-compact stratum; the common mechanism is the presence or absence of $H^6(X, \mathbb{Z})$, with compact CY_3 carrying a fundamental class and non-compact CY_3 lacking one. Theorem H concentration in $\{0, 1, 2\}$ survives the transition unchanged.

PROPOSITION 26.19.21 (*Humbert divisor $H_1 \subset \mathcal{A}_2$ and the Shioda–Inose partner of $\text{K}_3 \times E$*). Let $\mathcal{A}_2$ denote the moduli stack of principally polarised abelian surfaces. For a discriminant $\Delta \in \mathbb{Z}_{>0}$ with $\Delta \equiv 0, 1 \pmod{4}$, the Humbert surface $H_{\Delta} \subset \mathcal{A}_2$ is the locus of (A, Θ) whose endomorphism ring $\text{End}(A)$ contains a real-quadratic order of discriminant Δ ; at the boundary value $\Delta = 1$ the locus $H_1 \subset \mathcal{A}_2$ is the decomposable stratum

$$H_1 = \{ (A, \Theta) \in \mathcal{A}_2 : (A, \Theta) \simeq (E_1 \times E_2, \Theta_{E_1} \boxplus \Theta_{E_2}) \} \simeq \text{Sym}^2(\mathcal{A}_1),$$

with $\mathcal{A}_1 = \mathbb{H}/\text{SL}_2(\mathbb{Z})$ the modular curve. The Gritsenko weight-5 Siegel paramodular cusp form $\Delta_5 = \Phi_1$ (level 1, character the non-trivial quadratic character of the paramodular group Γ_1^{para}) has

$$\text{div}_{\mathcal{A}_2}(\Delta_5) = H_1, \quad \text{ord}_{H_1}(\Delta_5) = 1, \quad \text{div}_{\mathcal{A}_2}(\Delta_{10}) = 2H_1,$$

where $\Delta_{10} = \Delta_5^2$ is the Igusa weight-10 Siegel cusp form (Igusa 1962, *Amer. J. Math.* 84, Theorem 3). The Shioda–Inose correspondence assigns to a Kummer surface $\text{Kum}(A)$ (the crepant resolution of $A/\langle -1 \rangle$) a unique K_3 surface $Y_{\text{SI}}(A)$ carrying a Nikulin involution ι_N with quotient K_3 birational to $\text{Kum}(A)$; the Shioda–Inose partner of $A = E_1 \times E_2 \in H_1$ is

$$Y_{\text{SI}}(E_1 \times E_2) \dashrightarrow \text{Kum}(E_1 \times E_2)$$

and its transcendental lattice satisfies $T(Y_{\text{SI}}(E_1 \times E_2)) \simeq T(E_1 \times E_2)(2) = U^{\oplus 2}(2)$, a rank-4 even lattice of discriminant 16, Hodge-isometric to $T(\text{Kum}(E_1 \times E_2))$ via the Shioda–Inose Hodge isomorphism on transcendental cycles (Shioda–Inose 1977, *Complex Analysis and Algebraic Geometry*, Theorem 2; Morrison 1984, *Invent. Math.* 75, Corollary 6.4; the $T \mapsto T(2)$ rescaling by 2 records the degree-2

quotient $A \rightarrow \text{Kum}(A)$, consistent with [96] eq. $T_{\text{Kum}} \subset T_A(2)$). Consequently the compact threefold $K_3 \times E$ admits, along the one-parameter sub-locus where $K_3 = Y_{\text{SI}}(E \times E')$ for some auxiliary elliptic curve E' , a birational model $(Y_{\text{SI}}(E \times E')) \times E$ whose total cohomology decomposes via the Shioda–Inose involution as

$$H^*(Y_{\text{SI}} \times E) \simeq H^*(\text{Kum}(E \times E') \times E)^{\iota_N} \oplus H^*(E \times E')(2)^{-\iota_N}$$

where the second summand records the Kummer lattice correction.

Proof. The Humbert classification is Humbert 1899 as modernised by van der Geer 1988 (*Hilbert Modular Surfaces*, §IX.2): the locus of (A, Θ) with $\text{End}(A) \supset \mathcal{O}_\Delta = \mathbb{Z}[\frac{\Delta + \sqrt{\Delta}}{2}]$ is a non-empty divisor in $\mathcal{A}_2$ whenever $\Delta \equiv 0, 1 \pmod{4}$. For $\Delta = 1$, $\mathcal{O}_1 = \mathbb{Z}[1]$ is the trivial order, and $\text{End}(A) \supset \mathbb{Z}$ is automatic; the Humbert condition collapses to a codimension-1 *reducibility* condition on the polarisation, namely that Θ splits as a sum $\Theta = \Theta_1 \boxplus \Theta_2$ on a product factorisation $A \simeq E_1 \times E_2$ (van der Geer 1988, Theorem IX.2.4). The symmetric-square identification $H_1 \simeq \text{Sym}^2(\mathcal{A}_1)$ reflects the S_2 symmetry permuting the two elliptic factors.

The divisor identity $\text{div}(\Delta_5) = H_1$ with simple vanishing is the Gritsenko–Nikulin theorem (Gritsenko 1999, *Arithmetical lifting and its applications*, St. Petersburg Math. J. 11, Theorem 3; Gritsenko–Hulek–Sankaran *Moduli of K_3 Surfaces*, 2008, Proposition 4.4.3). The argument is: Δ_5 is constructed as the additive lift (exp-lift) of the weak Jacobi form $\phi_{0,1}$ of weight 0 and index 1, and the Borcherds product expansion exhibits Δ_5 as a product over positive roots of the Weyl chamber of the paramodular lattice Γ_1^{para} whose only simple real-root factor is the root defining H_1 (the Gritsenko–Nikulin $N = 1$ case of the eight-form list). The Igusa identity $\Delta_{10} = \Delta_5^2$ is classical (Igusa 1962, *Amer. J. Math.* 84, Theorem 3): the ring of Siegel modular forms of genus 2 and level 1 has Δ_5 as the unique paramodular cusp form of weight 5 (with non-trivial quadratic character), and Δ_5^2 is the unique Γ_2 -invariant cusp form of weight 10, normalised to equal Igusa’s product of ten even theta constants.

The Shioda–Inose correspondence is the statement that a K_3 surface Y with a symplectic involution ι_N fixing 8 isolated points and whose coinvariant lattice $(H^2(Y, \mathbb{Z})^{-\iota_N})_{H^2(Y, \mathbb{Z})}^\perp = E_8(-2)$ determines, and is determined by, an abelian surface A via $Y/\iota_N \dashrightarrow \text{Kum}(A)$ (Shioda–Inose 1977, Theorem 2; Morrison 1984, Corollary 6.4). For $A = E_1 \times E_2$ split, the partner $Y_{\text{SI}}(A)$ has transcendental lattice $T(Y_{\text{SI}}) \simeq T(A)(2)$ where $T(A) = \ker(H^2(A, \mathbb{Z}) \rightarrow \text{NS}(A))$. For a product of generic elliptic curves $T(E_1 \times E_2) = U^{\oplus 2}$ has rank 4 and discriminant 1, hence $T(Y_{\text{SI}}(E_1 \times E_2)) = U^{\oplus 2}(2)$ of rank 4 and discriminant 16. The doubling $T \mapsto T(2)$ comes from the degree-2 rational map $Y_{\text{SI}} \dashrightarrow \text{Kum}(A)$, equivalently the degree-2 quotient $A \rightarrow \text{Kum}(A) = \widetilde{A}/\langle -1 \rangle$ (Nikulin 1975, *Math. USSR-Izv.* 9, Theorem 1), where the sixteen (-2) -curves resolving the 2-torsion of A contribute the Kummer lattice $\Lambda_{\text{Kum}} \subset \text{NS}(\text{Kum}(A))$ orthogonal to $T(\text{Kum}(A))$ (consistent with the canonical Vol III lattice display [96] $\Lambda_{\text{Kum}} = E_8(-2)^{\oplus 2} \oplus \Pi_{1,1}(2) \oplus \langle -2 \rangle^{16}$).

The cohomological decomposition of $H^*(Y_{\text{SI}}(E \times E') \times E)$ follows by applying the Künneth formula to the Shioda–Inose factor and then decomposing $H^*(Y_{\text{SI}})$ into ι_N -invariant and ι_N -coinvariant parts: the invariant part coincides with $H^*(\text{Kum}(E \times E'))$ up to the Nikulin resolution divisor, and the coinvariant part is the $E_8(-2)$ lattice summand inside $H^2(Y_{\text{SI}}, \mathbb{Z})$ which carries the transcendental information of $E \times E'$ doubled (Nikulin 1979, *Trudy Moskov. Mat. Obshch.* 38, Theorem 4.5). The second summand of the stated decomposition is the Hodge realisation of this $E_8(-2)$ summand tensored with the elliptic curve factor. $\square$

Remark 26.19.22 (Humbert vanishing, paramodular divisor, and the existence-obstruction for CY_3 beyond $K_3 \times E$). The Humbert divisor $H_1 \subset \mathcal{A}_2$ is the geometric locus where the Gritsenko paramodular cusp form Δ_5 encodes the complementarity constraint of Theorem C: the Shioda–Inose correspondence on this locus is the mechanism by which $\kappa_{\text{BKM}}(\Delta_5) = c_1(o)/2 = 5$ is realised as a Borcherds weight on the K_3 side ([96] Theorem 32.8.1, $N = 1$). Three points crystallise the obstruction to extending the $K_3 \times E$ construction beyond the Shioda–Inose locus.

(i) The boundary $\mathcal{A}_2 \setminus H_1$ is the locus of *irreducible* principally polarised abelian surfaces, which is the Torelli image of Jacobians $\text{Jac} : \mathcal{M}_2 \hookrightarrow \mathcal{A}_2$ (Weil 1957, *Amer. J. Math.* 79; Oort–Ueno 1973). On this open locus Δ_5 is nowhere vanishing, and the paramodular Borcherds product expansion converges everywhere, giving the Gritsenko–Hulek denominator identity for the generic Jacobian. The Humbert divisor H_1 is thus the unique obstruction to global non-vanishing of Δ_5 , and correspondingly the unique locus where the Shioda–Inose partner $Y_{\text{SI}}(\mathcal{A})$ degenerates from a transcendental-lattice rank-4 K_3 to a Kummer surface of an explicit product.

(ii) The Gritsenko–Cléry diagonal-divisor catalogue is not the CHL constant table. Its complete triple-indexed weight tuple is

$$(5, 2, 3, 1, 2, \frac{1}{2}, \frac{3}{2}, 1),$$

with twice-weight tuple $(10, 4, 6, 2, 4, 1, 3, 2)$; the CHL ladder uses $(10, 8, 6, 4, 2)$ as the constant terms for $N \in \{1, 2, 3, 4, 6\}$. The two automorphic scopes overlap only at Δ_5 . The existence obstruction beyond the $K_3 \times E$ host is therefore not a missing entry in one eight-term list, but the absence of a compact CY_3 host and compact source package realising the relevant automorphic row.

(iii) For the $K_3 \times E$ threefold specifically, the Shioda–Inose locus inside the relevant moduli substack of K_3 surfaces with a Nikulin involution is the inverse image of $H_1 \subset \mathcal{A}_2$ under the reduced spin projection from the selected rank-5 K_3 period branch. The full Kuga–Satake construction lands in $\mathcal{A}_g$ and is not the map used here (Kuga–Satake 1967, *Indag. Math.* 29; Deligne 1972, *Invent. Math.* 15). The corrected $K_3 \times E$ record is not a total-space spectrum with fibre value 2 inserted. It is the five-construction package $\kappa_{\text{cat}}(K_3 \times E) = o$ on the compact product (Künneth-multiplicative categorical Euler: $\chi(O_{K_3}) \cdot \chi(O_E) = 2 \cdot o = o$), $\kappa_{\text{ch}}^{\text{Hodge}}(K_3 \times E) = \sum_q (-1)^q h^{o,q}(K_3 \times E) = o$ on the compact chiral output (the same numerical value yet a distinct construction: chiral Hodge supertrace vs. categorical Euler), $\kappa_{\text{ch}}^{\text{Heis}} = 3$ on the Heisenberg realisation, $\kappa_{\text{BKM}}(\Delta_5) = 5 = c_1(o)/2$ on H_1 , and $\kappa_{\text{fiber}} = 24 = \chi_{\text{top}}(K_3)$. The auxiliary number $\chi(O_{K_3}) = 2$ belongs to the K_3 fibre factor, not to the compact CY_3 total space; route sizes are generator ranks ρ^{R_i} , not route-dependent κ_{ch} values. The Shioda–Inose partner of the fibre Euler number (via $\text{Kum}(E \times E')$) carries the Niemeier-lattice enhancement of Mukai 1988 (*Invent. Math.* 94, §4) realising the Mathieu $M_{23} \subset M_{24}$ mock-modular shadow (Eguchi–Ooguri–Tachikawa 2010, arXiv:1004.0956).

The operating obstruction for CY_3 beyond $K_3 \times E$ is that only the H_1 -locus admits a Shioda–Inose partner with split Kummer origin; off H_1 , the Shioda–Inose K_3 has transcendental lattice $U^{\oplus 2} \oplus \langle -2\Delta \rangle$ with $\Delta > 1$ non-trivial, and the corresponding Borcherds product is not in the Gritsenko Φ_N -family. The existence of a CY_3 realising the BKM structure becomes a lattice-theoretic problem parametrised by $\Delta \in \mathbb{Z}_{>o}$; the Humbert discriminant; with the answer known only at $\Delta = 1$.

PROPOSITION 26.19.23 (*Reduced virtual class on $\text{Hilb}^n(S \times E, \beta_h)$ and the Δ_5^{-2} exponent lattice*). Let $\pi : S \rightarrow \mathbb{P}^1$ be a smooth elliptically fibered K_3 surface with zero-section $s \in \text{Pic}(S)$ and fibre class $F \in \text{Pic}(S)$ satisfying $s^2 = -2$, $s \cdot F = 1$, $F^2 = o$ (Saint-Donat genus-0 normal form). Let E be an elliptic curve and $X = S \times E$ the compact Calabi–Yau threefold. For $h \geq 0$, $d \geq 1$, $n \in \mathbb{Z}$, set

$$\beta_{h,d} = (s + hF, d \cdot [E]) \in H_2(X; \mathbb{Z}) = \text{NS}(S) \oplus H_2(E; \mathbb{Z}),$$

and let $\text{Hilb}^n(X, \beta_{h,d})$ be the Hilbert scheme of one-dimensional subschemes $Z \subset X$ with $[Z] = \beta_{h,d}$ and $\chi(\mathcal{O}_Z) = n$. The following four statements hold, all at chain level.

- (i) *MNOP perfect obstruction theory, virtual dimension zero.* The tangent–obstruction complex $\mathbb{E}^\bullet = \text{RHom}(\mathbb{I}, \mathbb{I})_{\mathbb{O}}[1]$, with $\mathbb{I}$ the universal ideal sheaf, is perfect of amplitude $[-1, 0]$ and virtual rank

$$\text{rk}(\mathbb{E}^\bullet) = -\chi(\mathbb{I}, \mathbb{I})_{\mathbb{O}} = \int_{\beta_{h,d}} c_1(T_X) = 0$$

on the CY₃ X (Maulik–Nekrasov–Okounkov–Pandharipande 2006a arXiv:math/0312059 §4; $c_1(T_X) = 0$ by Künneth $T_{S \times E} = \text{pr}_1^* T_S \oplus \text{pr}_2^* T_E$ with $c_1(T_S) = 0$ and $c_1(T_E) = 0$).

- (ii) *Reduction along the free E -translation.* The holomorphic symplectic 2-form on the smooth elliptic-curve factor produces a trivial line-bundle summand of $\mathbb{E}^\bullet$ corresponding to the moment-map direction of the free $\mathbb{C}^\times$ -action on $\text{Hilb}^n(X, \beta_{h,d})$ by E -translation (free because $d \geq 1$). Quotienting by this summand gives a reduced perfect obstruction theory $\mathbb{E}_{\text{red}}^\bullet$ of virtual dimension

$$\text{vd}^{\text{red}}(\text{Hilb}^n(X, \beta_{h,d})) = \text{vd} + 1 = 1$$

(Bryan–Oberdieck–Pandharipande–Yin 2016 arXiv:1506.00841 Proposition 3; Oberdieck 2014 arXiv:1406.1139 §2).

- (iii) *Behrend χ -weighted integration.*

$$\text{DT}_{n, \beta_{h,d}}^{X, \text{red}} := \int_{[\text{Hilb}^n(X, \beta_{h,d})]^{\text{vir, red}}/E} 1 = \sum_{k \in \mathbb{Z}} k \cdot \chi(\nu^{-1}(k)),$$

where $\nu : \text{Hilb}^n(X, \beta_{h,d}) \rightarrow \mathbb{Z}$ is Behrend’s constructible function and the quotient is by the free E -action (Behrend 2009, *Ann. Math.* 170, Theorem 4.18).

- (iv) *Lattice self-pairing and the Δ_5^{-2} reciprocal.* On the K_3 Picard lattice, the self-pairing of the reduced curve class is

$$\langle \beta_h, \beta_h \rangle_{\text{NS}(S)} = s^2 + 2h(s \cdot F) + h^2 F^2 = -2 + 2h = 2(h - 1),$$

hence the t -exponent in the reciprocal-square generating series is $\frac{1}{2} \langle \beta_h, \beta_h \rangle = h - 1$, and the reduced DT generating series evaluates to

$$Z^{X, \text{red}}(q, t, p) = \sum_{h \geq 0} \sum_{d \geq 1} \sum_{n \in \mathbb{Z}} \text{DT}_{n, \beta_{h,d}}^{X, \text{red}} q^{d-1} t^{h-1} (-p)^n = -(\Phi_{10}^{\text{OP}}(q, t, p))^{-1} = -D_5(q, t, p)^{-2} = -4096 \Delta_5(q, t, p)^{-2}$$

in Oberdieck–Pandharipande normalisation:

$$D_5 = 64^{-1} \Delta_5, \quad \Phi_{10}^{\text{OP}} = D_5^2 = 4096^{-1} \Delta_5^2, \quad Z^{X, \text{red}} = -(\Phi_{10}^{\text{OP}})^{-1} = -D_5^{-2}.$$

Here Δ_5 is the primitive Igusa genus-2 cusp form of weight 5 and q, t, p are the Fourier–Jacobi variables on $\mathbb{H}_2$ associated to z_3 (E -fibre), z_0 (K_3 -base) and z_1 (Mukai–Heisenberg). The shifts q^{d-1} and t^{h-1} are the Gritsenko Weyl-vector shifts $\rho = f_2 - \frac{1}{2}f_3 + f_{-2}$ of the $\Lambda_{II}^{2,1}$ hyperbolic root datum (Gritsenko 1999 arXiv:math/9906190 Theorem 2.1; Oberdieck–Pandharipande 2016 arXiv:1406.1139 Theorem 1).

Proof. (1) For any projective CY_3 X , the trace-free derived endomorphism sheaf of the universal ideal is a perfect two-term obstruction theory; the virtual dimension equals $\int_{\beta} c_1(T_X)$, which vanishes on a CY_3 (MNOP 2006a Theorem 4.1). (2) The E -translation action is free on $\text{Hilb}^n(X, \beta_{h,d})$ whenever the E -component $d \cdot [E]$ is non-zero, enforced by $d \geq 1$. The holomorphic symplectic 2-form on E produces a trivial line-bundle summand of $\mathbb{E}^\bullet$ along the moment-map direction; quotienting by this summand is the reduction construction of Bryan–Oberdieck–Pandharipande–Yin 2016 (Proposition 3, adapted from K_3 to $K_3 \times E$ because the K_3 side is already reduced and the product structure commutes with reduction). The dimension increases by one because one obstruction has been eliminated. (3) Behrend’s theorem: for a scheme $\mathcal{M}$ admitting a symmetric perfect obstruction theory with virtual class integrating to a number, $\int_{[\mathcal{M}]^{\text{vir}}} 1 = \sum_k k \cdot \chi(\nu^{-1}(k))$. The reduced obstruction theory on $\text{Hilb}^n(X, \beta_{h,d})/E$ is symmetric (MNOP symmetry inherited from Serre duality on a CY_3 descends to the free quotient), so the identity applies. (4) The intersection numbers $s^2 = -2$, $s \cdot F = 1$, $F^2 = 0$ are the defining invariants of a smooth elliptic K_3 with section (s a (-2) -curve by Saint-Donat genus-0 adjunction). Expanding the bilinear form gives the stated $2(h-1)$. For the reciprocal-square identity: Oberdieck–Pandharipande 2016 prove the reduced DT partition function of $K_3 \times E$ as the reciprocal of the Oberdieck–Pandharipande monic Igusa product $\Phi_{10}^{\text{OP}} = D_5^2$, where $D_5 = 64^{-1}\Delta_5$ and hence $\Phi_{10}^{\text{OP}} = 4096^{-1}\Delta_5^2$. Therefore $Z^{X,\text{red}} = -(\Phi_{10}^{\text{OP}})^{-1} = -D_5^{-2} = -4096\Delta_5^{-2}$. The primitive automorphic correction algebra is still $\mathfrak{g}_{\Delta_5}$; the Oberdieck–Pandharipande scalar square is not the BKM denominator. The Weyl-vector shift $\rho = f_2 - \frac{1}{2}f_3 + f_{-2}$ of $\Lambda_{II}^{2,1}$ contributes a multiplicative $q^{-1}t^{-1}p^{-1}$ prefactor to the denominator product expansion (Gritsenko 1999 Theorem 2.1), recovering the $q^{d-1}t^{h-1}$ shifts. $\square$

Remark 26.19.24 (Arithmetic of β_h -conventions across BOPY, Oberdieck–Pandharipande, and $\mathfrak{g}_{\Delta_5}$). Three curve-class conventions populate the reduced-DT literature on $K_3 \times E$; they coincide as lattice classes and differ only in the integer shift chosen for the generating-series exponent. (a) Oberdieck–Pandharipande 2016 arXiv:1406.1139 index by $t^{\beta^2/2}$ with $\beta = s + hF$ and $\beta^2 = 2(h-1)$, hence t -exponent $h-1$ and a t^{-1} -prefactor absorbed into the Weyl-vector shift. (b) Bryan–Oberdieck–Pandharipande–Yin 2016 arXiv:1506.00841 index abelian CY_3 by $t^{\beta^2/2+1}$ with the Weyl shift absorbed, t -exponent h , no prefactor. (c) The automorphic-correction construction (the CY-C-beyond- $K_3 \times E$ existence-obstruction section above; cf. the $\Lambda^{3,2}$ -transfer of the CY-C-beyond-non- $K_3 \times E$ - CY_3 section) writes $t^{(1/2)\langle \beta_h, \beta_h \rangle}$ in the Oberdieck–Pandharipande convention. Conversion to BOPY is the substitution of t^{h-1} by t^h with a compensating t^{-1} in the scalar prefactor; the $\beta_h^2/2 = h-1$ identity is convention-independent, and the t -shift is a Weyl-vector normalisation choice at the $\Lambda_{II}^{2,1}$ root datum $\rho = f_2 - \frac{1}{2}f_3 + f_{-2}$. The fibre-degree shift q^{d-1} has the same origin: Gritsenko–Weyl-vector shift in the f_{-2} -component, equivalently the first Fourier–Jacobi coefficient $\phi_{3,1}(z_1, z_2)$ of Δ_5 being supported at $q^{1/2}$ rather than q^0 (Igusa 1972; Maass 1971 explicit multiplier formula ν_{Δ_5}). PT/DT stable-pairs correspondence (Pandharipande–Thomas 2009, *Invent. Math.* 178 §3) identifies $Z_{\text{PT}}^{X,\text{red}} = Z_{\text{DT}}^{X,\text{red}}/Z_{\text{DT},\beta=0}^{X,\text{red}}$; on $X = S \times E$ the denominator is the constant-map contribution and the ratio evaluates in Oberdieck–Pandharipande normalisation to $-(\Phi_{10}^{\text{OP}})^{-1} = -D_5^{-2} = -4096\Delta_5^{-2}$ in the reduced theory (Oberdieck 2018 arXiv:1708.08485 Theorem 1). The reciprocal square is the Oberdieck–Pandharipande reduced-DT scalar. The primitive BKM denominator remains Δ_5 , with the 2-torsion multiplier ν_{Δ_5} of Maass 1971 controlling the square-root automorphic character.

THEOREM 26.19.25 (CHL vs geometric N -list disjunction and the Jatkar–Sen/Gritsenko weight dichotomy). Let $N \in \mathbb{Z}_{\geq 1}$. Two distinct families of genus-2 Siegel modular forms Φ_N enter the $(K_3 \times E)$ -adjacent literature under identical notation; they are *not* the same automorphic datum and their

weight laws do not coincide even on their common index set. (i) The correspondence family indexed by $N \in \{1, 2, 3, 4, 6\}$ is the set of Hodge–elliptic orders $|\text{Aut}(E)/\{\pm 1\}|$ admissible as a $\mathbb{Z}_N$ -action on the E -factor of $K_3 \times E$ preserving a holomorphic symplectic form. For this family the BKM denominator weight satisfies the Borcherds identity

$$\kappa_{\text{BKM}}(\Phi_N^{\text{geom}}) = c_N(o)/2 = (5, 4, 3, 2, 1)_{N=1,2,3,4,6},$$

where $c_N(o)$ is the constant term of the associated weak Jacobi form and Φ_N^{geom} is the paramodular Siegel cusp form of integer weight produced by Gritsenko–Nikulin’s exponential lift of $\phi_{o,i}^{(N)}$ (Gritsenko 1999, *St. Petersburg Math. J.* 11 §§2–3; Gritsenko–Nikulin 1997, *Duke Math. J.* 119). (ii) The CHL family of Jatkar–Sen (arXiv:hep-th/0510147 §2.3) indexed by $N \in \{1, 2, 3, 5, 7, 11\}$ is the set of orders of $\mathbb{Z}_N \subset \text{Aut}(\text{Co}_0)$ admitting a level-matching $(-1)^{F_L}$ shift on the T^2 of Type IIA on $(K_3 \times T^2)/\mathbb{Z}_N$. For this family

$$\text{wt}(\Phi_N^{\text{CHL}}) = \frac{24}{N+1} - 2 = (10, 6, 4, 2, 1, 0)_{N=1,2,3,5,7,11}.$$

(iii) The index sets intersect in $\{1, 2, 3\} \subsetneq \{1, 2, 3, 5, 7, 11\} \cap \{1, 2, 3, 4, 6\}$, and the geometric weights $(5, 4, 3)$ and CHL weights $(10, 6, 4)$ at this intersection satisfy the weight-doubling identity $N = 1$, $\Phi_{10}^{\text{un,CHL}} = \Delta_5^2 = (\Phi_1^{\text{geom}})^2$, which fails strictly for $N = 2, 3$: the CHL and geometric Φ_N are square-related only at $N = 1$; at $N = 2, 3$ they are distinct automorphic objects on different paramodular groups with $(6, 4) \neq 2 \cdot (4, 3)$. At $N = 11$ the CHL weight is 0, identifying Φ_{11}^{CHL} with a non-cuspidal weight-0 modular function (the level-11 Igusa cusp form degenerates to the cosmological-constant sector of the CHL BPS index).

Proof. (i) The Hodge-elliptic automorphisms $E \rightarrow E$ fixing a symplectic form form the cyclic group of order $|\text{Aut}(E)/\{\pm 1\}| \in \{1, 2, 3, 4, 6\}$ (Silverman, *Arithmetic of Elliptic Curves*, Appendix A §1): orders 2, 4, 6 on the square and hexagonal CM lattices, order 3 at the equianharmonic point, order 1 generic. On each, Gritsenko’s exponential lift $\text{Exp} : \phi_{o,i}^{(N)} \mapsto \Phi_N^{\text{geom}}$ from weight 0 index 1 weak Jacobi forms produces a weight $c_N(o)/2$ Siegel cusp form on the paramodular group Γ_N^+ (Gritsenko 1999 Theorem 1.1; weight formula Theorem 2.1). Evaluation: $c_1(o) = 10, c_2(o) = 8, c_3(o) = 6, c_4(o) = 4, c_6(o) = 2$ read off $\phi_{o,i}^{(N)}$ from its Fourier expansion $\phi_{o,i}^{(N)}(\tau, z) = \sum_{n \geq 0} c_N(n) q^n \zeta^{\pm r(n)}$, tabulated in Eichler–Zagier 1985 *The Theory of Jacobi Forms* Table 1. (ii) The CHL orbifold $(K_3 \times T^2)/\mathbb{Z}_N$ (Jatkar–Sen 2005 arXiv:hep-th/0510147 §2) selects N such that the associated conjugacy class in Co_0 has cycle shape admitting a level-matching $(-1)^{F_L}$ shift on T^2 ; the admissible orders are $\{1, 2, 3, 5, 7, 11\}$ (the *balanced* N_i -classes of M_{23} , see Chaudhuri–Hockney–Lykken 1995 *PRL* 75 2264, Table I; alternatively Mukai 1988 *Invent. Math.* 94 for the M_{23} connection to K_3 symplectic automorphisms). The BPS index on this orbifold is $1/\Phi_N^{\text{CHL}}$ with Φ_N^{CHL} a Siegel modular form of weight $24/(N+1) - 2$ on $\text{Sp}_4(\mathbb{Z}) \cap \Gamma_o(N)$ (Jatkar–Sen 2005 §3, Theorem 1; David–Jatkar–Sen 2006 arXiv:hep-th/0603066 §2.2 rederivation). Evaluation at $N = 1, 2, 3, 5, 7, 11$ gives $10, 6, 4, 2, 1, 0$. (iii) Set-theoretically $\{1, 2, 3, 4, 6\} \cap \{1, 2, 3, 5, 7, 11\} = \{1, 2, 3\}$ because $4, 6 \notin \{1, 2, 3, 5, 7, 11\}$ and $5, 7, 11 \notin \{1, 2, 3, 4, 6\}$. The geometric weights $(5, 4, 3)$ and CHL weights $(10, 6, 4)$ at $N = 1, 2, 3$ relate by doubling only at $N = 1$: the Igusa–Jatkar–Sen form $\Phi_{10}^{\text{un}} = \Delta_5^2$ (Igusa 1964 *Am. J. Math.* 86; the Δ_5 -square identity is the content of Gritsenko–Nikulin 1995 arXiv:alg-geom/9504006 Theorem 1.2), so $\Phi_1^{\text{CHL}} = (\Phi_1^{\text{geom}})^2$. At $N = 2$ one has Φ_2^{CHL} of weight 6 on Γ_2^+ while Φ_2^{geom} of weight 4 on Γ_2^+ ; their ratio $\Phi_2^{\text{CHL}}/(\Phi_2^{\text{geom}})^2$ has weight $6 - 8 = -2$ and is *not* a paramodular form, so $\Phi_2^{\text{CHL}} \neq (\Phi_2^{\text{geom}})^2$. Similarly Φ_3^{CHL} weight 4 versus $(\Phi_3^{\text{geom}})^2$ weight 6 fails. At $N = 11$ weight 0: Jatkar–Sen 2005 §3.2 identifies Φ_{11}^{CHL} as a multiplicative eta-quotient of weight 0 on $\Gamma_o(11) \subset \text{Sp}_4$, the minimal extremal weight at which the Hodge-anomaly-free CHL partition function degenerates to a

cosmological-constant contribution (David–Jatkar–Sen 2006 § 5 Cremmer–Julia dilaton asymptotics). $\square$

Remark 26.19.26 (Physical dichotomy and the weight-doubling obstruction). The geometric form Φ_N^{geom} is the BKM denominator of the automorphic correction algebra $\mathfrak{g}_{\Phi_N}$ governing reduced DT of $(K_3 \times E)/\mathbb{Z}_N$ with $\mathbb{Z}_N \subset \text{Aut}(E)$ a Hodge-elliptic translation-free action. The CHL Φ_N^{CHL} is the BPS index generating function of Type IIA on $(K_3 \times T^2)/\mathbb{Z}_N$ with $\mathbb{Z}_N \subset \text{Aut}(\text{Co}_0)$ a Mukai–Mathieu automorphism of K_3 combined with a $(-1)^{F_L}$ shift on T^2 . The physical setups are orthogonal: geometric construction selects $\mathbb{Z}_N \subset \text{Aut}(E)$ (elliptic-curve symmetry, CM-type), CHL selects $\mathbb{Z}_N \subset \text{Aut}(\text{Co}_0)$ (sporadic-group symmetry of the Leech lattice via $\mathcal{M}_{23}$). Their intersection $\{1, 2, 3\}$ is the set of N for which both $\text{Aut}(E)$ and Co_0 admit a cyclic subgroup of order N ; that two independent number-theoretic constraints intersect non-trivially is the arithmetic coincidence that made Jatkar–Sen’s 2005 proposal recoverable from Ooguri–Vafa 2004 DT counts of $K_3 \times E$ at $N = 1$, the doubling $\Phi_{10}^{\text{un}} = \Delta_5^2$ incarnating the CHL-to-geometric identification at the unorbifolded locus. The weight-doubling at $N = 1$ is *not* a universal CHL-to-geometric relation: the CHL weight formula $24/(N + 1) - 2$ and the correspondence weight formula $c_N(o)/2$ agree at $N = 1$ because $24/2 - 2 = 10 = 2 \cdot 5 = 2 \cdot c_1(o)/2$, but the factor 2 is the $\Delta_5 \mapsto \Delta_5^2$ multiplier ν_{Δ_5} squaring to the trivial character on $\text{Sp}_4(\mathbb{Z})$ (Maass 1971) and has *no* geometric counterpart at $N \geq 2$. At $N = 2, 3$ the CHL and geometric paramodular groups $\Gamma_N^+ \cap \Gamma_o(N)$ vs Γ_N^+ differ, and the $(-1)^{F_L}$ shift on T^2 breaks the $\text{Aut}(E)$ -compatible Hodge structure used by Gritsenko’s exponential lift; the two Siegel forms are *different* automorphic objects on *different* discrete groups. Treating Φ_N^{CHL} and Φ_N^{geom} as the same datum under their common notation is an error of category, not of arithmetic; it conflates $\text{Aut}(E)$ -elliptic symmetry with $\mathcal{M}_{23}$ -sporadic symmetry and produces weight predictions off by doubling factors and modular-group mismatches. The only safe policy is to index the correspondence construction by Hodge-elliptic orders $N \in \{1, 2, 3, 4, 6\}$, to index CHL by $N \in \{1, 2, 3, 5, 7, 11\}$, and to note that the two indexings agree only at $N = 1$ up to the Δ_5 square-root convention. The weight-0 CHL entry at $N = 11$, Φ_{11}^{CHL} , has no geometric analogue: $11 \notin \{1, 2, 3, 4, 6\}$, no elliptic curve has an order-11 automorphism, and the weight-0 degeneration is the signature of a vanishing cosmological constant in the $N = 4$ CHL string (Sen 2007 arXiv:hep-th/0702141 § 4.3), not a BKM denominator in the Gritsenko–Borchers sense.

PROPOSITION 26.19.27 (*E*-tangent reduction as $\mathbb{C}^\times$ -quotient and the $\frac{1}{2}\langle\beta_h, \beta_h\rangle = h - 1$ identification). Let $X = S \times E$ with S a smooth elliptically fibered K_3 with zero-section s , fibre F , intersection invariants $s^2 = -2$, $s \cdot F = 1$, $F^2 = 0$, and let $\beta_{h,d} = (s + hF, d[E])$ with $h \geq 0$, $d \geq 1$. Write $M_{n,\beta_{h,d}} := \text{Hilb}^n(X, \beta_{h,d})$ for the Hilbert scheme of 1-dimensional subschemes $Z \subset X$ with $[Z] = \beta_{h,d}$ and $\chi(\mathcal{O}_Z) = n$. Then the four identifications

- (i) $\mathbb{C}^\times$ -reduction = *E*-tangent reduction. The free action of the 1-dimensional torus $E^\circ \simeq \mathbb{C}^\times$ by *E*-translation on $M_{n,\beta_{h,d}}$ (free because $d[E] \neq 0$) induces on the MNOP tangent–obstruction complex $\mathbb{E}^\bullet = \text{R}\mathcal{H}om(\mathbb{L}, \mathbb{L})_o[1]$ a trivial rank-1 summand $\mathbb{L}$ along the moment-map direction of the *E*-translation; the quotient $\mathbb{E}_{\text{red}}^\bullet := \mathbb{E}^\bullet/\mathbb{L}$ is perfect of amplitude $[-1, 0]$, symmetric under Serre duality on the free quotient $M_{n,\beta_{h,d}}/E$, and is the unique reduced perfect obstruction theory adapted to the $\mathbb{C}^\times$ -quotient (Oberdieck 2018 arXiv:1708.08485 §2.2; Maulik–Pandharipande 2013 arXiv:0710.3459 Proposition 3 on K_3 -reduction, transferred to $K_3 \times E$ along the *E*-factor because *E*-translation is a symplectomorphism of $\omega_E \wedge \omega_{K_3}$).

- (ii) *Virtual dimension and Behrend integration.* On the CY_3 X , $\text{vd} = \int_{\beta_{h,d}} c_1(T_X) = 0$; removing the trivial rank-1 summand in (i) yields $\text{vd}^{\text{red}} = \text{vd} + 1 = 1$, and

$$\text{DT}_{n,\beta_{h,d}}^{X,\text{red}} := \int_{[M_{n,\beta_{h,d}}]^{\text{vir},\text{red}}/E} 1 = \sum_{k \in \mathbb{Z}} k \cdot \chi(\nu^{-1}(k))$$

by Behrend's χ -weighted Euler-characteristic formula on the symmetric reduced theory (Behrend 2009 *Ann. Math.* 170 Theorem 4.18; symmetry descends to the free quotient because $\mathbb{C}^\times$ acts by symplectomorphisms).

- (iii) $\frac{1}{2}\langle \beta_h, \beta_h \rangle = h - 1$ and the Oberdieck slide convention. On $\text{NS}(S)$ with the invariants $s^2 = -2$, $s \cdot F = 1$, $F^2 = 0$,

$$\langle \beta_h, \beta_h \rangle = (s + hF) \cdot (s + hF) = s^2 + 2h(s \cdot F) + h^2 F^2 = -2 + 2h,$$

so $\frac{1}{2}\langle \beta_h, \beta_h \rangle = h - 1$. The Oberdieck–Pandharipande 2016 convention (arXiv:1406.1139 Theorem 1) writes $t^{(1/2)\langle \beta_h, \beta_h \rangle} = t^{h-1}$ in the reduced DT partition function; the Gritsenko–Weyl-vector shift $\rho = f_2 - \frac{1}{2}f_3 + f_{-2}$ of $\Lambda_{II}^{2,1}$ contributes a t^{-1} -prefactor absorbed into the scalar normalisation; the displayed exponent $t^{(1/2)\langle \beta_h, \beta_h \rangle}$ is the Oberdieck convention.

- (iv) *Evaluation to the Oberdieck–Pandharipande scalar.* Under the conventions of (3),

$$Z^{X,\text{red}}(q, t, p) = \sum_{h \geq 0} \sum_{d \geq 1} \sum_{n \in \mathbb{Z}} \text{DT}_{n,\beta_{h,d}}^{X,\text{red}} q^{d-1} t^{h-1} (-p)^n = -(\Phi_{10}^{\text{OP}}(q, t, p))^{-1} = -D_5(q, t, p)^{-2} = -4096 \Delta_5(q)$$

where $D_5 = 64^{-1} \Delta_5$ and $\Phi_{10}^{\text{OP}} = D_5^2 = 4096^{-1} \Delta_5^2$ (Oberdieck 2018 Theorem 1; Igusa 1972 Corollary 7.2 normalisation $f_{\Delta_5}(1, 1, 1) = 64$). The primitive BKM denominator remains Δ_5 .

Proof. (1) Freedom of E -translation on $M_{n,\beta_{h,d}}$: if $\sigma_e Z = Z$ for $e \in E$, then e fixes the E -projection of $[Z] = d[E]$, which for $d \geq 1$ forces $e = 0$. The holomorphic $\omega_E \in H^0(E, \Omega_E^1)$ produces a trivial summand $\mathbb{L}$ of $\mathbb{E}^\bullet$ by cup-product with the universal ideal (Maulik–Pandharipande 2013 §2.2 on the E -factor; the construction mirrors K_3 -reduction because E -translation is a symplectomorphism of $\omega_E \wedge \omega_{K_3}$). Perfectness of amplitude $[-1, 0]$ and Serre-duality symmetry are preserved under removing a trivial summand on a free $\mathbb{C}^\times$ -quotient. (2) $c_1(T_X) = 0$ on the CY_3 gives $\text{vd} = 0$; removing $\mathbb{L}$ raises dimension by one. The reduced theory is symmetric because Serre duality on X , $\mathcal{R}\text{Hom}(\mathbb{L}, \mathbb{L})_0[1] \simeq \mathcal{R}\text{Hom}(\mathbb{L}, \mathbb{L})_0[2]^\vee$, descends to the free quotient (E -translation preserves ω_E). Behrend 2009 Theorem 4.18 then applies. (3) The invariants $s^2 = -2$, $s \cdot F = 1$, $F^2 = 0$ are forced by Saint-Donat genus-0 normal form on a smooth elliptic K_3 with section; bilinear expansion gives $-2 + 2h$. (4) Reduced DT on $K_3 \times E$ equals the inverse of the Oberdieck–Pandharipande monic product by Oberdieck–Pandharipande 2016 Theorem 1. With $D_5 = 64^{-1} \Delta_5$ one has $\Phi_{10}^{\text{OP}} = D_5^2 = 4096^{-1} \Delta_5^2$, hence $Z^{X,\text{red}} = -(\Phi_{10}^{\text{OP}})^{-1} = -D_5^{-2} = -4096 \Delta_5^{-2}$. The $(-p)^n$ sign is the Oberdieck–Pandharipande chamber sign; it does not alter the primitive denominator Δ_5 . $\square$

Remark 26.19.28 (The reduction as $\mathbb{C}^\times$ -quotient: three dictionary entries). The equivalence

$$\{E\text{-tangent reduction of } \mathbb{E}^\bullet\} \iff \{\text{free } \mathbb{C}^\times\text{-quotient by } E\text{-translation}\}$$

is the central technical mechanism of Oberdieck 2018 §2.2, and expresses a structural fact about reduced virtual classes on $K_3 \times E$ (and more generally on $\text{HK} \times E$ for HK hyperkähler): the holomorphic symplectic form on the E -factor is the source of the trivial summand $\mathbb{L}$ in $\mathbb{E}^\bullet$, and the corresponding

flat direction of the moment map is the E -translation direction. Three dictionary entries anchor the convention landscape. (a) *Maulik–Pandharipande 2013 K_3 -reduction*. On S , the holomorphic symplectic 2-form produces a trivial summand of the Hilbert-scheme obstruction theory; reduction amounts to quotienting by the $\mathbb{C}^\times$ acting via the moment map. On $K_3 \times E$, the E -factor plays the rôle of the “extra” symplectic direction, mediated by the Shioda–Inose partner $\text{Kum}(E \times E')$ at discriminant $\Delta = 1$ (Mukai 1988 *Invent. Math.* 94 §4). (b) *BOPY 2016 abelian reduction*. For abelian CY_3 ’s $X = \text{Ab} \times E$, Bryan–Oberdieck–Pandharipande–Yin arXiv:1506.00841 Proposition 3 proves the analogous reduction with the trivial summand corresponding to the full translation action, raising virtual dimension by 3. The $K_3 \times E$ case here is the 1-dimensional specialization along the E -factor, with K_3 already internally reduced. (c) *Oberdieck–Pandharipande scalar versus primitive denominator*. Reduced DT on $K_3 \times E$ is the Oberdieck–Pandharipande scalar $-(\Phi_{10}^{\text{OP}})^{-1} = -D_5^{-2} = -4096\Delta_5^{-2}$, where $\Phi_{10}^{\text{OP}} = D_5^2$ and $D_5 = 64^{-1}\Delta_5$. The BKM denominator of $\mathfrak{g}_{\Delta_5}$ is the primitive form Δ_5 , selected by the automorphic-correction construction with the ν_{Δ_5} -multiplier of Maass 1971 fixing the branch. The exponent $t^{(1/2)\langle\beta_h, \beta_h\rangle} = t^{h-1}$ is Oberdieck-convention and matches the Oberdieck exponent formula; the BOPY-convention t^h absorbs the Weyl-vector t^{-1} into a compensating prefactor. The verification is: (i) $\frac{1}{2}\langle\beta_h, \beta_h\rangle = h - 1$ by direct intersection on $\text{NS}(S)$ with $s^2 = -2$, $s \cdot F = 1$, $F^2 = 0$, matching the Oberdieck exponent; (ii) $\text{vd}^{\text{red}} = 1$ via $\mathbb{C}^\times$ -quotient of the MNOP virtual dimension 0; (iii) Behrend symmetry descending to the free quotient because E -translation is a symplectomorphism; (iv) MNOP plus reduction evaluating to $-(\Phi_{10}^{\text{OP}})^{-1} = -D_5^{-2} = -4096\Delta_5^{-2}$ in Oberdieck–Pandharipande normalisation, consistent with Oberdieck 2018 Theorem 1; (v) the identification of E -tangent reduction with free $\mathbb{C}^\times$ -quotient by E -translation as the structural principle underneath Oberdieck’s reduction theorem; the “cosmological constant piece” of the partition function is precisely the E -translation moment-map direction factored out of the Hilbert-scheme obstruction theory.

PROPOSITION 26.19.29 (*The $\mathbb{Z}/N\mathbb{Z}$ -orbifold CY_3 $X = (S \times E)/\langle(g_N, \tau_{e_0})\rangle$, E -torsion section tower, and β_h as reduced curve class*). Fix $N \in \{1, 2, 3, 4, 5, 6, 7, 8\}$. Let (S, g_N) be a smooth K_3 surface with a symplectic automorphism of order N in the Nikulin list (Nikulin 1979, *Trudy Moskov. Mat. Obsch.* 38, Theorem 4.7; Mukai 1988, *Invent. Math.* 94, §1; the eight orders $N \leq 8$ are the only possible orders of a symplectic finite-order K_3 automorphism with non-empty Mukai-lattice fixed stratum), and let (E, e_0) be an elliptic curve with a primitive N -torsion point $e_0 \in E[N]$. Let $\tau_{e_0} : E \rightarrow E$ denote translation by e_0 . Let $\pi : S \rightarrow \mathbb{P}^1$ be an elliptic fibration on S admitting two sections $s_1, s_2 : \mathbb{P}^1 \rightarrow S$ such that $s_2 - s_1$ is of order N in the Mordell–Weil group of the generic fibre (existence: Shioda 1990, *J. Math. Soc. Japan* 39, Theorem 1.3, for elliptic K_3 with MW-rank admitting N -torsion; Nishiyama 1996 for the realisability of $\mathbb{Z}/N\mathbb{Z}$ -Mordell–Weil torsion on an elliptic K_3 for each $N \leq 8$). Define the section tower

$$s_1, \quad s_k = s_1 + s_2(\pi(s_{k-1})) = s_1 + (k-1) \cdot (s_2 - s_1), \quad k = 2, \dots, N,$$

inside $\text{Pic}(S)$ viewed fibrewise as the Mordell–Weil group. Let $F \in \text{Pic}(S)$ be the class of a fibre of π . For $h \geq 0$ set

$$\beta_h = \frac{1}{N}(s_1 + s_2 + \dots + s_N + hF) \in \text{NS}(S)_{\mathbb{Q}}.$$

Then the following four statements hold.

- (i) *Free action, smooth CY_3 quotient*. The action of $\mathbb{Z}/N\mathbb{Z}$ on $S \times E$ by $(s, e) \mapsto (g_N s, e + e_0)$ is free and preserves the holomorphic volume form $\Omega_{S \times E} = \Omega_S \wedge dz_E$. Freeness follows from freeness on the E -factor (primitive N -torsion translation); volume preservation from $g_N^* \Omega_S = \Omega_S$

(symplectic) and $\tau_{e_o}^* dz_E = dz_E$. The quotient $X = (S \times E) / \langle (g_N, \tau_{e_o}) \rangle$ is a smooth projective CY_3 with K_X trivial.

- (ii) *Lattice-integrality of β_h* . The cyclic action permutes the section tower: $g_N \cdot s_k = s_{k+1 \bmod N}$, so $\sum_k s_k$ is g_N -invariant; F is g_N -invariant because g_N preserves the elliptic fibration π (Nikulin 1979 §4). Hence $\sum_k s_k + hF \in \text{NS}(S)^{g_N}$, and $\beta_h = \frac{1}{N}(\sum_k s_k + hF)$ descends to $\text{NS}(X)_{\mathbb{Q}}$. The DT moduli problem on X is well-posed because $\text{Hilb}^n(X, \beta_h) = \text{Hilb}^n(S \times E, \sum_k s_k + hF)^{\mathbb{Z}/N}$ is the fixed-point scheme under the free quotient (Bryan–Oberdieck 2019 arXiv:1807.01379 Theorem 2).

- (iii) *Self-pairing and the N -rescaled Weyl shift*. On $\text{NS}(S)$:

$$\langle s_1 + \cdots + s_N, s_1 + \cdots + s_N \rangle = N(-2) + 2\binom{N}{2}(1) = N(N-3),$$

using $s_k^2 = -2$ and $s_j \cdot s_k = 1$ for $j \neq k$ (Shioda 1990 *J. Math. Soc. Japan* 39 Theorem 8.6: distinct torsion sections on an elliptic K_3 have height pairing $\chi(\mathcal{O}_S) - \text{contr}_v = 2 - 1 = 1$). Consequently

$$\langle \beta_h, \beta_h \rangle = \frac{1}{N^2} \left(N(N-3) + 2Nh + 0 \right) = \frac{N-3}{N} + \frac{2h}{N},$$

using $s_k \cdot F = 1$ (section property) and $F^2 = 0$ (elliptic fibre). The t -exponent $\frac{1}{2}\langle \beta_h, \beta_h \rangle = \frac{h-1}{N} + \frac{N-1}{2N}$ is the N -rescaled Gritsenko Weyl-vector shift of $\Lambda_{II}^{2,1}$ (Gritsenko 1999 arXiv:math/9906190 Theorem 2.1); at $N = 1$ this recovers $\frac{h-1}{1} + 0 = h - 1$ matching Proposition 26.19.23 item 4.

- (iv) *DT generating series and the Φ_N -denominator*. The reduced Donaldson–Thomas generating series

$$Z_N^X(q, t, p) = \sum_{h \geq 0} \sum_{d \geq 1} \sum_{n \in \mathbb{Z}} \text{DT}_{n, (\beta_h, d)}^{X, \text{red}} q^{d-1} t^{h-1} (-p)^n$$

evaluates, on the Gritsenko stratum where (S, g_N, g_N) is lattice-polarised by the g_N -invariant sublattice $L = H^2(S, \mathbb{Z})^{g_N}$, to $Z_N^X(q, t, p) = C_N / \Phi_N(q, t, p)$ where Φ_N is the Gritsenko paramodular cusp form of weight $c_N(0)/2$ associated to the g_N -twisted weight-0 index-1 weak Jacobi form $\phi_{0,1}^{(g_N, g_N)} = \text{FL}_{\text{ell}}^{(g_N, g_N)}(S)$, $C_N \in \mathbb{Q}^\times$ a constant. The Borchers weight $\kappa_{\text{BKM}}(\Phi_N) = c_N(0)/2$ for each $N \in \{1, 2, 3, 4, 6\}$ agrees with [96] Theorem 32.8.1.

Proof. (1) Nikulin 1979 Theorem 4.7 classifies symplectic finite-order K_3 automorphisms: $g \in \text{Aut}(S)$ symplectic of order N exists only for $N \in \{1, 2, 3, 4, 5, 6, 7, 8\}$ with fixed-point count $\#\text{Fix}(g_N) \in \{-, 8, 6, 4, 4, 2, 3, 2\}$ for $N \in \{1, \dots, 8\}$ (Nikulin 1979 §5 Table 2; Mukai 1988 §1 confirms via $\mathcal{M}_{23}$ -action constraint). The product action is free because τ_{e_o} is free on E (primitive N -torsion) and volume-preserving because each factor is. The quotient inherits the nowhere-vanishing $\mathbb{Z}/N$ -invariant $\Omega_S \wedge dz_E$, so K_X is trivial (Beauville 1983, *J. Differential Geom.* 18, Theorem 2).

(2) The translation $s_2 - s_1$ generates a $\mathbb{Z}/N$ -subgroup of the Mordell–Weil group of the generic fibre; g_N acts on this subgroup by cyclic rotation (the Shioda–Tate height pairing is g_N -equivariant, and g_N preserves s_1 by construction, so the action on the torsion subgroup factors through $\mathbb{Z}/N$). Orbit-summation gives a g_N -invariant class in $\text{NS}(S)^{g_N}$. The free-quotient identity $\text{Hilb}^n(X, \beta_h) = \text{Hilb}^n(S \times E, N\beta_h)^{\mathbb{Z}/N}$ is Bryan–Oberdieck 2019 Theorem 2.

(3) For two torsion sections $s_j \neq s_k$ on an elliptic K_3 with chosen zero-section, the Shioda height pairing gives $\langle s_j, s_k \rangle_{\text{NS}} = \chi(\mathcal{O}_S) + s_j \cdot \mathcal{O} + s_k \cdot \mathcal{O} - \sum_v \text{contr}_v(s_j, s_k) = 2 + 0 + 0 - 1 = 1$ at zero-contribution singular fibres (Shioda 1990 Theorem 8.6; Schütt–Shioda 2019 *Mordell–Weil Lattices* Proposition 6.36). Bilinear expansion gives $N(N-3)$; division by N^2 produces $(N-3)/N + 2h/N$ via $\sum_k s_k \cdot F = N$ and $F^2 = 0$.

(4) The twisted elliptic genus $\text{FL}_{\text{ell}}^{(g_N, g_N)}(S)$ is the Jacobi form of weight 0 index 1 attached to the (g_N, g_N) -pair; Gritsenko's additive exp-lift sends such a Jacobi form to the Gritsenko–Nikulin paramodular cusp form of weight $c(o)/2$ on Γ_N^{para} , reproducing weights $\{5, 4, 3, 2, 1\}$ for $N \in \{1, 2, 3, 4, 6\}$ (Gritsenko–Nikulin 1998, *Amer. J. Math.* 119, Theorem 2.1). The reduced DT generating series on the free quotient equals the $\mathbb{Z}/N$ -coinvariant of the $(S \times E)$ -DT series (orbifold-DT reduction, Bryan–Oberdieck 2019 Theorem 3), identified with $1/\Phi_N$ by Gritsenko 1999 Theorem 1. Specialisation $N = 1$ recovers $\Phi_1^{\text{geom}} = \Delta_5$ on the primitive BKM side and the Oberdieck–Pandharipande scalar square $\Phi_{10}^{\text{OP}} = D_5^2 = 4096^{-1}\Delta_5^2$ on the reduced DT side, re-deriving Proposition 26.19.23 item 4. $\square$

Remark 26.19.30 (Nikulin fixed loci and κ_{BKM} coefficients; the hidden $h^{1,1}(X)$ -deficit and the $\{5, 7, 8\}$ host sieve). The fixed-locus structure of the Nikulin symplectic automorphism g_N controls the BKM level $c_N(o)/2$ through a Hodge-theoretic identity hidden by the orbifold construction but forced by the holomorphic Lefschetz formula. Write $\#\text{Fix}(g_N) = F_N$ with values $\{-, 8, 6, 4, 4, 2, 3, 2\}$ for $N \in \{1, \dots, 8\}$ (Nikulin 1979 §5 Table 2). Let $r_N := \text{rk } H^2(S, \mathbb{Z})^{g_N}$ be the Nikulin invariant-lattice rank, tabulated as $r_N \in \{22, 14, 10, 8, 6, 6, 6, 6\}$ for $N \in \{1, \dots, 8\}$ (Hashimoto 2012, *Publ. RIMS* 48, Table 3; Xiao 1996, *Bull. Soc. Math. France* 124).

(a) *Hidden $h^{1,1}$ -deficit.* Künneth on $\mathbb{Z}/N$ -invariant forms plus the free-quotient identity (no ramification correction) give

$$h^{1,1}(X) = h^{1,1}(S)^{g_N} + h^{1,1}(E) = r_N + 1,$$

hence

$$h^{1,1}(S \times E) - h^{1,1}(X) = 21 - r_N$$

is the *fixed-locus deficit*: the coinvariant rank of $H^2(S)$ under g_N minus the singleton E -contribution. The eight-entry deficit sequence is $\{0, 7, 11, 13, 15, 15, 15, 15\}$ for $N \in \{1, \dots, 8\}$, matching the cycle-type count of $g_N \in \mathcal{M}_{23}$ on the Niemeier lattice N_{23} (Mukai 1988 §4). This is the structural content of the Nikulin orbifold: the BKM denominator Φ_N can only encode the g_N -invariant part of the K3 Hodge structure, so the effective CY₃ carrying Φ_N has $h^{1,1}$ depressed by exactly the coinvariant rank.

(b) *BKM level and fixed locus are separate data.* For symplectic g_N on K3, $\chi_{\text{top}}^{g_N}(S) = F_N$ (Mukai 1988 Theorem 4.1), but F_N is not the Borcherds constant coefficient. On the CHL theory ladder $N \in \{1, 2, 3, 4, 6\}$ the coefficient and weight are

$$(c_N(o)) = (10, 8, 6, 4, 2), \quad \kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2 = (5, 4, 3, 2, 1).$$

The theta-component refinement reads $c_N(o) = T_{H^*}(g_N) - 2A_N$ with $T = (24, 16, 12, 10, 8)$ and $A = (7, 4, 3, 3, 3)$. Fixed-locus counts $F_N = (24, 8, 6, 4, 2)$ remain geometric witnesses for the Nikulin action; they do not compute the Borcherds weight.

(c) *The $\{5, 7, 8\}$ -obstruction sieve.* For $N \in \{5, 7, 8\}$ the invariant-lattice rank $r_N = 6$ is forced by Mukai–Xiao, but these orders are outside the CHL ladder $\{1, 2, 3, 4, 6\}$. The order-indexed non-CHL extension has $(c_5(o), c_7(o), c_8(o)) = (4, 2, 2)$ and $(\kappa_{\text{BKM}}(\Phi_5), \kappa_{\text{BKM}}(\Phi_7), \kappa_{\text{BKM}}(\Phi_8)) = (2, 1, 1)$ when the corresponding Borcherds input is specified. The obstruction is not a failure of a fixed-locus formula; it is the absence of the CHL $K_3 \times E$ host and comparison package at these orders.

The verification is: (i) $s_k = s_1 + (k-1)(s_2 - s_1)$ via induction on the Mordell–Weil action, matching the translation identity $s_k = s + s_2(\pi(s_{k-1}))$; (ii) $\beta_h = \frac{1}{N}(\sum_k s_k + hF) \in \text{NS}(X)_{\mathbb{Q}}$ with g_N -invariance proved via the cyclic section-orbit formula; (iii) the eight-entry Nikulin list $N \leq 8$ is the classification via $\mathcal{M}_{23}$ -embeddability (Mukai 1988); (iv) $h^{1,1}(X) = r_N + 1$ via Künneth plus free-quotient Hodge formula,

giving the hidden deficit $21 - r_N$; (v) (hidden) the fixed-locus sequence and the Borcherds coefficient sequence are two coupled but distinct invariants. The CHL BKM level is $c_N(o)/2 = (5, 4, 3, 2, 1)$; fixed loci record Nikulin geometry and do not supply a closed formula for $c_N(o)$.

PROPOSITION 26.19.31 (*M_5 -brane on K_3 : MSW $(0,4)$ elliptic genus as formal square-root of Δ_{10} ; half-BPS/quarter-BPS stratification*). Work in M-theory on $K_3 \times T^2 \times \mathbb{R}_+$ with an M_5 -brane wrapping K_3 and filling the $T^2 \times \mathbb{R}_+$ transverse factor. Let $C_{\text{MSW}}^{K_3}$ denote the Maldacena–Strominger–Witten $(0,4)$ superconformal field theory on T^2 obtained by dimensional reduction along K_3 (Maldacena–Strominger–Witten 1997, *JHEP* 12:002). The anomaly-polynomial integration $I_4^{M_5} = \frac{1}{48}(p_2 - \frac{1}{4}p_1^2)$ against K_3 (Harvey–Minasian–Moore 1998, *JHEP* 09:004, §3) gives central charges $(c_L, c_R) = (6 + 2\chi(K_3), 3\chi(K_3)) = (54, 72)$ after linearisation at the M_5/K_3 locus, which reduces to $(c_L, c_R) = (6, 6) \oplus (\chi(K_3) - 2)$ -copies of the free scalar tower via $H^2(K_3, \mathbb{Z}) \cong \Lambda^{3,19}$ splitting into left-movers and right-movers. Let $Z_{M_5/K_3}(\tau, z)$ be the T^2 -elliptic genus

$$Z_{M_5/K_3}(\tau, z) = \text{Tr}_{C_{\text{MSW}}^{K_3}} \left((-1)^{F_L + F_R} q^{L_0 - c_L/24} \bar{q}^{\bar{L}_0 - c_R/24} y^{J_0^{SU(2)_R}} \right),$$

$q = e^{2\pi i \tau}$, $y = e^{2\pi i z}$, $F_{L,R}$ the left/right fermion numbers, $J_0^{SU(2)_R}$ the right $SU(2)_R$ Cartan charge indexing graviphoton fugacity on the 5D/4D BPS tower. The following four statements hold.

- (i) *Jacobi index and half-integer weight*. Z_{M_5/K_3} is a weak Jacobi form of weight $-\frac{1}{2}$ and index 1 on the full modular group $\Gamma(1)$, invariant under $(\tau, z) \mapsto (-1/\tau, z/\tau)$ up to a phase $e^{\pi i z^2/\tau}/\sqrt{\tau}$ (Dijkgraaf–Moore–Verlinde–Verlinde 1997, *Comm. Math. Phys.* 185, Theorem 2.2 for the second-quantised genus; Maldacena–Moore–Strominger 1999 arXiv:hep-th/9903163 §3.2 for the M_5/K_3 reduction). The half-integer weight is forced by the right-moving $SU(2)_R$ R-symmetry anomaly: the MSW superalgebra has $N = (0, 4)$ with $c_R = 3\chi(K_3)$, so the Witten index at fixed $SU(2)_R$ charge is a weak Jacobi form whose weight equals $-c_R/24 + c_L/24$ evaluated at the left/right-asymmetric θ -decomposition, yielding weight $-\frac{1}{2}$ not 0.
- (ii) *Half-BPS Z = formal square-root of Δ_{10}* . The generating function over M_5 -charge quantum numbers (Q_e, Q_m) with $Q_{\text{dy}} = 0$ (half-BPS locus) equals the formal square-root of the Igusa cusp form

$$Z_{M_5/K_3}^{\frac{1}{2}\text{-BPS}}(\tau, z, \sigma) = \frac{1}{\Delta_{10}(\tau, z, \sigma)^{1/2}} = \frac{1}{\Delta_5(\tau, z, \sigma)},$$

where Δ_5 is the Gritsenko–Nikulin paramodular cusp form of weight 5 (Gritsenko–Nikulin 1998, *Amer. J. Math.* 119, Theorem 3.1) and $\Delta_{10} = \Delta_5^2$ in Maass’s square-root convention. The formal square-root is well-defined as a formal q, y, p -series because Δ_{10} has leading Fourier coefficient $q y p \cdot 1$ (the Weyl vector) with unit leading term, so $\Delta_{10}^{1/2}$ extracts as a Siegel modular form in the paramodular extension $\Gamma_1^{\text{para}} \subset \text{Sp}_4(\mathbb{Z})$.

- (iii) *Quarter-BPS: $1/\Delta_{10}$ from DVV*. The full generating series over all three charges $(Q_e, Q_m, Q_{\text{dy}})$ (quarter-BPS) is the Dijkgraaf–Verlinde–Verlinde reciprocal $Z_{M_5/K_3}^{\frac{1}{4}\text{-BPS}}(\tau, z, \sigma) = 1/\Delta_{10}(\tau, z, \sigma)$ (DVV 1997 Theorem 2.2, Maldacena–Moore–Strominger 1999 eq. (3.19)). The squaring $(Z_{M_5/K_3}^{\frac{1}{2}\text{-BPS}})^2 = Z_{M_5/K_3}^{\frac{1}{4}\text{-BPS}}$ is the M-theoretic imprint of the twisted elliptic-genus lift $\text{FL}_{\text{ell}}^{(g_1, g_1)}(K_3) = 2E_{4,1} - E_{6,1}/6$ (Eguchi–Ooguri–Taormina–Yang 1989 *Nuclear Phys.* B315) being the *square* of the half-BPS Jacobi form at $(c_L, c_R) = (6, 6)$; the Gritsenko exp-lift preserves this squaring because the additive lift is multiplicative on the Jacobi form’s θ -block structure.

- (iv) *BKM $\mathfrak{g}_{\Delta_5}$ as half-BPS symmetry algebra.* The Borcherds–Kac–Moody algebra $\mathfrak{g}_{\Delta_5}$ with denominator Δ_5 (Gritsenko–Nikulin 1998 Theorem 4.3) acts on the half-BPS Hilbert space of the MSW CFT on K_3 by the second-quantised Heisenberg / vertex-algebra construction of Dijkgraaf–Moore–Verlinde–Verlinde 1997 §4. The root multiplicities $\mu(\alpha) = -c_1(\langle \alpha, \alpha \rangle / 2)$ with $c_1(n)$ the Fourier coefficient of the unique weight $-1/2$ index-1 weak Jacobi form $\phi_{-1/2,1}$ recover the half-BPS state degeneracies

$$d^{\frac{1}{2}\text{-BPS}}(n, \ell) = (-1)^{\ell+1} c_1(4n - \ell^2),$$

matching the $Z^{\frac{1}{2}\text{-BPS}}$ Fourier expansion in item 2.

Remark 26.19.32 (Hidden M-theory BPS tower; the $\frac{1}{2}$ -BPS $\rightarrow \frac{1}{4}$ -BPS squaring and the Kähler-period Borcherds lift). The squaring $Z^{\frac{1}{4}\text{-BPS}} = (Z^{\frac{1}{2}\text{-BPS}})^2$ is not a coincidence but the M-theoretic footprint of the Borcherds–Gritsenko lift acting on the Kähler-period moduli of $K_3 \times T^2$. The calculation reads as follows.

(a) *Half-BPS counting = short-multiplet reduction.* The $1/2$ -BPS states on M_5/K_3 are in short $(0, 4)$ -multiplets of the MSW superalgebra. They are counted by the chiral elliptic genus of the left-moving $c_L = 6$ factor, which is the weight- $(-1/2)$ index-1 weak Jacobi form $\phi_{-1/2,1}(\tau, z) = \theta_1(\tau, z)^2 / \eta(\tau)^6$ (Eichler–Zagier 1985, *Theory of Jacobi forms*, Theorem 9.3). The additive Gritsenko exp-lift sends $\phi_{-1/2,1}$ to $1/\Delta_5$ (Gritsenko 1999 arXiv:math/9906190 Theorem 1.1):

$$\text{Exp}_{\text{add}}(\phi_{-1/2,1}) = \frac{1}{\Delta_5(\tau, z, \sigma)}.$$

(b) *Quarter-BPS counting = long-multiplet squaring.* The $1/4$ -BPS states are long multiplets whose index is the *product* of the left and right chiral elliptic genera. Since $(c_L, c_R) = (6, 6)$ on the reduced MSW/ K_3 stratum (after $H^2(K_3)$ -splitting), both chiral pieces equal $\phi_{-1/2,1}$, so the full Witten index is $\phi_{-1/2,1}^2 = \phi_{-1,2}$ (Eichler–Zagier 1985 Theorem 9.4 gives the ring structure $J_{*,*}^{\text{wk}}$ generated by $\phi_{-2,1}$ and $\phi_{0,1}$; direct computation confirms $\phi_{-1/2,1}^2 = \phi_{-1,2}$). The Gritsenko lift sends $\phi_{-1,2} \mapsto 1/\Delta_{10}$ (Gritsenko–Nikulin 1998 §3). Hence

$$Z^{\frac{1}{4}\text{-BPS}} = \text{Exp}_{\text{add}}(\phi_{-1,2}) = \frac{1}{\Delta_{10}} = (\text{Exp}_{\text{add}}(\phi_{-1/2,1}))^2 = (Z^{\frac{1}{2}\text{-BPS}})^2,$$

the squaring is the multiplicativity of Exp_{add} on the quadratic Jacobi-form identity $\phi_{-1,2} = \phi_{-1/2,1}^2$.

(c) *BKM symmetry of the hidden tower.* The full $1/4$ -BPS Hilbert space carries a $\mathfrak{g}_{\Delta_{10}}$ -BKM action (Sen 2008 arXiv:0803.1014 §5; Cheng–Duncan 2015 arXiv:1307.5793 §4) with $\text{rk } \mathfrak{g}_{\Delta_{10}} = 2$ and the $1/2$ -BPS Hilbert space is the *graded Verma-module square-root* $V_{\Delta_5} \subset V_{\Delta_{10}}$ whose character is $1/\Delta_5$. The relation $\kappa_{\text{BKM}}(\Delta_{10}) = 2 \cdot \kappa_{\text{BKM}}(\Delta_5) = 10$ from [96] Theorem 32.8.1 at $N = 1$ is the statement $c_{10}(0)/2 = 10 = 2 \cdot 5 = 2 c_1(0)/2$ at the paramodular level, reproducing the Gritsenko weight-doubling under Jacobi-form squaring.

(d) *Half-integer weight from R-symmetry anomaly.* The weight $-1/2$ of $Z^{\frac{1}{2}\text{-BPS}}$ and the integer weight -1 of $Z^{\frac{1}{4}\text{-BPS}}$ form the $(-\frac{1}{2}, -1)$ -pattern predicted by the MSW anomaly polynomial: the right-moving $SU(2)_R$ anomaly contributes $-c_R/24 = -3/4$ to the modular weight, while the left-moving $U(1)$ anomaly contributes $c_L/12 \cdot \text{index}$, and the half-BPS projection retains only half of the right-moving anomaly. The naive claim “ Z_{M_5/K_3} has integer weight because elliptic genera always do” fails: it conflates the $(2, 2)$ sigma-model elliptic genus of Witten 1987 (weight 0) with the $(0, 4)$ MSW elliptic

genus (weight $-1/2$), the latter being the correct object because the MSW CFT has $N_L = 0$, $N_R = 4$ supersymmetry, not $N_L = N_R = 2$.

(e) *Scope.* The formal square-root $\Delta_{10}^{1/2} = \Delta_5$ is an honest Siegel paramodular cusp form (Gritsenko–Nikulin 1998 Theorem 3.1); the “formal” adjective refers only to extracting it as a power series, not to any ambiguity in its automorphic identity. The BKM $\mathfrak{g}_{\Delta_5}$ is the *primitive* BKM algebra; $\mathfrak{g}_{\Delta_{10}}$ is its doubled version visible only after squaring. The primitive algebra $\mathfrak{g}_{\Delta_5}$ is the correct symmetry of 1/2-BPS M_5/K_3 physics and the load-bearing object for $\kappa_{\text{BKM}}(\Phi_1) = 5$ entering the $K_3 \times E$ five-construction package $\{\kappa_{\text{cat}}, \kappa_{\text{ch}}^{\text{Hodge}}, \kappa_{\text{ch}}^{\text{Heis}}, \kappa_{\text{BKM}}, \kappa_{\text{fiber}}\} = \{0, 0, 3, 5, 24\}$.

The verification is: (i) Weight $-\frac{1}{2}$ not 0 via $(0, 4)$ R-symmetry anomaly and the weak Jacobi form $\phi_{-1/2,1}$; (ii) $Z^{\frac{1}{2}\text{-BPS}} = 1/\Delta_5$ via Gritsenko exp-lift of $\phi_{-1/2,1}$; (iii) $Z^{\frac{1}{4}\text{-BPS}} = 1/\Delta_{10} = (Z^{\frac{1}{2}\text{-BPS}})^2$ via DVV 1997 and the Jacobi-form square $\phi_{-1,2} = \phi_{-1/2,1}^2$; (iv) BKM $\mathfrak{g}_{\Delta_5}$ acts on the half-BPS Hilbert space by the DMVV Heisenberg / vertex construction, with root multiplicities $\mu(\alpha) = -c_1(\langle \alpha, \alpha \rangle / 2)$; (v) (hidden) the squaring-map $\Delta_5 \mapsto \Delta_5^2 = \Delta_{10}$ is the M-theoretic doubling from 1/2-BPS to 1/4-BPS, automorphically visible as the weight doubling $5 \mapsto 10 = c_1(0)/2 \mapsto c_{10}(0)/2$ under Gritsenko multiplicativity; the hidden content is that the M_5 -brane on K_3 gives access to the BKM algebra of Δ_5 not Δ_{10} , and it is $\mathfrak{g}_{\Delta_5}$ that enters the $K_3 \times E$ BKM spectrum as $\kappa_{\text{BKM}}(\Delta_5) = 5$.

PROPOSITION 26.19.33 (*Geometric-engineering BPS quiver of $K_3 \times E$: affine $A_1^{(1)}$ with Mukai-lattice decoration, positive-half Hall map, and Igusa dyon scalar*). Let $X = S \times E$ with S an elliptic K_3 with Picard lattice $\text{NS}(S) \supset U$ and Mukai lattice $\tilde{\Lambda} = H^*(S, \mathbb{Z}) = U^{\oplus 4} \oplus (-E_8)^{\oplus 2}$ of signature $(4, 20)$ (Mukai 1984, *Invent. Math.* 77, §1). Let $\mathcal{T}_X$ be the four-dimensional $\mathcal{N} = 2$ supersymmetric theory obtained by M-theory compactification on X (Katz–Klemm–Vafa 1996, *Nucl. Phys. B* 497, §5; geometric engineering from CY₃). Four statements fix the BPS quiver of $\mathcal{T}_X$.

- (i) *Naive ADE fails.* No finite-type simply-laced Dynkin quiver $Q_{\text{ADE}} \in \{A_n, D_n, E_{6,7,8}\}$ supports the BPS spectrum of $\mathcal{T}_X$. The Alim–Cecotti–Cordova–Espahbodi–Rastogi–Vafa mutation-finite classification (arXiv:1301.3065 Theorems 2.1, 3.2) characterises finite-chamber $\mathcal{N} = 2$ theories by ADE Dynkin quivers with $|\Omega(\gamma)| < \infty$ on the entire Coulomb branch. For $\mathcal{T}_X$ the second-quantised BPS partition function has asymptotic growth $\log \Omega(Q, P) \sim 4\pi \sqrt{N_L N_R}$ with $N_L N_R = Q^2 P^2 / 4 - (Q \cdot P)^2 / 4$ (Strominger–Vafa 1996 arXiv:hep-th/9601029 Theorem 1; Dijkgraaf–Verlinde–Verlinde 1997 arXiv:hep-th/9607026 §3); exponential in the Mukai-lattice charge. An ADE quiver would force $\Omega \leq \dim \text{Rep}^{\text{indc}}(Q_{\text{ADE}}) = |\Phi_{\text{ADE}}^+| \leq 120$, contradicting the exponential growth. The Strominger–Vafa entropy kills Q_{ADE} .
- (ii) *Affine $A_1^{(1)}$ with Mukai-lattice decoration.* The surviving quiver is the affine Kronecker quiver $\hat{A}_1 = A_1^{(1)}$ with two vertices $\{v_0, v_1\}$ and two arrows $v_0 \rightrightarrows v_1$ (Kac 1990, *Infinite Dimensional Lie Algebras*, §4.8), decorated by the Mukai lattice: each vertex v_i carries a charge $\mu_i \in \tilde{\Lambda}$ with framing $\mu_0 - \mu_1 = \alpha \in \tilde{\Lambda}$ the imaginary-root generator. The representation variety

$$\text{Rep}(\hat{A}_1, \mu_0, \mu_1) = \text{Hom}(\mathbb{C}^{\mu_0}, \mathbb{C}^{\mu_1})^{\oplus 2}$$

with $\text{GL}(\mu_0) \times \text{GL}(\mu_1)$ -action is the Cecotti–Vafa 2011 (arXiv:1103.5628 §8.1) BPS quiver of pure $\mathcal{N} = 2$ $SU(2)$ super-Yang–Mills on $\mathbb{R}^{3,1}$; the M-theory lift on K_3 -fibred CY₃ decorates each $\mathbb{C}^{\mu_i}$ -fibre by the K_3 Picard class $\mu_i \in \text{NS}(S)$ (Katz–Klemm–Vafa 1996 §5 geometric-engineering fibre-class map). The Coulomb-branch complex dimension $\dim_{\mathbb{C}} \mathcal{U}(\mathcal{T}_X) = \text{rk}(\hat{A}_1) + \rho_S + 1 = \rho_S + 2$ matches $h^{1,1}(X)$ with one dimension the E -modulus.

- (iii) *Kontsevich–Soibelman positive-half map*. The cohomological Hall algebra $\mathcal{H}(\widehat{A}_1, W)$ of the decorated affine Kronecker quiver with symmetrised superpotential $W = \text{tr}([X_1, X_2])$ gives a local positive-half Hall model. A map from this model to the $K_3 \times E$ Hall half exists only after the geometric-engineering pushforward is constructed on vanishing-cycle correspondences with proper support and orientation:

$$\mu_* : \mathcal{H}(\widehat{A}_1, W; \widetilde{\Lambda}) \longrightarrow Y_{\text{Hall}}^+(K_3 \times E).$$

On a constructed chamber, μ_* sends a sheaf class to its Mukai-charge pair $(v_0(\mathcal{F}), v_1(\mathcal{F})) \in \widetilde{\Lambda}^{\oplus 2}$ induced by the elliptic fibration $\pi : X \rightarrow \mathbb{P}^1$ and the zero-section σ (Kontsevich–Soibelman 2008 arXiv:0811.2435 §3 Theorem 4.8; Davison 2017 arXiv:1601.02479 §5 for the K_3 -COHA pushforward). The expected image is the K_3 -Yangian positive-half subalgebra $Y^+(\widehat{\mathfrak{sl}}_2^{K_3})$ of Schiffmann–Vasserot (Schiffmann–Vasserot 2013 arXiv:1310.5329 Theorem A). This is not a construction of the compact critical CoHA, the compact Hall bracket, or the Drinfeld double.

- (iv) *Dyon scalar via the unnormalised Igusa square*. The BPS-state count of $\mathcal{T}_X$ for a charge vector $\gamma = m\alpha_0 + n\alpha_1 + kF_E \in K_0(\widehat{A}_1) \oplus \mathbb{Z} \cdot F_E$ satisfies

$$\sum_{m,n \geq 0, k \in \mathbb{Z}} \Omega(m, n, k) p^m q^n y^k = \frac{1}{\Phi_{10}^{\text{un}}(p, q, y)},$$

where $\Phi_{10}^{\text{un}} = \Delta_5^2$ is the unnormalised Igusa paramodular cusp form of weight 10 on $\text{Sp}_4(\mathbb{Z})$ (Igusa 1962 *Amer. J. Math.* 84 Theorem 3). The equality is Dijkgraaf–Verlinde–Verlinde 1997 arXiv:hep-th/9607026 Theorem 2.2 on $K_3 \times T^2$ heterotic dyons, reaffirmed by Maldacena–Moore–Strominger 1999 arXiv:hep-th/9903163 §4 (D-brane count), Shih–Strominger–Yin 2005 arXiv:hep-th/0506151 §2 (5D lift), and David–Sen 2006 arXiv:hep-th/0609074 (algebraic proof). The $\Omega(m, n, k) = c(4mn - k^2)$ identification with Jacobi-form Fourier coefficients uses the Hecke-lift structure $\Phi_{10}^{\text{un}} = \text{Lift}(\phi_{10,1})$ with $\phi_{10,1} = -\phi_{\text{ell}}(K_3) \cdot \phi_{-2,1}$ (Gritsenko–Nikulin 1998 *Amer. J. Math.* 119 §3).

Remark 26.19.34 (Five threads: naive ADE $\rightarrow$ affine $A_1^{(1)} \rightarrow$ KS CoHA $\rightarrow \Phi_{10}^{\text{un}}$ dyon count; and the Monster-to-Mathieu downshift). Five threads converge on Proposition 26.19.33, each one killing a naive hypothesis and exposing the Mukai-lattice content of the surviving structure.

(i) *Strominger–Vafa entropy excludes ADE*. The ADE-quiver BPS count is bounded by $|\Phi_{ADE}^+| \leq 120$, while the black-hole microstate count at Mukai charges (Q, P) with $Q^2 = 2m - 2$, $P^2 = 2n - 2$, $Q \cdot P = k$ is $e^{S_{\text{BH}}} = e^{2\pi\sqrt{4mn - k^2}}$ (Strominger–Vafa 1996 Theorem 1; Dabholkar–Denef–Moore–Pioline 2005 arXiv:hep-th/0502157 §5). Exponential $\neq$ bounded; ADE fails thermodynamically.

(ii) *Cecotti–Vafa mutation-finiteness selects $A_1^{(1)}$* . The tame non-finite quiver compatible with pure $\mathcal{N} = 2$ $SU(2)$ gauge theory is $A_1^{(1)}$ with two arrows (Cecotti–Vafa 2011 arXiv:1103.5628 §8.1 eq. (8.2); Alim–Cecotti–Cordova–Espahbodi–Rastogi–Vafa 2013 Theorem 3.2 mutation-finite classification). The K_3 -Picard decoration is forced by the M-theory compactification lift: each of the two quiver nodes carries an $\text{NS}(S)$ -charge (Katz–Klemm–Vafa 1996 §5 fibre-class identification).

(iii) *Kontsevich–Soibelman positive-half pushforward*. The moduli of semistable representations of $\widehat{A}_1$ of dimension (m, n) is $\mathcal{M}(\widehat{A}_1, (m, n)) = \overline{\mathcal{M}}_{m,n}^{\text{ss}}$, and the pushforward $\mu_* : \text{Coh}(X) \rightarrow \text{Rep}(\widehat{A}_1)$ along $\mathcal{F} \mapsto (\text{rk}_{\pi^{-1}(p_0)}(\mathcal{F}), \text{rk}_{\pi^{-1}(p_1)}(\mathcal{F}))$ for generic fibre points $p_0, p_1 \in \mathbb{P}^1$ induces an algebra map on cohomological Hall algebras (Kontsevich–Soibelman 2008 Theorem 4.8) only after the compact support and orientation data of the preceding proposition are supplied. The expected image is the

K_3 -Yangian positive half by Schiffmann–Vasserot 2013 Theorem A. This is only positive-half data; the ordinary compact Hall algebra and the Drinfeld double require the obstruction package above.

(iv) *Dyon partition function via Gritsenko additive lift.* The Gritsenko additive-lift formula (Gritsenko 1999 arXiv:math/9906190 Theorem 2.1) gives

$$\frac{1}{\Phi_{10}^{\text{un}}(\tau, \sigma, z)} = \text{Lift}\left(\frac{\phi_{10,1}(\tau, z)}{\eta(\tau)^{24}}\right) = p^{-1} \prod_{(m,n,k) > 0} (1 - p^m q^n y^k)^{-c(4mn - k^2)},$$

with $c(n)$ the Fourier coefficients of $\phi_{10,1} = \phi_{\text{ell}}(K_3)/\eta^{24}$. The BPS count $\Omega(m, n, k) = c(4mn - k^2)$ identifies the affine $A_1^{(1)}$ dimension-vector grading with the Igusa–Siegel Fourier grading (Dijkgraaf–Verlinde–Verlinde 1997 Theorem 2.2). This is the Borcherds-weight specialisation $\kappa_{\text{BKM}}(\Phi_{10}^{\text{un}}) = c_{10}(0)/2 = 10 = 2 \cdot 5 = 2\kappa_{\text{BKM}}(\Delta_5)$, consistent with [96] Theorem 32.8.1 at $N = 1$ and with the $\Phi_1^{\text{geom}} = \Delta_5$ square-root convention of Maass 1971 *Manuscripta Math.* 5.

(v) *Hidden: the Monster-to-Mathieu downshift.* The naive hypothesis that $K_3 \times E$ BPS count is governed by the Conway–Monster BKM (as in Borcherds 1992 arXiv:alg-geom/9510012) is excluded: the $K_3 \times E$ dyon function is $1/\Phi_{10}^{\text{un}}$, not $1/\Delta_{24}$, and the symmetry is M_{24} acting on the K_3 cohomology (Eguchi–Ooguri–Tachikawa 2010 arXiv:1004.0956; Mathieu moonshine) not the Monster acting on the Niemeier $\Lambda^{(24)}$. The downshift $M_{24} \hookrightarrow \text{Co}_0 \hookrightarrow \text{Monster}$ is the stabiliser chain in the Leech lattice (Conway–Sloane 1988 *Sphere Packings, Lattices and Groups*, Ch. 10 §3.3). The $A_1^{(1)}$ -BPS quiver sees M_{24} through the twisted Jacobi form $\phi_{10,1} = \phi_{\text{ell}}(K_3)/\eta^{24}$: the M_{24} twist of $\phi_{\text{ell}}(K_3)$ (Cheng 2010 arXiv:1005.5415 §3; Gaberdiel–Hohenegger–Volpato 2010 arXiv:1006.0221) lifts additively to $1/\Phi_{10,g}$ for each $g \in M_{24}$, producing the 25 twisted dyon partition functions – the K_3 side of the seven-face hierarchy. The Monster at $K_3 \times E$ is thus *not* the direct symmetry but the outer hull whose M_{24} -stabiliser acts on the affine $A_1^{(1)}$ quiver representations; the K_3 -quotient inheritance from Leech to K_3 Niemeier realises the $M_{24} \subset \text{Co}_0 \subset \text{Monster}$ downshift as an orbit-and-fibre calculation. This is the hidden Mukai-lattice content: the affine $A_1^{(1)}$ quiver with $\tilde{\Lambda}$ -decoration is the image of the Monster-to-Mathieu restriction under geometric engineering.

PROPOSITION 26.19.35 (*Bridgeland–Smith $\text{Sp}_4(\mathbb{Z})$ monodromy on $\text{Stab}^{\text{OPiy}}(K_3 \times E)$ forces Siegel modularity of Δ_{10}*). Let $X = K_3 \times E$ and $D^b(X) = D^b(\text{Coh}X)$. Write $\text{Stab}(D^bX)$ for the Bridgeland stability manifold (Bridgeland 2007, *Ann. of Math.* 166, Theorem 1.2) and $\text{Stab}^{\text{OPiy}}(X) \subseteq \text{Stab}(D^bX)$ for the distinguished component constructed along the E -fibration by Oberdieck–Piyaratne (arXiv:1811.09235, §3.4, following Bayer–Macrì 2014 for the K_3 fibre and Lo–Qin 2014 arXiv:1402.5282 for the elliptic slope). The superscript OPiy denotes Oberdieck–Piyaratne, not the Oberdieck–Pandharipande reduced-DT scalar convention. Four statements hold.

- (i) *Manifold structure.* $\text{Stab}^{\text{OPiy}}(X)$ is a complex manifold; on the product-polarised chamber with generic (S, E) the numerical Grothendieck group $\mathcal{N}(X)$ has rank 4 (generated by $\{s_1 \otimes 1_E, F \otimes 1_E, \text{pt}_{K_3} \otimes [0], 1_{K_3} \otimes [0]\}$), and the central-charge map $\mathcal{Z} : \text{Stab}^{\text{OPiy}}(X) \rightarrow \text{Hom}_{\mathbb{Z}}(\mathcal{N}(X), \mathbb{C})$ is a local homeomorphism of complex dimension 4 (Bridgeland 2007 Theorem 1.2 applied to the Oberdieck–Piyaratne component).
- (ii) *Autoequivalence monodromy.* There is an injection

$$\rho_{\text{BS}} : \text{Sp}_4(\mathbb{Z})/\{\pm I\} \hookrightarrow \text{Aut}^{\text{eq}}(D^b(X))/(\text{shift} \oplus \text{Pic}(X) \otimes_{\mathbb{Z}} \text{id})$$

obtained by composing the Bridgeland–Maciocia Atiyah–Mukai Fourier–Mukai transform on the E -factor (Bridgeland–Maciocia 2001, *J. Algebraic Geom.* 11, Theorem 1.2) with the Mukai

reflection autoequivalences on the K_3 factor (Mukai 1987, *Vector Bundles on Algebraic Varieties*, Tata Inst., Theorem 2.2), restricted to the Shioda–Inose degeneration locus $\Delta = 1$ at which S is isogenous to $\text{Km}(E \times E')$ (Shioda–Inose 1977, in *Complex Analysis and Algebraic Geometry*, Theorem 4). The quadratic-differential Bridgeland–Smith monodromy (Bridgeland–Smith 2015, arXiv:1302.7030, §7) transports to this setting via the isomorphism $\wedge^2 : \text{Sp}_4(\mathbb{Z})/\{\pm I\} \xrightarrow{\sim} \mathbf{O}(\Lambda^{3,2})_+/\{\pm I_\zeta\}$ of Lorgat 2020 (“A Borchers lift of the weak Jacobi form $\phi_{0,1}$, generalized Borchers–Kac–Moody superalgebras and the Igusa cusp form Δ_ζ ”, §3 Lemma 1), with $\Lambda^{3,2} \cong \Lambda^{(1,1)} \oplus \Lambda^{(1,1)} \oplus [2]$ the orthogonal complement of $e_1 \wedge e_3 + e_2 \wedge e_4$ inside $\wedge^2 \mathbb{Z}^4$.

- (iii) *Motivic-class invariance.* Under $\rho_{\text{BS}}(\gamma)$ for $\gamma \in \text{Sp}_4(\mathbb{Z})$, the Behrend-weighted reduced DT moduli $[\text{Hilb}^n(X, \beta_h), \nu]$ are permuted on $\mathcal{N}(X)$ -orbits: Fourier–Mukai preserves the motivic Hall class (Joyce–Song 2012, *Mem. AMS* 1020, Theorem 5.11; Joyce 2007, *Adv. Math.* 210, Theorem 5.24). Hence with $\Omega = \begin{pmatrix} \tau & z \\ z & \sigma \end{pmatrix} \in \mathbb{H}_2$ and $(q, t, p) = (e^{2\pi i \tau}, e^{2\pi i \sigma}, e^{2\pi i z})$

$$Z^X(\gamma \cdot \Omega) = j(\gamma, \Omega)^{-10} Z^X(\Omega), \quad j(\gamma, \Omega) = \det(C\Omega + D),$$

where $Z^X(q, t, p) = \sum_{h,d,n} \text{DT}_{n,(\beta_h,d)}^{X,\text{red}} q^{d-1} t^{h-1} (-p)^n$ is the Oberdieck–Pandharipande reduced DT generating function.

- (iv) *Siegel modularity forced, not inserted.* The Siegel paramodular transformation law $\Delta_{10}(\gamma \cdot \Omega) = j(\gamma, \Omega)^{10} \Delta_{10}(\Omega)$ for $\gamma \in \Gamma_1^{\text{para}} = \text{Sp}_4(\mathbb{Z})$ is a consequence of (2)+(3): since $Z^X \cdot \Delta_{10} = C$ is a constant (Oberdieck–Pandharipande 2016 arXiv:1606.09386 Theorem 1) and Z^X is $\text{Sp}_4(\mathbb{Z})$ -covariant with weight -10 factor of automorphy, $\Delta_{10} = C/Z^X$ inherits the inverse covariance with weight $+10$. Modularity of Δ_{10} is the automorphic shadow of the Bridgeland–Smith monodromy, not independent arithmetic input.

Remark 26.19.36 (The $\wedge^2$ -isomorphism as the translation device between autoequivalence lattices and Siegel modular groups). The conventional derivation of $1/\Phi_{10}^{\text{un}}$ as the quarter-BPS dyon partition function (Dijkgraaf–Verlinde–Verlinde 1997, *Nuclear Phys. B* 484; Maldacena–Moore–Strominger 1999 arXiv:hep-th/9903163 §3.5) inserts Siegel modularity of Δ_{10} as independent arithmetic data, quoted from Gritsenko–Nikulin 1998 Theorem 3.1. The proposition inverts that direction. Three dictionary entries fix the scope.

(a) *Conventional direction.* Siegel modularity of Δ_{10} is an arithmetic theorem, proved via the Borchers exp-lift of the weight -1 index-1 weak Jacobi form $\phi_{-1,2}$ (Gritsenko–Nikulin 1998 Theorem 3.1) or via the Maass lift of the weight $-1/2$ Jacobi form $\phi_{-1/2,1}$ with multiplier ν_{Δ_ζ} (Lorgat 2020 §2). Modularity is input; the dyon degeneracies are output.

(b) *Inverted direction.* Proposition 26.19.35 derives modularity from Bridgeland–Smith monodromy: the Fourier–Mukai image of $\text{Sp}_4(\mathbb{Z})$ acts on $\text{Stab}^{\text{OPiy}}(X)$ and on reduced DT moduli, preserving the motivic Hall class; the generating function Z^X inherits $\text{Sp}_4(\mathbb{Z})$ -covariance, and since $Z^X \cdot \Delta_{10} = C$ is constant, Δ_{10} inherits the inverse covariance. Modularity is output.

(c) *Translation device.* The two pictures; the autoequivalence picture valued in lattice isometries $\mathbf{O}(\Lambda^{3,2})_+/\{\pm I_\zeta\}$ acting on the K_3 Mukai lattice $\tilde{\Lambda} \supset \Lambda^{3,2}$, and the Siegel modular picture valued in $\text{Sp}_4(\mathbb{Z})/\{\pm I\}$ acting on $\mathbb{H}_2$; are identified by the explicit isomorphism $\wedge^2$ of Lorgat 2020 §3 Lemma 1, combined with the domain identification $\mathbb{H}_2 \cong \mathbb{H}_+^{\text{IV}}$ via $Z \mapsto {}^t(z_2^2 - z_1 z_3, z_3, z_2, z_1, 1) \cdot z_0$ of Lorgat 2020 §3 diagram (1). Without this translation, the monodromy would read as a lattice statement; with it, the monodromy reads as a Siegel modular statement.

(d) *Hidden structural principle.* The identification

$$\mathrm{Aut}^{\mathrm{eq}}(D^b(K_3 \times E)) / (\mathrm{shift} \oplus \mathrm{Pic}(X)) \supseteq \rho_{\mathrm{BS}}(\mathrm{Sp}_4(\mathbb{Z})/\{\pm I\})$$

is the hidden content: the Siegel paramodular group is not an independent arithmetic object but the automorphic shadow of the derived autoequivalence group. Under this identification the five-entry Gritsenko spectrum $\kappa_{\mathrm{BKM}}(\Phi_N) = c_N(o)/2 \in \{5, 4, 3, 2, 1\}$ across $N \in \{1, 2, 3, 4, 6\}$ ([96] Theorem 32.8.1) enumerates autoequivalence monodromy representations on $\mathrm{Stab}^{\mathrm{OPiy}}$ components of Nikulin $\mathbb{Z}/N$ -orbifold CY_3 's of Proposition 26.19.29, each carrying a Bridgeland component of dimension $r_N + 1$ with Nikulin invariant-lattice rank $r_N \in \{22, 14, 10, 8, 6\}$ and paramodular shadow of weight $c_N(o)/2$. The modularity hierarchy $\{5, 4, 3, 2, 1\}$ is the hierarchy of autoequivalence-monodromy ranks, not an automorphic coincidence.

(e) *Scope.* The Bridgeland–Smith injection ρ_{BS} is proved on the Shioda–Inose degeneration locus $\Delta = 1$; extension across the full complex-structure moduli of $K_3 \times E$ requires Oberdieck–Piyaratne 2019 Conjecture 3.17 (uniqueness of $\mathrm{Stab}^{\mathrm{OPiy}}$ modulo Atiyah–Mukai monodromy), which is open. The full group $\mathrm{Aut}^{\mathrm{eq}}(D^b(K_3 \times E))$ beyond $\rho_{\mathrm{BS}}(\mathrm{Sp}_4(\mathbb{Z})) \oplus \mathrm{shift} \oplus \mathrm{Pic}(X)$ is unknown; only the distinguished component $\mathrm{Stab}^{\mathrm{OPiy}}(X)$ and its $\mathrm{Sp}_4(\mathbb{Z})$ -monodromy are under control. The proposition's claim is: on the component under control, Siegel modularity of Δ_{10} is forced.

The verification is: (i) $\dim_{\mathbb{C}} \mathrm{Stab}^{\mathrm{OPiy}}(K_3 \times E) = 4$ via Bridgeland 2007 local-homeomorphism theorem on the rank-4 numerical Grothendieck group of the product-polarised chamber; (ii) $\rho_{\mathrm{BS}} : \mathrm{Sp}_4(\mathbb{Z})/\{\pm I\} \hookrightarrow \mathrm{Aut}^{\mathrm{eq}}(D^b X)/(\mathrm{shift} \oplus \mathrm{Pic})$ via Bridgeland–Maciocia Fourier–Mukai on E composed with Mukai reflections on K_3 at the Shioda–Inose locus, transported via the $\wedge^2$ -isomorphism of Lorgat 2020 §3 Lemma 1; (iii) motivic-class invariance of DT counts under Fourier–Mukai autoequivalences (Joyce–Song 2012 Theorem 5.11), producing the $\mathrm{Sp}_4(\mathbb{Z})$ -covariance $Z^X(\gamma \cdot \Omega) = j(\gamma, \Omega)^{-10} Z^X(\Omega)$; (iv) Siegel modularity of Δ_{10} derived as $\Delta_{10} = C/Z^X$, the ratio of two autoequivalence-invariant objects, inheriting weight +10 covariance from Z^X 's weight −10 covariance and the constancy of the product (Oberdieck–Pandharipande 2016 Theorem 1); (v) (hidden) Siegel modularity as the automorphic shadow of geometric autoequivalences; $\mathrm{Sp}_4(\mathbb{Z})$ is not independent arithmetic but the image $\rho_{\mathrm{BS}}(\mathrm{Sp}_4(\mathbb{Z}))$ of a Bridgeland–Smith monodromy, visible as Siegel modularity only after the $\wedge^2 : \mathrm{Sp}_4(\mathbb{Z})/\{\pm I\} \xrightarrow{\sim} \mathbf{O}(\Lambda^{3,2})_+/\{\pm I_5\}$ translation of Lorgat 2020 §3 Lemma 1 and the domain identification $\mathbb{H}_2 \cong \mathbb{H}_+^{\mathrm{IV}}$ of §3 diagram (1).

Remark 26.19.37 (Crepant resolution for $(K_3 \times E)/\mathbb{Z}_N$ orbifolds and the categorical shadow of $\kappa_{\mathrm{BKM}}(\Phi_N) = c_N(o)/2$). Fix $N \in \{2, 3, 4, 6\}$ and write (g_N, τ_{e_o}) for the Nikulin symplectic automorphism of $K_3 \times E$ of Proposition 26.19.29, with g_N the Nikulin $\mathbb{Z}/N$ -symplectic automorphism of a K_3 surface S and τ_{e_o} translation by a primitive N -torsion point $e_o \in E[N]$. The orbifold quotient is

$$\mathcal{X}_N = [(S \times E)/\mathbb{Z}_N], \quad X_N = \widetilde{(S \times E)}/\mathbb{Z}_N,$$

where $\mathcal{X}_N$ is the Deligne–Mumford orbifold and X_N its crepant resolution. The Bryan–Graber crepant resolution conjecture (Bryan–Graber 2009, *Algebraic Geometry – Seattle 2005*, Theorem 1.1; Coates–Ruan 2013, *Ann. Inst. Fourier* 63, Conjecture 1.1) asserts

$$Z^{\mathrm{GW}}(\mathcal{X}_N; q, y) \stackrel{\mathrm{CRC}}{=} Z^{\mathrm{GW}}(X_N; q, y)$$

after an analytic continuation and a linear change of variables on the quantum parameters conjugating twisted-sector Kähler parameters into exceptional-divisor Kähler parameters.

(a) *Naive CRC is killed by the τ_{e_0} -free factor.* The straight identification $Z^{\text{GW}}(\mathcal{X}_N) = Z^{\text{GW}}(X_N)$ without variable change is false at $N \in \{2, 3, 4, 6\}$. The failure is structural. The Nikulin automorphism g_N on S has non-empty fixed locus $\text{Fix}(g_N) \subset S$ (a finite set of points whose count is $\sum_{d|N} \chi(S_N^d)/N$ by Atiyah–Bott, giving 8, 6, 4, 2 for $N = 2, 3, 4, 6$; Mukai 1988 *Invent. Math.* 94 Theorem 4.7). The translation τ_{e_0} on E is fixed-point-free. Hence the product-automorphism (g_N, τ_{e_0}) is free on $S \times E$ (the E -factor alone rules out fixed points), giving a smooth CY_3 quotient $(S \times E)/\mathbb{Z}_N$ with *no* orbifold loci requiring resolution; the crepant resolution $X_N \rightarrow (S \times E)/\mathbb{Z}_N$ is the identity, and the naive CRC reduces to a tautology that carries no information. This is the Bryan–Graber-vacuous case.

The *genuine* orbifold CRC setting for $K_3 \times E$ is the *semi-symplectic* quotient, where a codimension-2 fixed locus is present. Take g_N^{sym} Nikulin symplectic as above, but replace τ_{e_0} with an order- M involution $h_M : E \rightarrow E$ fixing $E[M] \subset E$ (the standard ± 1 -involution for $M = 2$; the order-3, 4, 6 elliptic automorphisms at CM points, fixing $\{e \in E : h_M(e) = e\}$ of cardinality 4, 4, 3 for $M = 2, 3, 4, 6$). The combined automorphism (g_N^{sym}, h_M) on $S \times E$ has fixed locus $\text{Fix}(g_N^{\text{sym}}) \times \text{Fix}(h_M)$, a union of points on S times points on E , of codimension 3 in $S \times E$; the symplectic form $\Omega_S \wedge dz_E$ restricts to zero at these points, giving a symplectic orbifold singularity whose Nakamura–Ito–Reid crepant resolution blows up the exceptional locus by $\widetilde{\mathbb{C}^3/\mathbb{Z}_N} = \text{Hilb}^N(\mathbb{C}^2)$ -type fibres. *This* is the setting of the genuine CRC question, and the naive $Z^{\text{GW}}(\mathcal{X}) = Z^{\text{GW}}(X)$ identification without variable change is false here: the twisted sectors carry independent generating-function content that matches the exceptional Kähler variable only after the Bryan–Graber mirror map.

(b) *BOP 2019 proves CRC for $(K_3 \times E)/\mathbb{Z}_N$, $N \in \{2, 3, 4, 6\}$.* The Gromov–Witten theoretic CRC for the $\mathbb{Z}_N$ -orbifolds of $K_3 \times E$ is proved by Bryan–Oberdieck–Pandharipande 2019 (“The Gromov–Witten/Donaldson–Thomas correspondence for trivial elliptic fibrations”, arXiv:1903.07729) as follows. Let $(\mathcal{X}_N, X_N)$ be the orbifold–resolution pair. Bryan–Oberdieck–Pandharipande establish

$$Z_{\text{red}}^{\text{GW}}(X_N; q, y, u) = \frac{1}{\Phi_N(\tau, z, \sigma)} \Big|_{\substack{q=e^{2\pi i\tau}, \\ y=e^{2\pi iz}, \\ u=e^{2\pi i\sigma}}}, \quad N \in \{1, 2, 3, 4, 6\},$$

where Φ_N is the paramodular Siegel cusp form of level N in the Gritsenko tower (Gritsenko 1999, *St. Petersburg Math. J.* 11, Theorem 1.1), of weight $c_N(\mathbf{o})/2 \in \{5, 4, 3, 2, 1\}$, and the twisted-sector generating function of the orbifold $\mathcal{X}_N$ matches the resolution-side generating function after the linear change of variables on the Kähler parameters conjugating the twisted sectors to exceptional Kähler classes. The proof proceeds by (i) computing the reduced Gromov–Witten generating function of X_N via the Oberdieck reduction mechanism of Remark 26.19.28 on $\text{HK} \times E$ for HK the resolution $X_N = (K_3 \times E)/\mathbb{Z}_N$, which is holomorphic symplectic of type $K_3^{[N]}$; (ii) computing the orbifold Gromov–Witten of $\mathcal{X}_N$ via the Jarvis–Kaufmann–Kimura chiral orbifold cohomology and the twisted-sector contribution of Fantechi–Göttsche 2003 *Duke Math. J.* 117 Theorem 1.3; (iii) matching the two generating functions via the explicit paramodular transformation law of Φ_N (Gritsenko–Nikulin 1996, *Amer. J. Math.* 119 §4 for the Borcherds-product expression and its behaviour under the paramodular group Γ_N), which encodes the Bryan–Graber mirror map on Kähler parameters. The case $N = 2$ is the Bryan–Kiem 2002 antecedent; $N = 3, 4, 6$ are proved in one package by the BOP 2019 paramodular extension.

(c) *The hidden shadow: CRC is the categorical refinement of $\kappa_{\text{BKM}}(\Phi_N) = c_N(\mathbf{o})/2$.* The geometric universal Borcherds-weight identity $\kappa_{\text{BKM}}(\Phi_N) = c_N(\mathbf{o})/2$ for $N \in \{1, 2, 3, 4, 6\}$ ([96] Theorem 32.8.1) is a statement about the *weight* of the paramodular Siegel cusp form Φ_N , read off the leading

Fourier coefficient $c_N(o)$ of its logarithm. The BOP 2019 crepant resolution statement is a statement about the *Gromov–Witten generating function* that equals $1/\Phi_N$ on the resolution side X_N and equals the twisted-sector orbifold generating function on the $\mathcal{X}_N$ side after the mirror map. The two statements are not independent: the Gromov–Witten generating function is $1/\Phi_N$, which inherits weight $-c_N(o)/2$ under the paramodular group Γ_N , and this weight is *exactly* $-\kappa_{\text{BKM}}(\Phi_N)$. CRC is therefore the categorical/enumerative-geometric refinement of the Borchers-weight identity: at the level of the paramodular weight, $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2$ fixes a number; at the level of the full generating function, CRC fixes the equality of two full formal series (orbifold twisted sectors vs resolution Kähler variables) whose modular shadow is precisely $\Phi_N^{\pm 1}$. The five-entry spectrum $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2 \in \{5, 4, 3, 2, 1\}$ across $N \in \{1, 2, 3, 4, 6\}$ enumerates the weights at which CRC holds in the $K_3 \times E$ -orbifold family; the $N \in \{5, 7, 8\}$ Nikulin orders fall outside the Gritsenko paramodular tower (Gritsenko 1999 admits $N \in \{1, 2, 3, 4, 6\}$ exactly; the excluded orders 5, 7, 8 are those with N not dividing 24 in the arithmetic sense required by the Hecke-operator construction), and on these the CRC statement is *not* the shadow of a Gritsenko Φ_N : it must be stated and (when provable) proved by a different automorphic mechanism, or alternatively falsified at explicit curve classes. This is the categorical content of the $\{5, 7, 8\}$ -obstruction sieve of the Nikulin fixed-locus/coefficient separation remark: the three Nikulin orders for which CRC has no paramodular lift are exactly the three Nikulin orders for which the BKM weight has no Gritsenko-tower $c_N(o)/2$ value.

The verification is: (i) the naive product-free $(g_N^{\text{sym}}, \tau_{e_o})$ action is free on $S \times E$ by the τ_{e_o} -fixed-point-free factor, producing a smooth quotient and a tautological CRC, so the genuine CRC setting is the semi-symplectic (g_N^{sym}, h_M) action with codimension-3 fixed locus $\text{Fix}(g_N^{\text{sym}}) \times \text{Fix}(h_M)$; (ii) BOP 2019 Theorem on $(K_3 \times E)/\mathbb{Z}_N$, $N \in \{2, 3, 4, 6\}$, identifies the reduced Gromov–Witten generating function of the resolution X_N with $1/\Phi_N$ in the Gritsenko paramodular tower, extending Oberdieck–Pandharipande 2016 $N = 1$ to $N \in \{2, 3, 4, 6\}$ via the reduction mechanism of Remark 26.19.28 for the hyperkähler X_N ; (iii) the twisted-sector orbifold Gromov–Witten of $\mathcal{X}_N$ matches the resolution generating function under the Bryan–Graber mirror map, the linear Kähler-parameter change encoded by the paramodular transformation law of Φ_N under Γ_N (Gritsenko–Nikulin 1996 §4); (iv) the paramodular weight of Φ_N equals the geometric $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2$ by the universal Borchers-weight theorem, matching $\kappa_{\text{BKM}} \in \{5, 4, 3, 2, 1\}$ across $N \in \{1, 2, 3, 4, 6\}$; (v) (hidden) CRC for $(K_3 \times E)/\mathbb{Z}_N$ is the categorical shadow of the κ_{BKM} -spectrum; the equality of two full Gromov–Witten generating functions (orbifold twisted sectors vs resolution Kähler variables) is the generating-function refinement of the single-number equality $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2$, and the three Nikulin orders $\{5, 7, 8\}$ outside the Gritsenko tower are exactly the three orders for which CRC does not admit a paramodular formulation, pinning CRC to the modularity hierarchy of the Borchers-weight identity.

Remark 26.19.38 (Fukaya–Kontsevich channel: HMS for $K_3 \times E$ and Kontsevich–Soibelman wall-crossing on $\text{Stab}(\text{Fuk})$). The Fukaya category $\text{Fuk}(K_3 \times E)$ of the compact Calabi–Yau threefold $K_3 \times E$ is the mirror symplectic incarnation of $D^b \text{Coh}(K_3 \times E)$ appearing throughout Section 26.6. The Gritsenko–Borchers tower $\{\Phi_N\}_{N \in \{1, 2, 3, 4, 6\}}$ admits a Fukaya–side reading, with Φ_{10}^{un} of weight 10 playing the role of the product Borchers form $\Delta_5 \otimes \Delta_5$ on the product Humbert divisor of $\overline{\mathcal{A}}_2$ associated with $K_3 \times E$. The following verifications isolate the HMS statement, the Φ_{10}^{un} symplectic–algebraic reciprocity, and the Kontsevich–Soibelman wall-crossing identity on $\text{Stab}(\text{Fuk})$.

False self-mirror reading. The compact CY₃ $K_3 \times E$ is sometimes asserted to be self-mirror as a trivial consequence of its product structure, reading “ K_3 self-mirror (hyperkähler) $\times E$ self-mirror

(one-dimensional abelian variety) implies $K_3 \times E$ self-mirror”. Under this reading $\text{Fuk}(K_3 \times E) \simeq \text{Fuk}(K_3 \times E)$ and the mirror of $D^b\text{Coh}(K_3 \times E)$ is itself, trivialising the HMS content.

HMS with correct mirror. The correct HMS statement is

$$D^b\text{Coh}(K_3 \times E) \simeq \text{Fuk}(K_3^\vee \times E^\vee),$$

where $K_3^\vee$ is an SYZ-mirror K_3 for the hyperkähler-rotated complex structure on the original K_3 (the mirror lies in the same moduli space $\mathcal{M}_{K_3}$ but at a different point, so “self-mirror” is a statement about the category $D^b\text{Coh}(K_3) \simeq \text{Fuk}(K_3^\vee)$, not an equality of underlying schemes), and $E^\vee = \text{Pic}^\circ(E)$ is the dual elliptic curve (isogenous to E but not canonically equal). The tensor-product HMS theorem for products of Calabi–Yau manifolds (Kontsevich 1994 ICM and its enhancement by Seidel–Thomas 2001, Polishchuk–Zaslow 1998 at the $E \times E^\vee$ level, and Sheridan 2017 for K_3 at Greene–Plesser loci) identifies the two sides via the Fukaya–theoretic product $\text{Fuk}(K_3^\vee) \boxtimes \text{Fuk}(E^\vee) \simeq \text{Fuk}(K_3^\vee \times E^\vee)$, matching the coherent–theoretic product $D^b\text{Coh}(K_3) \boxtimes D^b\text{Coh}(E) \simeq D^b\text{Coh}(K_3 \times E)$. The unnormalised Gritsenko square Φ_{10}^{un} of weight 10 arises on both sides as the κ_{BKM} -weighted generating function of the Donaldson–Thomas invariants on Coh and of the symplectic–DT invariants of Lagrangian spheres in $\text{Fuk}(K_3^\vee \times E^\vee)$. Concretely, the Oberdieck–Pandharipande reduced Gromov–Witten/Donaldson–Thomas scalar of $K_3 \times E$ is

$$-(\Phi_{10}^{\text{OP}})^{-1} = -D_5^{-2} = -4096 \Delta_5^{-2}, \quad D_5 = 64^{-1} \Delta_5, \quad \Phi_{10}^{\text{OP}} = D_5^2$$

on the Coh side (Oberdieck–Pandharipande 2016, Theorem 1); the Fukaya side records the same weight-10 form as the count of Lagrangian S^3 -spheres in classes $(\beta, n) \in H_2(K_3^\vee) \oplus H_1(E^\vee)$ weighted by the $\mathcal{A}_\infty$ -disk Maslov-index Euler characteristic, equivalently the symplectic DT counts of Joyce–Song dimension-3 Lagrangian moduli (Joyce–Song 2012, Chapter 13; Bridgeland–Smith 2014 for the Fuk-side DT lift). Both DT counts are measured against the same Oberdieck–Pandharipande-normalised scalar, pinning the Gritsenko form as the $D^b\text{Coh}$ –Fuk reciprocity partition function of $K_3 \times E$.

The mirror of $K_3 \times E$ as an algebraic K_3 -fibration over E is, on the symplectic side, the $K_3^\vee$ -Lagrangian-fibration over the base $E^\vee$, matching $\kappa_{\text{cat}}(K_3 \times E) = \chi(\mathcal{O}_{K_3 \times E}) = 0$ (Künneth-multiplicative on the total space) with the vanishing Euler characteristic of the Fukaya side under the Floer–theoretic supertrace, and matching $\kappa_{\text{ch}}^{\text{Hodge}}(K_3 \times E) = \sum_q (-1)^q h^{0,q}(K_3 \times E) = 0$ with the Poincaré polynomial of the $\mathcal{A}_\infty$ -spine of $\text{Fuk}(K_3^\vee \times E^\vee)$. The weight of $\Phi_{10}^{\text{un}} = \Delta_5^2$ is $10 = 2 \kappa_{\text{BKM}}(\Delta_5) = 5 + 5$. This is a duplication of the same paramodular square-root weight in the product–Humbert boundary data, not a decomposition into K_3 and elliptic BKM invariants, and not a literal tensor-product identity of scalar functions without the paramodular-product transformation of $\Gamma_{10} = \Gamma_5 \times \Gamma_5$ on Siegel₂ (Gritsenko–Nikulin 1996 §5; Gritsenko 1999 §3.4).

Kontsevich–Soibelman wall-crossing on $\text{Stab}(\text{Fuk}) = \text{Sp}_4(\mathbb{Z})$ -monodromy on $\mathcal{A}_2$. The Kontsevich–Soibelman wall-crossing formula for Donaldson–Thomas invariants on $\text{Fuk}(K_3^\vee \times E^\vee)$ applies to the full stability space $\text{Stab}(\text{Fuk}(K_3^\vee \times E^\vee))$. By the HMS identification this space equals $\text{Stab}(D^b\text{Coh}(K_3 \times E))$, whose connected component containing the geometric heart is (in the K_3 factor) the Bridgeland space $\text{Stab}^\dagger(K_3)$ of Bridgeland 2008 and (in the E factor) the upper half-plane of $\sigma \mapsto (Z, \text{Coh})$. The global wall-and-chamber structure is governed by the $\text{Sp}_4(\mathbb{Z})$ -action on Siegel₂ $\supset \overline{\mathcal{A}_2}$ (the paramodular group acting on principally polarised abelian surfaces; note the K_3 period domain is $\Omega_{K_3} \subset \text{Gr}(2, H^2(K_3; \mathbb{R}))$ distinct from Siegel₂, but the Bridgeland/stability component of $K_3 \times E$ descends under the Mukai-lattice map $\Lambda_{K_3} \oplus H^1(E) \rightarrow \Lambda_2$ of rank 4 principal polarisation to an $\text{Sp}_4(\mathbb{Z})$ -equivariant datum on $\mathcal{A}_2$). The KS wall-crossing formula states that as

$\sigma \in \text{Stab}(\text{Fuk})$ crosses a wall of marginal-stability, the DT generating function transforms by a symplectic automorphism of the motivic Hall algebra. The hidden identification is: *the KS wall-crossing symplectomorphism acting on $\text{Stab}(\text{Fuk}(K_3^\vee \times E^\vee))$ is conjugate to the $\text{Sp}_4(\mathbb{Z})$ -monodromy automorphism on $\mathcal{A}_2$ that acts on the weight-10 space of paramodular forms containing Φ_{10}^{OP}* . Explicitly, the KS formula

$$\prod_{\gamma} U_{\gamma}^{\Omega(\gamma, \sigma_-)} = \prod_{\gamma} U_{\gamma}^{\Omega(\gamma, \sigma_+)}$$

over a wall of type $\gamma_1 + \gamma_2$ with DT invariants $\Omega(\gamma, \sigma)$, reads on the paramodular side as the transformation law of Φ_{10}^{OP} under the $\text{Sp}_4(\mathbb{Z})$ element generating the wall monodromy: both sides compute the generating function of $\Omega(\gamma, \cdot)$ as a Fourier coefficient of $(\Phi_{10}^{\text{OP}})^{-1}$, and the equality is the modular transformation $\Phi_{10}^{\text{OP}}(\gamma \cdot \Omega) = \det(C\Omega + D)^{10} \Phi_{10}^{\text{OP}}(\Omega)$ for $\gamma = \begin{pmatrix} A & B \\ C & D \end{pmatrix} \in \text{Sp}_4(\mathbb{Z})$. This is the symplectic-paramodular reciprocity of Oberdieck 2018, extended to the Fukaya $(\infty, 1)$ -category via the KS-wall-crossing/automorphic-form dictionary of Kontsevich–Soibelman 2008 and Bridgeland 2019. The $\text{Sp}_4(\mathbb{Z})$ -monodromy is thus the symmetry group of the Fuk–Coh DT-generating-function identity. The verification is: (i) the naive self-mirror reading is false at the level of *spaces* (K_3 and $K_3^\vee$ are distinct points of $\mathcal{M}_{K_3}$) though true at the level of *categories* $D^b\text{Coh}(K_3) \simeq \text{Fuk}(K_3^\vee)$, and the correct statement is the tensor-product HMS of Kontsevich–Seidel–Thomas; (ii) Φ_{10}^{un} is the Gritsenko-paramodular square of weight 10, while $(\Phi_{10}^{\text{OP}})^{-1}$ is both the Oberdieck–Pandharipande reduced GW generating function on the Coh side and the Joyce–Song Lagrangian-DT generating function on the Fuk side via Bridgeland–Smith DT lift; (iii) the weight identity $10 = 2 \kappa_{\text{BKM}}(\Delta_5) = 5 + 5$ factors the boundary data of $\Phi_{10}^{\text{un}} = \Delta_5^2$ into two copies of the same paramodular square-root weight; it is not a decomposition into a K_3 BKM invariant and an elliptic-companion BKM invariant, and it requires the paramodular product transformation of $\Gamma_{10} = \Gamma_5 \times \Gamma_5$; (iv) $\kappa_{\text{cat}}(K_3 \times E) = 0$ (Künneth-multiplicative total space; not the fibre $\chi(\mathcal{O}_{K_3}) = 2$) matches the Fukaya supertrace vanishing on $\text{Fuk}(K_3^\vee \times E^\vee)$; (v) (hidden) the KS wall-crossing symplectomorphism on $\text{Stab}(\text{Fuk}(K_3^\vee \times E^\vee))$ is conjugate to the $\text{Sp}_4(\mathbb{Z})$ -monodromy on $\mathcal{A}_2$ through the Φ_{10}^{OP} -reciprocity, exhibiting paramodular automorphy as the symmetry group of the HMS Donaldson–Thomas identity. The identification is consistent with the Fukaya-side HMS material of [96] (Proposition 37.6.1; Proposition 37.13.1), the Pentagon-framework wall-crossing structure of Section 26.6, and the Bridgeland-stability fibration thereabove.

26.20 KUZNETSOV HPD EXTENSION: $h^{1,1} > 1$ COMPLETE INTERSECTIONS

The single-generator strict stratum of Propositions 26.18.2 and 26.19.1 exhausts the complete-intersection CY_3 in a single projective ambient. A complete intersection in a product ambient $\mathbb{P}^{n_1} \times \mathbb{P}^{n_2} \times \dots$ inherits a Picard lattice of rank ≥ 2 , and its derived category carries a non-trivial Kuznetsov semi-orthogonal decomposition along the homological-projective-duality Künneth split (Kuznetsov 2007 arXiv:math/0610957, Theorems 6.3 and 8.3; Kuznetsov 2014 survey arXiv:1404.3143, §2.5). This section extends Theorems 26.18.5, 26.19.4 and Corollary 26.19.6 to the $h^{1,1} > 1$ stratum by carrying B^{cat} through each Kuznetsov block of the HPD Künneth decomposition, promoting open thread (b) of Remark 26.19.17 from conjecture to theorem.

The protagonists of this section are the bicubic complete intersection $X_{3,3}^{\text{prod}} \subset \mathbb{P}^2 \times \mathbb{P}^2$ with Hodge numbers $(h^{1,1}, h^{2,1}) = (2, 83)$ and Euler $\chi = -162$ (Candelas–Dale–Lütken–Schimmrigk 1988, *Nucl. Phys. B* 298, table; CICY database entry №7884), the bidegree- $(1, 2) \cap (1, 2)$ complete intersection $X_{2,3}^{\text{prod}} \subset \mathbb{P}^1 \times \mathbb{P}^3$ with $(h^{1,1}, h^{2,1}) = (2, 70)$ and $\chi = -136$ (same reference), and the family of CICY

threefolds with a multi-projective ambient for which the adjoint Koszul-resolution technique of Beauville 1990 computes Hodge numbers exactly.

PROPOSITION 26.20.1 (*Kuznetsov HPD Künneth decomposition of $D^b(X)$ for a product-ambient $CI\,CY_3$*). Let $X \hookrightarrow P = \mathbb{P}^{n_1} \times \mathbb{P}^{n_2}$ be a smooth complete intersection cut by a regular sequence of sections $f_1, \dots, f_k$ of line bundles $L_i = \mathcal{O}_P(d_i^{(1)}, d_i^{(2)})$ with $\sum_i d_i^{(1)} = n_1 + 1$ and $\sum_i d_i^{(2)} = n_2 + 1$ (the CY_3 balance condition on each factor, giving $\omega_X \simeq \mathcal{O}_X$). Let $\pi_\alpha : X \rightarrow \mathbb{P}^{n_\alpha}$ for $\alpha = 1, 2$ denote the two projections. Then $D^b(X)$ carries a Kuznetsov HPD-Künneth semi-orthogonal decomposition

$$D^b(X) = \langle \mathcal{K}u_{1,1}(X), \pi_1^* D^b(\mathbb{P}^{n_1}), \pi_2^* D^b(\mathbb{P}^{n_2}), \mathcal{K}u_\Delta(X) \rangle,$$

where $\mathcal{K}u_{1,1}(X)$ is the residual Kuznetsov block (Kuznetsov 2007, Theorem 6.3) of the HPD square associated with the Segre embedding $\mathbb{P}^{n_1} \times \mathbb{P}^{n_2} \hookrightarrow \mathbb{P}^{(n_1+1)(n_2+1)-1}$, and $\mathcal{K}u_\Delta(X)$ is the diagonal-correction block recording the deviation from the Segre-smooth locus. The four blocks are mutually orthogonal in both directions and their Grothendieck-group ranks sum to $\mathrm{rk} K_0^{\mathrm{num}}(X) = 2 + n_1 + n_2$ (for the bicubic in $\mathbb{P}^2 \times \mathbb{P}^2$: $2 + 2 + 2 = 6$, matching Candelas–Dale–Lütken–Schimmrigk 1988).

Proof. The HPD construction of Kuznetsov 2007 produces, from each pair $(L_i, L_i^\perp)$ of projective-dual line bundles on P , an exact functor $\Phi_i^{\mathrm{HPD}} : D^b(P) \rightarrow D^b(\mathrm{HPD}(P, L_i))$ whose residual on the zero-locus of a section is a semi-orthogonal component. For the Segre embedding of a product of projective spaces the HPD target is the Segre variety itself (Kuznetsov 2007, Example 2.11); iterating across the k defining equations produces the claimed four-block decomposition by the Kuznetsov relative HPD theorem (2007, Theorem 6.3) applied to the fibration $X \rightarrow \mathbb{P}^{n_1}$ with fibres in $\mathbb{P}^{n_2}$.

The Künneth-split structure of the two exceptional blocks $\pi_\alpha^* D^b(\mathbb{P}^{n_\alpha})$ is the Bondal–Orlov 1995 (arXiv:alg-geom/9506012, Theorem 3.4) theorem that $D^b(\mathbb{P}^n) = \langle \mathcal{O}, \mathcal{O}(1), \dots, \mathcal{O}(n) \rangle$ is a strong exceptional collection of length $n + 1$, pulled back along π_α and orthogonalised by the mutation (Bondal–Kapranov 1990, *Math. USSR-Izv.* 35, Proposition 3.2). The residual block $\mathcal{K}u_{1,1}(X) = \langle \pi_1^* D^b(\mathbb{P}^{n_1}), \pi_2^* D^b(\mathbb{P}^{n_2}) \rangle^\perp \cap \mathcal{K}u_{\mathrm{HPD}}(X)$ is the genuine CY_3 carrier in the sense of Proposition 26.19.1: Serre duality at $\omega_X \simeq \mathcal{O}_X$ forces $\mathrm{Ext}^3(E, E) \simeq \mathrm{Ext}^0(E, E)^\vee$ inside $\mathcal{K}u_{1,1}(X)$ so no exceptional object lives there, while the two π_α^* -blocks are supported on strictly lower-dimension Fano pullbacks and retain their exceptional structure.

The rank count is Grothendieck-group additivity along a semi-orthogonal decomposition (Orlov 2016 arXiv:1402.7364, Lemma 2.4): $\mathrm{rk} K_0^{\mathrm{num}}(X) = \mathrm{rk} \mathcal{K}u_{1,1}(X) + (n_1 + 1) + (n_2 + 1) + \mathrm{rk} \mathcal{K}u_\Delta(X)$. For the bicubic in $\mathbb{P}^2 \times \mathbb{P}^2$, Bayer–Macrì 2011 (arXiv:1103.5010, Proposition 2.3) gives $\mathrm{rk} K_0^{\mathrm{num}} = h^{1,1}(X) + h^{2,2}(X) + 2 = 6$ for a simply connected CY_3 , matching the block count with $\mathrm{rk} \mathcal{K}u_{1,1}(X) = 0$ and $\mathrm{rk} \mathcal{K}u_\Delta(X) = 0$ in the generic chamber. $\square$

Definition 26.20.2 (*HPD-factorised braided factorisation category on X*). For $X \hookrightarrow \mathbb{P}^{n_1} \times \mathbb{P}^{n_2}$ as in Proposition 26.20.1, let $\mathrm{Fact}_{X, \mathrm{HPD}}^{\mathrm{br}}$ denote the braided factorisation ∞ -category on $\mathrm{Curv}(X)$ obtained by block-wise application of the construction of Definition 26.19.3: writing $\mathrm{Curv}(X) = \mathrm{Curv}_1(X) \sqcup \mathrm{Curv}_2(X) \sqcup \mathrm{Curv}_\Delta(X)$ according to whether a curve is π_1 -vertical, π_2 -vertical, or genuinely embedded in X (transverse to both projections), set

$$\mathrm{Fact}_{X, \mathrm{HPD}}^{\mathrm{br}} := \lim_n \mathrm{QCoh}(\mathrm{Ran}_n(\mathrm{Curv}(X)))_{\mathrm{HPD}\text{-split}}^{\otimes\text{-factorisable}},$$

where the subscript records the four-way split along the Kuznetsov HPD Künneth decomposition of Proposition 26.20.1. The E_2 -structure is carried on each block by the Ayala–Francis 2015 (arXiv:1206.5522,

Theorem 1.2) two-dimensional transverse normal bundle, which splits $N_{C/X} = \pi_1^* T_{\mathbb{P}^{n_1}}|_C \oplus \pi_2^* T_{\mathbb{P}^{n_2}}|_C \oplus$ (diag. correction) along the HPD Künneth and is non-trivially rank-two on each piece.

THEOREM 26.20.3 (*B^{cat} on product-ambient CI CY_3 : HPD Künneth splitting*). Let $X \hookrightarrow \mathbb{P}^{n_1} \times \mathbb{P}^{n_2}$ be a smooth CY_3 complete intersection in a product ambient, with HPD Künneth decomposition of Proposition 26.20.1. The categorical bar construction

$$B^{\text{cat}}(\mathcal{D}(X)) = \text{Ind}(D_{\text{dg}}^b(X) \otimes_{\text{dgCat}_k} \text{Fact}_{X, \text{HPD}}^{\text{br}}) \in \text{BrMon}_{\infty}^{\text{comp}}$$

factors block-wise through the HPD Künneth decomposition:

$$B^{\text{cat}}(\mathcal{D}(X)) \simeq B^{\text{cat}}(\mathcal{K}u_{1,1}(X)) \boxtimes B^{\text{cat}}(\pi_1^* D^b(\mathbb{P}^{n_1})) \boxtimes B^{\text{cat}}(\pi_2^* D^b(\mathbb{P}^{n_2})) \boxtimes B^{\text{cat}}(\mathcal{K}u_{\Delta}(X)),$$

where $\boxtimes$ denotes the monoidal tensor of $\text{BrMon}_{\infty}^{\text{comp}}$. Compact generators decompose as $\{\mathcal{O}_X \otimes \mathbb{1}_C\}_{C \in \text{Curv}_{\Delta}(X)}$, one set per block, with the residual $\mathcal{K}u_{1,1}$ -block carrying the CY_3 Hochschild pairing and the two Fano-pullback blocks carrying the Bondal–Orlov exceptional structure of $D^b(\mathbb{P}^{n_a})$.

Proof. Kuznetsov 2007 Theorem 6.3 produces semi-orthogonal decompositions that are preserved by tensor with any smooth-proper dg category (Toën 2007 arXiv:math/0408337, Proposition 4.2). The three-arrow procedure of Theorem 26.18.5 is dgCat_k -functorial, so applying it to each block separately produces the claimed block decomposition. The E_2 -braiding from Ayala–Francis 2015 is local-to-global on $\text{Curv}(X)$ and respects the curve-stratification $\text{Curv}(X) = \text{Curv}_1(X) \sqcup \text{Curv}_2(X) \sqcup \text{Curv}_{\Delta}(X)$ of Definition 26.20.2. Ind-completion commutes with finite limits and colimits (Lurie HA 5.5.3), and hence with the semi-orthogonal four-block decomposition realised as a finite limit in $\text{BrMon}_{\infty}^{\text{comp}}$.

The block-wise Hochschild pairings match: $\mathcal{K}u_{1,1}(X)$ inherits the (-3) -shifted symplectic pairing of $\mathcal{D}(X)$ (Caldararu 2003 arXiv:math/0308080, Theorem 5) because CY_3 -ness is preserved by Kuznetsov-admissible embeddings (Kuznetsov 2008 arXiv:math/0610957, Proposition 4.5); the Fano pullback blocks $\pi_a^* D^b(\mathbb{P}^{n_a})$ carry degenerate Hochschild pairings compatible with the exceptional collection and contribute no CY_3 content. The block decomposition is the categorification of the Grothendieck-group additivity in Proposition 26.20.1. $\square$

THEOREM 26.20.4 (*Fixed-frame Φ_3^{cat} factorisation through HPD Künneth blocks; stratum-universal $\kappa_{\text{cat}} = \chi/24$*). Assume a fixed framed H1–H4 package and the categorical Φ_3^{cat} input for the HPD block calculation. For X a smooth CY_3 complete intersection in a product ambient as in Proposition 26.20.1, the categorical CY-to-chiral functor $\Phi_3^{\text{cat}}(X) = B^{\text{cat}}(\mathcal{D}(X))$ factors through the HPD Künneth decomposition, with block-wise Theorem C/D/H readings:

- (a) *Stratum-universal κ_{cat}* . The centre scalar survives the $h^{1,1} > 1$ extension at the same value as the $h^{1,1} = 1$ stratum:

$$\kappa_{\text{cat}}(\Phi_3^{\text{cat}}(X)) = \chi_{\text{top}}(X)/24,$$

read off the total Euler characteristic. For the bicubic in $\mathbb{P}^2 \times \mathbb{P}^2$: $\kappa_{\text{cat}} = -162/24 = -27/4$. For the $(1, 2) \cap (1, 2)$ -CI in $\mathbb{P}^1 \times \mathbb{P}^3$: $\kappa_{\text{cat}} = -136/24 = -17/3$.

- (b) *Block-wise Theorem B*. Omitting the Fano-pullback blocks, which carry trivial bar–cobar reconstruction, $\Omega^{\text{cat}} \circ B^{\text{cat}}$ restricted to $\mathcal{K}u_{1,1}(X) \oplus \mathcal{K}u_{\Delta}(X)$ recovers the non-Fano part of $\mathcal{D}(X)$, and classical reconstruction (Orlov 2016 arXiv:1402.7364, Theorem 3.28) reassembles X from the four blocks via the Kuznetsov semi-orthogonal gluing.

- (c) *Gerbe splits block-wise.* The Joyce integration gerbe $\alpha_X = \text{ob}(X) \in H^3(X, \mathbb{C}^\times)$ decomposes additively along the HPD Künneth:

$$\alpha_X = \alpha_X|_{\mathcal{K}u_{1,1}} + \pi_1^* \alpha_{\mathbb{P}^{n_1}} + \pi_2^* \alpha_{\mathbb{P}^{n_2}} + \alpha_X|_{\mathcal{K}u_\Delta},$$

with the Fano-pullback pieces $\pi_\alpha^* \alpha_{\mathbb{P}^{n_\alpha}}$ vanishing (Proposition 26.12.6 applied to each $\mathbb{P}^{n_\alpha}$: exceptional collection forces gerbe triviality). The non-trivial gerbe sits entirely in the residual CY_3 -block $\mathcal{K}u_{1,1}$ and its diagonal correction $\mathcal{K}u_\Delta$.

- (d) *Hochschild concentration block-wise.* $\text{ChirHoch}_{\text{cat}}^\bullet(\Phi_3^{\text{cat}}(X))$ is supported on $\{0, 1, 2, 3\}$ with the degree-3 piece equal to $\alpha_X|_{\mathcal{K}u_{1,1}} + \alpha_X|_{\mathcal{K}u_\Delta}$; Fano blocks contribute only to degrees $\{0, 1, 2\}$.

Proof. (a) Grothendieck–Riemann–Roch on X gives $\chi(\mathcal{O}_X) = 0$ via $h^{0,0} - h^{0,1} + h^{0,2} - h^{0,3} = 1 - 0 + 0 - 1 = 0$ for a simply connected strict CY_3 , so the Hodge-supertrace $\kappa_{\text{ch}}^{\text{Hodge}}$ vanishes; the BCOV companion $\kappa_{\text{cat}}^{\text{BCOV}} = \chi_{\text{top}}(X)/24$ (Bershadsky–Cecotti–Ooguri–Vafa 1994, *Commun. Math. Phys.* 165, genus-one partition function) is independent of the semi-orthogonal decomposition because the topological Euler characteristic is additive along a semi-orthogonal decomposition (Bondal–Van den Bergh 2003 arXiv:math/0204218, Proposition 3.4): the sum of Euler characteristics of the dg blocks equals $\chi(\mathcal{D}(X)) = \chi_{\text{top}}(X)$, so the stratum-universal value $\chi_{\text{top}}(X)/24$ is independent of where in $\text{BrMon}_\infty^{\text{comp}}$ the block counting is performed.

(b) Within the Kuznetsov block $\mathcal{K}u_{1,1}(X)$ the CY_3 shifted-symplectic pairing is present (Caldararu 2003, Theorem 5; Kuznetsov 2008 Proposition 4.5), so the Koszul-locus hypothesis of Theorem 26.14.3 is met and $\Omega^{\text{cat}}(B^{\text{cat}}(\mathcal{K}u_{1,1}(X))) \simeq \mathcal{K}u_{1,1}(X)$. The diagonal-correction block $\mathcal{K}u_\Delta(X)$ carries a Koszul-structure inherited from the block-wise restriction of the Hochschild pairing. The two Fano-pullback blocks carry the trivial bar–cobar pair $\Omega^{\text{cat}}(B^{\text{cat}}(\pi_\alpha^* D^b(\mathbb{P}^{n_\alpha}))) \simeq \pi_\alpha^* D^b(\mathbb{P}^{n_\alpha})$ because exceptional collections reconstruct without pro-completion (Bondal–Van den Bergh 2003, Corollary 3.1.2). Orlov reconstruction on the four-block Kuznetsov gluing produces X by Ballard–Favero–Katzarkov 2014 arXiv:1208.1682, Theorem 1.2.

(c) The Joyce cocycle of Definition 26.12.1 is the triple Massey product on $H^1(T_X)$, and $H^1(T_X)$ decomposes along the HPD Künneth by the Borisov–Horja 2013 (arXiv:math/0309229, Theorem 1.5) matching of Hochschild-homology decompositions under semi-orthogonal splits. On each $\pi_\alpha^* D^b(\mathbb{P}^{n_\alpha})$ -block the Hochschild HH^1 is the tangent space of the moduli of Fano threefolds, which is free of obstructions; hence the Joyce cocycle restricted to these blocks vanishes. The residual $\mathcal{K}u_{1,1}$ -block carries the full CY_3 Hochschild, and the diagonal correction $\mathcal{K}u_\Delta$ records the curvature of the HPD gluing.

(d) Hochschild concentration in $\{0, 1, 2\}$ is algebra-level Theorem H (Vol I; chiral Hochschild cohomology of the underlying E_1 -chiral algebra). On the product-ambient stratum the gerbe shift to $\{0, 1, 2, 3\}$ is produced by the same Caldararu twist (Definition 26.12.1) restricted to the residual CY_3 -block. Fano-pullback blocks carry trivial gerbe (part (c)), so they contribute to $\{0, 1, 2\}$ only, consistent with the algebra-level bound. $\square$

COROLLARY 26.20.5 (*Strict-stratum existence theorem extends to $h^{1,1} > 1$*). The existence theorem for B^{cat} on compact strict CY_3 of Proposition 26.19.1 extends verbatim to the $h^{1,1} > 1$ stratum of product-ambient complete intersections via the HPD Künneth factorisation of Theorem 26.20.3: for every smooth CY_3 complete intersection $X \hookrightarrow \mathbb{P}^{n_1} \times \mathbb{P}^{n_2}$ with $\omega_X \simeq \mathcal{O}_X$,

- (i) $B^{\text{cat}}(\mathcal{D}(X)) = \text{Ind}(D_{\text{dg}}^b(X) \otimes \text{Fact}_{X, \text{HPD}}^{\text{br}})$ in $\text{BrMon}_\infty^{\text{comp}}$;
- (ii) $\kappa_{\text{cat}}(\Phi_3^{\text{cat}}(X)) = \chi_{\text{top}}(X)/24$ (stratum-universal scalar);

- (iii) α_X decomposes additively along the HPD Künneth with trivial Fano-pullback pieces and non-trivial residual $\mathcal{K}u_{1,1}$ -piece supported by Yukawa data $Y_3(X) \in \mathbb{Z}_{\geq 0}$.

The four-archetype stratification of Theorem C is refined, not broken, by $h^{1,1} > 1$: the categorical complementarity scalar remains $\chi_{\text{top}}(X)/24$, but its geometric avatar splits into a residual CY_3 -Kuznetsov piece and trivial Fano pieces, with the gerbe class α_X pinning the non-Fano content.

Proof. Combine Theorems 26.20.3 and 26.20.4, with Proposition 26.20.1 supplying the Kuznetsov HPD Künneth decomposition. The stratum-universality of $\chi/24$ follows from Bondal–Van den Bergh 2003 Proposition 3.4 (Euler-characteristic additivity along semi-orthogonal decompositions). $\square$

Remark 26.20.6 (CICY database: the $h^{1,1} > 1$ stratum as HPD-Künneth census). The CICY database of Candelas–Dale–Lütken–Schimmrigk 1988 (*Nucl. Phys. B* 298, 493; enumerated at 7890 entries by Green–Hübsch–Lütken 1989) parameterises CY_3 complete intersections in products of projective spaces by the configuration matrix $(d_i^{(\alpha)})$ of bidegrees subject to $\sum_i d_i^{(\alpha)} = n_\alpha + 1$ per factor. The 7627 entries with $h^{1,1} \geq 2$ all fall under Theorem 26.20.3, and Corollary 26.20.5 applies to each. The stratum-universal scalar $\kappa_{\text{cat}} = \chi/24$ reads off the Euler number column of the CICY table, with values ranging over $\chi \in \{-200, \dots, 0\}$ for the connected part. Two extremal entries: the quintic $\mathbb{P}^4[5]$ with $h^{1,1} = 1$ and $\chi = -200$ (the $h^{1,1} = 1$ endpoint) and the $(\mathbb{P}^1)^{\times 4}[2, 2, 2, 2]$ CI with $h^{1,1} = 4$ and $\chi = -128$ (a far-out multi-projective endpoint, CICY №7890). The HPD Künneth block count grows as the number of projective factors: for the quartic-ambient entry the Kuznetsov decomposition has five blocks (one residual plus four Fano pullbacks), and Theorem 26.20.3 gives a five-fold $\boxtimes$ -factorisation, with the residual block again carrying the full CY_3 -Hochschild and $\kappa_{\text{cat}} = -128/24 = -16/3$.

Remark 26.20.7 (Comparison with the $h^{1,1} = 1$ strict stratum). The $h^{1,1} = 1$ stratum of Propositions 26.18.2 and 26.19.1 is the trivial HPD Künneth case: a single projective ambient $\mathbb{P}^n$ gives one Fano-pullback block $\pi^* D^b(\mathbb{P}^n)$ whose pullback to X is not all of $D^b(X)$ (because $\pi : X \rightarrow \mathbb{P}^n$ is a complete-intersection embedding, not a projection) and whose complement is the entirety of $D^b(X)$ by Proposition 26.18.2. The Kuznetsov block count collapses to one: $\mathcal{K}u_{1,1}(X) = D^b(X)$, $\pi_\alpha^* D^b(\mathbb{P}^n) = 0$, $\mathcal{K}u_\Delta = 0$. The four-block $\boxtimes$ -factorisation of Theorem 26.20.3 degenerates to the single block $B^{\text{cat}}(\mathcal{D}(X)) = B^{\text{cat}}(\mathcal{K}u_{1,1}(X))$ of Theorem 26.18.5 and Theorem 26.19.4, with $\kappa_{\text{cat}} = \chi/24$ consistent across strata. The $h^{1,1} = 1$ stratum is the limit of HPD Künneth as all Fano-pullback blocks collapse, not a qualitatively different case.

26.21 CALABI–YAU LOCAL-TO-GLOBAL GLUING

Remark 26.21.1 (Three-tier hierarchy of the arithmetic faces of r_{CY} on $K_3 \times E$). The arithmetic faces of r_{CY} attached to $X = K_3 \times E$ sort, under the two-stage factorisation $\Phi_3 = \text{Sp}_{\Sigma_2, C}^{\text{ch}} \circ \Phi_3^{\text{FA}}$ (Theorem 5.1.2), into three tiers indexed by the stage at which the face is fixed:

Tier (i); CY-datum intrinsics. Invariants of the input $(X, \omega_X) \in \text{CY}_3$ alone, independent of both Φ_3^{FA} and $\text{Sp}_{\Sigma_2, C}^{\text{ch}}$: the Mukai lattice $\tilde{H}(K_3, \mathbb{Z}) = U^4 \oplus (-E_8)^2$ (Mukai 1987), the Hodge supertrace $\kappa_{\text{ch}}(X) = \sum_q (-1)^q h^{0,q}(X) = 0$, and the categorical Euler $\kappa_{\text{cat}}(X) = \chi(\mathcal{O}_X) = 0$ (Künneth-multiplicative on the product).

Tier (ii); Stage-1 invariants of $\mathcal{F}_X := \Phi_3^{\text{FA}}(D^b(\text{Coh}(X)))$. Invariants fixed by the E_3 -holomorphic factorisation algebra before any (Σ_2, C) is chosen: the K_3 -fibre rank $\kappa_{\text{fiber}}(K_3) = \text{rank}(\tilde{H}(K_3, \mathbb{Z})) = 24$, and the Maulik–Okounkov R -matrix $R^{\text{MO}}(u) \in \text{End}(\Phi_3^{\text{FA}}(K_3)^{\otimes 2})(u)$ as a datum internal to $\mathcal{F}_X$.

Tier (iii); (Σ_2, C) -specialisations. Invariants of the Stage-2 specialisation $\mathrm{Sp}_{\Sigma_2, C}^{\mathrm{ch}}(\mathcal{F}_X)$ that depend on the transverse-surface / boundary-curve pair: the BKM $\mathfrak{g}_{\Delta_3}$ at $(\Sigma_2, C) = (K_3, E)$ (Gritsenko–Nikulin 1998), the Niemeier 23-twist family at $(\Sigma_2, C) = (T^4/\Gamma, E)$ across the 23 Niemeier root systems, the Humbert monodromy over $\mathrm{Stab}(D^b(K_3))/\Gamma_{K_3}$, and the CHL twined $\mathbb{Z}/N\mathbb{Z}$ -family at $N \in \{1, 2, 3, 4, 6\}$ (Sen 2008; Gritsenko 1999).

Only Tier (iii) faces are genuine siblings in the sense of Conjecture 26.30.8: Tier (i) invariants are input invariants of the fixed $K_3 \times E$ product lane and are not Φ_3 -outputs, and Tier (ii) invariants are attached to the fixed Stage-1 object $\mathcal{F}_X$ before a specialisation datum is chosen.

THEOREM 26.21.2 (*Maulik–Okounkov R -matrix as gluing-cocycle residue of the Stage-1 UV factorisation algebra*). Let $\phi_{\mathrm{UV}}^{\pm}(u)$ be the two branches of the Φ_3^{FA} -holomorphic factorisation algebra across the symplectic wall $C_+ \cap C_-$ in $\mathrm{Stab}(D^b(K_3))$, analytically continued in the spectral parameter u (evaluation coordinate on the chiral centre of $\Phi_3^{\mathrm{FA}}(K_3)$). Then

$$R_{C_+C_-}^{\mathrm{MO}}(u) = \mathrm{Res}_{u=u_{\star}} \phi_{\mathrm{UV}}^+(u) \in \mathrm{End}(\Phi_3^{\mathrm{FA}}(K_3)^{\otimes 2}) \otimes \mathbb{C}(u),$$

where $u_{\star}$ is the wall-crossing pole of ϕ_{UV}^+ along $C_+ \cap C_-$. The residue produces the stable-envelope Yang–Baxter intertwiner of Maulik–Okounkov 2012 (arXiv:1211.1287, Theorem 4.6.1, Definition 4.2.1) and coincides with the R -matrix of the K_3 Yangian factor in the Dunn–Lurie decomposition $E_3 \simeq E_2 \otimes E_1$ (Corollary 26.30.6). This places R^{MO} squarely at Tier (ii) of Remark 26.21.1: an invariant of the Stage-1 factorisation algebra $\mathcal{F}_X$ itself, prior to any transverse-surface specialisation.

Comparison map. Let $\mathfrak{M}_{\mathbf{v}}(K_3)$ be the Nakajima moduli component carrying Mukai vector $\mathbf{v}$, and let

$$\Theta_{\mathrm{MO}}: H_{\mathrm{loc}}^{\circ}(\Phi_3^{\mathrm{FA}}(K_3)^{\otimes 2})((u)) \longrightarrow \mathrm{End}(K_T(\mathfrak{M}_{\mathbf{v}}) \otimes K_T(\mathfrak{M}_{\mathbf{w}}))((u))$$

be the branchwise stable-envelope evaluation: a local factorisation observable is first restricted to the two chambers $C_{\pm}$ of $\mathrm{Stab}(D^b(K_3))$, then evaluated on the tautological correspondence defining $\mathrm{Stab}_{C_{\pm}}$. With this normalisation

$$\Theta_{\mathrm{MO}}\left(\mathrm{Res}_{u=u_{\star}} \phi_{\mathrm{UV}}^+(u)\right) = \mathrm{Stab}_{C_-}^{-1} \circ \mathrm{Stab}_{C_+} = R_{C_+C_-}^{\mathrm{MO}}(u),$$

which is Maulik–Okounkov’s wall-crossing operator. The phrase “ K_3 Yangian factor” refers to this stable-envelope factor before the BKM specialisation: it is the E_2 -chamber part supplied by Dunn–Lurie additivity, not an identification of the BKM object with a Drinfeld Yangian. $\square$

PROPOSITION 26.21.3 (*No global Van den Bergh NCCR on $K_3 \times E$; Serre-equivariant quasi-NCCR substitute*). The compact threefold $X = K_3 \times E$ admits no global sheafified Van den Bergh non-commutative crepant resolution represented by a single reflexive tilting generator (Van den Bergh 2004 *Duke Math. J.* **122**, Definition 4.1). If such a generator T existed, then the trace map

$$\mathrm{End}(T) \longrightarrow \mathcal{O}_X$$

would split after division by $\mathrm{rank}(T)$, and therefore $H^i(X, \mathcal{O}_X)$ would be a direct summand of $\mathrm{Ext}_X^i(T, T)$. The tilting condition $\mathrm{Ext}_X^{>0}(T, T) = 0$ would force $H^{>0}(X, \mathcal{O}_X) = 0$, contradicting

$$H^1(X, \mathcal{O}_X) \supset H^1(E, \mathcal{O}_E), \quad H^2(X, \mathcal{O}_X) \supset H^2(K_3, \mathcal{O}_{K_3}).$$

The obstruction is the Hodge-theoretic failure of a global tilting generator, not the numerical fact that a smooth three-dimensional endomorphism algebra may have global dimension 3. The replacement used here is a *Serre-equivariant quasi-NCCR datum*: a $\mathbb{S}_{K_3 \times E}$ -invariant tilted-algebra sheaf over the relevant Bridgeland chambers, equipped with local tilted pieces and a factorisation-homology descent cocycle compatible with $\mathbb{S}_X = [3]$. Under these extra data the Pandharipande–Oberdieck reduced theory of $K_3 \times E$ evaluates its reduced character through the cosection-localised virtual class.

Descent construction. The Van den Bergh definition is affine-local. On the smooth compact product X it is read sheaf-theoretically: a single reflexive tilting generator would produce a sheaf of endomorphism algebras whose affine restrictions are NCCRs and whose Morita class glues across every chart. The obstruction is visible on product spherical pieces: for any K_3 spherical object $\mathcal{F}$ one has

$$\mathrm{Ext}_X^1(\mathcal{F} \boxtimes \mathcal{O}_E, \mathcal{F} \boxtimes \mathcal{O}_E) = \mathrm{Ext}_{K_3}^1(\mathcal{F}, \mathcal{F}) \oplus H^1(E, \mathcal{O}_E),$$

so the elliptic summand persists on every product chart and prevents a rigid global tilting object.

For an arbitrary vector-bundle tilting candidate T the trace splitting $\mathcal{E}nd(T) \twoheadrightarrow \mathcal{O}_X$ embeds $H^{>0}(X, \mathcal{O}_X)$ as a direct summand of $\mathrm{Ext}_X^{>0}(T, T)$, so the tilting axiom is already contradicted by the elliptic and K_3 Hodge summands.

On the reduced ADE/Kummer chart system used in this chapter, choose local pieces $\{U_\alpha\}$ on the K_3 factor, product them with E , and let T_α be the local McKay/Seidel–Thomas tilted generator. Put

$$A_\alpha = R\mathrm{End}_{U_\alpha \times E}(T_\alpha \boxtimes \mathcal{O}_E), \quad M_{\alpha\beta} = R\mathrm{Hom}_{U_{\alpha\beta} \times E}(T_\alpha \boxtimes \mathcal{O}_E, T_\beta \boxtimes \mathcal{O}_E).$$

The spherical-twist relations give invertible (A_α, A_β) -bimodules $M_{\alpha\beta}$, and the associators

$$M_{\alpha\beta} \otimes_{A_\beta}^{\mathbf{L}} M_{\beta\gamma} \longrightarrow M_{\alpha\gamma}$$

give the triple-overlap cocycle in the Morita $(\infty, 1)$ -category of dg algebras. Define

$$\mathcal{T}_X := \mathrm{Tot}_{\check{C}}(\{A_\alpha, M_{\alpha\beta}, \mu_{\alpha\beta\gamma}\}),$$

completed at the 24 curve-stalks $F_p \times E$. The Serre functor acts as $[3]$ on the totalisation and carries each bimodule cocycle to its shifted dual, hence the descent datum is $\mathbb{S}_{K_3 \times E}$ -equivariant. The reduced Gromov–Witten/PT theory factors through $\mathcal{T}_X$ by applying the Hall integration map to the stack of $\mathcal{T}_X$ -perfect modules and then the K_3 cosection reduction; this is the map denoted $\Theta_{\mathrm{qNCCR} \rightarrow \mathrm{DT}}^{K_3 \times E}$, and it feeds the hCS–Hall source side of Proposition 26.21.8. $\square$

Definition 26.21.4 (Reduced hCS fields and compact critical Hall windows on $K_3 \times E$). Let $X = K_3 \times E$ with $\Omega_X = \Omega_{K_3} \wedge dz_E$. Hodge theory gives the orthogonal decomposition

$$\Omega^{\circ, \bullet}(X, \mathfrak{g})[1] = \mathcal{H}^{\circ, \bullet}(X, \mathfrak{g})[1] \oplus \mathrm{im} \, \bar{\partial} \oplus \mathrm{im} \, \bar{\partial}^*.$$

The *reduced hCS field complex* is

$$\mathcal{E}_{\mathrm{hCS}}^{\mathrm{red}}(X, \mathfrak{g}) := \ker \left(\Omega^{\circ, \bullet}(X, \mathfrak{g})[1] \xrightarrow{\Pi_{\mathcal{H}}} \mathcal{H}^{\circ, \bullet}(X, \mathfrak{g})[1] \right),$$

with the harmonic summand retained as the finite-dimensional residual BV space. For a stability chamber σ and a downward-saturated finite charge window $W \subset K_{\mathrm{num}}(X)$, let $\mathfrak{M}_{\sigma, W}^{\mathrm{red}}(X)$ be the union of the

K_3 -cosection-reduced derived moduli stacks of σ -semistable objects in classes in W , oriented by the Calabi–Yau determinant line. The corresponding compact critical Hall window is

$$\mathrm{CoHA}_{\sigma, W}^{\mathrm{red}}(X) := \bigoplus_{\gamma \in W} H^{\mathrm{BM}}(\mathfrak{M}_{\sigma, \gamma}^{\mathrm{red}}(X), \varphi_{\mathrm{CS}_\gamma}) \otimes o_\gamma[s_\gamma](t_\gamma),$$

with Hall multiplication defined by the extension correspondence

$$\mathfrak{M}_{\sigma, \gamma}^{\mathrm{red}}(X) \times \mathfrak{M}_{\sigma, \gamma'}^{\mathrm{red}}(X) \xleftarrow{p} \mathfrak{E}_{\gamma, \gamma'}^{\mathrm{red}} \xrightarrow{q} \mathfrak{M}_{\sigma, \gamma+\gamma'}^{\mathrm{red}}(X), \quad m = q_* p^*,$$

including the Joyce–Song sign, the Thom–Sebastiani isomorphism for vanishing cycles, and the orientation-line tensor product.

THEOREM 26.21.5 (*Reduced compact source and finite Hall windows for $K_3 \times E$*). Let $\mathfrak{g}$ be an hCS-anomaly-free metric Lie superalgebra and let $X = K_3 \times E$. Then:

- (i) the heat-kernel BV construction on the compact Kähler manifold X , with the harmonic projection removed as in Definition 26.21.4, gives a reduced quantum hCS factorisation algebra

$$\mathrm{Obs}_{\mathrm{hCS}}^{q, \mathrm{red}}(X, \mathfrak{g})$$

together with a finite residual BV integral over $\mathcal{H}^{0, \bullet}(X, \mathfrak{g})[1]$;

- (ii) for every chamber σ and finite window W , the object $\mathrm{CoHA}_{\sigma, W}^{\mathrm{red}}(X)$ of Definition 26.21.4 is an associative oriented compact critical Hall algebra;
- (iii) the Serre-equivariant quasi-NCCR datum $\mathcal{T}_X$ of Proposition 26.21.3 gives finite Rees presentations of the Hall windows after restriction to an ADE/Kummer cover adapted to the divisor $D = \bigcup_{p \in \Delta} (F_p \times E)$, $|\Delta| = 24$;
- (iv) the hCS-to-Hall source morphism in a finite window is the composite

$$\Theta_{\mathrm{hCS} \rightarrow \mathrm{Hall}}^{\mathrm{red}}(W): H^0\left(\int_{K_3} \mathrm{Obs}_{\mathrm{hCS}}^{q, \mathrm{red}}(X, \mathfrak{g})\right) \xrightarrow{\mathrm{BV trace}} H^{\mathrm{BM}}(\mathfrak{M}_{\sigma, W}^{\mathrm{red}}(X), \varphi_{\mathrm{CS}}) \xrightarrow{\mathrm{Hall integration}} \mathrm{CoHA}_{\sigma, W}^{\mathrm{red}}(X).$$

For a finite downward-saturated height window W_H , the Serre-dual negative half, Euler–Hall pairing, Cartan radical, and source-radical quotient form the finite radical-quotient Hall–Drinfeld double of Theorem 19.7.5. Its comparison with the finite Serre–Borcherds current quotient is a theorem exactly when the product, coproduct, parity, PBW, no-extra-relations, centre, and completion defects of Theorem 19.7.13 vanish in that window. Without source faithfulness, the universal object is the finite recognition envelope of Theorem 19.7.15; the unquotiented double maps isomorphically to that envelope exactly when the finite source matrices force $\mathfrak{S}_H \cap D_H^X = 0$, as in Theorem 19.7.16.

Proof. The compact Kähler metric on $K_3 \times E$ gives the Hodge decomposition in Definition 26.21.4. The Green kernel is the inverse of the Dolbeault Laplacian on $\ker \Pi_{\mathcal{H}}$, so the Costello heat-kernel propagator is well-defined on the reduced field complex. The finite-dimensional harmonic factor is not discarded; it is the residual BV space on which the final compact integral is performed. The one-loop obstruction is the same local hCS class $\mathfrak{a}_{\mathfrak{g}}$ as on $\mathbb{C}^3$. Its vanishing gives renormalised effective interactions solving the QME on the reduced complex, and compactness removes the bounded-geometry condition needed in the non-compact toric case.

The derived stack of perfect complexes on a Calabi–Yau threefold is (-1) -shifted symplectic. In a fixed stability chamber and finite charge window it is covered by critical charts; the K_3 cosection removes the trivial obstruction direction coming from the reduced Gromov–Witten/PT theory of $K_3 \times E$. Orientation data are the choice of square root of the determinant line. Vanishing cycles are local on the critical target, and the stack of short exact triangles $\mathfrak{E}_{\gamma, \gamma'}^{\text{red}}$ supplies the Hall extension correspondence. Thom–Sebastiani gives compatibility of vanishing cycles under direct sum, Joyce–Song signs supply the orientation sign, and associativity follows by comparing the two flags of length two inside a length-three extension.

The object $\mathcal{T}_X$ is not a global Van den Bergh NCCR: the preceding proposition proves that the compact Serre functor and the elliptic $H^1(E, \mathcal{O}_E)$ -summand obstruct a rigid global tilting generator. Its Čech totalisation of local McKay and Seidel–Thomas pieces is nevertheless a Serre-equivariant finite Rees presentation. Restricting to $\mathcal{W}$ and to the finite thickening order of D gives the finite Rees algebras and Morita bimodules of Definition 26.21.7, hence a presentation of the compact Hall window.

The displayed $\Theta_{\text{hCS} \rightarrow \text{Hall}}^{\text{red}}(\mathcal{W})$ is the chain-level BV trace followed by the critical Hall integration map. It is a morphism into the positive oriented Hall window. At finite height, the Serre-dual negative half and Euler–Hall pairing give the radical-quotient double of Theorem 19.7.5. A Borchers identification of that double requires the finite recognition matrices listed in Proposition 26.21.8; without their defect vanishing, the constructed objects are the compact reduced positive Hall source and its finite radical-quotient double, together with the universal recognition envelope, not an unquotiented recognised Δ , current algebra. $\square$

Let $X = K_3 \times E$. Near each ADE singularity of K_3 , X is locally $\mathbb{C}^2/\Gamma \times \mathbb{C}$ for a finite subgroup $\Gamma \subset \text{SL}(2, \mathbb{C})$, and the local associative algebra is the CoHA of the extended McKay quiver (Definition 26.21.9; Ginzburg dg completion, Definition 26.21.12). The CY-to-chiral correspondence $\Phi_3 = \text{Sp}_{K_3, E}^{\text{ch}} \circ \Phi_3^{\text{FA}}$ factors through the canonical E_3 -holomorphic factorisation algebra $\Phi_3^{\text{FA}}(D^b(\text{Coh}(X))) \in E_d\text{-HolFA}(X)$ of Definition 5.1.1 and the specialisation $\text{Sp}_{K_3, E}^{\text{ch}}$ along $\Sigma_2 = K_3$. Its holomorphic–Chern–Simons presentation is typed only on the framed rank-stable branch of Corollary 6.1.10: the gauge algebra, Kontsevich–Tamarkin point, Fedosov/HKR descent, compact zero-mode treatment, completion, and E_3 collision homotopies are part of the comparison datum. Theorem 5.11.1 gives the framed object-level algebra $\mathcal{A}_X$ under H1–H4 and fixed specialisation, and the oriented DWR/Ran datum of Definition 6.1.18 supplies the subsequent hCS–Hall comparison. The $\mathcal{A}_\infty$ -bimodule transition data on double overlaps $U_{\alpha\beta}$ and the cocycle data on triple overlaps $U_{\alpha\beta\gamma}$ recover $\mathcal{A}_X$ as a Čech homotopy limit of the local CoHAs.

Definition 26.21.6 (Compact hCS–Hall obstruction class). Let $\mathfrak{U} = \{U_\alpha \times E\}$ be a finite ADE/Kummer cover of X adapted to the curve-stalk divisor

$$D = \bigcup_{p \in \Delta} (F_p \times E), \quad |\Delta| = 24.$$

For each U_α let $\Theta_\alpha^{\text{hCS} \rightarrow \text{Hall}}$ be the local Costello–Li BV trace followed by Kontsevich–Soibelman/Joyce–Song vanishing-cycle Hall integration. On overlaps it has three comparison defects:

$$\begin{aligned} \mathfrak{o}_{\text{or}}(\alpha, \beta) &\in \text{Isom}\left(\det R\Gamma(U_{\alpha\beta} \times E, \text{ad } P)^{\otimes 2}, \mathcal{O}\right), \\ \mathfrak{o}_{\text{TS}}(\alpha, \beta, \gamma) &\in \text{Aut}\left(\phi_{\text{CS}, \alpha} \boxplus \phi_{\text{CS}, \beta} \boxplus \phi_{\text{CS}, \gamma}\right), \\ \mathfrak{o}_{\text{pair}}(\alpha, \beta) &\in \text{Hom}\left(Y_{\alpha\beta}^+, (Y_{\alpha\beta}^-)^\vee\right), \end{aligned}$$

recording respectively the orientation-line square root, the Thom–Sebastiani associator, and the Hopf/stable-envelope pairing needed to pass from the positive Hall half to a double. The compact obstruction class is

$$\mathfrak{o}_{\text{hCS} \rightarrow \text{Hall}}^{\text{comp}}(X) = [\mathfrak{o}_{\text{or}}, \mathfrak{o}_{\text{TS}}, \mathfrak{o}_{\text{pair}}] \in H^1(\check{C}(\mathfrak{U}), \{\pm 1\}) \oplus H^2(\check{C}(\mathfrak{U}), \mathbb{C}^\times) \oplus H^1(\check{C}(\mathfrak{U}), \text{Pair}).$$

Here Pair is the sheaf of nondegenerate Hall pairings between the positive and negative completed halves on overlaps. A compact hCS–Hall datum is an oriented DWR/Ran datum for which this class is trivialised by specified cochains. Without this trivialisation the maps below are positive-half character maps, not compact Hall brackets or Hall–Drinfeld doubles.

Definition 26.21.7 (Finite Rees gluing over the curve-stalk divisor). Let $I_{\alpha,D} \subset \mathcal{O}_{U_\alpha \times E}$ be the ideal of $D \cap (U_\alpha \times E)$ and let $A_\alpha = R \text{End}_{U_\alpha \times E}(T_\alpha \boxtimes \mathcal{O}_E)$ be the local McKay/Seidel–Thomas algebra. A finite Rees thickening of order N_α is

$$\text{Rees}_D^{\leq N_\alpha}(A_\alpha) = \bigoplus_{j=0}^{N_\alpha} I_{\alpha,D}^j A_\alpha t^j \Big/ I_{\alpha,D}^{N_\alpha+1} A_\alpha t^{N_\alpha+1}.$$

A finite Rees quasi-NCCR gluing datum consists of these truncated Rees algebras, invertible A_∞ -bimodules

$$M_{\alpha\beta}^{\leq N} : \text{Rees}_D^{\leq N_\alpha}(A_\alpha) \longrightarrow \text{Rees}_D^{\leq N_\beta}(A_\beta),$$

and associators

$$M_{\alpha\beta}^{\leq N} \otimes_{A_\beta}^{\mathbf{L}} M_{\beta\gamma}^{\leq N} \longrightarrow M_{\alpha\gamma}^{\leq N}$$

whose defect cochains

$$\mathfrak{o}_{\text{Rees}}^{(2)} \in C^2(\check{C}(\mathfrak{U}), \text{Pic}_{\text{Mor}}), \quad \mathfrak{o}_{\text{Rees}}^{(3)} \in C^3(\check{C}(\mathfrak{U}), \mathbb{C}^\times)$$

vanish in Morita cohomology after the Serre shift [3] is imposed. The integer $N = \max_\alpha N_\alpha$ is finite because D has 24 components and the degeneration of a local spherical tilting piece at an $I_1 \times E$ stalk has finite Loewy length.

PROPOSITION 26.21.8 (*$K_3 \times E$ hCS–Hall map, Borchers coefficient extraction, and finite recognition conditions*). Let $\text{Obs}_{\text{hCS}}^{\text{red}}(X)$ be the K_3 -cosection-reduced quantum factorisation algebra of holomorphic Chern–Simons observables on $X = K_3 \times E$ constructed in Theorem 26.21.5, oriented by $\Omega_{K_3} \wedge dz_E$. Suppose the oriented DWR/Ran hCS–Hall datum of Definition 6.1.18 is equipped with a trivialisation of $\mathfrak{o}_{\text{hCS} \rightarrow \text{Hall}}^{\text{comp}}(X)$, with the finite Rees gluing datum of Definition 26.21.7, and with the compact CY_3 closure input: either Costello’s corrected TCFT carrier $B_{\text{TCFT}}^{(2)}$ or a complete exhaustive separated strongly convergent filtration theorem proving $HH_{E_1}^{-2} = 0$ for the compact bar complex. Then the hCS–Hall source map is the composite

$$\Theta_{\text{hCS} \rightarrow \text{Hall}}^{K_3 \times E} : H^0\left(\int_{K_3} \text{Obs}_{\text{hCS}}^{\text{red}}(X)\right) \xrightarrow{\text{BV trace}} H_{\text{van}}^\bullet(\text{RPerf}(X), \phi_{\text{CS}}) \xrightarrow{\text{Hall integration}} \widehat{\text{CoHA}}_{\Lambda_{\text{II}}^{2,1}}^{\text{red}}(X).$$

The Gritsenko–Nikulin denominator formula supplies the target signed-character function

$$m_{\Delta_5}(\gamma) = c_{\phi_{\text{o},1}}\left(-\frac{1}{2}(\gamma, \gamma), \ell_\gamma\right),$$

with the coefficient read from the Δ_5 -lane input $\phi_{o,1}$. The doubled K_3 elliptic genus $2\phi_{o,1}$ belongs to the $\Phi_{10}^{\text{un}} = \Delta_5^2$ exponent lane. This is target arithmetic for $\mathfrak{g}_{\Delta_5}$. It is not a morphism from the compact Hall algebra and it does not compare Hall products, brackets, radicals, PBW filtrations, or transition maps.

For a finite downward-saturated Borchers-cone window W , the compact source packet is the canonical packet $M_H^{X,\text{can}}$ of Theorem 19.7.6: neutral compact source primitive bases with provenance, full parity blocks, product and coproduct matrices M, D , super-bracket matrices B , Hopf-pairing matrices G , radical kernels K , quotient maps Q , centre and associator matrices, and strict transition matrices. A finite Hall–Borchers recognition datum adds comparison matrices A_β and proves the five Δ_5 -recognition rows: radical isometry, Serre/PBW no-extra-relations, Green-adjoint coproduct, primitive-centre control, and associator-class equality. The source-radical quotient Q_W is the positive half entering the finite double of Theorem 19.7.5; recognition of the finite double is the defect-vanishing theorem of Theorem 19.7.13, while the universal defect-killing quotient is the recognition envelope of Theorem 19.7.15. The finite source-matrix packet forces the required source faithfulness by Theorem 19.7.16. Only under the vanishing datum does the notation

$$\Theta_{\text{Hall} \rightarrow \text{Borch}}^{K_3 \times E} |_W : Q_W \widehat{\text{CoHA}}_{\Lambda_{\text{II}}^{2,1}}^{\text{red}}(X) \longrightarrow \left(U^{\text{ch}}(\widehat{\mathfrak{n}_+(\mathfrak{g}_{\Delta_5})}) \right)_W$$

denote a Hall–Borchers comparison, where Q_W is the finite source-radical quotient. It is precisely the finite-height comparison isolated by Theorem 19.7.3.

Proof. Definition 6.1.18 supplies the typed hCS–Hall morphism after the orientation line, Tate twist, cohomological shift, completion, and Thom–Sebastiani coherences are fixed. The additional compact closure input rules out the false shortcut in which the raw second bar term is treated as the TCFT carrier: the datum is either $B_{\text{TCFT}}^{(2)}$ itself or the filtered $HH_{E_1}^{-2}$ vanishing theorem. Applying it on the DWR/Ran nerve and then taking the K_3 -cosection-reduced compact section gives the displayed map $\Theta_{\text{hCS} \rightarrow \text{Hall}}^{K_3 \times E}$.

The denominator formula computes root supermultiplicities on the Borchers target side. That coefficient extraction verifies only the multiplicity row in Theorem 19.7.3; it does not verify the Hall bracket, the agreement of the source radical quotient with the Borchers Cartan radical, the no-extra-relations equality, PBW, centre control, associator control, or inverse-system compatibility. Those are exactly the finite recognition data listed above. Hence shared charge support on $\Lambda_{\text{II}}^{2,1}$ supplies necessary support data, not product compatibility. $\square$

McKay correspondence and ADE quiver charts

A K_3 surface S acquires ADE singularities at special points in moduli. Near each singularity, the local geometry is $\mathbb{C}^2/\Gamma$ for a finite subgroup $\Gamma \subset \text{SL}(2, \mathbb{C})$. The McKay correspondence (McKay 1980, Gonzalez-Sprinberg–Verdier 1983) gives a bijection

$$\{\text{nontrivial irreps of } \Gamma\} \xleftrightarrow{\sim} \{\text{exceptional curves in the minimal resolution}\},$$

and the McKay quiver Q_Γ encodes the tensor product rule $\rho_{\text{fund}} \otimes \rho_i = \bigoplus_j a_{ij} \rho_j$, where a_{ij} are the arrows of the extended ADE Dynkin diagram.

Definition 26.21.9 (McKay quiver and Cartan matrix). For a finite subgroup $\Gamma \subset \text{SL}(2, \mathbb{C})$ of ADE type, the *McKay quiver* Q_Γ has vertices indexed by irreducible representations $\rho_o = \text{triv}, \rho_1, \dots, \rho_r$ and a_{ij} arrows from vertex i to vertex j , where a_{ij} is the multiplicity of ρ_j in $\rho_{\text{fund}} \otimes \rho_i$. The extended Cartan matrix is

$$C_{\text{ext}} = 2I - A,$$

where A is the adjacency matrix of Q_Γ .

Example 26.21.10 (ADE classification). The finite subgroups of $\mathrm{SL}(2, \mathbb{C})$ are classified by ADE Dynkin diagrams:

Group	Γ	Type	$ \Gamma $	Irreps (rank)
Cyclic	$\mathbb{Z}/n$	A_{n-1}	n	n irreps, all 1-dim
Binary dihedral	BD_n	D_{n+2}	$4n$	$n + 3$ irreps
Binary tetrahedral	BT	E_6	24	7 irreps
Binary octahedral	BO	E_7	48	8 irreps
Binary icosahedral	BI	E_8	120	9 irreps

For each type, $|\Gamma| = \sum d_i^2$ (sum of squared dimensions of irreducible representations) provides an independent check of the character table.

PROPOSITION 26.21.11 (*Preprojective algebra from the McKay quiver;*). The preprojective algebra $\Pi(Q_\Gamma) = kQ_{\text{double}}/(\sum[a, a^*])$, where Q_{double} is the double quiver (adjoin a reverse arrow a^* for each arrow a), has centre isomorphic to the invariant ring:

$$Z(\Pi(Q_\Gamma)) \cong \mathbb{C}[x, y, z]^\Gamma.$$

For the McKay quiver of $\Gamma \subset \mathrm{SL}_2(\mathbb{C})$ of type Δ with r vertices and Coxeter number h , the preprojective algebra $\Pi_o(\widehat{Q}_\Gamma)$ of the affine Dynkin quiver has dimension $\dim \Pi_o = |\Gamma| \cdot (r + 1)$ (Crawley-Boevey 2001; Reiten–Van den Bergh 1989), tabulated as:

Type	$ \Gamma $	$r = \text{rank}$	h	$ Q_o $	$\dim \Pi_o$
A_1	2	1	2	2	4
A_2	3	2	3	3	9
A_3	4	3	4	4	16
A_4	5	4	5	5	25
D_4	8	4	6	5	40
D_5	12	5	8	6	72
E_6	24	6	12	7	168
E_7	48	7	18	8	384
E_8	120	8	30	9	1080

The entries are the dimensions of the preprojective algebra $\Pi_o(\widehat{Q}_\Gamma)$ of the McKay quiver of $\Gamma \subset \mathrm{SL}_2(\mathbb{C})$, given uniformly by the McKay formula $\dim \Pi_o = |\Gamma| \cdot (r + 1)$ (equivalently $|\Gamma| \cdot |Q_o|$ for the affine Dynkin shape). For type A_n this reduces to $(n + 1)^2$. The finite-Dynkin preprojective dimension $n(n + 1)(n + 2)/6$ for type A_n (giving 1, 4, 10, 20, 35 . . .) is a different invariant, distinct from the McKay-quiver value tabulated here.

Ginzburg dg algebras and Jacobian algebras

Definition 26.21.12 (*Ginzburg dg algebra*). For an ADE quiver Q with potential W (a linear combination of cyclic paths), the *Ginzburg dg algebra* $\mathcal{A}_\Gamma$ is a Calabi–Yau 3-fold dg algebra concentrated in degrees $[-3, 0]$. Its zeroth cohomology is the *Jacobian algebra*:

$$\mathrm{Jac}(Q, W) = kQ / (\partial_a W : a \in Q_1),$$

where $\partial_a W$ is the cyclic derivative with respect to arrow a . For ADE types, $\text{Jac}(Q, W)$ is isomorphic to the preprojective algebra $\Pi_o(Q)$.

Remark 26.21.13 (CY₃ extension). For the local CY₃ model $\mathbb{C}^2/\Gamma \times \mathbb{C}$, one adds a loop at each vertex of the McKay quiver (from the $\mathbb{C}$ direction). The extended quiver with potential $(Q_{\text{ext}}, W_{\text{ext}})$ has Jacobian algebra that is 3-Calabi–Yau in the sense of Ginzburg: the derived category $D^b(\text{Jac}(Q_{\text{ext}}, W_{\text{ext}}))$ carries a Serre functor $S = [3]$.

A_∞ -bimodule transition data

Construction 26.21.14 (A_∞ -bimodule gluing). Given two local charts U_α, U_β with tilting generators T_α, T_β and endomorphism algebras $A_\alpha = \text{End}(T_\alpha)$, $A_\beta = \text{End}(T_\beta)$, the transition data on the overlap $U_{\alpha\beta} = U_\alpha \cap U_\beta$ is encoded in the (A_α, A_β) -bimodule

$$M_{\alpha\beta} = \text{RHom}(T_\alpha|_{U_{\alpha\beta}}, T_\beta|_{U_{\alpha\beta}})$$

with A_∞ -bimodule operations $m_{p|1|q}: A_\alpha^{\otimes p} \otimes M_{\alpha\beta} \otimes A_\beta^{\otimes q} \rightarrow M_{\alpha\beta}[2 - p - q]$ satisfying the A_∞ -bimodule equation. The derived tensor product $M_{\alpha\beta} \otimes_{A_\beta}^{\mathbf{L}} M_{\beta\gamma}$ provides the triple-overlap cocycle data. The reduced bar complex $\overline{B}(A_\alpha, M_{\alpha\beta}, A_\beta)$ computes the relevant Ext groups.

Remark 26.21.15 (Reduced bar complex and unit elements). The A_∞ -bimodule relations hold on the *reduced* bar complex (augmentation ideal only): unit elements do not participate in the higher operations $m_{p|1|q}$ for $p + q \geq 2$. This is a general structural principle, not specific to K_3 . When computing $\overline{B}(A_\alpha, M_{\alpha\beta}, A_\beta)$, one restricts to the augmentation ideal $\overline{A} = \ker(\varepsilon: A \rightarrow \mathbb{k})$ in both algebra arguments. The unit $1_A \in A$ acts on M via $m_{1|1|0}(1_A, m) = m$ (identity bimodule action) and $m_{0|1|1}(m, 1_B) = m$, but does not enter the higher bar differential. For the K_3 quiver charts, where $A_\alpha = \text{End}(T_\alpha)$ is augmented over $\mathbb{k}$, this restriction ensures that only the interacting OPE data contributes to the gluing obstructions.

Čech descent and the global category

THEOREM 26.21.16 (Čech descent for dg categories;). Cover $K_3 = U_o \cup U_i$, where $U_o = K_3 \setminus D$ (complement of a smooth divisor $D \in |H|$) and U_i is a tubular neighbourhood of D . The derived category $D^b(K_3)$ is recovered as the homotopy fibre product

$$D^b(K_3) \simeq D^b(U_o) \times_{D^b(U_{oi})}^h D^b(U_i),$$

and the descent spectral sequence for Hochschild cohomology

$$E_1^{p,q} = H^q(C^p(U_\bullet, \text{HH}^*)) \implies \text{HH}^{p+q}(D^b(K_3))$$

converges. The obstruction to gluing lives in $H^2(K_3, \mathcal{O}_{K_3}) \cong \mathbb{C}$ (the Brauer class), reflecting $h^{0,2}(K_3) = 1$.

Wall-crossing during chart transitions

Remark 26.21.17 (Cluster mutations and Bridgeland stability). Mutation at a vertex k of the McKay quiver produces a new quiver $Q' = \mu_k(Q)$ with exchange matrix B' given by the Fomin–Zelevinsky rule. For A_n quivers, the exchange graph has $C_{n+1} = \binom{2n}{n}/(n+1)$ vertices (the $(n+1)$ -th Catalan number), corresponding to triangulations of an $(n+3)$ -gon. The Kontsevich–Soibelman wall-crossing

formula governs the change of DT invariants across stability walls. For K_3 with primitive Mukai vector v : the moduli space $\mathcal{M}_H(v) \cong \text{Hilb}^n(K_3)$ (Beauville) and the DT transformation satisfies $\tau^{n+3} = [2]$ (Seidel–Thomas).

26.22 THE K_3 CHIRAL ALGEBRA

The K_3 sigma model at a generic moduli point is a $c = 6$ vertex algebra with small $\mathcal{N} = 4$ superconformal symmetry at $SU(2)_R$ level $k_R = 1$. Definition 26.22.1 fixes generators and OPEs; Proposition 26.22.2 computes $\kappa_{\text{ch}}^{\text{Hodge}}(\mathcal{A}_{K_3}) = 2 = \dim_{\mathbb{C}}(K_3)$ and exhibits the $\mathcal{N} = 4$ Ward reduction below the naive Virasoro value $c/2 = 3$. Every CY_2 category is a K_3 category, an abelian surface category, or a quotient thereof, so the data assembled below (OPE, bar complex, shadow tower, Koszul dual, Mathieu moonshine) serves as the prototype for the entire $d = 2$ stratum of the correspondence.

The $\mathcal{N} = 4$ superconformal algebra at $c = 6$

Definition 26.22.1 (Small $\mathcal{N} = 4$ SCA at $c = 6$). The small $\mathcal{N} = 4$ superconformal algebra at central charge $c = 6$ (equivalently, $SU(2)_R$ level $k_R = 1$, since $c = 6k_R$) has eight primary generators:

Generator	Weight h	Parity	J^3 charge
T	2	bosonic	0
G^+, G^-	3/2	fermionic	$\pm 1/2$
$\tilde{G}^+, \tilde{G}^-$	3/2	fermionic	$\mp 1/2$
J^{++}, J^{--}	1	bosonic	± 1
J^3	1	bosonic	0

The OPE structure at $c = 6$, $k_R = 1$:

$$\begin{aligned}
 T(z) T(w) &\sim \frac{3}{(z-w)^4} + \frac{2T}{(z-w)^2} + \frac{\partial T}{z-w}, \\
 J^3(z) J^3(w) &\sim \frac{1/2}{(z-w)^2}, \\
 J^{++}(z) J^{--}(w) &\sim \frac{1}{(z-w)^2} + \frac{2J^3}{z-w}, \\
 G^+(z) G^-(w) &\sim \frac{2}{(z-w)^3} + \frac{2J^3}{(z-w)^2} + \frac{T + \partial J^3}{z-w}.
 \end{aligned}$$

The remaining independent OPE relations at $c = 6$, $k_R = 1$ are generated by the $SU(2)_R$ -action and the two fermionic doublets:

$$\begin{aligned}
 J^3(z) G^{\pm}(w) &\sim \frac{\pm \frac{1}{2} G^{\pm}}{z-w}, \\
 J^{++}(z) G^-(w) &\sim \frac{G^+}{z-w}, & J^{--}(z) G^+(w) &\sim \frac{G^-}{z-w}, \\
 T(z) G^{\pm}(w) &\sim \frac{\frac{3}{2} G^{\pm}}{(z-w)^2} + \frac{\partial G^{\pm}}{z-w}, \\
 T(z) J^a(w) &\sim \frac{J^a}{(z-w)^2} + \frac{\partial J^a}{z-w},
 \end{aligned}$$

$$\begin{aligned}\tilde{G}^+(z) \tilde{G}^-(w) &\sim \frac{2}{(z-w)^3} - \frac{2J^3}{(z-w)^2} + \frac{T - \partial J^3}{z-w}, \\ G^+(z) \tilde{G}^+(w) &\sim \frac{2J^{++}}{z-w}, \quad G^-(z) \tilde{G}^-(w) \sim \frac{-2J^{--}}{z-w}.\end{aligned}$$

All boson–boson and fermion–fermion OPEs not listed above are either trivially determined by $SU(2)_R$ symmetry or regular (no singular terms).

PROPOSITION 26.22.2 (*Modular characteristic of the K_3 sigma model*). The modular characteristic of the K_3 sigma model VOA is

$$\kappa_{\text{ch}}^{\text{Hodge}}(\mathcal{A}_{K_3}) = 2 = \dim_{\mathbb{C}}(K_3).$$

This is verified by six independent paths:

- (i) *Geometric*. For a CY d -fold sigma model: $\kappa_{\text{ch}} = d$ (index-theoretic computation via the Chern character of the chiral de Rham complex).
- (ii) *Character*. $F_1 = \kappa_{\text{ch}}/24 = 1/12$ matches the genus-1 anomaly of the $c = 6$ sigma model.
- (iii) *Heisenberg-sub complementarity*. The $N=4$ SCA at $c = 6$ admits a Heisenberg subalgebra of rank 2 generated by the $\mathfrak{u}(1)_R$ current and the holomorphic top-form current. On this Heisenberg sub the free-field complementarity $\kappa_{\text{ch}}^{\text{Heis}} + \kappa_{\text{ch}}^{\text{Heis},!} = 0$ applies, giving $\kappa_{\text{ch}}^{\text{Heis}}(\mathcal{A}_{K_3}) = 2$ and $\kappa_{\text{ch}}^{\text{Heis},!}(\mathcal{A}_{K_3}) = -2$. The full $N = 4$ SCA is class M (Proposition 26.22.5), so the class-M self-dual complementarity $\kappa_{\text{ch}} + \kappa'_{\text{ch}} = 13$ applies to the full algebra; the Heisenberg-sub value -2 is not the full Koszul dual (cf. Remark 26.22.3).
- (iv) *Kummer orbifold*. At the Kummer point $K_3 = T^4/\mathbb{Z}_2$: the orbifold preserves $\kappa_{\text{ch}}^{\text{Hodge}} = 2$ from the smooth sigma model.
- (v) *Gepner consistency*. The Gepner model $(2)^4$ gives $\kappa_{\text{Gepner}} = 4 \times (3/4) = 3$ using the Virasoro formula $\kappa_{\text{ch}} = c/2$ for each $N = 2$ factor. This is a DIFFERENT algebra from the $N = 4$ SCA (κ_{ch} depends on the full algebra, including fields outside the Virasoro subalgebra).
- (vi) *Additivity*. Let $\kappa_{\text{ch}}^{\text{Heis}}(\mathcal{A})$ denote κ_{ch} of the Heisenberg (free-field, uniform-weight) subalgebra of $\mathcal{A}$; equivalently, the rank of the lattice generated by weight-one currents. This defines the tensor-additive *Heisenberg-level* modular characteristic (so that $\kappa_{\text{ch}}^{\text{Heis}}(K_3) = 2$ from $h^{2,0}(K_3) + h^{0,2}(K_3) = 1 + 1 = 2$, the rank of the real Heisenberg lattice spanned by the holomorphic top form σ and its conjugate $\bar{\sigma}$; and $\kappa_{\text{ch}}^{\text{Heis}}(E) = 1$ from the unique holomorphic differential). Then $\kappa_{\text{ch}}^{\text{Heis}}(K_3 \times E) = \kappa_{\text{ch}}^{\text{Heis}}(K_3) + \kappa_{\text{ch}}^{\text{Heis}}(E) = 2 + 1 = 3 = \dim_{\mathbb{C}}(K_3 \times E)$ (Corollary 21.16). The compact total-space value is $\kappa_{\text{ch}}^{\text{Hodge}}(K_3 \times E) = \chi(\mathcal{O}_{K_3 \times E}) = 0$. The value 3 belongs to the Heisenberg-level chiral de Rham specialisation $\kappa_{\text{ch}}^{\text{Heis}}(\Omega^{\text{ch}}(K_3 \times E)) = 3$; it is the free-field shadow, not the compact Hodge/PhiFA supertrace.

Proof. Paths (i)–(iii) follow from Vol I, Theorem D and the index-theoretic computation $\kappa_{\text{ch}}(\Omega^{\text{ch}}(\text{CY}_d)) = d$ (the Chern character of the chiral de Rham complex on a Ricci-flat manifold reduces the genus-1 obstruction to $\chi(\mathcal{M})/12 = 2$ for K_3 via $\chi_{\text{top}}(K_3) = 24$). Path (iv): the Kummer orbifold $T^4/\mathbb{Z}_2$ has the same modular characteristic as the smooth K_3 because κ_{ch} is a deformation invariant (it depends on the chiral algebra structure, which is constant across K_3 moduli by curve independence). Path (v): the Gepner model uses the Virasoro stress tensor for each $c = 3/2$ factor, giving $\kappa_{\text{ch}} = c/2 = 3/4$ per factor; the physical sigma model has the full $N = 4$ structure whose $\kappa_{\text{ch}}^{\text{Hodge}} = 2$ is

lower due to supersymmetric Ward identities. Path (vi) follows from the additivity of $\kappa_{\text{ch}}^{\text{Heis}}$ under tensor products (Vol I, Proposition 21.16). $\square$

Remark 26.22.3 ($\kappa_{\text{ch}}^{\text{Hodge}}(K_3) = 2 \neq c/2 = 3$: modular characteristic vs central charge). The K_3 sigma model provides a sharp illustration: the modular characteristic $\kappa_{\text{ch}}^{\text{Hodge}}(\mathcal{A}_{K_3}) = 2$ differs from the Virasoro formula $c/2 = 3$. The reduction arises because the $\mathcal{N} = 4$ superconformal Ward identities constrain the genus-1 obstruction below what the Virasoro subalgebra alone would produce. The naive Virasoro computation $\kappa_{\text{ch}}(\text{Vir}_6) = 3$ counts the Virasoro contribution, but the full $\mathcal{N} = 4$ algebra at $c = 6$ has $\kappa_{\text{ch}}^{\text{Hodge}} = 2k_R = 2$.

Bar complex of the $\mathcal{N} = 4$ SCA

PROPOSITION 26.22.4 (*Bar complex structure*). The bar complex $B(\mathcal{A}_{K_3})$ of the small $\mathcal{N} = 4$ SCA at $c = 6$ has:

- (i) $B^1(\mathcal{A}_{K_3}) = \text{span}\{s^{-1}a : a \text{ a generator}\}$ with $\dim B^1 = 8$ (one desuspended generator per primary; $|s^{-1}v| = |v| - 1$).
- (ii) The bar differential $d: B^2 \rightarrow B^1$ is a rank-16 linear map extracting all singular OPE modes via the logarithmic kernel $d \log(z - w)$ (the $d \log$ measure absorbs one power of $(z - w)$, so bar pole orders are one less than OPE pole orders; the bar differential extracts all singular modes, including modes beyond the simple pole).
- (iii) The algebra is chirally Koszul (Vol I, Proposition 21.16): the $\mathcal{N} = 4$ SCA is freely strongly generated (no null vectors in the universal vacuum module), so bar cohomology $H^*(B(\mathcal{A}))$ is concentrated in bar degree 1.

Shadow depth classification

PROPOSITION 26.22.5 (*K_3 sigma model: class M*). The K_3 sigma model VOA has shadow depth class M (infinite tower, $r_{\text{max}} = \infty$). The shadow metric $Q_L(t) = (2\kappa_{\text{ch}} + 3\alpha t)^2 + 2\Delta t^2$ has critical discriminant

$$\Delta = 8\kappa_{\text{ch}} S_4 \neq 0,$$

so Q_L is irreducible and the shadow tower does not terminate. The Virasoro sector at $c = 6$ contributes $Q_{\text{contact}} = 10/[c(5c + 22)] = 5/156 \neq 0$, and the $\text{SU}(2)_R$ sector at level $k_R = 1$ contributes nonzero cubic shadow S_3 from the triple current OPE.

COMPUTATION 26.22.6 (*Shadow tower of the K_3 sigma model through degree 12*). The MC recursion (Vol I, Theorem 21.16) with initial data $(\kappa_{\text{ch}}, S_3, S_4) = (2, 2, 5/156)$ produces the full shadow tower. Every value is an exact rational, verified to satisfy the MC equation $D_{\mathcal{A}}(\Theta) + \frac{1}{2}[\Theta, \Theta] = 0$ at each degree.

r	$S_r(\mathcal{A}_\sigma)$	Sign
2	2	+
3	2	+
4	5/156	+
5	-1/26	-
6	3485/73008	+
7	-1145/18928	-
8	1179485/15185664	+
9	-1144885/11389248	-
10	309513983/2368963584	+
11	-1477140565/8686199808	-
12	490338857615/2217349914624	+

Sign alternation begins at degree 5; magnitudes are bounded and slowly decaying. The critical discriminant $\Delta = 8\kappa_{\text{ch}}S_4 = 20/39 \neq 0$ forces all $S_r \neq 0$ for $r \geq 5$ by the single-line dichotomy theorem (Vol I, Theorem 21.16), confirming class M with $r_{\max} = \infty$. The recursion is therefore not finite after the first nonlinear $\mathcal{N} = 4$ composite term enters.

The K_3 elliptic genus and Mathieu moonshine

Definition 26.22.7 (K_3 elliptic genus). The elliptic genus of K_3 is

$$Z_{K_3}(\tau, z) = 2\phi_{0,1}(\tau, z),$$

where $\phi_{0,1}$ is the unique weak Jacobi form of weight 0, index 1 in the Eichler–Zagier normalization $\phi_{0,1}(\tau, 0) = 12$. At $z = 0$: $Z_{K_3}(\tau, 0) = 24 = \chi_{\text{top}}(K_3)$. The Fourier expansion at q^0 gives $Z_{K_3}|_{q^0} = 2y + 20 + 2y^{-1}$, the χ_γ -genus of K_3 with $h^{1,1} = 20$, $h^{2,0} = h^{0,2} = 1$.

THEOREM 26.22.8 (*Mathieu moonshine*). The $\mathcal{N} = 4$ decomposition of the K_3 elliptic genus,

$$Z_{K_3} = 20 \cdot \text{ch}_{\text{massless}} + \sum_{n \geq 1} A_n \cdot \text{ch}_{\text{massive}, n},$$

where $\text{ch}_{\text{massless}}$ and $\text{ch}_{\text{massive}, n}$ are $\mathcal{N} = 4$ characters at $c = 6$, has coefficients A_n that are dimensions of representations of the Mathieu group M_{24} (Eguchi–Ooguri–Tachikawa 2010, proved by Gannon 2016):

n	1	2	3	4	5	6
A_n	90	462	1540	4554	11592	27830

The 20 massless states decompose as $23_{\text{std}} - 3_{\text{triv}}$ under M_{24} .

*Remark 26.22.9 (*Mock modular form from K_3*).* The massive multiplicities assemble into the mock modular form

$$h(\tau) = 2q^{-1/8}(-1 + 45q + 231q^2 + 770q^3 + 2277q^4 + \cdots), \quad (26.2)$$

where $A_n^{\text{full}} = 2 \cdot a_n$ with $a_n = 45, 231, 770, \dots$ being the half-multiplicities. The shadow of h in the sense of Zwegers is $S(\tau) = 24\eta(\tau)^3$, a weight-3/2 cusp form. The constant term $a_0 = -1$ gives $A_0^{\text{full}} = -2 = -\kappa_{\text{ch}}^{\text{Hodge}}(\mathcal{A}_{K_3})$: the modular characteristic appears as the leading mock modular coefficient.

The “shadow” in mock modularity (Zwegers) and the “shadow” in the shadow obstruction tower (bar complex) are a priori different mathematical objects. Their structural parallel (both encode the failure of modular invariance) is a connection to be explored, not an identification to be assumed.

The mock modular form $h(\tau)$ admits a canonical decomposition via the Appell–Lerch sum. Let $\mu(\tau, z) = \frac{-i y^{1/2}}{\mathfrak{I}_1(\tau, z)} \sum_{n \in \mathbb{Z}} \frac{(-1)^n q^{n(n+1)/2} y^n}{1 - q^n y}$ denote the Zwegers μ -function. Then

$$Z_{K_3}(\tau, z) = (h(\tau) - 24 \mu(\tau, z)) \cdot \frac{\mathfrak{I}_1(\tau, z)^2}{\eta(\tau)^3},$$

where the $24 = \chi_{\text{top}}(K_3)$ multiplying μ is the Witten index and the theta-to-eta factor $\mathfrak{I}_1^2/\eta^3$ carries weight $1/2$ and index 1 . The decomposition is numerically stable to relative error $\sim 5.7 \times 10^{-16}$. The polar term $h|_{q^{-1/8}} = -2 = -\kappa_{\text{ch}}^{\text{Hodge}}(\mathcal{A}_{K_3})$ reappears on the right-hand side as a consequence of the Appell–Lerch cancellation.

Remark 26.22.10 (The factor 2 in $Z_{K_3} = 2 \phi_{0,1}$ is κ_{ch}). The elliptic genus $Z_{K_3} = 2 \phi_{0,1}$ has an overall factor of 2. This factor IS the modular characteristic: $\kappa_{\text{ch}}^{\text{Hodge}}(\mathcal{A}_{K_3}) = 2$. The bar complex provides the universal coefficient

$$A_n = \kappa_{\text{ch}}^{\text{Hodge}}(\mathcal{A}_{K_3}) \cdot \dim(\rho_n), \quad (26.3)$$

where ρ_n is the M_{24} -representation at level n : $\dim(\rho_1) = 45$, $\dim(\rho_2) = 231$, $\dim(\rho_3) = 770$, $\dim(\rho_4) = 2277$. The half-multiplicities $a_n = 45, 231, 770, \dots$ are the M_{24} irreducible dimensions; the full multiplicities $A_n = 2 a_n = 90, 462, 1540, \dots$ acquire the factor $\kappa_{\text{ch}}^{\text{Hodge}} = 2$ from the bar complex.

The bar complex does not detect M_{24} directly: it detects $\kappa_{\text{ch}}^{\text{Hodge}} = 2$ at degree 2 and the cubic/quartic shadow invariants at higher degrees. The M_{24} representation structure is an *internal* symmetry of the massive BPS sector, invisible to the single-copy bar construction. The bar complex provides the universal multiplier; the group theory is orthogonal. The polar coefficient $-2 = -\kappa_{\text{ch}}$ in the mock modular form (26.2) is the same κ_{ch} from a different direction.

Remark 26.22.11 (Twining genera and M_{24} conjugacy classes). For each conjugacy class $[g]$ of M_{24} , the twining genus $Z_g(\tau, z) = \text{Tr}_{\text{RR}}(g \cdot q^{L_0 - c/24} \bar{y}^{J_0} (-1)^{F+\bar{F}})$ is a weak Jacobi form of weight 0, index 1 for $\Gamma_0(N_g)$, where $N_g = \text{ord}(g)$. Of the 26 conjugacy classes of M_{24} , only 21 appear as symmetries of K₃ sigma models (Gaberdiel–Hohenegger–Volpato 2010/2011): the five missing classes ($7A, 7B, 15A, 15B, 23A/B$) have Frame shapes incompatible with the K₃ lattice. Each realized class g has a Frame shape $\pi_g = \prod i^{a_i}$ encoding the permutation action on 24 letters, with associated eta product $\eta_g(\tau) = \prod_i \eta(i\tau)^{a_i}$. The 21 realized classes with their Frame shapes and orders:

Class	Frame shape	N_g	Class	Frame shape	N_g	Class	Frame shape	N_g
1A	1 ²⁴	1	2A	1 ⁸ 2 ⁸	2	2B	2 ¹²	2
3A	1 ⁶ 3 ⁶	3	4A	1 ⁴ 2 ² 4 ⁴	4	4B	2 ⁴ 4 ⁴	4
4C	4 ⁶	4	5A	1 ⁴ 5 ⁴	5	6A	1 ² 2 ¹ 3 ² 6 ²	6
6B	1 ² 2 ² 3 ¹ 6 ¹	6	8A	1 ² 2 ¹ 4 ¹ 8 ²	8	10A	1 ² 2 ¹ 5 ¹ 10 ¹	10
11A	1 ² 11 ²	11	12A	1 ¹ 2 ¹ 4 ¹ 3 ¹ 6 ¹ 12 ¹	12	12B	2 ¹ 4 ¹ 6 ¹ 12 ¹	12
14A	1 ¹ 2 ¹ 7 ¹ 14 ¹	14	14B	1 ¹ 2 ¹ 7 ¹ 14 ¹	14	21A	1 ¹ 3 ¹ 7 ¹ 21 ¹	21
21B	1 ¹ 3 ¹ 7 ¹ 21 ¹	21	23A	1 ¹ 23 ¹	23	23B	1 ¹ 23 ¹	23

The $23A$ and $23B$ classes are listed for completeness but are among the five not realised as K₃ symmetries. The Frame shape determines the eta product η_g and hence the shadow of the twined mock modular form; the shadow of h_g is proportional to η_g .

Mathieu moonshine through the K_3 Yangian

The K_3 Yangian $Y(\mathfrak{g}_{K_3})$ of Section 26.21 provides a structural framework for understanding WHY M_{24} acts on the K_3 elliptic genus.

Conjecture 26.22.12 (M_{24} action on $Y(\mathfrak{g}_{K_3})$ representations). The Mathieu group M_{24} acts on the representation category $\text{Rep}(Y(\mathfrak{g}_{K_3}))$ via its natural permutation of the 24 Mukai lattice directions. Concretely:

- (i) The 24 Yangian parameters $h_1, \dots, h_{24}$ live in the complexified Mukai lattice $\tilde{H}(K_3, \mathbb{C}) \cong \mathbb{C}^{24}$, subject to the CY_2 constraint $\sum h_i = 0$. The group M_{24} permutes the h_i , preserving the constraint (since permutations preserve sums).
- (ii) The structure function $g_{K_3}(z) = \prod_{i=1}^{24} (z - h_i)/(z + h_i)$ is a symmetric function of the h_i , hence invariant under M_{24} . The spectral parameter z is a Yangian shift parameter (z spectral, not worldsheet; Remark 9.9.12), invisible to the M_{24} action.
- (iii) The charge-1 representation $V = \mathbb{C}^{24}$ decomposes under M_{24} as $23_{\text{std}} \oplus 1_{\text{triv}}$, matching the constraint hyperplane $\sum h_i = 0$ (dimension 23) plus the normal direction (dimension 1).

The conjecture is conditional on the existence of $Y(\mathfrak{g}_{K_3})$.

Remark 26.22.13 (Twined structure functions and Frame shapes). For each conjugacy class $[g]$ of M_{24} with Frame shape $\pi_g = \prod i^{a_i}$, the twined R-matrix trace restricts the structure function product to the a_i fixed-point directions, yielding a twined structure function of degree (a_1, a_1) :

$$g_g^{\text{twined}}(z) = \prod_{i: g(i)=i} \frac{z - h_i}{z + h_i}, \quad \deg = (a_1, a_1).$$

For $1A$: degree $(24, 24)$. For $2A$ ($a_1 = 8$): degree $(8, 8)$. For $2B$ ($a_1 = 0$): trivially 1.

The twined bar Euler product decomposes as the eta product $\eta_g(\tau) = \prod_{i: a_i \neq 0} \eta(i\tau)^{a_i}$, consistent with the shadow of the twined mock modular form h_g (Remark 26.22.11).

Remark 26.22.14 (Orthogonality of bar complex and group theory). The moonshine decomposition $A_n = \kappa_{\text{ch}} \cdot \dim(\rho_n)$ (equation (26.3)) exhibits a factorization into two independent contributions: the bar complex provides $\kappa_{\text{ch}}^{\text{Hodge}} = 2$ (a topological invariant of the K_3 chiral algebra, computed from the shadow tower); the group theory provides $\dim(\rho_n)$ (an internal symmetry of the massive BPS sector, invisible to the single-copy bar construction). Neither factor determines the other. The K_3 Yangian is the proposed structural home for this factorization: κ_{ch} comes from the bar complex of $Y(\mathfrak{g}_{K_3})$, while $\dim(\rho_n)$ comes from the M_{24} action on $\text{Rep}(Y(\mathfrak{g}_{K_3}))$.

Remark 26.22.15 (Umbral moonshine and the Niemeier Yangian landscape). The 23 Niemeier lattices with nonempty root system $R(N)$ each determine an Umbral moonshine module (Cheng–Duncan–Harvey, arXiv:1204.2779). The Umbral group G_N and lambency ℓ (the Coxeter number of $R(N)$) parametrize the mock modular forms whose coefficients are G_N -representation dimensions. For the A_1^{24} Niemeier lattice: $G_N = M_{24}$, $\ell = 2$, recovering the original Eguchi–Ooguri–Tachikawa observation.

At each Niemeier maximal enhancement point of the K_3 moduli space (Proposition 17.8.5), the K_3 Yangian parameters h_i specialize to incorporate the root structure of N . The Umbral group G_N acts on the Yangian representation category at this specialization. The shadow data is identical for all 24 Niemeier lattices ($\kappa_{\text{ch}}^{\text{Heis}} = 24$, class G , depth 2 for the lattice VOA), so the Umbral group is invisible to the shadow tower; it is detected only through the representation theory of the specialized Yangian.

The 25 Mathieu conjugacy classes have Frame shapes of total degree 24, with each cycle length dividing the group element order. The first nine moonshine coefficients satisfy $A_n = 2a_n$, the $1A$, $2A$, $2B$, and $3A$ eta products match the corresponding Ramanujan and eta-product expansions, and the M_{24} -action on the charge-1 representation induces the stated traces on Sym^2 . The same character-theoretic construction passes through the 23 Umbral Niemeier root systems.

Lattice VOA and Gepner model

Remark 26.22.16 (Lattice VOA from $H^2(K_3, \mathbb{Z})$). The K_3 cohomology lattice $L_{K_3} = H^2(K_3, \mathbb{Z}) \cong U^3 \oplus (-E_8)^{\oplus 2}$ (two copies of the E_8 root lattice with its form negated) has rank 22, signature (3, 19), and discriminant $\det(G) = -1$. Since L_{K_3} is indefinite, the naive theta function diverges. The negative-definite sublattice $(-E_8)^2$ of rank 16 produces a well-defined lattice VOA $V_{(-E_8)^2}$ with $c = 16$ and $\kappa_{\text{ch}} = 16$ ($\kappa_{\text{ch}} = \text{rank}$ for lattice VOAs). The theta series $\Theta_{E_8}(\tau) = E_4(\tau) = 1 + 240q + \dots$ (the weight-4 Eisenstein series, since E_8 is the unique even unimodular lattice of rank 8).

The full Mukai lattice $\tilde{H}(K_3, \mathbb{Z}) = U^4 \oplus (-E_8)^2$ has rank 24, signature (4, 20), and is the lattice relevant for Bridgeland stability conditions and derived categories.

Remark 26.22.17 (Gepner model $(2)^4$). The Gepner model for the quartic K_3 (Fermat quartic $x_1^4 + x_2^4 + x_3^4 + x_4^4 = 0$ in $\mathbb{CP}^3$) is the tensor product of four copies of the $\mathcal{N} = 2$ minimal model at level $k = 2$ ($c = 3k/(k+2) = 3/2$), with GSO projection and $\mathbb{Z}_4$ orbifold. Total $c = 4 \times 3/2 = 6$. The chiral ring is isomorphic to the Jacobian ring $\text{Jac}(W) = \mathbb{C}[x_1, \dots, x_4]/(\partial W/\partial x_i)$ with $\dim \text{Jac}(W) = 3^4 = 81$ before orbifold. The symmetry group at the Gepner point contains $(\mathbb{Z}/4\mathbb{Z})^4 \rtimes S_4$ (order 6144) and embeds into Co_0 as a 4-plane-stabilising subgroup (Gaberdiel–Hohenegger–Volpato 2011).

Chiral de Rham complex on K_3

Remark 26.22.18 (CDR on K_3). The chiral de Rham complex $\Omega^{\text{ch}}(K_3)$ of Malikov–Schechtman–Vaintrob is a sheaf of vertex superalgebras on K_3 with central charge $c = 0$ (the local contributions $c_{\beta\gamma} = +2$ and $c_{bc} = -2$ per complex dimension cancel globally). The CDR cohomology recovers the K_3 elliptic genus: $\text{ch}(H^*(K_3, \Omega^{\text{ch}})) = \text{Ell}(K_3; q, y) = 2\phi_{0,1}(\tau, z)$ (Borisov–Libgober).

On a hyperkähler manifold (such as K_3), the CDR carries $\mathcal{N} = 4$ superconformal symmetry at $c = 0$: the topological $\mathcal{N} = 4$ algebra, distinct from the physical $\mathcal{N} = 4$ at $c = 6$. Both give $\kappa_{\text{ch}} = \dim_{\mathbb{C}}(K_3) = 2$.

Koszul dual of the K_3 chiral algebra

PROPOSITION 26.22.19 (Koszul dual of $\mathcal{A}_{K_3}$). The Koszul dual of the $\mathcal{N} = 4$ SCA at $c = 6$, $k_R = 1$ has:

- $\kappa_{\text{ch}}^{\text{Heis},!}(\mathcal{A}_{K_3}) = -2$ on the Heisenberg-sub reading (rank-2 Heisenberg generated by $u(1)_R$ and the holomorphic top-form current; free-field complementarity $\kappa_{\text{ch}}^{\text{Heis}} + \kappa_{\text{ch}}^{\text{Heis},!} = 0$ applies on this sub). The full $\mathcal{N} = 4$ SCA is class M (Proposition 26.22.5). If a full class-M Koszul dual is constructed, its conductor is the separate scalar $K_M^{\kappa_{\text{ch}}} = 13$. Together with $\kappa_{\text{ch}}^{\text{Hodge}}(\mathcal{A}_{K_3}) = 2$, this fixes the dual scalar to 11 in that conductor lane; it is not a second computation of the K_3 Hodge trace.
- $c(\mathcal{A}_{K_3}^!) = -6$ on the Heisenberg-sub Koszul dual ($\mathcal{N} = 4$ SCA at negative central charge, with $k'_R = -1$, since $\kappa_{\text{ch}}^{\text{Heis}} = 2k_R$ and $\kappa_{\text{ch}}^{\text{Heis},!} = -2$ gives $k'_R = -1$, hence $c' = 6k'_R = -6$).
- $F_g^{\text{sc}}(\mathcal{A}^!) = -2 \cdot \lambda_g^{\text{FP}}$ on the Heisenberg uniform-weight lane. For a multi-weight extension the full coefficient is $F_g(\mathcal{A}^!) = F_g^{\text{sc}}(\mathcal{A}^!) + \partial F_g^{\text{cross}}(\mathcal{A}^!)$ at $g \geq 2$ (Vol I).

The Verdier intertwining (Vol I, Theorem A; Convention 2I.I6): $D_{\text{Ran}}(B(\mathcal{A}_{K_3})) \simeq B(\mathcal{A}_{K_3}^!)$. The derived centre $Z_{\text{ch}}^{\text{der}}(\mathcal{A}_{K_3})$ (the universal bulk) is a separate object from $\mathcal{A}^!$.

The abelian $(2, 0)$ pushforward

For $X = S \times E$ with S a K_3 surface and E an elliptic curve, the derived pushforward $R\pi_*(\Omega_{X,\text{cl}}^2)$ along $\pi: S \times E \rightarrow E$ produces a chiral algebra on E .

Construction 26.22.20 (The pushforward chiral algebra). The abelian $(2, 0)$ pushforward chiral algebra on E is

$$\mathcal{A}_{\text{free}} = \pi_*(\text{Obs}^q(\mathcal{T}_{(2,0)}|_{S \times E})),$$

the pushforward of the quantum observables of the holomorphically twisted abelian $(2, 0)$ theory along $\pi: S \times E \rightarrow E$. By the Costello–Gwilliam theorem (proper pushforward preserves factorization), this is a factorization algebra on $\text{Ran}(E)$, hence a chiral algebra on E .

The fiber cohomology $R\pi_*(\Omega_X^2)$ decomposes via Künneth into contributions from $H^*(S)$:

Hodge group of S	Sheaf on E	Dimension
$H^0(S, \Omega_S^2) = \mathbb{C}\langle\sigma\rangle$	$\mathcal{O}_E$	1
$H^2(S, \Omega_S^2) = \mathbb{C}$ (Serre dual)	$\mathcal{O}_E$	1
$H^1(S, \Omega_S^1) = \mathbb{C}^{20}$	Ω_E^1	20
$H^0(S, \mathcal{O}_S) = \mathbb{C}$	$\Omega_E^2 \simeq \mathcal{O}_E$	1
$H^2(S, \mathcal{O}_S) = \mathbb{C}$	$\Omega_E^2 \simeq \mathcal{O}_E$	1
Total before closure constraint		24

The closure condition modifies this count: a section $\sigma \otimes f(z)$ of the $H^{2,0}(S) \otimes \mathcal{O}_E$ summand is closed only when $d_E(f) = 0$, i.e. f is constant. The naive total of 24 is therefore an upper bound for the rank of the pushforward of closed 2-forms. The $H^{1,1}(S)$ sector (contributing 20 weight-1 currents) survives the closure condition, as its members are closed along S and the Ω_E^1 factor prevents a d_E -constraint.

PROPOSITION 26.22.21 (OPE structure of the pushforward;). The chiral algebra $\mathcal{A}_{\text{free}}$ is of Heisenberg/lattice type. Its OPE is determined by the propagator of the 6-dimensional theory pushed forward along S :

- (i) The 20 currents $J_a(z)$ from $H^{1,1}(S) \otimes \Omega_E^1$ have double-pole OPE:

$$J_a(z) J_b(w) \sim \frac{\eta_{ab}}{(z-w)^2},$$

where $\eta_{ab} = \int_S \omega_a \wedge \omega_b$ is the intersection form restricted to $H^{1,1}(S)$, of signature $(1, 19)$.

- (ii) The remaining generators (from $H^{2,0}$, $H^{0,2}$, $H^0(\mathcal{O}_S)$, $H^2(\mathcal{O}_S)$) have at most double-pole OPE.
 (iii) No poles of order ≥ 3 appear: the 6-dimensional theory is free with at most quadratic action.

In particular, $\mathcal{A}_{\text{free}}$ is a lattice vertex algebra V_Λ with Λ determined by the fiber cohomology surviving the closure constraint. By the Vol I lattice curvature theorem, $\kappa_{\text{ch}}^{\text{Heis}}(V_\Lambda) = \text{rank}(\Lambda)$ for any lattice VA, shadow class **G** (Gaussian, $r_{\text{max}} = 2$), and the shadow obstruction tower terminates: $\Theta_{\mathcal{A}_{\text{free}}} = \kappa_{\text{ch}}^{\text{Heis}} \cdot \omega_g$ at all genera (uniform-weight, class G; the scalar formula is exact because every chiral generator of $\mathcal{A}_{\text{free}}$ has the same conformal weight).

Remark 26.22.22 (The κ_{ch} -collapse: $\text{rank} \rightarrow \dim_{\mathbb{C}}$). The passage from the abelian $(2, 0)$ pushforward to the K_3 sigma model exhibits a non-perturbative collapse of the modular characteristic:

$$\kappa_{\text{ch}}^{\text{Heis}}(\mathcal{A}_{\text{free}}) = \text{rank}(\Lambda) \in \{22, 24\}, \quad \kappa_{\text{ch}}^{\text{Hodge}}(\mathcal{A}_{\sigma}) = 2 = \dim_{\mathbb{C}}(K_3).$$

This is not a small correction. No deformation of $\mathcal{A}_{\text{free}}$ within the class of lattice vertex algebras can produce $\kappa_{\text{ch}}^{\text{Hodge}} = 2$: the Vol I lattice curvature theorem gives $\kappa_{\text{ch}}^{\text{Heis}}(V_{\Lambda}) = \text{rank}(\Lambda)$ for all lattice VAs independent of deformation parameters. The $\mathcal{N} = 4$ supersymmetry constrains the genus-1 curvature to equal the complex dimension of the target, regardless of the free-field rank.

The three levels of structure are:

Object	Symbol	$\kappa_{\bullet}$	Class	Depth
Abelian $(2, 0)$ pushforward	$\mathcal{A}_{\text{free}}$	$\kappa_{\text{ch}} = \text{rank}(\Lambda) \in \{22, 24\}$	G	2
K_3 sigma model VOA	$\mathcal{A}_{\sigma}$	$\kappa_{\text{ch}}^{\text{Hodge}} = 2$	M	∞
BKM global	$G(K_3 \times E)$	$\kappa_{\text{BKM}}(\Delta_5) = 5$	M	∞

The BKM row records target arithmetic ($\kappa_{\text{BKM}}(\Delta_5) = \text{wt}(\Delta_5) = 5$, while $\text{wt}(\Phi_{10}^{\text{un}}) = 10$ for the dyonic square) extracted from the Borchers/Igusa side. The symbol $G(K_3 \times E)$ is the conditional comparison target attached to $\mathfrak{g}_{\Delta_5}$; it is available only after the hCS–Hall source map, the finite Hall–Borchers recognition conditions of Proposition 26.21.8, and the Drinfeld-centre assembly data are supplied. It is not produced by coefficient projection and not by functoriality of Φ_3 alone. The chain $\text{rank}(\Lambda) \rightarrow 2 \rightarrow 5$ reflects: (i) the $\mathcal{N} = 4$ SCA constraining κ_{ch} from rank to $\dim_{\mathbb{C}}$ (introducing $S_3, S_4 \neq 0$ and upgrading the shadow class from **G** to **M**); (ii) the passage from the single-copy chiral algebra ($\kappa_{\text{ch}}^{\text{Heis}} = 3 = \kappa_{\text{ch}}^{\text{Heis}}(K_3) + \kappa_{\text{ch}}^{\text{Heis}}(E) = 2 + 1$, by additivity) to the second-quantized BKM modular characteristic ($\kappa_{\text{BKM}}(\Delta_5) = 5$).

26.23 THE CALABI–YAU THREEFOLD $K_3 \times E$: GEOMETRY AND INVARIANTS

The K_3 chiral algebra has been built locally (Čech-glued from quiver charts, augmented by the $\mathcal{N} = 4$ SCA at $c = 6$). The CY_3 refinement $K_3 \times E$ adds an elliptic factor whose chiral data combine with K_3 's via Künneth. The geometric invariants below fix what the chiral combination must reproduce: Hodge ranks ($h^{p,q}(K_3 \times E)$), holomorphic Euler characteristic $\chi(\mathcal{O}_{K_3 \times E})$, and the lattice $H^*(K_3 \times E, \mathbb{Z})$ that the chiral algebra's modular characters will pair with.

Hodge diamond and topological invariants

PROPOSITION 26.23.1 (*Hodge diamond of $K_3 \times E$; .*). The Künneth formula gives the Hodge diamond of $K_3 \times E$ ($\dim_{\mathbb{C}} = 3$):

$$\begin{array}{ccccccc}
 & & & & \mathbf{I} & & \\
 & & & & \mathbf{I} & & \mathbf{I} \\
 & & & \mathbf{I} & & \mathbf{2I} & & \mathbf{I} \\
 & & \mathbf{I} & & \mathbf{2I} & & \mathbf{2I} & & \mathbf{I} \\
 & & \mathbf{I} & & \mathbf{2I} & & \mathbf{I} & & \\
 & & & & \mathbf{I} & & \mathbf{I} & & \\
 & & & & & & & & \mathbf{I}
 \end{array}$$

Key invariants:

- $h^{1,1} = h^{2,1} = 21$, giving $\chi(K_3 \times E) = 2(h^{1,1} - h^{2,1}) = 0$.
- Betti numbers: $b_0 = b_6 = 1$, $b_1 = b_5 = 2$, $b_2 = b_4 = 23$, $b_3 = 44$. Total: $\sum b_k = 96$.
- $K_0(K_3 \times E) \cong \mathbb{Z}^{48} (K_0(K_3) \otimes K_0(E) = \mathbb{Z}^{24} \otimes \mathbb{Z}^2)$.

Proof. Apply Künneth: $h^{p,q}(K_3 \times E) = \sum_{a+c=p, b+d=q} h^{a,b}(K_3) \cdot h^{c,d}(E)$. For example: $h^{1,1} = h^{1,1}(K_3) \cdot h^{0,0}(E) + h^{0,0}(K_3) \cdot h^{1,1}(E) = 20 + 1 = 21$. The alternating sum $1 - 2 + 23 - 44 + 23 - 2 + 1 = 0$ verifies $\chi = 0$. $\square$

HKR decomposition and deformation space

PROPOSITION 26.23.2 (*Deformation space of $D^b(K_3 \times E)$*). By the HKR isomorphism for a smooth CY 3-fold: $\mathrm{HH}^n(X) = \bigoplus_{p+q=n} h^{3-p,q}(X)$. For $K_3 \times E$:

$\mathrm{HH}^0 = 1$	automorphisms	$h^{3,0}$
$\mathrm{HH}^1 = 2$	outer derivations	$h^{3,1} + h^{2,0}$
$\mathrm{HH}^2 = 23$	first-order deformations	$h^{3,2} + h^{2,1} + h^{1,0}$
$\mathrm{HH}^3 = 44$	obstructions	$h^{3,3} + h^{2,2} + h^{1,1} + h^{0,0}$

The 23-dimensional deformation space: 21 complex structure (from $h^{2,1}$), 1 B-field (from $h^{1,0}$), 1 volume (from $h^{3,2}$). Serre duality on a CY 3-fold gives $\mathrm{HH}^n \cong \mathrm{HH}^{6-n}$, so $\mathrm{HH}^4 = 23$, $\mathrm{HH}^5 = 2$, $\mathrm{HH}^6 = 1$, and the full range $0 \leq n \leq 6$ has total $\dim \mathrm{HH}^* = 1 + 2 + 23 + 44 + 23 + 2 + 1 = 96$.

Noncommutative deformations and Brauer group

Remark 26.23.3 (*Brauer group of $K_3 \times E$*). $\mathrm{Br}(K_3 \times E) = \mathrm{Br}(K_3) \oplus \mathrm{Br}(E)$ contains $(\mathbb{Q}/\mathbb{Z})^{21}$ (K_3 at Picard rank $\rho = 1$) plus $\mathbb{Q}/\mathbb{Z}$ from E . The K_3 symplectic form provides the unique Poisson structure $\pi = \omega^{-1}$ (since $\dim H^0(\wedge^2 T_{K_3}) = 1$), but the E -direction carries none ($\wedge^2 T_E = 0$).

Autoequivalences and semiorthogonal structure

PROPOSITION 26.23.4 (*Indecomposability of $D^b(K_3 \times E)$*). $D^b(K_3)$ admits no proper semiorthogonal decomposition (Bridgeland, Kawamata, Huybrechts: $\omega_{K_3} = \mathcal{O}$ forces Serre functor [2], and the only fractional CY category with Serre [2] is $D^b(K_3)$ itself). Hence $D^b(K_3 \times E) = D^b(K_3) \otimes D^b(E)$ is indecomposable.

Autoequivalences: $\mathrm{Aut}(D^b(K_3)) \rightarrow O^+(H(K_3, \mathbb{Z}))$ via oriented Hodge isometries (line bundle twists, shifts, spherical twists T_E with $T_E^2 = [-2]$). $\mathrm{Aut}(D^b(E)) = (E \times E^\vee) \rtimes (\mathrm{SL}(2, \mathbb{Z}) \rtimes \mathbb{Z})$. The virtual dimension of all moduli problems on $K_3 \times E$ vanishes: $\mathrm{vdim} = -\chi(\mathcal{E}, \mathcal{E}) = 0$.

Factorization homology

Remark 26.23.5 (*Factorization homology on $K_3 \times E$*). The factorization homology of the HT-twisted sigma model: $\int_{K_3 \times E} A^{\mathrm{HT}} \simeq H^*(K_3 \times E, \Omega^{\mathrm{ch}})$. The CDR character gives $\chi(\Omega^{\mathrm{ch}}) = 0$, but the Hodge-graded character is nontrivial. $\dim \mathrm{HH}^*(D^b(K_3 \times E)) = 96$.

Torelli–GK Hodge-supertrace target for the Borchers weight $\kappa_{\mathrm{BKM}}(\Delta_5) = 5$

The paramodular cusp form $\Delta_5 \in S_5(\Gamma_2^{\mathrm{para}})$ has weight $5 = c_N(0)/2|_{N=1}$ with $c_1(0)$ the Fourier seed of the normalized singular-theta input $\phi_{0,1}$ (Gritsenko–Nikulin 1995 Pt II *Int. J. Math.* 9 Theorem 2.1; Borchers 1998 *Invent. Math.* 132 Theorem 13.3). The K_3 elliptic genus is $2\phi_{0,1}$ and gives the Igusa-square lane, not the primitive Δ_5 denominator. The proved source of $\kappa_{\mathrm{BKM}}(\Delta_5) = 5$ is this Borchers-lift construction. The chain-level Hodge-supertrace object below is a conditional Torelli–Getzler–Kapranov

pullback target for the same weight: if the Stage-1 modular-operadic supertrace identifies with $\bar{j}^* \Delta_5$, its weight coefficient is 5. It is not a fifth $\kappa_\bullet$ -invariant and not an independent derivation of $\kappa_{\text{BKM}}(\Delta_5)$ from the compact Hodge supertrace.

THEOREM 26.23.6 (*Atiyah class on $K_3 \times E$ is block-diagonal and Kapranov minimal model truncates*). Let $X = K_3 \times E$ with projections $p_1: X \rightarrow K_3$, $p_2: X \rightarrow E$. The Atiyah class of the holomorphic tangent bundle decomposes block-diagonally,

$$\text{At}(T_X) = p_1^* \text{At}(T_{K_3}) \oplus p_2^* \text{At}(T_E) \in H^1(X, \Omega_X^1 \otimes \text{End} T_X),$$

and the elliptic summand vanishes on the nose, $\text{At}(T_E) = 0$, because $T_E \simeq \mathcal{O}_E$ admits a flat translation-invariant holomorphic connection (Atiyah 1957 *Trans. AMS* 85 Theorem 1). Hence $\text{At}(T_X) = p_1^* \text{At}(T_{K_3})$. The Kapranov L_∞ -structure on $T_X[-1]$ (Kapranov 1999 *Compositio Math.* 115 Theorem 4.1) is therefore pulled back from K_3 ; by Bogomolov–Tian–Todorov unobstructedness of K_3 (Bogomolov 1978; Tian 1987; Todorov 1989) every higher bracket $\ell_n^{\min}$ for $n \geq 3$ vanishes on the minimal model pulled back from the K_3 factor.

Proof. Naturality of the 1-jet exact sequence $0 \rightarrow \Omega_X^1 \otimes T_X \rightarrow J^1(T_X) \rightarrow T_X \rightarrow 0$ along the Cartesian projections p_1, p_2 places the Atiyah class in the diagonal summand of $H^1(X_1 \times X_2, (\Omega^1 \otimes \text{End} T)_{X_1 \times X_2})$ under Künneth. Triviality of T_E trivialises its Atiyah class via any translation-invariant connection. Bogomolov–Tian–Todorov unobstructedness of K_3 forces every higher L_∞ bracket $\ell_n^{\min}$ for $n \geq 3$ on the minimal model of $\Omega^{\circ,*}(K_3, T_{K_3})$ to vanish. $\square$

PROPOSITION 26.23.7 (*Three Atiyah cocycles on $K_3 \times E$ are Hodge-disjoint; BCOV one-loop cancels via $\chi = 0$*). On $X = K_3 \times E$ the Atiyah class of T_X sources three cohomologically distinct cocycles, each in its own Hodge slot of the Dolbeault-polyvector diamond:

- (i) **Kapranov generator** $\text{At}(T_X) \in H^1(X, \Omega_X^1 \otimes \text{End} T_X)$ the L_∞ -bracket ℓ_2 (Kapranov 1999).
- (ii) **Tree-level Yukawa** $Y_3 = \ell_3^{\min} \in H^{\circ,3}(X) = H^3(X, \mathcal{O}_X)$ paired with the holomorphic volume form Ω_X to give a symmetric cubic form on $H^1(X, T_X)$ (Kapranov 1999 §4).
- (iii) **One-loop BCOV curving** $\alpha_{\text{BCOV}} = (\chi_{\text{top}}(X)/24) [\Omega_X]^{\circ,1} \in H^{\circ,1}(X)$ the BV anomaly of the Costello–Li BCOV action (Costello–Li 2016 arXiv:1605.09930 Proposition 5.2).

The three live in pairwise distinct Hodge bidegrees, so conflation is a Hodge-degree distinction. On $K_3 \times E$ the topological Euler characteristic is Künneth-multiplicative, $\chi_{\text{top}}(K_3 \times E) = \chi_{\text{top}}(K_3) \cdot \chi_{\text{top}}(E) = 24 \cdot 0 = 0$, so

$$\alpha_{\text{BCOV}}(K_3 \times E) = \frac{\chi_{\text{top}}(K_3 \times E)}{24} [\Omega_X]^{\circ,1} = 0,$$

and the BV quantisation of the BCOV action admits no one-loop obstruction from the $(0,1)$ -curving slot.

Proof. Hodge bidegree counting: $(0,1)$ -with- $\text{End} T$ -coefficients, $(0,3)$, and $(0,1)$ -without- End -coefficients are three distinct receptacles in the Dolbeault-polyvector diamond; Serre duality pairs $H^{\circ,3}(X) \cong H^0(X, \Omega_X^3)^\vee$ with the volume form Ω_X , and pairs $H^{\circ,1}(X) \cong H^1(X, \Omega_X^3)^\vee$ after tensoring by ω_X . All three are sourced by $\text{At}(T_X)$ via derived compositions but do not collapse to a single class. The BCOV cancellation follows from the Künneth computation $\chi_{\text{top}}(K_3 \times E) = 24 \cdot 0 = 0$ and the Costello–Li BCOV formula $\alpha_{\text{BCOV}} = (\chi/24) [\Omega]^{\circ,1}$. $\square$

Remark 26.23.8 (Hodge diamond pointwise data). The Hodge-supertrace column of $K_3 \times E$ reads $(h^{\circ,0}, h^{\circ,1}, h^{\circ,2}, h^{\circ,3}) = (1, 1, 1, 1)$ (Künneth of K_3 diamond $(1, 0, 1)$ with E diamond $(1, 1)$); its alternating sum is $\sum_q (-1)^q h^{\circ,q}(K_3 \times E) = 1 - 1 + 1 - 1 = 0 = \chi(\mathcal{O}_{K_3 \times E}) = \kappa_{\text{ch}}^{\text{Hodge}}(K_3 \times E) = \kappa_{\text{cat}}(K_3 \times E)$. This pointwise vanishing of the compact Hodge supertrace is *not* the Borchers weight of $\mathfrak{g}_{\Delta_5}$: $\kappa_{\text{BKM}}(\Delta_5) = 5$ is carried by the $\overline{\mathcal{M}}_{2,0}$ -fibration of the supertrace twisted by the Hodge line bundle $\mathcal{L}$, not by the pointwise scalar.

Definition 26.23.9 (Chain-level Hodge-supertrace integrand). Let $B_3^{E_3}(\Phi_3^{\text{FA}}(\text{Coh}(K_3 \times E)))$ be the bar complex of the canonical Stage-1 E_3 -holomorphic factorisation algebra on $X = K_3 \times E$. Its cyclic E_3 -structure (from the CY-3 Serre pairing) assembles into a Getzler–Kapranov modular envelope (Getzler–Kapranov 1998 *Compositio Math.* 110 §3, §6; Costello 2007 *Adv. Math.* 210 Theorem A), producing for each stable (g, n) a chain complex $\text{GK}_{g,n}(X)$ over $\overline{\mathcal{M}}_{g,n}$. The *chain-level Hodge-supertrace integrand* at genus two is

$$I_{\text{GK},2}^{\text{Hodge}}(K_3 \times E) := \text{str}(\text{GK}_{2,0}(X) \otimes_{\overline{\mathcal{M}}_{2,0}} \mathcal{L}^{\wedge 5}) \in H^\bullet(\overline{\mathcal{M}}_{2,0}, \mathcal{L}^{\wedge 5}),$$

with $\mathcal{L}$ the Hodge line bundle on $\overline{\mathcal{M}}_{2,0}$. The exponent 5 is the automorphic Borchers weight appearing in the Torelli–GK comparison of Theorem 26.23.II.

Remark 26.23.10 (Why genus two, why weight five). Selection of $(g, n) = (2, 0)$ is forced by the Howe dual pair $(O(2, 2), \text{Sp}_4)$ of Howe 1979 *Proc. Sympos. Pure Math.* 33 §5: the Borchers lift of $\phi_{0,1}$ carries a Jacobi form of signature $(2, 2)$ through the dual pair onto Sp_4 -automorphic output, *not* onto Sp_6 or higher. Higher-genus $\overline{\mathcal{M}}_{g,0}$ fibres of the Getzler–Kapranov envelope encode different BKM algebras via different Howe-dual inputs; they are structurally decoupled from $\mathfrak{g}_{\Delta_5}$. The exponent 5 on the Hodge bundle is pinned by the automorphic Borchers weight and becomes a chain-level statement through the Torelli–GK comparison of Theorem 26.23.II.

THEOREM 26.23.II (Conditional Torelli–GK pullback target for Δ_5). Let $X = K_3 \times E$, let $\tilde{j}: \overline{\mathcal{M}}_{2,0} \dashrightarrow \overline{\mathcal{A}}_2$ denote the Torelli map from the Deligne–Mumford moduli of genus-two stable curves to the Satake compactification of the moduli of principally polarised abelian surfaces, let $\mathcal{L}$ be the Hodge line bundle, let Φ_3^{FA} be the Stage-1 canonical E_3 -holomorphic factorisation algebra functor of the two-stage factorisation $\Phi_3 = \text{Sp}_{\Sigma_2, C}^{\text{ch}} \circ \Phi_3^{\text{FA}}$, and let $I_{\text{GK},2}^{\text{Hodge}}(X)$ be the chain-level Hodge-supertrace integrand of Definition 26.23.9. Assume that the Stage-1 modular-operadic supertrace comparison from the GK integrand to the Borchers line on $\overline{\mathcal{A}}_2$ has been constructed on the fixed H1–H4 branch, with the compact CY₃ closure input of either $B_{\text{TCFT}}^{(2)}$ or the filtered $HH_{E_1}^{-2}$ theorem, and that this comparison matches the Gritsenko–Nikulin divisor and leading coefficient. Then

- (i) $I_{\text{GK},2}^{\text{Hodge}}(X) = \tilde{j}^* \Delta_5$ as a section of $\mathcal{L}^{\wedge 5}$ on $\overline{\mathcal{M}}_{2,0}$, where $\Delta_5 \in S_5(\Gamma_2^{\text{para}})$ is the Gritsenko–Nikulin paramodular cusp form of weight 5.
- (ii) The chain-level Hodge-supertrace coefficient

$$a_{\text{Hodge} \rightarrow \text{BKM}}(\mathfrak{g}_{\Delta_5}) := \text{wt}(I_{\text{GK},2}^{\text{Hodge}}(K_3 \times E)) = \text{wt}(\Delta_5) = 5,$$

coincides with the automorphic Borchers weight on this comparison locus.

- (iii) The equality $a_{\text{Hodge} \rightarrow \text{BKM}} = c_N(0)/2|_{N=1} = 10/2 = 5$ holds for the Fourier seed $c_1(0)$ of the normalized singular-theta input $\phi_{0,1}$; the K_3 elliptic genus is $2\phi_{0,1}$, but the paramodular denominator uses the half-genus normalization. This matches the universal Borchers weight identity $\kappa_{\text{BKM}}(\Phi_N) = c_N(0)/2$ at $N = 1$ (Theorem 32.8.1 of Chapter 32).

Proof. The automorphic part is unconditional. The Borcherds singular-theta lift (Borcherds 1998 Theorem 13.3) carries the Jacobi form $\phi_{o,1} \in J_{o,1}(\Gamma_o(1))$ under the $(O(2, 2), \mathrm{Sp}_4)$ Howe dual pair to a paramodular cusp form of weight $c(o)/2$ on $\mathrm{Sp}_4(\mathbb{Z})$; Gritsenko–Nikulin 1995 Pt II Theorem 2.1 identifies the output with Δ_5 of weight 5. Bruinier 2002 *Lecture Notes Math.* 1780 Proposition 5.1 and Example 5.3 give the same Hodge-line exponent by Heegner Chern-class reciprocity, and the K_3 elliptic-genus seed has $c_1(o) = 10$.

The chain-level assertion is exactly the stated comparison hypothesis. Under that hypothesis the genus-two Getzler–Kapranov supertrace lands in $\tilde{j}^* H^o(\overline{\mathcal{A}}_2, \mathcal{L}^{\wedge 5})$ with the same divisor and leading coefficient as the Gritsenko–Nikulin section. The one-dimensionality of the normalised Borcherds line on this locus then identifies the image with $\tilde{j}^* \Delta_5$. Thus the GK equality is a conditional bridge statement, while the numerical Borcherds value $\kappa_{\mathrm{BKM}}(\Delta_5) = c_1(o)/2 = 5$ is already proved by the automorphic denominator theorem. $\square$

PROPOSITION 26.23.12 (*Two automorphic proofs and one conditional bridge for $\kappa_{\mathrm{BKM}}(\Delta_5) = 5$*). The equality $\kappa_{\mathrm{BKM}}(\Delta_5) = 5$ has two independent primary-literature derivations and one conditional chain-level GK–Torelli consistency comparison converging on the same number:

Path 1 (conditional Hodge-supertrace comparison). Theorem 26.23.11: chain-level Getzler–Kapranov modular-operadic pairing on $\overline{\mathcal{M}}_{2,o}$, Torelli-pulled to $\overline{\mathcal{A}}_2$ and identified with Δ_5 after the modular-operadic comparison and compact CY_3 closure inputs are supplied. The Hodge line-bundle exponent is then 5.

Path 2 (Gritsenko additive lift). Gritsenko–Nikulin 1995 Pt I *Int. J. Math.* 9 Theorem 1.3 constructs Δ_5 from the normalized Jacobi input $\phi_{o,1}$; in the additive convention the corresponding constant term gives weight 5.

Path 3 (Bruinier Heegner Chern-class reciprocity). Bruinier 2002 *Lecture Notes Math.* 1780 Proposition 5.1, Example 5.3: the Borcherds Chern-class reciprocity $c_1(\mathrm{BL}_\Theta(\phi_{o,1})) = 5 \cdot c_1(\mathcal{L})$ reads the weight off the Heegner divisor sum on the orthogonal Shimura variety $\mathcal{A}_2^{\mathrm{para}}$.

The two automorphic paths are independent of the chain-level GK–Torelli comparison; all three share the primary-literature input that Δ_5 is the Borcherds lift of $\phi_{o,1}$ (Lorgat 2020 reproduces the explicit construction). The proved conclusion is the Borcherds value $\kappa_{\mathrm{BKM}}(\Delta_5) = 5$; the genus-two chain-level Hodge supertrace remains a conditional comparison class until the comparison and compact closure inputs are constructed.

Proof. Path 1 is the conditional comparison theorem 26.23.11. Path 2 is Gritsenko–Nikulin 1995 Pt I Theorem 1.3 and Gritsenko 1999 *Abh. Math. Sem. Hamburg* 69 §3. Path 3 is Bruinier 2002 §5. The independence claim applies to the two automorphic proofs and to the chain-level comparison construction: the latter depends on E_3 -formality, the Getzler–Kapranov modular envelope, and the projected K_3 period correspondence; the automorphic paths depend respectively on additive theta-series and Heegner divisors. $\square$

Remark 26.23.13 (*Object-level chain-level comparison*). Theorem 26.23.11 is an object-level chain-level comparison target on the specific CY datum $K_3 \times E$: it requires the specific chain complex $B^{E_3}(\Phi_3^{\mathrm{FA}}(\mathrm{Coh}(K_3 \times E)))$, the specific Hodge decomposition of $K_3 \times E$, and the specific Borcherds lift of $\phi_{o,1}$. No morphism-preservation of Φ_3^{FA} across CY_3 inputs is required, no $(\infty, 1)$ -categorical functoriality is invoked, and the enhancement to Φ_3^{FA} -as-functor on $(\infty, 1)$ -categories of CY data is

orthogonal. The comparison target above is conditional on the Torelli–GK identification and does not define a new $\kappa_\bullet$ -invariant.

Twenty-four curve-stalks, not twenty-four $\mathbb{C}^3$ -points

The locality of the $K_3 \times E$ chiral datum refers to the *curve-stalks* of the elliptic Kodaira fibration on K_3 pulled back to $K_3 \times E$, not to 24 smooth $\mathbb{C}^3$ -points. Conflating the two produces a toric-quiver skeleton where a curve-fibration belongs; it undercounts the local dimension of the protected sector by one.

PROPOSITION 26.23.14 (*Kodaira I_1 curve-stalks on $K_3 \times E$*). Let $\pi : K_3 \rightarrow \mathbb{P}^1$ be a generic elliptic fibration (étale-generic K_3 lattice-polarised by U ; Huybrechts 2016, *Lectures on K_3* , Chapter 11). Kodaira’s canonical divisor formula gives $\chi_{\text{top}}(K_3) = \sum_p \chi_{\text{top}}(F_p) = 24$, with 24 singular fibres $F_p = I_1$ (each a nodal rational curve). On the CY₃ $Y = K_3 \times E$ with second projection $\text{pr}_E : Y \rightarrow E$ suppressed, the discriminant locus $\Delta \subset \mathbb{P}^1$ of $\pi \circ \text{pr}_1$ consists of 24 points and pulls back to 24 curve-stalks

$$F_p \times E \subset K_3 \times E, \quad p \in \Delta, \quad |\Delta| = 24,$$

each a nodal elliptic curve $I_1 \times E$ of complex dimension 2; the *union* is a divisor of class $\pi^*[\text{pt}] \cdot 24 + \text{pr}_E^*[\text{pt}] \cdot 0 = 24 \cdot [F] \times E$ with $[F]$ the class of a generic elliptic K_3 fibre.

Attribution. Kodaira 1963 (*Ann. Math.* 77:563); Miranda 1989 (*The basic theory of elliptic surfaces*, Dottorato di Ricerca, Pisa) classifies singular fibres; the sum $\sum \chi_{\text{top}}(F_p) = c_2(K_3) = 24$ is the topological Euler-characteristic relation for a smooth elliptic K_3 . Base-change via pr_E preserves fibre type; $F_p \times E$ is of complex dimension 2 since $\dim F_p = 1$ and $\dim E = 1$. $\square$

PROPOSITION 26.23.15 (*Curve-stalk positive-half firewall*). The 24 singular pieces of $K_3 \times E$ are $I_1 \times E$ curve-stalks, not toric $\mathbb{C}^3$ vertices. A toric $\mathbb{C}^3$ -point carries the critical CoHA

$$\text{CoHA}(\mathbb{C}^3) \cong Y^+(\widehat{\mathfrak{gl}}_1),$$

the positive half of the affine Yangian; the full affine Yangian, its centre, and the $\mathcal{W}_{1+\infty}$ vacuum module appear only after the Drinfeld double/centre/vacuum passage. An $I_1 \times E$ curve-stalk carries a 2-dimensional nodal model whose quiver is the A_1 Dynkin quiver with a loop at each node, and whose Yangian is $Y(\widehat{\mathfrak{sl}}_2)^E$ -coupled, not $Y(\widehat{\mathfrak{gl}}_1)$ on 24 copies. The local algebra at the Kodaira node $F_p \cap E_q$ of the $I_1 \times E$ stalk is

$$\mathcal{O}_{F_p \times E, (p,q)} \simeq \mathbb{C}[[x_1, x_2, z]]/(x_1 x_2), \quad z \in T_q E,$$

a two-sheet crossing times a smooth curve, *not* $\mathbb{C}^3$. The chiral-datum counts factorise as (K₃-fibre contribution) $\otimes_{\mathbb{C}}$ (E-contribution), not as 24 copies of a three-dimensional local model.

Proof. The completed local ring of a nodal Kodaira fibre is $\mathbb{C}[[x_1, x_2]]/(x_1 x_2)$; base-change along the elliptic factor tensors this ring with $\mathbb{C}[[z]]$. Its singularity category is therefore the A_1 surface node transported along a smooth curve. The Jordan-quiver cubic potential giving $\text{CoHA}(\mathbb{C}^3)$ is absent: there is no regular completed local ring $\mathbb{C}[[x, y, z]]$ and no isolated toric fixed point. Schiffmann–Vasserot identify the toric critical CoHA with $Y^+(\widehat{\mathfrak{gl}}_1)$; the vacuum $\mathcal{W}_{1+\infty}$ module is obtained only after adjoining the opposite half and evaluating the centre. Hence replacing the 24 curve-stalks by 24 copies of $\mathbb{C}^3$ changes both the singularity category and the algebra half. $\square$

PROPOSITION 26.23.16 (*Quasi-NCCR character under finite Rees and compact hCS–Hall hypotheses*). Let $X = K_3 \times E$. There is no global Van den Bergh NCCR on X . Assume instead the following data.

- (i) A Serre-equivariant finite Rees quasi-NCCR datum $\mathcal{A}_X^{\text{qNCCR}}$ in the sense of Definition 26.21.7.
- (ii) A compact hCS–Hall trivialisation $\mathfrak{o}_{\text{hCS} \rightarrow \text{Hall}}^{\text{comp}}(X) = \mathfrak{o}$ in the sense of Definition 26.21.6.
- (iii) The compact CY_3 closure input: either the corrected TCFT carrier $B_{\text{TCFT}}^{(2)}$ for the second-order bracket comparison, or a complete exhaustive separated strongly convergent filtration theorem proving $HH_{E_i}^{-2} = \mathfrak{o}$ for the compact bar complex.
- (iv) A reduced character map

$$\Theta_{\text{qNCCR} \rightarrow \text{DT}}^{K_3 \times E}: K_0\left(\text{Perf}(\mathcal{A}_X^{\text{qNCCR}})\right)_{\Lambda_{\text{II}}^{2,1}} \longrightarrow \mathbb{Z}[[q, \tilde{q}, y^{\pm 1}]]$$

compatible with K_3 -cosection reduction and Hall integration.

Write OP for the Oberdieck–Pandharipande/Oberdieck reduced PT/DT scalar normalisation and OPi for the Oberdieck–Pixton stability component. The theta-normalised primitive section and the OP monic square are

$$D_5 = 64^{-1} \Delta_5, \quad \Phi_{10}^{\text{OP}} = D_5^2 = 4096^{-1} \Delta_5^2.$$

Then the reduced character is the OP/DT scalar

$$\chi(\mathcal{A}_X^{\text{qNCCR}})(q, \tilde{q}, y) = -(\Phi_{10}^{\text{OP}}(\tau, z, \sigma))^{-1} = -D_5^{-2} = -4096 \Delta_5^{-2},$$

equal to the Behrend-weighted reduced Donaldson–Thomas scalar partition function in this normalisation. The primitive BKM denominator remains the Gritsenko–Nikulin Δ_5 datum, with monic denominator section $D_5(2Z) = 64^{-1} \Delta_5(2Z)$ for $\mathfrak{g}_{\Delta_5}$; the OP/DT square forgets the orientation character and does not by itself construct the compact critical CoHA or identify the finite radical-quotient Hall–Drinfeld double with the Borchers current quotient. The Fake-Monster form Φ_{12} belongs to the $d = 5$ Borchers lift on $\text{II}_{25,1}$ and is not a normalisation of the $K_3 \times E$ scalar.

The obstruction to a global NCCR has one decisive tilting obstruction and four failed production routes:

- (a) $\omega_{K_3 \times E} = \mathcal{O}$, but the trace splitting $\text{End}(T) \rightarrow \mathcal{O}_X$ forbids a global reflexive tilting generator: $\text{Ext}^{>0}(T, T) = \mathfrak{o}$ would force $H^{>0}(X, \mathcal{O}_X) = \mathfrak{o}$, whereas $H^1(E, \mathcal{O}_E)$ and $H^2(K_3, \mathcal{O}_{K_3})$ survive in $H^{>0}(X, \mathcal{O}_X)$.
- (b) The derived McKay route (Bridgeland–King–Reid 2001) requires a finite group acting linearly with a fixed point; the K_3 lattice autoequivalences and the elliptic translations are not such a global orbifold datum.
- (c) The HPD route (Kuznetsov 2007) does not respect the product polarisation: the HPD base change along pr_E distinguishes polarisations on K_3 and $K_3 \times E$.
- (d) The Mukai-rigidity route does not globalise off the K_3 factor:

$$\text{Ext}_{K_3 \times E}^1(\mathcal{F} \boxtimes \mathcal{O}_E, \mathcal{F} \boxtimes \mathcal{O}_E) = \text{Ext}_{K_3}^1(\mathcal{F}, \mathcal{F}) \oplus H^1(E, \mathcal{O}_E) \neq \mathfrak{o}.$$

- (e) The finite critical-chart route is local but not global. The derived stack $\text{RPerf}(K_3 \times E)$ has the global (-1) -shifted symplectic form of PTVV, and the classical truncations carry the Thomas–Behrend–Fantechi symmetric obstruction theory. Brav–Bussi–Joyce Darboux charts do not supply a single

finite algebra $\text{End}(T)$ whose representation stack globalises those charts and whose orientation is invariant under K_3 spherical-twist monodromy.

Proof. NCCR obstruction. The trace-splitting argument in (a) proves the non-existence of a global reflexive tilting generator. The remaining items record the standard construction mechanisms which do not evade that obstruction (Van den Bergh 2004, *Duke* 122, §3; Bridgeland–King–Reid 2001, *JAMS* 14; Kuznetsov 2007, *Adv. Math.* 210; Mukai 1987, *Nagoya Math. J.* 106; Pantev–Toën–Vaquié–Vezzosi 2013, *Publ. IHÉS* 117).

Finite Rees descent. Seidel–Thomas 2001 (*Duke* 108, §3) construct spherical twist autoequivalences T_E on $D^b(K_3)$; pulled back along $\text{pr}_1: K_3 \times E \rightarrow K_3$ they supply the local tilting pieces on the complement of the 24 curve-stalks. At each curve-stalk $F_p \times E$ the tilting piece degenerates by one order. The finite Rees datum records this degeneration by the truncated algebras $\text{Rees}_{\leq N}^D(A_\alpha)$ and asks for the Morita defects $\mathfrak{o}_{\text{Rees}}^{(2)}$ and $\mathfrak{o}_{\text{Rees}}^{(3)}$ to vanish. Thus the quasi-NCCR input is exactly the finite Rees descent datum, not a consequence of spherical twists alone.

Compact hCS–Hall map. The trivialisation $\mathfrak{o}_{\text{hCS} \rightarrow \text{Hall}}^{\text{comp}}(X) = 0$ identifies the local BV traces and Hall integrations on the Čech nerve. The compact closure input supplies the missing second-order TCFT or filtered $HH_{E_1}^{-2}$ vanishing needed to promote those traces to compact Hall brackets. Without these data the construction stops at a local positive-half character and cannot be promoted to compact Hall brackets.

OP/DT scalar. After applying $\Theta_{\text{qNCCR} \rightarrow \text{DT}}^{K_3 \times E}$, the derived character on the BPS lattice $\Lambda_{\text{II}}^{2,1}$ is the generating function of Ext^* -graded dimensions of the Rees-glued tilting object, evaluated against $(q, \tilde{q}, y)$. Oberdieck–Pandharipande 2016 (arXiv:1411.1514, Theorem 1) and Oberdieck’s reduced DT theorem identify this scalar with $-(\Phi_{10}^{\text{OP}})^{-1}$. With $D_5 = 64^{-1}\Delta_5$ and $\Phi_{10}^{\text{OP}} = D_5^2 = 4096^{-1}\Delta_5^2$, the scalar is $-4096 \Delta_5^{-2}$.

Primitive denominator. Gritsenko–Nikulin 1998 (arXiv:alg-geom/9611028; see also [108]) supply the primitive BKM denominator algebra $\mathfrak{g}_{\Delta_5}$ with denominator section $D_5(2Z) = 64^{-1}\Delta_5(2Z)$ and Borchers weight $\kappa_{\text{BKM}}(\Delta_5) = 5$. Squaring to the OP/DT scalar changes the scalar partition function and the weight-10 Igusa square; it does not change the primitive BKM denominator and does not introduce Φ_{12} . $\square$

Remark 26.23.17 (Cartan rank of the Δ_5 BKM). The Cartan lattice of the primitive Δ_5 Borchers algebra in the $K_3 \times E$ lane is the rank-3 hyperbolic lattice $\Lambda_{\text{II}}^{2,1}$. It is not the quotient $\text{II}_{4,20}/U$ and it receives no Leech addback. The quotient $\text{II}_{4,20}/U \simeq \text{II}_{3,19}$ is the transverse K_3 middle-cohomology lattice of rank 22; the full Mukai lattice has rank 24 and lives on the fibre-Heisenberg axis. The Leech lattice belongs to the Fake-Monster lane on $\text{II}_{25,1}$, hence to a different Borchers input.

Remark 26.23.18 (Humbert divisor H_1 monodromy order $8 = 2c_+ \nu(\mu_0)$ with $c_+ = 4$). The Humbert divisor $H_1 \subset \overline{\mathcal{A}}_2$ of discriminant 1 parametrises principally polarised abelian surfaces that split as products $E_1 \times E_2$ of two elliptic curves (Gritsenko–Nikulin 1998, *Int. J. Math.* 9, §2); around this divisor the Δ_5 -automorphic $\mathcal{D}$ -module $\mathcal{L}^{\Delta_5}$ carries local monodromy of order 8. The order decomposes as

$$8 = 2 \cdot c_+ \cdot \nu(\mu_0), \quad c_+ = 4, \quad \nu(\mu_0) = 1,$$

with $c_+ = c_+(\tilde{H}(K_3, \mathbb{Z})) = 4$ the positive-signature rank of the Mukai lattice and $\nu(\mu_0) = 1$ the multiplicity of the fundamental Humbert eigenvalue. The signature $(4, 20)$ of $\tilde{H}(K_3, \mathbb{Z}) = H^0 \oplus H^2 \oplus H^4 \cong U^{\oplus 4} \oplus (-E_8)^{\oplus 2}$ decomposes additively through the Hodge structure as

$$(1, 1)_{H^0 \oplus H^4} \oplus (2, 0)_{(H^{2,0} \oplus H^{0,2})_{\mathbb{R}}} \oplus (1, 19)_{H_{\mathbb{R}}^{1,1}},$$

where: the hyperbolic plane $U \cong H^0 \oplus H^4$ under the off-diagonal Mukai pairing $\langle (r_1, s_1), (r_2, s_2) \rangle = -r_1 s_2 - r_2 s_1$ contributes $(1, 1)$; the real slice $(H^{2,0} \oplus H^{0,2})_{\mathbb{R}}$ spanned by $\operatorname{Re}(\omega_{K_3})$ and $\operatorname{Im}(\omega_{K_3})$ is positive-definite of dimension 2 via the Kähler identity $\int_{K_3} \omega \wedge \bar{\omega} > 0$; $H_{\mathbb{R}}^{1,1}$ under the cup product has signature $(1, 19)$ with the one positive direction being the Kähler class. Summing the positive contributions gives $c_+ = 1 + 2 + 1 = 4$. Under the Mukai Hodge involution ι_{Muk} (fixing $H^0 \oplus H^{1,1} \oplus H^4$, flipping $H^{2,0} \oplus H^{0,2}$) the $+1$ -eigenspace has signature $(2, 20)$ and the -1 -eigenspace has signature $(2, 0)$; the four positive Mukai directions thus split $2 + 2$ across the two ι_{Muk} -eigenspaces. The prefactor 2 is the $\operatorname{Sp}_4 \rightarrow \operatorname{SO}_+(\Lambda^{3,2})$ double cover. The comparison with Bruinier's Heegner Chern-class formula and with a Lusztig order is separate data.

The same integer 8 is the bar-cobar complementarity value on the $\mathcal{B}$ -family:

$$K_{\mathcal{B}}^{\text{comp}} := 2c_+(\operatorname{Mukai}(K_3)) = 8 \in \{0, 8, 13, 250/3, 98/3\},$$

where $K_{\mathcal{B}}^{\text{comp}}$ denotes the paired derived-centre complementarity conductor and the bucket $\{0, 8, 13, 250/3, 98/3\}$ is the canonical five-archetype G/L/C/M/B ceiling. The $\mathcal{B}$ -row is the Mukai-enhanced K_3 Heisenberg derived-centre complementarity; the Chern-class reciprocity route is recorded in Chapter 20, Theorem 20.14.4.

26.2.4 ENUMERATIVE GEOMETRY OF $K_3 \times E$

Gromov–Witten theory and BPS invariants

Remark 26.24.1 (Reduced GW theory on K_3). For K_3 , the standard virtual class vanishes for $\beta \neq 0$ (cosection from $H^{2,0}(K_3) = \mathbb{C}$). The reduced theory (Bryan–Leung, Maulik–Pandharipande–Thomas) removes this obstruction. The KKV formula (proved by Pandharipande–Thomas 2016) gives the BPS state counts. The genus-0 BPS invariants satisfy the Yau–Zaslow formula:

$$\sum_{h \geq 0} n_h^0 q^h = \prod_{n \geq 1} \frac{1}{(1 - q^n)^{24}}.$$

PROPOSITION 26.24.2 (*BPS invariants of K_3*). Selected BPS invariants (all integers, proved by Pandharipande–Thomas 2016):

h	0	1	2	3	4	5	6	7
n_h^0	1	24	324	3200	25650	176256	1073720	5930496
n_h^1	0	-2	-54	-800	-8550	-73440	-536860	-3464264
n_h^2	0	0	3	104	1701	19656	176358	1316808
n_h^3	0	0	0	-4	-155	-2832	-34470	-320320

Signed convention: $n_h^g = (-1)^g |n_h^g|$. The genus-0 values are the Yau–Zaslow numbers (OEIS A006922); $n_1^0 = 24 = \chi_{\text{top}}(K_3)$. The Hilbert scheme Euler characteristics $\chi(\operatorname{Hilb}^n(K_3))$ provide the genus-0 column: $\chi(\operatorname{Hilb}^n) = n_h^0$, with generating function $\sum_{n \geq 0} \chi(\operatorname{Hilb}^n) q^n = \prod_{k \geq 1} (1 - q^k)^{-24}$ (Göttsche formula). The first eight values are 1, 24, 324, 3200, 25650, 176256, 1073720, 5930496.

Bridgeland stability on K_3

Remark 26.24.3 (Stability conditions). $\operatorname{Stab}^{\dagger}(K_3) \rightarrow P^+(K_3)$ is a covering of the period domain (Bridgeland 2008). Walls of marginal stability for Mukai vectors $v = v_1 + v_2$ are semicircles in the (B, ω) -plane; crossing them applies the KS wall-crossing. For primitive v with $v^2 = 2n - 2$: $\Omega(v) = \chi(\operatorname{Hilb}^n(K_3))$.

26.25 BPS SPECTRUM AND BLACK HOLE ENTROPY

The Hodge data and topological invariants of $K_3 \times E$ fix the geometric stage. The chiral algebra $\mathcal{A}_{K_3 \times E}$ must encode these invariants and the BPS spectrum of Type IIA compactified on $K_3 \times E$: $\frac{1}{4}$ -BPS dyons whose degeneracies are organised by the unnormalised Igusa square $\Phi_{10}^{\text{un}} = \Delta_5^2$ (DVV; (26.7) below). The arithmetic of the charge lattice $\Gamma = H^{\text{even}}(K_3 \times E, \mathbb{Z})$, the Cardy growth of black-hole entropy, and the Rademacher expansion of $1/\Phi_{10}^{\text{un}}$ together pin the modular content the chiral algebra must reproduce.

Charge lattice and BPS states

The lattice on which the Igusa form acts must be specified before the BPS spectrum can be tabulated. We record its generators and intersection form.

PROPOSITION 26.25.1 (*Charge lattice*). Type IIA on $K_3 \times E$ gives 4d $\mathcal{N} = 4$ supergravity with 22 vector multiplets. The D-brane charge lattice $\Gamma = H^{\text{even}}(K_3 \times E, \mathbb{Z})$:

Cohomology	Brane type	Rank
$H^0 = \mathbb{Z}$	D6-branes	1
$H^2 = \mathbb{Z}^{23}$	D4-branes	23
$H^4 = \mathbb{Z}^{23}$	D2-branes	23
$H^6 = \mathbb{Z}$	Do-branes	1

Total: rank $\Gamma = 48$.

Black hole entropy from $1/\Phi_{10}^{\text{un}}$

PROPOSITION 26.25.2 (*BMPV and $\frac{1}{4}$ -BPS entropy*). In 5d (IIA on $K_3 \times S^1$): the BMPV black hole with charges (Q_1, Q_5, n) has $S_{\text{BH}} = 2\pi\sqrt{Q_1 Q_5 n}$ (Cardy with $c_L = 6 Q_1 Q_5$). In 4d (IIA on $K_3 \times T^2$): the $\frac{1}{4}$ -BPS dyon with discriminant Δ has

$$S_{\text{BH}} = 4\pi\sqrt{\Delta},$$

and the DVV formula $Z_{1/4\text{-BPS}} = 1/\Phi_{10}^{\text{un}}$ ((26.7)) gives the exact microscopic count. For large Δ : $\log d(\Delta) \sim 4\pi\sqrt{\Delta} - \frac{3}{2}\log \Delta + \dots$, where the subleading term is the universal one-loop correction (Sen 2005, 2012). The asymptotic expansion is the leading term of the Rademacher exact formula for the Fourier coefficients of $1/\Phi_{10}^{\text{un}}$:

$$d(\Delta) = \frac{2\pi}{\sqrt{\Delta}} \sum_{c=1}^{\infty} \frac{K(c, \Delta)}{c} I_{27/2}\left(\frac{4\pi\sqrt{\Delta}}{c}\right) + \text{polar contributions},$$

where $I_{27/2}$ is the modified Bessel function of the first kind of order $27/2$ and $K(c, \Delta)$ is a Kloosterman-type sum over $\text{Sp}(4, \mathbb{Z})$. The $c = 1$ term dominates at large Δ . Combining the Bessel asymptotic $I_{27/2}(z) \sim e^z / \sqrt{2\pi z}$ at $z = 4\pi\sqrt{\Delta}$ with the $1/\sqrt{\Delta}$ Rademacher prefactor and the one-loop measure on the polar contour ($\text{Sp}(4, \mathbb{Z})$ stationary-phase determinant) gives $d(\Delta) \sim e^{4\pi\sqrt{\Delta}} \cdot \Delta^{-3/2}$, matching $\log d(\Delta) \sim 4\pi\sqrt{\Delta} - \frac{3}{2}\log \Delta$. The convergence of the Rademacher series is exponentially fast: the $c = 2$ correction is suppressed by $e^{-2\pi\sqrt{\Delta}}$ relative to the leading term.

Remark 26.25.3 (*OSV conjecture*). The Ooguri–Strominger–Vafa relation $Z_{\text{BH}} = |Z_{\text{top}}|^2$ connects the black hole partition function to the topological string. For $K_3 \times E$, the topological string is exactly solvable at genus 0 and 1. The shadow tower gives $F_g = 3 \cdot \lambda_g^{\text{FP}}$ at each genus, exact at $g = 1$ and with multi-weight cross-channel correction $\delta F_g^{\text{cross}}$ at $g \geq 2$ (Vol I).

Fourier–Jacobi as genus escalation

PROPOSITION 26.25.4 (*Bridge: elliptic R -matrix data determines BKM root system*). The Fourier–Jacobi expansion of the unnormalised Igusa cusp form $\Phi_{10}^{\text{un}}(\Omega) = \sum_{m \geq 1} \phi_m(\tau, z) p^m$ uses Jacobi forms $\phi_m(\tau, z)$ on E_τ . The leading coefficient

$$\phi_1(\tau, z) = \eta(\tau)^{18} \mathfrak{J}_1(\tau, z)^2$$

is built from the same theta function $\mathfrak{J}_1(\tau, z)$ that defines the elliptic propagator $d \log \mathfrak{J}_1(z|\tau)$ ((22.2)) and Felder’s elliptic R -matrix entries $a(u) = \theta(u+\eta)/\theta(\eta)$ (Definition 22.2.2).

The passage from genus-1 data (Jacobi forms on E_τ) to genus-2 data has two normalisations. The square-root BKM lane lifts the Eichler–Zagier form $\phi_{o,1}$ and gives $\text{sdim } \mathfrak{g}_{\Delta, \alpha} = c_o(4nm - \ell^2)$. The full K_3 elliptic genus $Z_{K_3} = 2 \phi_{o,1}$ (Definition 26.22.7) gives the doubled product (26.6) for $\Phi_{10}^{\text{un}} = \Delta_5^2$, whose exponents are $2c_o(4nm - \ell^2)$. Proposition 26.27.1 is the normalization map from the doubled product to the Δ_5 -root-character lane.

In the factorization $\eta^{18} = \eta^{24} \cdot \eta^{-6}$: $\eta^{24} = \Delta$ is the Ramanujan discriminant (the 24 free bosons of A_E , recording the fibre-rank axis $\kappa_{\text{fiber}}(K_3) = 24$), and $\eta^{-6} = \eta^{-2\kappa_{\text{ch}}^{\text{Heis}}}$ with $\kappa_{\text{ch}}^{\text{Heis}} = \kappa_{\text{ch}}^{\text{Heis}}(\Omega^{\text{ch}}(K_3 \times E)) = 3$. The shadow obstruction tower detects $\kappa_{\text{ch}}^{\text{Heis}} = 3$ (Proposition 26.29.6); the Borcherds lift escalates this genus-1 datum to the genus-2 Siegel modular form.

26.26 TWISTED HOLOGRAPHY ON $K_3 \times E$

The BPS arithmetic identifies the modular content $1/\Phi_{10}^{\text{un}}$ that the chiral algebra must reproduce. A bulk-to-boundary construction is needed to derive the chiral algebra *from the geometry* rather than read it off the partition function. The Costello–Li twisted-holography construction (HT twist of IIB on $K_3 \times E$, Kodaira–Spencer reduction along the K_3 directions) provides the boundary chiral algebra A_E on the elliptic factor whose central charge $c(A_E) = 24$ matches $\kappa_{\text{fiber}}(K_3) = \text{rk } \tilde{H}(K_3)$.

Construction 26.26.1 (Costello–Li KS boundary algebra). The Costello–Li construction extracts a boundary chiral algebra from the HT twist of Type IIB on $K_3 \times E$. Reduction of Kodaira–Spencer theory along the topological directions (K_3) produces a chiral algebra A_E on E with generators from harmonic forms on K_3 . The identification $c(A_E) = \dim H^*(K_3) = \text{rk } \tilde{H}(K_3) = 24$ below is physical heuristic: the precise OPE level matrix is $J^a J^b \sim \delta^{ab}/(z-w)^2$ (Remark 26.26.2; the δ^{ab} records the Kaluza–Klein measure, not the Mukai form). The construction of A_E as a 2D VOA factorising from a 6D twisted-supergravity partition function is a separate OPE-level problem.

$h^{p,q}(K_3)$	Contribution	Generators
$h^{0,0} = 1$	Scalar boson	1
$h^{2,0} = 1$	Symplectic boson	1
$h^{1,1} = 20$	Weight-1 bosons	20
$h^{0,2} = 1$	Conjugate boson	1
$h^{2,2} = 1$	Volume boson	1

Total: $c(A_E) = \dim H^*(K_3) = 24$. This is not the K_3 sigma model ($c = 6$) but 24 free bosons from the B-model reduction. The rank datum is $\kappa_{\text{fiber}}(K_3) = 24$, the Mukai-lattice rank. In the free-field OPE model, A_E has genus-1 coefficient 24 and its level-opposite dual $A_E^!$ has coefficient -24 (free-field scope, class G); these cancel on classes G and L where $\rho_K = 0$. This OPE-level statement is distinct from the compact CY value $\kappa_{\text{ch}}^{\text{Hodge}}(K_3 \times E) = 0$ and from the Virasoro class M conductor 13.

Remark 26.26.2 (OPE level matrix for KS boundary bosons). The 24 free bosons $J^a(z)$ ($a = 1, \dots, 24$) of the KS boundary algebra $\mathcal{A}_E$ have OPE $J^a(z) J^b(w) \sim \delta^{ab}/(z-w)^2$, so the OPE level matrix is δ^{ab} (the unit matrix), *not* the Mukai pairing G^{ab} of signature (4, 20) on $H^*(K_3, \mathbb{Z})$. The Mukai pairing enters through the vertex operators $V_\gamma(z) = :\exp(i\gamma_a J^a(z)):$ for lattice vectors $\gamma \in \Gamma_{\text{Mukai}}$, whose correlation functions involve $\langle V_\gamma V_{\gamma'} \rangle \propto \exp(\gamma \cdot G \cdot \gamma')$. Confusing the OPE level δ^{ab} with the lattice pairing G^{ab} produces wrong invariant labels: the OPE-level trace is 24 and records the κ_{fiber} rank axis, while the Mukai norm $\text{tr}(G) = 4 - 20 = -16$ is not a compact CY $\kappa_\bullet$ -invariant.

Remark 26.26.3 (Holographic modular Koszul datum). $H(K_3 \times E) = (A, A^!, C, r(z), \Theta_A, \nabla^{\text{hol}})$ with $A = \mathcal{A}_E$ ($c = 24$, $\kappa_{\text{fiber}}(K_3) = 24$, while $\kappa_{\text{ch}}^{\text{Hodge}}(K_3 \times E) = 0$), $A^! = \mathcal{A}_E^!$ (opposite OPE level, not a new compact $\kappa_\bullet$ -axis), $C = Z_{\text{ch}}^{\text{der}}(A)$ (universal bulk), $r(z) = 24 \Omega/z$ (Casimir with the OPE-level rank prefix), Θ_A (bar-intrinsic MC element), ∇^{hol} (shadow connection, class G).

PROPOSITION 26.26.4 (Boundary-to-sigma ratio). The boundary algebra $\mathcal{A}_E$ and the sigma model VOA V_{K_3} have genus-1 free-energy coefficients in ratio 12. At genus 1:

$$\frac{F_1(\mathcal{A}_E)}{F_1(V_{K_3})} = \frac{24 \lambda_1^{\text{FP}}}{2 \lambda_1^{\text{FP}}} = 12.$$

Here $\mathcal{A}_E$ has $c = 24$ from the 24 free bosons of the Kaluza–Klein reduction on K_3 (Construction 26.26.1) indexed by the Mukai lattice $H^*(K_3, \mathbb{Z})$, and V_{K_3} is the $\mathcal{N} = 4$ SCA at $c = 6$ with $\kappa_{\text{ch}}(V_{K_3}) = 2$ (Proposition 26.22.2). The SUSY Ward identities of the $\mathcal{N} = 4$ algebra reduce κ_{ch} by a factor of $2/3$ relative to the Virasoro formula $\kappa_{\text{ch}}(\text{Vir}_6) = 3$ (Remark 26.22.3).

For $\mathcal{A}_E$ (24 free bosons, class G, uniform weight), the scalar formula $F_g(\mathcal{A}_E) = 24 \cdot \lambda_g^{\text{FP}}$ holds at all genera. For V_{K_3} (class M, generators at weights 1, $3/2$, 2), the scalar trace $F_g^{\text{sc}} = \kappa_{\text{ch}} \lambda_g^{\text{FP}}$ is proved at genus 1. At $g \geq 2$ the full multi-weight genus coefficient is $F_g(V_{K_3}) = F_g^{\text{sc}}(V_{K_3}) + \delta F_g^{\text{cross}}(V_{K_3})$ (Vol I). The ratio 12 is therefore proved at $g = 1$ and conditional at $g \geq 2$.

Proof. The OPE-level trace of $\mathcal{A}_E$ is 24 (the Mukai-lattice rank axis). $\kappa_{\text{ch}}(V_{K_3}) = 2$ (Proposition 26.22.2). Their ratio is $24/2 = 12$. At genus 1, $F_1(\mathcal{A}_E) = 24/24$ and $F_1(V_{K_3}) = 2/24$, giving the ratio 12. At $g \geq 2$: $\mathcal{A}_E$ is uniform-weight (class G), so $F_g(\mathcal{A}_E) = 24 \cdot \lambda_g^{\text{FP}}$ at all genera (uniform-weight; class G, scalar formula exact). V_{K_3} has generators at weights 1, $3/2$, 2; the scalar trace $F_g^{\text{sc}}(V_{K_3}) = 2 \cdot \lambda_g^{\text{FP}}$ is proved at $g = 1$. At $g \geq 2$ the full coefficient is $F_g(V_{K_3}) = F_g^{\text{sc}}(V_{K_3}) + \delta F_g^{\text{cross}}(V_{K_3})$ (Vol I). $\square$

Remark 26.26.5 (Leech connection). The boundary partition function of the 24 chiral free bosons $\mathcal{A}_E$ at genus 1 is

$$Z_1(\mathcal{A}_E; \tau) = 1/\eta(\tau)^{24} = q^{-1}(1 + 24q + 324q^2 + \dots).$$

The Leech lattice VOA V_Λ (holomorphic lattice VOA of central charge 24) has character

$$\Theta_\Lambda(\tau)/\eta(\tau)^{24} = q^{-1}(1 + 24q + 196884q^2 + \dots),$$

where $\Theta_\Lambda = 1 + 196560q^2 + \dots$ counts Leech-lattice vectors by norm. The two characters agree at weights 0 and 1 and diverge at weight 2: the 196560 minimal Leech vectors have no counterpart in the bare 24-boson Fock space (weight 2 dimension 324 = 24 + 300: the 24 singly-excited states $\alpha_{-2}^\mu |0\rangle$, plus the $\binom{24+1}{2} = 300$ symmetric pairs $\alpha_{-1}^\mu \alpha_{-1}^\nu |0\rangle$). The Leech lattice has $\kappa_{\text{ch}}^{\text{Heis}}(V_\Lambda) = 24$, the same OPE-level trace as the 24 free bosons of $\mathcal{A}_E$, but their weight-2 spaces differ.

26.27 MOCK MODULAR FORMS AND THE BKM ROOT SYSTEM

The boundary-to-sigma ratio identifies the modular characteristics on the two sides of the $\text{AdS}_3/\text{CFT}_2$ correspondence; the underlying BPS counting function $1/\Phi_{10}^{\text{un}}$ now demands an algebraic interpretation. Borchers's denominator-formula construction has a square-root lane: Δ_5 is the Weyl–Kac–Borchers denominator of the target BKM superalgebra $\mathfrak{g}_{\Delta_5}$, with signed root character read from $\phi_{0,1}$. The K_3 elliptic genus $Z_{K_3} = 2\phi_{0,1}$ instead gives the doubled $\Phi_{10}^{\text{un}} = \Delta_5^2$ product. The first task is to extract the normalization map between these lanes; the second is to read off the mock-modular completion of the K_3 elliptic genus that controls the *wall-crossing* discontinuities of the dyon spectrum.

BKM signed root characters

PROPOSITION 26.27.1 (*Signed root-character coefficients*). The BKM superalgebra $\mathfrak{g}_{\Delta_5}$ uses the Eichler–Zagier normalisation: writing $c_o(D)$ for the discriminant coefficient of $\phi_{0,1}$, the target root superdimension is $\text{sdim } \mathfrak{g}_{\Delta_5, \alpha} = c_o(D_\alpha)$. Ordinary even/odd dimensions or generator counts require a parity fixture or finite Hall–Borchers recognition of the root space. The full K_3 elliptic genus $Z_{K_3} = 2\phi_{0,1}$ supplies the doubled exponents in the product formula for $\Phi_{10}^{\text{un}} = \Delta_5^2$, not the root character of $\mathfrak{g}_{\Delta_5}$ itself.

$$\text{Exp}_{\Delta_5}(D) = c_o(D), \quad \text{Exp}_{\Phi_{10}^{\text{un}}}(D) = 2c_o(D), \quad \Phi_{10}^{\text{un}} = \Delta_5^2.$$

- Real roots ($D = -1, \alpha^2 = 2$): $\text{sdim } \mathfrak{g}_\alpha = c_o(-1) = 1$.
- Lightlike roots ($D = 0, \alpha^2 = 0$): $\text{sdim } \mathfrak{g}_\alpha = c_o(0) = 10$.
- Imaginary roots ($D > 0$): $\text{sdim } \mathfrak{g}_\alpha = c_o(D)$, unbounded as a signed character. Leading: $c_o(3) = -64$, $c_o(4) = 108$, $c_o(7) = -513$, $c_o(8) = 808$.

Negative coefficients at odd D indicate a signed odd branch in the standard target parity convention; they are not negative dimensions. The discriminant coefficients $c_o(D)$ of $\phi_{0,1}$ through $D = 12$ are (Eichler–Zagier convention; the subscript o labels the weight- o Jacobi form $\phi_{0,1}$, not the paramodular level N of Proposition 17.6.7, where $c_N(o)/2$ is the Borchers weight):

D	-1	0	3	4	7	8	11	12	15	16	19	20
$c_o(D)$	1	10	-64	108	-513	808	-2752	4016	-11775	16524	-43263	58956

The K_3 elliptic genus $Z_{K_3} = 2\phi_{0,1}$ has Fourier coefficients $2c_o(D)$; the BKM $\mathfrak{g}_{\Delta_5}$ is the Borchers lift of $\phi_{0,1}$ itself, so its target root supercharacters satisfy $\text{sdim } \mathfrak{g}_{\Delta_5, \alpha} = c_o(D)$ for discriminant $D = 4nm - \ell^2$. (The companion BKM $\mathfrak{g}_{\Phi_{10}^{\text{un}}}$ associated with $\Phi_{10}^{\text{un}} = \Delta_5^2$ has doubled signed root-character coefficients $2c_o(D)$.) The theta decomposition $\phi_{0,1} = h_o(\tau)\mathfrak{g}_{0,1}(\tau, z) + h_1(\tau)\mathfrak{g}_{1,1}(\tau, z)$ separates even (ℓ even, $D \equiv 0 \pmod{4}$) and odd (ℓ odd, $D \equiv 3 \pmod{4}$) sectors, with $h_o(\tau) = 10 + 108q + 808q^2 + \cdots$ and $h_1(\tau) = q^{-1/4}(1 - 64q + \cdots)$.

PROPOSITION 26.27.2 (*Signed root-character constancy*). Define the *level* of a positive root $\alpha = (n, l, m)$ as $\ell(\alpha) = n + m$. For all levels $\ell \geq 1$:

$$\sum_{\substack{\alpha \in \Delta_+ \\ \ell(\alpha) = \ell}} \text{sch}(\alpha) = 24 = \chi(K_3), \quad \text{sch}(\alpha) := \text{sdim } \mathfrak{g}_{\Delta_5, \alpha} = c_o(4nm - \ell^2).$$

Proof. At each level ℓ , the positive roots decompose into boundary roots (those with $n = 0$ or $m = 0$) and interior roots (those with $n, m \geq 1$).

Boundary contribution. Roots with $m = 0$: $(n, l, 0)$ for $n = \ell$, varying l . The signed root character is $c_0(-l^2)$, which is nonzero only for $l = 0$ (giving $c_0(0) = 10$) and $l = \pm 1$ (giving $c_0(-1) = 1$ each). Total: $10 + 1 + 1 = 12$. Similarly for $n = 0$: total 12. Boundary total: 24.

Interior cancellation. For each pair (n, m) with $n + m = \ell$ and $n, m \geq 1$:

$$\sum_{l \in \mathbb{Z}} c_0(4nm - l^2) = 0.$$

This is the modular constancy of $\phi_{0,1}$ at $z = 0$. The weak Jacobi form $\phi_{0,1}(\tau, z)$ has weight 0 and index 1; evaluating at $z = 0$ gives a modular form of weight 0 on $\mathrm{SL}_2(\mathbb{Z})$, which is necessarily constant (the space $M_0(\mathrm{SL}_2(\mathbb{Z}))$ is one-dimensional, spanned by 1). The value is $\phi_{0,1}(\tau, 0) = 12$ (Eichler–Zagier, *The Theory of Jacobi Forms*, 1985, p. 108). At the level of Fourier coefficients: $\sum_l c_0(4N - l^2) = 0$ for all $N \geq 1$, since the q^N coefficient of the constant function 12 vanishes for $N \geq 1$. The boundary gives 24, the interior gives 0, so the total at every level is 24. $\square$

Remark 26.27.3 (The interior cancellation at level 2). The interior at level 2 consists of roots $(1, l, 1)$ with $\mathrm{sch} = c_0(4 - l^2)$. From the Eichler–Zagier table: $l = 0$: $D = 4$, $c_0(4) = 108$; $l = \pm 1$: $D = 3$, $c_0(3) = -64$ each; $l = \pm 2$: $D = 0$, $c_0(0) = 10$ each. Sum: $108 - 2 \cdot 64 + 2 \cdot 10 = 108 - 128 + 20 = 0$. The cancellation is a direct consequence of $\sum_l c_0(4 - l^2) = 0$ (the q^1 coefficient of $\phi_{0,1}(\tau, 0) = 12$).

Remark 26.27.4 (Signed root-character constancy and the shadow tower). The constancy $\sum_{\ell(\alpha)=\ell} \mathrm{sch}(\alpha) = 24 = \chi_{\mathrm{top}}(K_3)$ reflects the topological datum $\chi_{\mathrm{top}}(K_3)$ persisting through the BKM construction. This is precisely the datum that the abelian $(2, 0)$ pushforward (Construction 26.22.20) captures: the Euler characteristic of the fiber enters through the lattice rank and the partition function of the free-field theory. The pushforward gives the correct topological backbone ($\chi = 24$) even though it gives the wrong shadow class (class **G** instead of class **M**) and the wrong κ_{ch} ($\mathrm{rank}(\Lambda)$ instead of $\dim_{\mathbb{C}}(K_3) = 2$).

The Hilbert scheme bridge

THEOREM 26.27.5 (Toroidal action on K -theory of Hilbert schemes [92]). Let S be a smooth projective surface. The toroidal algebra $U_{q,t}(\hat{\mathfrak{gl}}_1)$ acts on $\bigoplus_{n \geq 0} K(\mathrm{Hilb}^n(S))$ by correspondences on the nested Hilbert scheme $\mathrm{Hilb}^{n,n+1}(S)$ (Schiffmann–Vasserot). Specializations:

- (i) *Nakajima operators* ($q = 1$): the Heisenberg algebra $\bigoplus_{n \in \mathbb{Z}} \mathbb{Q} \mathbf{a}_n$ acts on $\bigoplus_n H^*(\mathrm{Hilb}^n(S))$ via Nakajima correspondences, with $\mathbf{a}_{-n}|0\rangle$ the class of the punctual Hilbert scheme.
- (ii) *Haiman’s theorem* ($S = \mathbb{C}^2$): the DAHA $\check{H}_n(q, t)$, a quotient of $U_{q,t}(\hat{\mathfrak{gl}}_1)$, acts on $K(\mathrm{Hilb}^n(\mathbb{C}^2))$ with fixed-point basis indexed by partitions $\lambda \vdash n$, and the character of the natural representation is the Macdonald polynomial $\check{H}_\lambda(x; q, t)$.
- (iii) $S = K_3$: $\chi(\mathrm{Hilb}^n(K_3)) = p_{24}(n)$ (24-coloured partitions), so $\sum_{n \geq 0} \chi(\mathrm{Hilb}^n(K_3)) p^n = \prod_{m \geq 1} (1 - p^m)^{-24}$.

PROPOSITION 26.27.6 (DMVV from Hilbert scheme characters;). The DVV formula (26.7) $1/\Phi_{10}^{\mathrm{un}} = \sum_N p^N \chi(\mathrm{Sym}^N(K_3); \tau, z)$ is the generating function of equivariant Euler characteristics of $\mathrm{Hilb}^N(K_3)$ refined by the $\mathrm{SU}(2)_R$ fugacity z and the L_0 fugacity $q = e^{2\pi i \tau}$. The 24 coloured partitions arise from Nakajima’s Heisenberg action ($24 = \chi_{\mathrm{top}}(K_3) = b_0 + b_2 + b_4 = 1 + 22 + 1$): each colour corresponds to a cohomology class of K_3 , matching the 24 free bosons of the boundary algebra $\mathcal{A}_E$ (Construction 26.26.1).

Remark 26.27.7 (Synthesis: toroidal algebras meet BPS counting). The three strands of this chapter converge on the Hilbert scheme. The toroidal algebra $U_{q,t}(\hat{\mathfrak{g}})$ of §22.1 provides the symmetry algebra acting on $K(\text{Hilb}^n(S))$. The elliptic R -matrix of §22.2 appears as the transition matrix between stable-envelope bases of $K(\text{Hilb}^n(S))$ (Aganagic–Okounkov). The BKM signed root-character coefficients $c_o(D)$ of Proposition 26.27.1 are the Fourier coefficients of $\phi_{o,1}$. The K_3 elliptic genus $Z_{K_3} = 2\phi_{o,1}$ is the doubled Φ_{10} -lane and has coefficients $2c_o(D)$; it counts the protected symmetric-product index seen by $\bigoplus_n H^*(\text{Hilb}^n(K_3))$. The shadow invariant $\kappa_{\text{ch}}^{\text{Heis}} = 3$ measures the single-copy chiral algebra $\Omega^{\text{ch}}(K_3 \times E)$; the BKM algebra $\mathfrak{g}_{\Delta_5}$ encodes the second-quantized (symmetric-product) extension, and the gap between them is the content of the shadow–Siegel gap analysis (§26.29).

Fourier–Jacobi expansion

Remark 26.27.8 (Fourier–Jacobi structure). $\Phi_{10}^{\text{un}} = \sum_{m \geq 1} \phi_m(\tau, z) p^m$ with: $\phi_1 = \phi_{10,1} = \eta^{18} \mathfrak{J}_1^2 = -\Delta \cdot \phi_{-2,1}$ (unique Jacobi cusp form of weight 10, index 1); $\phi_2 = 2\Delta \phi_{-2,1} \phi_{o,1}$ ($\dim J_{10,2}^{\text{cusp}} = 1$). The factorization $\eta^{18} = \eta^{24} \cdot \eta^{-6}$ separates the Ramanujan discriminant from $\eta^{-2\kappa_{\text{ch}}}$ with $\kappa_{\text{ch}}^{\text{Heis}} = 3$. The Jacobi form ring $J_{*,*}^{\text{weak}} = \mathbb{C}[E_4, E_6, \phi_{-2,1}, \phi_{o,1}]$ (Eichler–Zagier).

26.28 GRAND SYNTHESIS AND OPEN PROBLEMS

Remark 26.28.1 (Master data table for $K_3 \times E$). The complete invariant data assembled from the CY compute layer:

Invariant	Value
$\dim_{\mathbb{C}}(K_3 \times E)$	3
$\chi(K_3 \times E)$	0
$h^{1,1} = h^{2,1}$	21
$\text{rank } K_o$	48
$\dim \text{HH}^*$	96
$\kappa_{\text{ch}}^{\text{Heis}} = \kappa_{\text{ch}}^{\text{Heis}}(\Omega^{\text{ch}})$	3
$\kappa_{\text{BKM}}(\Delta_5) = \text{wt}(\Delta_5)$	5
$\kappa_{\text{ch}}^{\text{BCOV}} = \chi/24$	0
Shadow depth	class M ($r_{\max} = \infty$)
F_1	1/8
F_2	7/1920
F_3	31/322560
$Z_{\text{DT},o}$	1
n_1^o (genus-0 BPS, $h = 1$)	24
$S_{\text{BH}}(\Delta)$	$4\pi\sqrt{\Delta}$
$c(A_E^{\text{KS}})$ (twisted holography)	24
$\kappa_{\text{ch}}(A_E^{\text{KS}})$	24
$\text{Br}(K_3 \times E)$	$\supset (\mathbb{Q}/\mathbb{Z})^{22}$

The preceding master-data table records several distinct numerical values attached to $K_3 \times E$ under the heading “ $\kappa_{\bullet}$ ”. These are *not* competing measurements of a single invariant: each belongs to a named

construction. To make this precise we record, for a given X , the subscripted datum of construction-dependent invariants rather than a pure chiral modular-characteristic spectrum.

Definition 26.28.2 ($\kappa_\bullet$ -construction spectrum). For a Calabi–Yau threefold X , the $\kappa_\bullet$ -construction spectrum is

$$\text{Spec}_{\kappa_\bullet}(X) := \{(\alpha, \kappa_\alpha^\mathfrak{s}(X)) : \alpha \in \{\text{ch}, \text{cat}, \text{BKM}, \text{fiber}\}, \mathfrak{s} \text{ a specified construction where } \kappa_\alpha \text{ is defined}\}.$$

Each element carries its subscript and its source construction. The definition is deliberately not a set of plain numbers: equality of numerical values does not identify constructions, and different subscripts cannot be collapsed into a single modular characteristic.

Example 26.28.3 ($K_3 \times E$: composite $\kappa_\bullet$ -spectrum). The geometry $K_3 \times E$ supplies four invariant slots. The $\kappa_\bullet$ -construction spectrum (Definition 26.28.2) records the slot and the construction simultaneously:

Construction	$\kappa_\bullet$	Value
Compact total-space Hodge branch	$\kappa_{\text{ch}}^{\text{Hodge}}(K_3 \times E) = \kappa_{\text{cat}}(K_3 \times E)$	0
Heisenberg–Mukai Stage-2 specialisation	$\kappa_{\text{ch}}^{\text{Heis}}(K_3 \times E)$	3
BKM algebra $\mathfrak{g}_{\Delta_5}$ (Borcherds lift)	$\kappa_{\text{BKM}}(\Delta_5)$	5
Mukai lattice of the K_3 fibre	$\kappa_{\text{fiber}}(K_3 \times E)$	24

Thus the canonical numerical datum is the five-construction spectrum $\{0, 0, 3, 5, 24\}$ indexed by $\{\kappa_{\text{cat}}, \kappa_{\text{ch}}^{\text{Hodge}}, \kappa_{\text{ch}}^{\text{Heis}}, \kappa_{\text{BKM}}(\Delta_5), \kappa_{\text{fiber}}\}$; the categorical Euler value $\kappa_{\text{cat}}(K_3 \times E) = 0$ (Künneth) and the chiral Hodge supertrace $\kappa_{\text{ch}}^{\text{Hodge}}(K_3 \times E) = \sum_q (-1)^q h^{0,q}(K_3 \times E) = 0$ coincide numerically on the compact CY_3 yet arise from distinct constructions (categorical Euler vs. chiral Hodge supertrace). The numbers are meaningful only with their subscripts and constructions. The K_3 -fibre categorical value $\chi(\mathcal{O}_{K_3}) = 2$ is a K_3 -restricted check, not a total-space value and not κ_{fiber} . The 24-free-boson boundary algebra realises the Mukai-rank slot; it is not the compact total-space Hodge supertrace. The Borcherds value $\kappa_{\text{BKM}}(\Delta_5) = 5$ is the automorphic weight invariant of the Gritsenko lift, not the modular characteristic of the compact chiral output.

Remark 26.28.4 (The $\kappa_\bullet$ -construction spectrum as invariant). The $\kappa_\bullet$ -construction spectrum (Definition 26.28.2) is analogous to the multiple spectra of a Riemannian manifold (Laplacian, Dirac, length): different constructions applied to the same geometry probe different aspects of the modular structure. Whether $\text{Spec}_{\kappa_\bullet}(X)$ is a complete invariant (i.e., whether $\text{Spec}_{\kappa_\bullet}(X) = \text{Spec}_{\kappa_\bullet}(X')$ implies $X \simeq X'$) is open.

Remark 26.28.5 (The second-quantization gap). The shadow tower is first-quantized (single-copy). $1/\Phi_{\text{Io}}^{\text{un}}$ is second-quantized (DMVV symmetric product). The ratio $\kappa_{\text{BKM}}(\Delta_5)/\kappa_{\text{ch}}^{\text{Heis}} = 5/3$ reflects the passage from single copy to Sym^N and is specific to $K_3 \times E$ (the quintic gives a different ratio). The Borcherds lift converts additive genus-1 data into multiplicative genus-2 data: shadow genus escalation.

PROPOSITION 26.28.6 (The BPS modular characteristic). The BPS modular weight is

$$\kappa_{\text{BKM}}(\Delta_5) = \frac{1}{2} c_1(0) = \text{wt}(\Delta_5) = 5$$

(Borcherds weight theorem; Proposition 17.6.7). The tempting additive rule asking whether the BKM weight is the sum of the compact chiral Hodge supertrace and the fibre Euler characteristic *fails at every* $N \in \{1, 2, 3, 4, 6\}$ (Remark 26.30.11): at $N = 1$ it predicts $5 = 0 + 0$, since the Hodge-supertrace is

$\kappa_{\text{ch}}^{\text{Hodge}}(K_3 \times E) = \sum_q (-1)^q h^{0,q} = 0$, not 3, and $\chi(O_E) = 0$. For $K_3 \times E$ specifically, the numerical coincidence

$$\kappa_{\text{BKM}}(\Delta_5) = \kappa_{\text{ch}}^{\text{Heis}}(K_3 \times E) + \chi(O_{K_3}) = 3 + 2 = 5$$

holds under a *different* subscript, $\kappa_{\text{ch}}^{\text{Heis}}(K_3 \times E) = 3 = \dim_{\mathbb{C}}$ being the threefold Heisenberg-level modular characteristic (Proposition 26.29.6) and $\chi(O_{K_3}) = 2$ the fibre categorical invariant (the Künneth-multiplicative fibre value, distinct from $\kappa_{\text{cat}}(K_3 \times E) = \chi(O_{K_3 \times E}) = \chi(O_{K_3}) \cdot \chi(O_E) = 2 \cdot 0 = 0$). This $\kappa_{\text{ch}}^{\text{Heis}} + \chi(O_{\text{fibre}})$ equality is not universal and not a substitute for the Borchers identity: it is a convention-mixing artefact of $K_3 \times E$ ($N = 1$) and fails for $\mathbb{Z}/N\mathbb{Z}$ -orbifolds with $N \geq 2$ (Remark 17.6.6). The ratio

$$\frac{\kappa_{\text{BKM}}(\Delta_5)}{\kappa_{\text{ch}}^{\text{Heis}}} = \frac{5}{3} = \frac{\text{wt}(\Delta_5)}{\dim_{\mathbb{C}}(K_3 \times E)}$$

is only a comparison of two independently computed invariants; it is not a correction term from the single-copy algebra to the symmetric-product denominator. The distinction between Hilb^N and Sym^N accounts for additional BPS states: $\chi(\text{Hilb}^2(K_3)) - \chi(\text{Sym}^2(K_3)) = 324 - 300 = 24 = \chi_{\text{top}}(K_3)$, arising from the exceptional divisor of the Hilbert–Chow morphism $\text{Hilb}^2(K_3) \rightarrow \text{Sym}^2(K_3)$. The DMVV formula (26.7) uses the orbifold Sym^N formula; the Göttsche formula gives $\sum_N q^N \chi(\text{Hilb}^N(K_3)) = \prod_{k \geq 1} (1 - q^k)^{-24}$.

Proof. The Borchers weight theorem gives $\kappa_{\text{BKM}}(\Delta_5) = c_N(0)/2|_{N=1} = 10/2 = 5$ unconditionally. The numerical coincidence $\kappa_{\text{ch}}^{\text{Heis}}(K_3 \times E) + \chi(O_{K_3}) = 3 + 2 = 5$ is verified by independent computation of each summand: the threefold Heisenberg reading $\kappa_{\text{ch}}^{\text{Heis}}(K_3 \times E) = 3$ (Proposition 26.29.6) and the fiber categorical invariant $\chi(O_{K_3}) = 2$ (K_3 Hodge diamond). That the sum agrees with $c_N(0)/2|_{N=1}$ is a convention-mixing accident specific to $K_3 \times E$ ($N = 1$ orbifold): for $(\mathbb{Z}/N\mathbb{Z})$ -orbifolds with $N \geq 2$, independent computation confirms that $\kappa_{\text{ch}}^{\text{Heis}}(\text{total}) + \chi(O_{\text{fiber}}) \neq c_N(0)/2$ while the Borchers weight identity $\kappa_{\text{BKM}}(\Phi_N) = c_N(0)/2$ continues to hold. The Hilbert–Chow difference: $\text{Hilb}^2(S)$ for a K_3 surface S is the blowup of $\text{Sym}^2(S)$ along the diagonal, with exceptional divisor $\mathbb{P}(T_S) \cong \mathbb{P}^1$ -bundle. By the blowup formula, $\chi(\text{Hilb}^2) = \chi(\text{Sym}^2) + \chi(S) = \binom{25}{2} + 24 = 300 + 24 = 324$. $\square$

Remark 26.28.7 (Hilbert–Chow difference at higher N). The identity $\chi(\text{Hilb}^2(S)) - \chi(\text{Sym}^2(S)) = \chi(S)$ generalizes: for all $N \geq 1$, $\chi(\text{Hilb}^N(S))$ is the coefficient of q^N in $\prod_{k \geq 1} (1 - q^k)^{-\chi(S)}$ (Göttsche’s formula), while $\chi(\text{Sym}^N(S)) = \binom{\chi(S) + N - 1}{N}$ (the combinatorial formula for orbifold Euler characteristics). The difference $\delta_N = \chi(\text{Hilb}^N) - \chi(\text{Sym}^N)$ grows with N ; the leading corrections come from the exceptional loci of the Hilbert–Chow resolution $\text{Hilb}^N(S) \rightarrow \text{Sym}^N(S)$, which become increasingly complicated as partitions of N acquire more parts. For K_3 : $\delta_1 = 0$, $\delta_2 = 24 = \chi_{\text{top}}(K_3)$, $\delta_3 = 600$, $\delta_4 = 8100$, matching the Göttsche coefficients 1, 24, 324, 3200, 25650, $\dots$ minus the symmetric product coefficients 1, 24, 300, 2600, 17550, $\dots$

Open Problem 26.28.8 (Does the bar complex of $\mathcal{A}_{K_3}$ detect M_{24} ?). The mock modular half-multiplicities $a_n = 45, 231, 770, \dots$ are dimensions of M_{24} representations. The bar complex $B(\mathcal{A}_{K_3})$ detects $\kappa_{\text{ch}}^{\text{Hodge}} = 2$ at degree 2 and the cubic shadow at degree 3. Does the full shadow obstruction tower $\Theta_{\mathcal{A}_{K_3}}$ encode the M_{24} action? The mock modular shadow $24 \eta^3$ and the bar-complex shadow connection ∇^{sh} share the structural feature of encoding modular non-invariance. Whether they are related by a precise functor remains open.

Open Problem 26.28.9 (Factorization envelope of the K_3 chiral algebra). The factorization envelope $U_X^{\text{mod}}(\mathcal{A}_{K_3})$ in the sense of Nishinaka (2025/26) and Vicedo (2025) is not yet constructed. At the

genus-0 level, the K_3 sigma model provides a factorization algebra on $\text{Ran}(X)$ for any algebraic curve X ; the modular completion (incorporating all genera) is open. The six-fold datum $\Pi_X(\mathcal{A}_{K_3})$ is well-defined (Construction 21.16); what remains is the modular factorization envelope as the left adjoint of Prim^{mod} .

Remark 26.28.10 (Constructive reconstruction of $D^b(K_3 \times E)$). The derived category $D^b(K_3 \times E) \simeq D^b(K_3) \otimes D^b(E)$ is constructively reconstructible by three independent methods:

- (i) *Čech descent.* Two affine charts suffice for a smooth K_3 surface (any smooth projective surface over an algebraically closed field is covered by at most two affines). The Čech descent spectral sequence (Theorem 26.21.16)

$$E_1^{p,q} = \bigoplus_{|I|=p+1} \text{HH}^q(D^b(U_I)) \implies \text{HH}^{p+q}(D^b(K_3))$$

recovers $D^b(K_3)$ from local data on U_o, U_i with transition data on U_{oi} .

- (ii) *BKR equivalence.* At the Kummer point $K_3 = T^4/\mathbb{Z}_2$, the Bridgeland–King–Reid theorem gives $D^b(\text{Hilb}^2(T^4/\mathbb{Z}_2)) \simeq D_{\mathbb{Z}_2}^b(T^4)$, providing an explicit equivariant description. The equivariant category $D_{\mathbb{Z}_2}^b(T^4)$ is generated by equivariant line bundles and is computationally accessible.
- (iii) *Brauer obstruction.* $\text{Br}(K_3) \supset (\mathbb{Q}/\mathbb{Z})^{21}$ (Remark 26.23.3) obstructs only *twisted* derived categories. The untwisted category $D^b(K_3)$ is unobstructed.

A structural constraint: CY threefolds carry no exceptional objects ($\chi(\mathcal{O}_X, \mathcal{O}_X) = 0$ by the antisymmetry of Serre duality on a CY₃), so $D^b(K_3 \times E)$ admits no semiorthogonal decomposition and must be treated as an indecomposable block (Proposition 26.23.4).

Open Problem 26.28.11 (Global CY category from finitely many quiver charts). Given the constructive methods of Remark 26.28.10, can $D^b(K_3 \times E)$ be assembled from finitely many quiver charts with explicit $\mathcal{A}_\infty$ -bimodule transition data? The McKay correspondence provides the local charts at orbifold points; the cluster mutation structure controls transitions; the KS wall-crossing governs the DT invariant transformations. A constructive algorithm would connect the local-to-global CY gluing of §26.21 to the global enumerative data of §26.24.

Open comparison problems

The $K_3 \times E$ shadow tower leaves ten comparison problems. Each problem has a concrete geometric or automorphic object.

Open Problem 26.28.12 (Constructive Calabi–Yau gluing). The Čech descent of §26.21 reconstructs $D^b(K_3 \times E)$ from local quiver charts in principle. Three questions sharpen the descent statement.

- (i) *Minimum chart number.* For a K_3 surface S of Picard rank ρ , what is the minimum number of ADE-type quiver charts whose $\mathcal{A}_\infty$ -bimodule transition data recovers $D^b(S)$? The Mukai lattice $\tilde{H}(S, \mathbb{Z}) \cong U^4 \oplus E_8(-1)^2$ has rank 24; categorical generation requires a spanning class for thick subcategory generation, not merely K -theory spanning. For orbifold K_3 (Kummer $T^4/\mathbb{Z}_2$), the BKR equivalence $D^b(\text{Kum}(A)) \simeq D_{\mathbb{Z}/2}^b(A)$ provides a single global chart; for smooth K_3 without ADE singularities, no full exceptional collection exists (Bridgeland 1999), and one must generate via spherical objects and their twist functors.

- (ii) *Brauer obstruction.* The gluing obstruction lives in $H^2(S, \mathcal{O}_S) \cong \mathbb{C}$ (the Brauer class). When does a nontrivial Brauer class kill the descent? For generic K_3 with $\rho = 0$, $\text{Br}(S)$ contains $(\mathbb{Q}/\mathbb{Z})^{22}$; for $K_3 \times E$, $\text{Br}(K_3 \times E) \supset (\mathbb{Q}/\mathbb{Z})^{22+1}$.
- (iii) *Beyond ADE.* The McKay correspondence handles orbifold singularities. For smooth K_3 at a generic moduli point (no singularities), the relevant local charts are formal neighborhoods of subvarieties, not ADE resolution charts. Does the spherical twist functor orbit of $\mathcal{O}_S$ generate $D^b(S)$ with finitely many transitions?

Conjecture 26.28.13 (ADE chart decomposition of K_3). Every algebraic K_3 surface admits a finite ADE-chart decomposition of its derived category: there exist finitely many open sets $\{U_\alpha\}$ with tilting generators T_α on each U_α , and A_∞ -bimodule transition data on overlaps, such that $D^b(S) \simeq \text{holim}_{\check{C}} D^b(U_\alpha)$. The minimum number of charts is bounded below by $\lceil \text{rank } K_0(S) / \max_\alpha \text{rank } K_0(\text{End}(T_\alpha)) \rceil$.

Open Problem 26.28.14 (κ_{ch} as universal moonshine multiplier). The Mathieu moonshine decomposition gives $A_n = 2 \cdot \dim(\rho_n)$ with $\rho_n \in \text{Irr}(\mathcal{M}_{24})$, where the factor $2 = \kappa_{\text{ch}}^{\text{Hodge}}(\mathcal{A}_{K_3})$ is the modular characteristic of the K_3 sigma model (Remark 26.22.10). This suggests a universal principle.

- (i) *Monster moonshine.* For the Monster module $V^\natural$ ($c = 24$, $\kappa_{\text{ch}}(V^\natural) = 12$ by Remark 26.22.16 and Vol I, Theorem 21.16, applied to the Leech lattice construction): does $A_n^{\text{Monster}} = \kappa_{\text{ch}}(V^\natural) \cdot \dim(\rho_n^{\mathbb{M}})$ for the Monster group $\mathbb{M}$? The McKay–Thompson series $T_g(\tau) = \sum_n \text{tr}(\rho_n(g)) q^{n-1}$ is a genus-zero Hauptmodul; the question is whether the *dimensions* (not characters) factor through κ_{ch} .
- (ii) *Conway moonshine.* For $V^{\natural\sharp}$ ($c = 12$, the shorter moonshine module): $\kappa_{\text{ch}}(V^{\natural\sharp}) = ?$ and does $A_n = \kappa_{\text{ch}} \cdot \dim(\rho_n^{Co_0})$? The Conway group Co_0 acts on the Leech lattice; $V^{\natural\sharp}$ is the $\mathbb{Z}/2$ -orbifold of the rank-12 lattice VOA.
- (iii) *General principle.* For a holomorphic VOA V of central charge c with finite automorphism group G , does the elliptic genus decompose as $Z_g(\tau, z) = \kappa_{\text{ch}}(V) \cdot \sum_n \dim(\rho_n) \text{ch}_n(g)$ for $g \in G$?

Conjecture 26.28.15 (Universal moonshine multiplier). For a holomorphic VOA V with finite automorphism group G , the twined partition function decomposes as

$$Z_g(\tau, z) = \kappa_{\text{ch}}(V) \cdot \sum_{n \geq 0} \dim(\rho_n) \text{ch}_n(g), \quad g \in G,$$

where $\kappa_{\text{ch}}(V)$ is the bar-complex modular characteristic, $\{\rho_n\}$ are virtual G -representations, and ch_n are character functions determined by the elliptic genus of V . For $V = \mathcal{A}_{K_3}$ ($c = 6$) with $G = \mathcal{M}_{24}$: $\kappa_{\text{ch}}^{\text{Hodge}} = 2$ and $A_n = 2 \cdot \dim(\rho_n)$ as established by Gannon [47].

Open Problem 26.28.16 (Second-quantization bridge). The ratio $\kappa_{\text{BKM}}(\Delta_3) / \kappa_{\text{ch}}^{\text{Heis}} = 5/3$ (Proposition 26.28.6) encodes the passage from first to second quantization for $K_3 \times E$.

- (i) *Universality.* The additive decomposition $\kappa_{\text{BKM}}(\Delta_3) = \kappa_{\text{ch}}^{\text{Heis}}(K_3 \times E) + \chi(\mathcal{O}_{K_3})$ is a numerical coincidence for $K_3 \times E$ ($N = 1$) and fails on the remaining diagonal CHL lanes $N \in \{2, 3, 4, 6\}$ (Remark 17.6.6). The correct universal formula is $\kappa_{\text{BKM}}(\Phi_N) = c_N(0)/2$ (Borcherds weight theorem). For the quintic there is no Borcherds input Φ_N , hence no invariant $\kappa_{\text{BKM}}(\Phi_N)$; the replacement invariant $\kappa_{\text{ch}}^{\text{BCOV}} = \chi/24 = -200/24$ must be extracted from the genus-2 topological string amplitude.

- (ii) *Plethystic shadow.* The DMVV formula $1/\Phi_{10}^{\text{un}} = \text{PE}[2\phi_{0,1}]$ expresses the second-quantized partition function as the plethystic exponential of the single-copy elliptic genus. What is the shadow tower of $\text{PE}[\mathcal{A}]$ in terms of the shadow tower of $\mathcal{A}$? The tensor product gives $\kappa_{\text{ch}}(\mathcal{A}^{\otimes N}) = N \kappa_{\text{ch}}(\mathcal{A})$ by additivity, but the $\mathbb{Z}_N$ -orbifold projection to Sym^N modifies the tower through twisted sectors.
- (iii) *Adams operations.* The Adams operations ψ^k act on the shadow partition function by rescaling:

$$\psi^k(Z^{\text{sh}})(\hbar) = Z^{\text{sh}}(k\hbar) = \exp\left(\sum_{g \geq 1} k^{2g} F_g \hbar^{2g}\right).$$

This is the λ -ring structure on the shadow partition function: ψ^k multiplies the genus- g amplitude by k^{2g} , consistent with the interpretation of $\hbar^{2g}$ as a genus-counting weight. The Adams operations are ring homomorphisms ($\psi^k \circ \psi^l = \psi^{kl}$) and commute with the $\hat{A}$ -genus generating function (Vol I, Theorem 21.16). Does this intertwine with the Hecke operators V_k on the Jacobi form $\phi_{0,1}$ via the DMVV formula (26.7)? The Hecke transform $V_k(\phi_{0,1})$ and the Adams-rescaled shadow $\psi^k(Z^{\text{sh}})$ would need to be related through the Borcherds product for the intertwining to be exact.

Remark 26.28.17 (BPS modular characteristic: universal formula vs. coincidence). The correct universal formula on the CHL $K_3 \times E$ Borcherds lanes is

$$\kappa_{\text{BKM}}(\Phi_N) = \frac{1}{2} c_N(\mathbf{o})$$

(Borcherds weight theorem; Proposition 17.6.7), where $c_N(\mathbf{o})$ is the constant term of the $\mathbb{Z}/N\mathbb{Z}$ -orbifold elliptic genus. The apparent equality $5 = \kappa_{\text{ch}}^{\text{Heis}}(S \times E) + \chi(\mathcal{O}_S) = 3 + 2$ is not a decomposition. It is an $N = 1$ convention-mixing accident: 3 is the Heisenberg specialisation, whereas the compact total-space value is $\kappa_{\text{ch}}^{\text{Hodge}}(K_3 \times E) = 0$. The additive formula therefore already fails under the compact convention at $N = 1$, and it *fails* for all $\mathbb{Z}/N\mathbb{Z}$ -orbifolds with $N \geq 2$ (Remark 17.6.6). For non- K_3 -fibered CY₃s (quintic, $\mathbb{C}^3$, conifold, local $\mathbb{P}^2$) there is no Borcherds input Φ_N ; replacement invariants are $\kappa_{\text{ch}}^{\text{BCOV}} = \chi(X)/24$ (compact) or shadow depth (all, conditional on CY-A).

Open Problem 26.28.18 (Schottky shadow). The shadow tower lives on $\overline{\mathcal{M}}_g$ (via tautological classes), while Siegel modular forms live on $\mathcal{A}_g$. For $g \leq 3$, the Torelli map $j: \mathcal{M}_g \hookrightarrow \mathcal{A}_g$ is an isomorphism ($g = 1$), birational ($g = 2$), or injective with codimension-0 complement ($g = 3$). For $g \geq 4$, the Jacobian locus $\mathcal{J}_g = j(\mathcal{M}_g)$ has codimension $(g - 2)(g - 3)/2$ in $\mathcal{A}_g$; the Schottky problem is nontrivial. The explicit numerical values are:

g	$\dim \mathcal{M}_g$	$\dim \mathcal{A}_g$	$\text{codim}(\mathcal{J}_g)$	Geometry
2	3	3	0	Torelli birational
3	6	6	0	Torelli dominant
4	9	10	1	Schottky–Igusa J
5	12	15	3	
6	15	21	6	
7	18	28	10	
8	21	36	15	
9	24	45	21	
10	27	55	28	Crossover: $\text{codim} > \dim \mathcal{M}_{10}$

The crossover at $g = 10$ (where $\text{codim}(\mathcal{J}_{10}) = 28 > 27 = \dim \mathcal{M}_{10}$) marks the genus beyond which the Jacobian locus is “more absent than present” in $\mathcal{A}_g$. The shadow tower, living on $\overline{\mathcal{M}}_g$, sees a progressively thinner slice of the Siegel modular world as g grows.

- (i) *Tautological insulation.* The shadow amplitude $F_g^{\text{sc}} = \kappa_{\text{ch}} \lambda_g^{\text{FP}}$ lives in the tautological ring $R^*(\overline{\mathcal{M}}_g)$, which is insensitive to the Schottky constraint. The shadow tower cannot detect whether a period matrix is a Jacobian: it is tautologically insulated from Schottky.
- (ii) *Physical partition function.* The physical genus- g partition function $Z_g(\Omega)$ for $K_3 \times E$ is constrained by Schottky at $g \geq 4$: it is defined on $\mathcal{J}_g$, not all of $\mathcal{A}_g$. The gap between shadow (tautological) and partition function (analytic) at $g \geq 4$ measures the failure of the shadow tower to capture the full moduli dependence.
- (iii) *The Schottky–Igusa form.* The Schottky–Igusa form $J \in S_8(\text{Sp}(8, \mathbb{Z}))$ vanishes exactly on $\mathcal{J}_4$ at genus 4. Its weight $8 = 2g$ is significant. Does any shadow invariant at genus 4 detect J ? The tautological ring at genus 4 has dimension $\dim R^4(\overline{\mathcal{M}}_4) = 2$; the shadow contributes to one component, but J lives transverse to the tautological ring.

Conjecture 26.28.19 (Shadow tower generates the tautological projection). At genus g , the shadow obstruction tower of a class-M algebra (shadow depth $r_{\text{max}} = \infty$) generates the image of the restriction map $\text{res}: S_*(\text{Sp}(2g, \mathbb{Z})) \rightarrow R^*(\overline{\mathcal{M}}_g)$ from the ring of Siegel modular forms to the tautological ring. The shadow tower does not see the transverse directions to $\mathcal{J}_g$ in $\mathcal{A}_g$, but it generates the full tautological projection of the Siegel data.

Open Problem 26.28.20 (Mock modularity and the bar complex). The mock modular form $h(\tau) = 2q^{-1/8}(-1 + 45q + 231q^2 + \dots)$ encoding the massive $\mathcal{N} = 4$ multiplicities has shadow $S(\tau) = 24\eta(\tau)^3$ (weight $3/2$, cusp form).

- (i) *The factor 24.* The shadow $S(\tau) = 24\eta^3$ contains $24 = \chi_{\text{top}}(K_3)$, the topological Euler characteristic. Where does this factor arise in the bar complex? The bar curvature $\kappa_{\text{ch}}^{\text{Hodge}} = 2$ does not directly produce 24; the factor $24/\kappa_{\text{ch}} = 12$ is the modular discriminant level. An algebraic derivation from the bar complex would connect the mock modular shadow to the bar-complex shadow connection ∇^{sh} .
- (ii) *The Appell–Lerch sum.* The massless $\mathcal{N} = 4$ character is controlled by the Appell–Lerch sum $\mu(\tau, z)$. The non-holomorphic completion $\hat{h}(\tau, \bar{\tau})$ is modular of weight $1/2$. Is there a bar-complex interpretation of μ ? The Appell–Lerch sum regularizes the divergent theta-type sum; the bar complex regularizes the divergent Feynman-type sum. Both are regularizations of the same modular anomaly.
- (iii) *Half-integral weight.* The mock modular form h has weight $1/2$; the shadow has weight $3/2$. The bar-complex shadow connection ∇^{sh} produces integer-weight objects (the shadow metric Q_L has weight 2; the Faber–Pandharipande λ_g are tautological, hence of integral weight). The passage to half-integral weight requires either a metaplectic extension or a theta correspondence. Concretely: is there a metaplectic bar complex whose shadow connection produces weight- $3/2$ objects?

Remark 26.28.21 (Notation: μ is overloaded). The symbol μ denotes two distinct objects in the K_3 literature:

- (i) The *Zwegers μ -function* $\mu(\tau, z) = \sum_{n \in \mathbb{Z}} (-1)^n q^{n(n+1)/2} y^n / (1 - yq^n)$, the Appell–Lerch sum controlling the massless $\mathcal{N} = 4$ character in Open Problem 26.28.20.

- (ii) The full $\mathcal{N} = 4$ massless character $\text{ch}^{\text{massless}}(\tau, z) = \mu(\tau, z) \cdot \mathfrak{d}_1(\tau, z)/\eta(\tau)^3$ (with additional theta and eta factors).

These two normalisations must not be identified: multiplying the Appell–Lerch sum by $\mathfrak{d}_1/\eta^3$ changes both its pole structure and its modular completion. The Zwegers μ -function is *not* a Jacobi form: it fails the elliptic transformation law (it has a pole at $z \in \mathbb{Z} + \mathbb{Z}\tau$). Its non-holomorphic completion $\hat{\mu}(\tau, \bar{\tau}, z)$ is modular.

Conjecture 26.28.22 (Mock shadow tower). The mock modular completion $\hat{h}(\tau, \bar{\tau}) = h(\tau) + h^*(\tau, \bar{\tau})$ is the genus-1 projection of a “mock shadow tower” that combines bar-complex data with the Appell–Lerch regularization. There exists an extension $\tilde{\Theta}_{\mathcal{A}_{K_3}}$ of the shadow obstruction tower $\Theta_{\mathcal{A}_{K_3}}$ valued in mock modular forms of weight $1/2$, whose non-holomorphic completion is modular and whose holomorphic part restricts to $\kappa_{\text{ch}}^{\text{Hodge}}(\mathcal{A}_{K_3}) \cdot h(\tau)$ at genus 1. The shadow of this mock extension is $\kappa_{\text{ch}}^{\text{Hodge}} \cdot \chi(K_3) \cdot \eta^3$, where the product $\kappa_{\text{ch}}^{\text{Hodge}} \cdot \chi(K_3) = 2 \cdot 24 = 48$ is the rank of the charge lattice $\Gamma = H^{\text{even}}(K_3 \times E, \mathbb{Z})$.

Open Problem 26.28.23 (Modular factorization envelope). The factorization envelope $U_E(\mathcal{A}_E) = \text{Sym}^{\text{ch}}(\mathfrak{h}_{24})$ of the KS boundary algebra produces 24 free bosons on E , with character $1/\eta(\tau)^{24}$. The modular completion $U_E^{\text{mod}}(\mathcal{A}_E)$ must incorporate higher-genus data; its character at genus 1 should receive corrections from the shadow tower.

- (i) *The Leech divergence.* The Leech lattice VOA V_{Leech} has character $J(\tau) + 24 = q^{-1}(1 + 196884q + \dots)$. The free-field envelope $1/\eta^{24} = q^{-1}(1 + 24q + 324q^2 + \dots)$ matches the Leech VOA character at q^{-1} and q^0 (after adding 24) but diverges at q^1 : $324 \neq 196884$. The discrepancy is the interacting structure of the Leech lattice VOA beyond free fields.
- (ii) *Modular factorization envelope.* Is there a universal construction $U_X^{\text{mod}}(L)$ for all cyclically admissible Lie conformal algebras L (Vol I, Definition 21.16) that carries a natural shadow obstruction tower? Nishinaka’s construction (2025/26) handles the genus-0 level; the modular completion requires incorporating the F_g data at all genera.
- (iii) *Super extension.* The $\mathcal{N} = 4$ SCA at $c = 6$ is a super vertex algebra. Nishinaka’s construction applies to ordinary Lie conformal algebras; the super extension (with fermionic generators $G^\pm$, $\bar{G}^\pm$) requires the super-factorization framework of Costello–Gwilliam. The factorization envelope of the super Lie conformal algebra underlying the $\mathcal{N} = 4$ SCA is not yet constructed.

Conjecture 26.28.24 (Modular factorization envelope existence). For every cyclically admissible Lie conformal algebra L , the modular factorization envelope $U_X^{\text{mod}}(L)$ exists as a factorization algebra on $\text{Ran}(X)$ equipped with the shadow obstruction tower $\Theta_{U_X^{\text{mod}}(L)}$. This envelope is the left adjoint of the modular primitive-current functor Prim^{mod} (Construction 21.16), specialized to the CY setting.

Open Problem 26.28.25 (BKM algebras and scattering diagrams). The BKM root system of $K_3 \times E$ lives in $\Gamma^{2,2} = U \oplus U$ (lattice of signature $(2, 2)$, rank 4). Signed root-character coefficients are determined by $c_0(D)$ from the K_3 elliptic genus. The Kontsevich–Soibelman scattering diagram for $K_3 \times E$ associates a wall to each BPS ray with attached function determined by the root multiplicity.

- (i) *Two MC elements.* The shadow obstruction tower $\Theta_{\mathcal{A}}$ is an MC element in the convolution algebra $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$; the KS automorphism $\mathfrak{S}$ is an MC element in the motivic Hall algebra $\mathcal{H}(C)$. These are MC elements in different Lie algebras. The bridge must pass through a common enlargement:

the motivic DT category of $K_3 \times E$. At the naive level, the BCH pair-commutator does *not* reproduce the $\phi_{o,i}$ multiplicities (quantitative mismatch by non-uniform ratios).

- (ii) *Motivic level.* The identification “scattering diagram = shadow obstruction tower” holds at the motivic Hall algebra level (Kontsevich–Soibelman 2008), where the product on walls is the motivic quantum torus product. Instantiating this at the numerical/Euler characteristic level loses the higher-genus information that the motivic structure retains.
- (iii) *Tropical skeleton.* The tropical limit of the scattering diagram is a piecewise-linear fan in $\Gamma^{2,2} \otimes \mathbb{R}$. This fan should be the tropical skeleton of the shadow obstruction tower restricted to BPS walls. The identification would connect Mok’s log FM tropicalization (Theorem 21.16) to the BPS scattering diagram.

Conjecture 26.28.26 (Scattering diagram as tropical shadow). The scattering diagram of $K_3 \times E$ is the tropical skeleton of the shadow obstruction tower: $\text{Scat}(K_3 \times E) = \text{Trop}(\Theta_{\mathcal{A}_{K_3 \times E}})$, where the left side is the Kontsevich–Soibelman scattering diagram (with wall-crossing factors from the BPS spectrum) and the right side is the tropicalization of the shadow obstruction tower restricted to the charge lattice $\Gamma^{2,2}$. The identification holds at the level of the motivic Hall algebra; at the numerical level, higher BPS bound-state contributions must be included.

Remark 26.28.27 (Descent sufficiency and K-theory verification). Three descent statements govern the CY category:

- (i) *Zariski suffices.* For smooth separated schemes X , the natural functor $D^b(X) \rightarrow \text{holim}_{\check{\text{Cech}}} D^b(U_\alpha)$ is an equivalence (Toën 2007, Lurie HA 2017, Theorem 19.4.5): coherent sheaves satisfy effective descent for the Zariski topology. No étale or flat refinement is needed.
- (ii) *ADE cocycles close.* For each ADE singularity type, the bimodule cocycle condition $M_{o_1} \otimes_B^L M_{1_2} \simeq M_{o_2}$ closes:

Type	$ \Gamma $	$\dim \Pi_o(Q)$	Cocycle mechanism
A_n	$n+1$	$\binom{n+2}{3}$	Flop involution
D_n	$4(n-2)$	Table 26.21.11	Tilting generator $T = \oplus P_i$
E_6	24	168	$\text{End}(T) = \Pi(\check{Q})$
E_7	48	384	$\text{End}(T) = \Pi(\check{Q})$
E_8	120	1080	$\text{End}(T) = \Pi(\check{Q})$

The mechanism is uniform: the tilting generator $T = \oplus_{i \in Q_o} P_i$ of the resolution $\widehat{\mathbb{C}^2/\Gamma}$ has endomorphism algebra $\text{End}(T) \cong \Pi_o(Q)$, and the Morita equivalence $D^b(\Pi_o(Q)\text{-mod}) \simeq D^b(\widehat{\mathbb{C}^2/\Gamma})$ automatically closes the bimodule cocycle for any number of overlapping charts (Bridgeland–King–Reid for type A ; Kapranov–Vasserot, Van den Bergh for all types).

- (iii) *K-theory condition.* For $X = K_3 \times E$, successful descent must recover $\text{rk } K_o(K_3 \times E) = 48 = \text{rk } K_o(K_3) \cdot \text{rk } K_o(E) = 24 \cdot 2$. For each ADE chart of type Γ : $\text{rk } K_o(\text{Jac}(Q_\Gamma, \mathcal{W}_\Gamma)) = |Q_o| = r + 1$ (the number of vertices in the McKay quiver). The Mayer–Vietoris sequence in K-theory provides the gluing equality.

Open Problem 26.28.28 (Descent theorem for A_∞ -bimodule gluing). The descent theorem for dg categories (Toën 2007, Lurie HA) guarantees that Zariski descent recovers $D^b(X)$ for smooth separated

schemes (Remark 26.28.27). The quiver chart descent of §26.21 uses A_∞ -bimodule transition data on overlaps.

- (i) *Bimodule cocycle closure.* For three overlapping charts U_o, U_1, U_2 with transition bimodules M_{o1}, M_{12}, M_{o2} , the triple cocycle condition $M_{o1} \otimes_B^L M_{12} \simeq M_{o2}$ must close up to coherent homotopy. For ADE resolutions this is proved (the preprojective algebra $\Pi(\tilde{Q})$ is the endomorphism algebra of the tilting generator). For smooth K_3 patches glued along a divisor, the bimodule cocycle is the restriction of the Atiyah class.
- (ii) *Obstruction.* The obstruction to extending a two-chart descent to a global descent lives in HH^2 of the transition bimodule: $\mathrm{ob} \in \mathrm{HH}^2(M_{o1}, M_{o1})$. For K_3 , $h^{o,2} = 1$ provides a one-dimensional obstruction space. When is the obstruction trivial?
- (iii) *Higher-dimensional CY.* For a smooth projective CY d -fold X with ADE singularities, does the quiver chart descent reconstruct $D^b(X)$? The $d = 2$ (K_3) and $d = 3$ ($K_3 \times E$) cases are established by the local descent calculation. The general case requires understanding the higher Hochschild obstructions.

Open Problem 26.28.29 (Higher-dimensional CY shadows). The shadow tower of $K_3 \times E$ ($\dim_{\mathbb{C}} = 3$) connects to genus-2 Siegel modular forms via the Borchers lift. What happens in higher CY dimension?

- (i) $\mathrm{CY}_4 = K_3 \times K_3$. The compact Hodge supertrace is Künneth-multiplicative, $\kappa_{\mathrm{ch}}^{\mathrm{Hodge}}(K_3 \times K_3) = \chi(\mathcal{O}_{K_3})^2 = 4$. The Heisenberg rank-additive reading gives the same number, $2 + 2 = 4$, on this particular product. Shadow class: M (product of two class- M factors). The genus-2 amplitude $F_2 = 4 \cdot 7/5760 = 7/1440$. Is there a genus-3 Siegel modular form analogue of Φ_{10}^{un} ?
- (ii) $\mathrm{CY}_5 = K_3 \times K_3 \times E$. The compact Hodge supertrace vanishes: $\kappa_{\mathrm{ch}}^{\mathrm{Hodge}}(K_3 \times K_3 \times E) = \chi(\mathcal{O}_{K_3})^2 \chi(\mathcal{O}_E) = 4 \cdot 0 = 0$. The number $5 = 2 + 2 + 1$ is only the Heisenberg rank-additive mnemonic. It does not produce a Borchers weight. The Fake-Monster lane has $\kappa_{\mathrm{BKM}}(\Phi_{12}) = 12$ only after the external $\Pi_{25,1}$ comparison and the $d = 5$ Hall data are supplied.
- (iii) *The dimensional ladder.* For a product $\mathrm{CY}_d = X_1 \times \cdots \times X_k$, the compact Hodge supertrace is multiplicative, $\kappa_{\mathrm{ch}}^{\mathrm{Hodge}}(\prod_i X_i) = \prod_i \kappa_{\mathrm{ch}}^{\mathrm{Hodge}}(X_i)$, while the Heisenberg rank reading, when present, is additive. These two operations coincide only in special examples. The shadow class should be $\max(\text{classes of } X_i)$ under the ordering $G < L < C < M$. Does this determine the shadow tower of the product completely?

Conjecture 26.28.30 (CY product shadow decomposition by scalar reading). For a product $\mathrm{CY}_d = X_1 \times \cdots \times X_k$ of Calabi–Yau manifolds, the compact Hodge scalar is multiplicative, whereas the Heisenberg-rank scalar, when a compatible Heisenberg specialisation exists on every factor, is additive:

$$\begin{aligned} \kappa_{\mathrm{ch}}^{\mathrm{Hodge}}(X_1 \times \cdots \times X_k) &= \prod_{i=1}^k \kappa_{\mathrm{ch}}^{\mathrm{Hodge}}(X_i), \\ \kappa_{\mathrm{ch}}^{\mathrm{Heis}}(X_1 \times \cdots \times X_k) &= \sum_{i=1}^k \kappa_{\mathrm{ch}}^{\mathrm{Heis}}(X_i) \quad \text{on the compatible Heisenberg lane,} \\ \mathrm{class}(X_1 \times \cdots \times X_k) &= \max_i \mathrm{class}(X_i) \end{aligned}$$

(under the ordering $G < L < C < M$). The scalar part of $\Theta_{X_1 \times \cdots \times X_k}$ is therefore determined only after the scalar reading is named; the higher-degree components are controlled by the factor of maximal shadow class.

Open Problem 26.28.31 (Convergence, divergence, and non-perturbative completions). The shadow partition function $Z^{\text{sh}}(\hbar) = \sum_{g \geq 1} F_g \hbar^{2g}$ converges absolutely for $|\hbar| < 2\pi$ (Proposition 26.29.7), is entire after Borel summation, and shows no resurgent structure. The convergence radius 2π arises because $F_g^{\text{sc}} = \kappa_{\text{ch}} \cdot \lambda_g^{\text{FP}}$ with $\lambda_g^{\text{FP}} \sim (2\pi)^{-2g}$, so Z^{sh} converges where $|\hbar/(2\pi)| < 1$. The function $(\hbar/2)/\sin(\hbar/2)$ has poles at $\hbar = 2n\pi$ for $n \in \mathbb{Z} \setminus \{0\}$; this is $\sin(\hbar/2)$, not $\sin(\hbar)$, so the radius is 2π , not π . The topological string partition function $Z_{\text{top}}(\hbar)$ diverges as $(2g)!$ (Gevrey-1), is resurgent, and exhibits Stokes phenomena.

- (i) *The shadow as convergent piece.* The shadow tower extracts the *tautological* content of the genus expansion: intersection numbers on $\overline{\mathcal{M}}_g$. The topological string adds *non-tautological* contributions (worldsheet instantons, non-perturbative effects). Is $Z_{\text{top}} = Z^{\text{sh}} \cdot (1 + Z_{\text{np}})$ where Z_{np} encodes worldsheet instantons?
- (ii) *Non-perturbative corrections.* For $K3 \times E$, the non-perturbative corrections are controlled by D-brane instantons wrapping holomorphic curves. The GV invariants n_β^g count the BPS content. The shadow tower, being insensitive to curve class, misses this data entirely. The full topological string combines the shadow (universal, convergent) with the enumerative (curve-class-dependent, divergent).
- (iii) *The OSV bridge.* The OSV conjecture $Z_{\text{BH}} = |Z_{\text{top}}|^2$ relates the black hole partition function (computed via $1/\Phi_{\text{io}}^{\text{un}}$ for $K3 \times E$) to the topological string. Since Z^{sh} extracts the tautological piece of Z_{top} , the shadow controls the tautological piece of the black hole entropy. The precise relationship at subleading order ($\log \Delta$ corrections to S_{BH}) is governed by $F_1 = \kappa_{\text{ch}}/24$ (Sen's logarithmic correction formula).

PROPOSITION 26.28.32 (Class G free-field point: shadow = topological string). For a class G algebra at a free-field B-model point with no effective curve classes and no worldsheet instanton sector,

$$F_g^{\text{sh}}(\mathcal{A}) = F_g^{\text{top}}(\mathcal{A}) \quad \text{for all } g \geq 1.$$

The shadow tower terminates at degree 2, and the shadow partition function $Z^{\text{sh}} = \exp(\sum_{g \geq 1} F_g \hbar^{2g})$ with $F_g^{\text{sc}} = \kappa_{\text{ch}} \cdot \lambda_g^{\text{FP}}$ receives no worldsheet instanton corrections because the bar complex is formal ($m_n = 0$ for $n \geq 3$), so the generating function is the $\hat{A}$ -genus $(\hbar/2)/\sin(\hbar/2)$ evaluated at κ_{ch} . For class L, C, and M algebras, the higher-degree shadow components $S_3, S_4, \dots$ contribute additional “instanton-like” corrections to F_g at genus $g \geq 2$ that modify the free-field $\hat{A}$ -genus formula. For the KS boundary algebra $\mathcal{A}_E$ of $K3 \times E$: $\mathcal{A}_E$ is 24 free bosons, hence class G, hence $F_g^{\text{sh}}(\mathcal{A}_E)$ is exact on the free-field lane. The $K3$ sigma model $\mathcal{A}_{K3}$ is class M (infinite depth), so its shadow tower receives corrections at all degrees.

Proof. For a class-G algebra, $\Theta_{\mathcal{A}}^{\leq r} = \Theta_{\mathcal{A}}^{\leq 2}$ for all $r \geq 2$ (the tower terminates). The shadow obstruction tower collapses to its scalar projection κ_{ch} : the genus- g amplitude is $F_g = F_g^{\text{sc}} = \kappa_{\text{ch}} \cdot \lambda_g^{\text{FP}}$ with no higher-degree corrections. This is the full content of the bar-intrinsic MC element $\Theta_{\mathcal{A}}$ for class G. Since the free-field B-model point has no effective curve classes and receives no worldsheet instanton corrections, $F_g^{\text{top}} = F_g^{\text{sh}}$. $\square$

PROPOSITION 26.28.33 (Bar descent over Čech homotopy limits). Let $\{A_\sigma\}_{\sigma \in I}$ be a diagram of dg algebras indexed by a small category I , and suppose $A \simeq \text{holim}_{\sigma \in I} A_\sigma$ in augmented dg algebras. Then

$$B(A) \simeq \text{holim}_{\sigma \in I} B(A_\sigma) \tag{26.4}$$

as dg coalgebras (quasi-isomorphism).

Proof. The bar–cobar adjunction is $\Omega \dashv B$ (Vol I, Theorem 21.16); therefore B is the right Quillen functor and preserves derived homotopy limits. Applying B to $A \simeq \operatorname{holim}_\sigma A_\sigma$ gives (26.4). For ADE charts of $K_3 \times E$, the Bridgeland–King–Reid, Kapranov–Vasserot, and Van den Bergh equivalences identify the local quiver diagrams with the crepant charts; hence the chain model and the derived Čech homotopy limit represent the same object. $\square$

Remark 26.28.34 (Descent for bar complexes). Proposition 26.28.33 gives a descent theorem for bar complexes: the global bar complex of the Čech homotopy limit is recovered from the local bar complexes and their transition data. For the constructive gluing of $K_3 \times E$ from quiver charts (§26.21), this means the global shadow obstruction tower $\Theta_{\mathcal{A}_{K_3 \times E}}$ can be assembled from local shadow towers $\Theta_{\mathcal{A}_\sigma}$ on each chart, with transition maps controlled by the A_∞ -bimodule data of Construction 26.21.14.

Remark 26.28.35 (The ten comparison problems). The ten comparison problems form three families. The algebraic family concerns the bar complex, moonshine multipliers, mock modularity, factorisation envelopes, and higher-dimensional shadows. The physical family concerns second quantisation, Schottky constraints, and the separation between the convergent shadow tower and the divergent topological string. The categorical family concerns motivic scattering and A_∞ -bimodule descent.

26.29 THE BORCHERDS–KAC–MOODY ALGEBRA OF $K_3 \times E$

The preceding sections developed the elliptic bar complex on a single elliptic curve E_τ . The following sections examine a fundamentally different role for genus-2 modular forms: the Calabi–Yau threefold $K_3 \times E$ produces a Borcherds–Kac–Moody (BKM) superalgebra whose primitive denominator is Δ_5 , while the DVV/DMVV square is the unnormalised Igusa cusp form $\Phi_{10}^{\text{un}} = \Delta_5^2$ of weight 10 on $\operatorname{Sp}(4, \mathbb{Z})$. The shadow obstruction tower of $K_3 \times E$ detects the topological skeleton of this structure, but the passage from shadow amplitudes to the full BPS partition function encounters four independent obstructions. The bridge, and its limitations, require precise quantification.

The Igusa cusp form and the DVV formula

Definition 26.29.1 (Unnormalised Igusa cusp form). The *unnormalised Igusa cusp form* Φ_{10}^{un} is the unique Siegel cusp form of weight 10 on $\operatorname{Sp}(4, \mathbb{Z})$, with scalar fixed by the product expansion below:

$$\dim S_{10}(\operatorname{Sp}(4, \mathbb{Z})) = 1.$$

It admits three equivalent constructions:

- (i) *Product of even theta characteristics.* Let $\Delta_5(\Omega)$ denote the weight-5 product of the ten even genus-2 theta constants, with the standard character and the Fourier–Jacobi leading term fixing the scalar. Then

$$\Phi_{10}^{\text{un}}(\Omega) = \Delta_5(\Omega)^2 = 2^{-12} \prod_{\text{even } m} \mathcal{J}[m](\Omega)^2,$$

where the product runs over the 10 even theta characteristics of genus 2.

- (ii) *Fourier–Jacobi expansion.* $\Phi_{10}^{\text{un}}(\Omega) = \sum_{m \geq 1} \phi_m(\tau, z) p^m$ with $p = e^{2\pi i \sigma}$ and $\Omega = \begin{pmatrix} \tau & z \\ z & \sigma \end{pmatrix} \in \mathfrak{H}_2$. The leading coefficient is

$$\phi_1 = \phi_{10,1}(\tau, z) = \eta(\tau)^{18} \mathfrak{J}_1(\tau, z)^2, \quad (26.5)$$

the unique Jacobi cusp form of weight 10, index 1.

- (iii) *Borcherds multiplicative lift.* Let $Z_{K_3}(\tau, z) = 2 \phi_{0,1}(\tau, z)$ be the K_3 elliptic genus, where $\phi_{0,1}$ is the unique weak Jacobi form of weight 0, index 1 (Eichler–Zagier normalization: $\phi_{0,1}(\tau, 0) = 12$). Then

$$\Phi_{10}^{\text{un}}(\Omega) = p q y \prod_{(n,\ell,m) > 0} (1 - q^n y^\ell p^m)^{2c_0(4nm - \ell^2)}, \quad (26.6)$$

where $q = e^{2\pi i \tau}$, $y = e^{2\pi i z}$, $p = e^{2\pi i \sigma}$, and $c_0(D)$ are the Fourier coefficients of $\phi_{0,1}$ indexed by discriminant D (Eichler–Zagier convention; the factor 2 in the exponent records the K_3 elliptic genus normalization $Z_{K_3} = 2 \phi_{0,1}$).

Remark 26.29.2 (Conventions). We follow the Eichler–Zagier convention for the Jacobi input and write $\Phi_{10}^{\text{un}} = \Delta_5^2$ for the DVV/DMVV square. The Oberdieck–Pandharipande reduced DT scalar uses the monic section $D_5 = 64^{-1} \Delta_5$ and $\Phi_{10}^{\text{OP}} = D_5^2 = 4096^{-1} \Phi_{10}^{\text{un}}$, so

$$Z_{OP/DT} = -(\Phi_{10}^{\text{OP}})^{-1} = -D_5^{-2} = -4096 \Delta_5^{-2}.$$

The elliptic genus $Z_{K_3} = 2 \phi_{0,1}$ evaluates to $Z_{K_3}(\tau, 0) = 24 = \chi_{\text{top}}(K_3)$ at $z = 0$.

The DVV formula (Dijkgraaf–Verlinde–Verlinde, [35]) identifies the $\frac{1}{4}$ -BPS partition function of Type IIA on $K_3 \times T^2$:

$$Z_{\frac{1}{4}\text{-BPS}}(\Omega) = \frac{1}{\Phi_{10}^{\text{un}}(\Omega)} = \sum_{N \geq 0} p^N \chi(\text{Sym}^N(K_3); \tau, z), \quad (26.7)$$

where the second equality is the DMVV infinite-product formula expressing $1/\Phi_{10}^{\text{un}}$ as the generating function for the orbifold elliptic genera of the symmetric products $\text{Sym}^N(K_3)$.

PROPOSITION 26.29.3 (*Genus-2 nature of Φ_{10}^{un}* ;). The unnormalised Igusa cusp form Φ_{10}^{un} is *intrinsically* a genus-2 object: it is a Siegel modular form on $\text{Sp}(4, \mathbb{Z})$, whose natural domain is the Siegel upper half-space $\mathfrak{H}_2 = \{\Omega \in \text{Mat}_{2 \times 2}(\mathbb{C}) : \Omega = \Omega^t, \text{Im}(\Omega) > 0\}$ of complex dimension 3. The three variables (τ, z, σ) of the period matrix $\Omega = \begin{pmatrix} \tau & z \\ z & \sigma \end{pmatrix}$ encode the three chemical potentials conjugate to the electric, magnetic, and dyonic charge invariants of $\frac{1}{4}$ -BPS states. No genus-1 modular form captures the full dyonic spectrum: the Fourier–Jacobi coefficient $\phi_{10,1}$ is the $m = 1$ term in the p -expansion, retaining only the single-centered contribution.

The Borcherds multiplicative lift

Two distinct lifts send the genus-1 Jacobi datum of K_3 to a genus-2 Siegel modular form, and they encode complementary physical content. The Saito–Kurokawa additive lift

$$\text{SK}: J_{k,1}^{\text{cusp}} \longrightarrow S_k(\text{Sp}(4, \mathbb{Z})), \quad \text{SK}(\phi_{10,1}) = \Delta_{10}^{\text{Maass}}$$

is the *perturbative / single-center skeleton*: it is linear in the input Jacobi cusp form, its image is the Maass Spezialschar, and it captures only the $\frac{1}{4}$ -BPS states visible in a single-instanton expansion of the genus-2 partition function. The $\frac{1}{4}$ -BPS wall-crossing spectrum – the essential content of Φ_{10}^{un} controlling dyonic degeneracies across moduli-space walls – is invisible to SK because wall-crossing is non-linear in the elliptic-genus input.

The Borcherds multiplicative lift below is the *non-perturbative* completion: its output is an *infinite product* whose exponents sum the $\frac{1}{4}$ -BPS multiplicities over all discriminants, recovering the full unnormalised Igusa cusp form ($\Phi_{10}^{\text{un}} = \text{SK}(\phi_{10,1})^2 / \text{correction}$ in the Gritsenko normalisation; equivalently, $\Delta_5 = \sqrt{\Phi_{10}^{\text{un}}}$ is the Borcherds product of weight 5). Additive $\leftrightarrow$ multiplicative thus mirrors perturbative $\leftrightarrow$ non-perturbative on the Siegel side.

THEOREM 26.29.4 (Borcherds lift). Let $\phi_{o,1}(\tau, z)$ be the unique weak Jacobi form of weight o , index 1. The Borcherds multiplicative lift

$$\text{Borch}: J_{o,1}^{\text{weak}} \longrightarrow S_{10}(\text{Sp}(4, \mathbb{Z}))$$

sends $2\phi_{o,1}$ to Φ_{10}^{un} , producing the infinite product (26.6). This is the genus-1 to genus-2 bridge: the genus-1 datum $Z_{K_3} = 2\phi_{o,1}$ encodes the exponents of the genus-2 Siegel modular form Φ_{10}^{un} .

Remark 26.29.5 (Structure of the lift). The Borcherds lift converts additive data (Fourier coefficients of Z_{K_3}) into multiplicative data (exponents in the product formula for Φ_{10}^{un}). The exponent $2c_o(D)$ at discriminant $D = 4nm - \ell^2$ in the product formula for $\Phi_{10}^{\text{un}} = \Delta_5^2$ is twice the signed root character of the target BKM superalgebra $\mathfrak{g}_{\Delta_5}$: real roots ($D < 0$) have signed character $c_o(-1) = 1$, lightlike roots ($D = 0$) have signed character $c_o(0) = 10$, and imaginary roots ($D > 0$) have unbounded signed character. Ordinary root-space dimensions or generator counts require a parity fixture or finite Hall–Borcherds recognition.

The leading Fourier–Jacobi coefficient $\phi_1 = \phi_{10,1} = \eta^{18} \mathfrak{S}_1^2$ (equation (26.5)) is itself a product of genus-1 objects. The factorization $\eta^{18} = \eta^{24} \cdot \eta^{-6}$ separates the Ramanujan discriminant $\Delta = \eta^{24}$ (controlling the modular discriminant) from $\eta^{-6} = \eta^{-2\kappa_{\text{ch}}^{\text{Heis}}}$ with $\kappa_{\text{ch}}^{\text{Heis}} = 3$ (the shadow tower’s genus-1 partition function $Z_1(\tau) = \eta(\tau)^{-2\kappa_{\text{ch}}^{\text{Heis}}}$ for $K_3 \times E$ at $\kappa_{\text{ch}}^{\text{Heis}} = \dim_{\mathbb{C}}(K_3 \times E) = 3$).

Shadow tower data for $K_3 \times E$

The modular Koszul framework assigns to $K_3 \times E$ a well-defined shadow obstruction tower. We record the explicit values.

PROPOSITION 26.29.6 (Shadow amplitudes of $K_3 \times E$). Let $\mathcal{A} = \Omega^{\text{ch}}(K_3 \times E)$ be the chiral de Rham complex of $K_3 \times E$. Its Heisenberg shadow has modular characteristic $\kappa_{\text{ch}}^{\text{Heis}}(\mathcal{A}) = \dim_{\mathbb{C}}(K_3 \times E) = 3$ (this is not $c/2$ in general; here the central charge is $c = 2 \cdot 3 = 6$, and $c/2 = 3$ coincides with $\kappa_{\text{ch}}^{\text{Heis}}$ only because $\dim_{\mathbb{C}} = 3$). The shadow amplitudes (Vol I, Theorem D; Theorem 21.16), in the generating function convention $\sum_{g \geq 1} F_g \hbar^{2g}$, are

$$F_g^{\text{Heis}}(K_3 \times E) = \kappa_{\text{ch}}^{\text{Heis}} \cdot \lambda_g^{\text{FP}} = 3 \cdot \frac{(2^{2g-1} - 1) |B_{2g}|}{2^{2g-1} (2g)!} \quad (\text{Heisenberg uniform-weight scalar trace}),$$

where λ_g^{FP} is the Faber–Pandharipande intersection number. Explicitly:

g	1	2	3	4	5
λ_g^{FP}	$\frac{1}{24}$	$\frac{7}{5760}$	$\frac{31}{967680}$	$\frac{127}{154828800}$	$\frac{73}{3503554560}$
F_g^{Heis}	$\frac{1}{8}$	$\frac{7}{1920}$	$\frac{31}{322560}$	$\frac{127}{51609600}$	$\frac{73}{1167851520}$

The genus-1 amplitude $F_1^{\text{Heis}} = \kappa_{\text{ch}}^{\text{Heis}}/24 = 1/8$ matches the leading behaviour of $Z_1(\tau) = \eta(\tau)^{-6}$, since $\log \eta(\tau) = 2\pi i\tau/24 + O(q)$ and the η -power is $-2\kappa_{\text{ch}}^{\text{Heis}} = -6$.

Proof. Direct from Vol I, Theorem D (Theorem 21.16) with $\kappa_{\text{ch}}^{\text{Heis}} = 3$. The value $\kappa_{\text{ch}}^{\text{Heis}} = 3$ is the Heisenberg modular characteristic of $\Omega^{\text{ch}}(K_3 \times E)$, equal to $\dim_{\mathbb{C}}(K_3 \times E)$ by the Chern character computation for the chiral de Rham complex of a Calabi–Yau manifold. Each F_g is verified by three independent paths: direct Bernoulli computation, the $\hat{A}$ -generating function $(t/2)/\sin(t/2) - 1 = \sum_{g \geq 1} \lambda_g^{\text{FP}} t^{2g}$, and the additivity $\kappa_{\text{ch}}^{\text{Heis}}(K_3 \times E) = \kappa_{\text{ch}}^{\text{Heis}}(K_3) + \kappa_{\text{ch}}^{\text{Heis}}(E) = 2 + 1 = 3$ (Vol I, Corollary 21.16). $\square$

PROPOSITION 26.29.7 (*Convergence of the shadow generating function*;). The shadow generating function $Z^{\text{sh}}(t) := \kappa_{\text{ch}}((t/2)/\sin(t/2) - 1) = \sum_{g \geq 1} F_g t^{2g}$ has the following analytic properties:

- (i) *Convergence radius.* $R = 2\pi$. The nearest singularities of $(t/2)/\sin(t/2)$ are the simple poles of $1/\sin(t/2)$ at $t = \pm 2\pi$, giving $R = 2\pi \approx 6.283$.
- (ii) *Closed form.* $Z^{\text{sh}}(t) = \kappa_{\text{ch}}((t/2)/\sin(t/2) - 1)$, an algebraic function of $\sin(t/2)$.
- (iii) *Borel transform.* The Borel transform $\hat{Z}(u) = \sum_{g \geq 1} F_g u^{2g}/(2g)!$ is an *entire* function of u (no singularities on $\mathbb{R}_+$). There is no resurgence: the Borel sum recovers Z^{sh} exactly.

This contrasts sharply with the topological string partition function $Z_{\text{top}}(\lambda) = \exp(\sum_{g \geq 0} F_g^{\text{top}} \lambda^{2g-2})$, which is Gevrey-1 divergent: $F_g^{\text{top}} \sim (2g)!$ from the volume growth of $\mathcal{M}_g$. For $K_3 \times E$ with $\kappa_{\text{ch}}^{\text{Heis}} = 3$: $Z^{\text{sh}}(t) = 3((t/2)/\sin(t/2) - 1)$ converges absolutely for $|t| < 2\pi$.

Proof. The function $f(t) = (t/2)/\sin(t/2)$ is meromorphic with poles at $t = 2\pi k$ for $k \in \mathbb{Z} \setminus \{0\}$ (zeros of $\sin(t/2)$). The nearest pole to $t = 0$ is at $|t| = 2\pi$, giving convergence radius $R = 2\pi$ for the Taylor series about $t = 0$. The Borel transform replaces t^{2g} by $u^{2g}/(2g)!$, which grows as $|B_{2g}|/(2g)! \sim 2/(2\pi)^{2g}$ (from the Bernoulli asymptotics), so the Borel series has infinite radius. Since $\hat{Z}$ is entire, the Laplace integral $\int_0^\infty e^{-u/t} \hat{Z}(u) du/t$ converges for all $t > 0$ and reproduces $Z^{\text{sh}}(t)$ term by term. No Stokes phenomenon occurs. $\square$

The shadow–Siegel gap

The shadow amplitudes F_g and the unnormalised Igusa cusp form Φ_{10}^{un} are related but categorically distinct objects. Several obstructions prevent the shadow tower from reconstructing Φ_{10}^{un} ; of the four itemised below, (O₂) and (O₃) share the DMVV second-quantisation mechanism and are not logically independent, while (O₁) and (O₄) are genuinely orthogonal.

THEOREM 26.29.8 (*Shadow–Siegel gap*). The shadow obstruction tower of $K_3 \times E$ does not produce the unnormalised Igusa cusp form. The gap decomposes into four obstructions (of which (O₂) and (O₃) share the DMVV second-quantisation mechanism):

- (O₁) **Categorical.** F_g is a rational number (a tautological intersection number on $\overline{\mathcal{M}}_g$); $\Phi_{10}^{\text{un}}(\Omega)$ is a holomorphic function on $\mathfrak{H}_2$ (a Siegel cusp form). The shadow captures the topological skeleton of the genus- g amplitude, not the full analytic partition function.

- (O₂) **Modular characteristic.** The shadow tower uses $\kappa_{\text{ch}}^{\text{Heis}} = 3$ (the modular characteristic of the single-copy chiral algebra $\Omega^{\text{ch}}(K_3 \times E)$, equal to $\dim_{\mathbb{C}} = 3$). The unnormalised Igusa cusp form has weight $\text{wt}(\Phi_{10}^{\text{un}}) = 10 = 2\kappa_{\text{BKM}}(\Delta_5)$ with $\kappa_{\text{BKM}}(\Delta_5) = c_N(\mathfrak{o})/2|_{N=1} = 10/2 = 5$ (Borcherds weight theorem; Proposition 17.6.7). The ratio $\kappa_{\text{BKM}}(\Delta_5)/\kappa_{\text{ch}}^{\text{Heis}} = 5/3$ reflects the passage from single-copy to symmetric-product via the DMVV formula (26.7), and is specific to $K_3 \times E$ (it is not a universal constant: for the quintic, $\chi = -200$ gives a different ratio).
- (O₃) **Second quantization.** The shadow tower is first-quantized: F_g is the genus- g amplitude of a *single* copy of $\mathcal{A}$. The partition function $1/\Phi_{10}^{\text{un}}$ is second-quantized: it sums over *all* symmetric products $\text{Sym}^N(K_3)$ via the DMVV formula. The Borcherds lift, the DMVV infinite product, and the symmetric-product orbifold construction are second-quantized operations not captured by the shadow tower alone.
- (O₄) **Schottky at $g \geq 4$.** The Torelli map $j: \mathcal{M}_g \rightarrow \mathcal{A}_g$ has image of codimension $(g-2)(g-3)/2$ in $\mathcal{A}_g$ for $g \geq 4$. Explicitly:

g	1	2	3	4	5	6	7
$\dim \mathcal{M}_g$	1	3	6	9	12	15	18
$\dim \mathcal{A}_g$	1	3	6	10	15	21	28
codim	0	0	0	1	3	6	10

For $g \leq 3$, the Torelli map is an isomorphism ($g = 1$), birational ($g = 2$), or injective with dense image ($g = 3$), so the shadow tower sees equivalently all Siegel modular form data. At $g = 4$, the Schottky–Igusa form of weight 8 vanishes precisely on the Jacobian locus $\mathcal{J}_4 = j(\mathcal{M}_4)$: this is information accessible to Siegel forms but invisible to the shadow tower. For $g \rightarrow \infty$, the ratio $\text{codim}/\dim \mathcal{A}_g \rightarrow 1$: the Jacobian locus becomes asymptotically negligible.

Proof. (O₁) is immediate from the definitions: $F_g \in \mathbb{Q}$ while Φ_{10}^{un} is a holomorphic function of three complex variables. (O₂) follows from the two independent computations $\kappa_{\text{ch}}^{\text{Heis}} = \dim_{\mathbb{C}} = 3$ (Proposition 26.29.6) and $\text{wt}(\Phi_{10}^{\text{un}}) = 10$ (Definition 26.29.1), together with the identification $\kappa_{\text{BKM}}(\Delta_5) = c_N(\mathfrak{o})/2|_{N=1} = 10/2 = 5$ (Borcherds weight theorem). (O₃) is the content of the DMVV formula: the second equality in (26.7) expresses $1/\Phi_{10}^{\text{un}}$ as a sum over symmetric products, an operation external to single-copy chiral algebra theory. (O₄): the codimension formula $\text{codim}(\mathcal{J}_g, \mathcal{A}_g) = g(g+1)/2 - (3g-3) = (g-2)(g-3)/2$ for $g \geq 2$ is classical (Riemann, Schottky). $\square$

Remark 26.29.9 (The genus-2 Torelli bridge). At genus 2, the Torelli map $j: \mathcal{M}_2 \rightarrow \mathcal{A}_2$ is birational: its complement $\mathcal{A}_2 \setminus j(\mathcal{M}_2)$ is the product locus (abelian surfaces isomorphic to a product of two elliptic curves). This means Φ_{10}^{un} restricts to a well-defined form on $\mathcal{M}_2$ (vanishing on the product locus at the boundary of the Satake compactification), and the genus-2 partition function $Z_2(\Omega)$ related to $1/\Phi_{10}^{\text{un}}$ has a shadow amplitude

$$F_2 = \int_{\mathcal{M}_2} \kappa_{\text{ch}} \cdot \lambda_2^{\text{FP}} = \frac{7}{1920}$$

as its topological residue. The shadow F_2 is what remains of $1/\Phi_{10}^{\text{un}}$ after integrating out all modular dependence: a tautological intersection number in the Chow ring of $\overline{\mathcal{M}}_2$.

THEOREM 26.29.10 (Full genus-2 partition function of $K_3 \times E$). Assume the full genus-2 shadow-correction form $R_{\text{shadow}}^{K_3}$ is constructed as a Siegel modular correction compatible with the Heisenberg

base and with the Gritsenko–Nikulin denominator normalisation. The full genus-2 chiral partition function of $K_3 \times E$ decomposes as

$$Z_2^{K_3 \times E}(\Omega) = Z_2^{\text{Heis}, c=24}(\Omega) \cdot R_{\text{shadow}}^{K_3}(\Omega), \quad (26.8)$$

where the Heisenberg base is $Z_2^{\text{Heis}, c=24}(\Omega) = 1/\Phi_{10}^{\text{un}}(\Omega)$, a meromorphic Siegel form of weight -10 on $\text{Sp}(4, \mathbb{Z})$ (reciprocal of the weight-10 unnormalised Igusa cusp form Φ_{10}^{un}). The Gritsenko–Nikulin squaring identity $\Phi_{10}^{\text{un}}(\Omega) = \Delta_5(\Omega)^2|_{\text{Sp}(4, \mathbb{Z})}$ relates the two forms: $\Delta_5 \in S_5(\Gamma_{\text{para}})$ is the weight-5 paramodular Gritsenko cusp form on the level-1 paramodular group $\Gamma_{\text{para}} \supset \text{Sp}(4, \mathbb{Z})$ (Γ_{para} extends the Siegel modular group by a Fricke involution, and a weight-5 cusp form does not exist on $\text{Sp}(4, \mathbb{Z})$ alone). The square $\Delta_5^2 \in S_{10}(\Gamma_{\text{para}})$ is Fricke-invariant and therefore descends to $\text{Sp}(4, \mathbb{Z})$, where it is Φ_{10}^{un} in the DVV/DMVV square convention. The shadow correction factor is

$$R_{\text{shadow}}^{K_3}(\Omega) = 1 + \sum_{k \geq 3} S_k^{K_3} \cdot C_k(\Omega). \quad (26.9)$$

Here $S_k^{K_3}$ are the shadow tower coefficients of the K_3 sigma model VOA (the small $\mathcal{N} = 4$ SCA at $c = 6$, $k_R = 1$; $\kappa_{\text{ch}}^{\text{Hodge}} = 2$, $\alpha = 2$, $S_4 = 5/156$, class $\mathcal{M}$), and $C_k(\Omega)$ are genus-2 modular cocycles arising from integrating the k -point OPE kernel over Σ_2 .

The shadow correction $R_{\text{shadow}}^{K_3}$ is *not* a Siegel modular form: it transforms as a mock Siegel modular form of weight 0, with the mock-modular source being the quasi-modular Eisenstein series E_2 in the leading cocycle C_3 . The shadow series is Gevrey-1 divergent (class $\mathcal{M}$: Borel summable but not convergent).

The framed algebra $\mathcal{A}_{K_3 \times E}^{(\Sigma_2, C)}$ is available after choosing the H1–H4 datum and fixed specialisation of Theorem 5.6.16; this is the object-level $d = 3$ assignment, not a global Φ_3 functor. The theorem’s content is the factorisation structure (26.8) and the identification of the shadow correction factor. The shadow tower data of the K_3 sigma model is proved at $d = 2$ (CY-A₂, Theorem 5.3.11).

Proof. The Heisenberg factor is the DMVV genus-two lift for the rank-24 Mukai Heisenberg algebra, hence equals $1/\Phi_{10}^{\text{un}}$ by the Gritsenko–Nikulin square relation $\Phi_{10}^{\text{un}} = \Delta_5^2$. The remaining first-quantised A_∞ contribution is the shadow tower of the K_3 sigma model; CY-A₂ identifies its coefficients $S_k^{K_3}$, and the Getzler–Kapranov clutching construction gives the genus-two cocycles $C_k(\Omega)$. Multiplying the DMVV base by this shadow correction gives (26.8). The $\text{Sp}(4, \mathbb{Z})$ -weight is the sum of the DMVV weight and the weights of the clutching cocycles, while the Borel resummation follows from the factorial bound on the $S_k^{K_3} C_k(\Omega)$ expansion. Thus the analytic and chain-level presentations agree. $\square$

Remark 26.29.11 (Shadow–Siegel bridge at genus 2). The identity $Z_2^{\text{Heis}, c=24} = 1/\Phi_{10}^{\text{un}}$ says that the Heisenberg base *already is* the DMVV answer. The shadow correction $R_{\text{shadow}}^{K_3}$ therefore represents first-quantised A_∞ corrections *beyond* the DMVV formula: the non-perturbative, mock-modular sector invisible to the symmetric product.

At $z = 0$ (separating degeneration $\Sigma_2 \rightarrow \Sigma_1 \cup \Sigma_1$), all cocycles C_k vanish and $R_{\text{shadow}} = 1$, recovering the DMVV answer. The departure from $1/\Phi_{10}^{\text{un}}$ is controlled by the propagator $|z|^2/(\text{Im}(\tau) \text{Im}(\sigma))$ between the two handles.

The E_3 bar spectral sequence at genus g for $K_3 \times E$ (class $\mathbf{M}$) has

$$E_4(B^{E_3}(\mathcal{A})) = (3t(1+t))^g, \quad \dim E_4 = 6^g.$$

For $g \leq 3$ degree reasons force $E_4 = E_\infty$, so this gives the actual bar cohomology dimension. For $g \geq 4$ the first possible higher differential is d_5 , and the proved statement is only $\dim E_\infty \leq 6^g$ until that differential is computed. At $g = 2$ one obtains 36 with Poincaré polynomial $(3t(1+t))^2 = 9t^2 + 18t^3 + 9t^4$.

Euler characteristic and Donaldson–Thomas structure

PROPOSITION 26.29.12 ($\chi(K_3 \times E) = 0$ and its consequences;). The Euler characteristic of $K_3 \times E$ vanishes:

$$\chi(K_3 \times E) = \chi(K_3) \cdot \chi(E) = 24 \cdot 0 = 0.$$

This has three structural consequences for the enumerative geometry:

- (i) *MacMahon trivialization.* The degree-0 DT partition function of a Calabi–Yau threefold X is $Z_{\text{DT},0}(X) = M(-q)^{\chi(X)}$, where $M(q) = \prod_{n \geq 1} (1 - q^n)^{-n}$ is the MacMahon function counting plane partitions. For $\chi = 0$: $M(-q)^0 = 1$, so $Z_{\text{DT},0}(K_3 \times E) = 1$. There is no degree-0 contribution from plane-partition-type combinatorics.
- (ii) *DT/PT correspondence.* The vanishing $\chi = 0$ implies that the Donaldson–Thomas and Pandharipande–Thomas partition functions agree without a MacMahon prefactor correction:

$$Z_{\text{DT}}(K_3 \times E) = Z_{\text{PT}}(K_3 \times E).$$

This is the “clean” case of the DT/PT wall-crossing formula: the wall-crossing factor $M(-q)^\chi$ is trivial.

- (iii) *BCOV anomaly coefficient.* The BCOV holomorphic anomaly coefficient $\kappa_{\text{ch}}^{\text{BCOV}} = \chi(X)/24$ vanishes for $K_3 \times E$. The anomaly equation $\bar{\partial}_i F_g = \frac{1}{2} C_i^{jk} (D_j D_k F_{g-1} + \sum_{r=1}^{g-1} D_j F_r D_k F_{g-r})$ is therefore unobstructed at the topological level, consistent with the shadow tower being controlled by the single parameter $\kappa_{\text{ch}}^{\text{Heis}} = 3$ without BCOV corrections.

Remark 26.29.13 (*The $\kappa_\bullet$ -family for $K_3 \times E$: four distinct invariants*). The canonical displayed spectrum uses $\{\kappa_{\text{ch}}^{\text{Heis}}, \kappa_{\text{cat}}, \kappa_{\text{BKM}}(\Delta_5), \kappa_{\text{fiber}}\}$, each computed by a *different construction* on the same $\Phi_3^{\text{FA}}(D^b(\text{Coh}(K_3 \times E)))$ output read through four distinct specialisations or construction routes, never conflated. The compact Hodge-supertrace invariant is separate and equals $\kappa_{\text{ch}}^{\text{Hodge}}(K_3 \times E) = 0$. For $K_3 \times E$ the four displayed values are:

Symbol	Value	Source
$\kappa_{\text{ch}}^{\text{Heis}}(\mathcal{A})$	3	Heisenberg modular characteristic (Vol I, Theorem D); $\dim_{\mathbb{C}}(K_3 \times E)$
$\kappa_{\text{cat}}(K_3 \times E)$	0	Künneth-multiplicative: $\chi(\mathcal{O}_{K_3}) \cdot \chi(\mathcal{O}_E) = 2 \cdot 0$
$\kappa_{\text{BKM}}(\Delta_5)$	5	Primitive Borchers weight: $\text{wt}(\Delta_5) = c_N(0)/2 _{N=1}$; $\Phi_{10}^{\text{un}} = \Delta_5^2$ has weight 10
$\kappa_{\text{fiber}}(K_3)$	24	Mukai lattice rank: $\text{rank}(\tilde{H}(K_3, \mathbb{Z})) = \text{rank}(U^4 \oplus (-E_8)^2) = 24$

The canonical $\kappa_{\text{fiber}} = 24$ is the Mukai lattice rank (the K_3 -fibre lattice invariant, identified with the central charge of the 24-free-boson Kuga–Satake boundary algebra of Example 26.28.3), not the K_3 -fibre categorical value $\chi(\mathcal{O}_{K_3}) = 2$: the latter is the K_3 -restricted reading of κ_{cat} (total-space value 0 on $K_3 \times E$ by Künneth; fibre-restricted value 2), a different invariant. The full $K_3 \times E$ spectrum is the five-construction datum $\{0, 0, 3, 5, 24\}$: categorical Euler value $\kappa_{\text{cat}} = 0$ (Künneth-multiplicative on $\chi(\mathcal{O}_{K_3}) \cdot \chi(\mathcal{O}_E) = 2 \cdot 0$), compact chiral Hodge supertrace $\kappa_{\text{ch}}^{\text{Hodge}}(K_3 \times E) = \sum_q (-1)^q h^{0,q}(K_3 \times E) = 0$ (the same numerical value but a distinct construction, the Hodge supertrace of the chiral output), Heisenberg specialisation $\kappa_{\text{ch}}^{\text{Heis}} = 3$, primitive BKM weight $\kappa_{\text{BKM}}(\Delta_5) = 5$, and fibre Mukai rank

$\kappa_{\text{fiber}} = 24$ (cf. Theorem 5.11.1 and [96], Remark after Proposition on the rank-24 Mukai Heisenberg). The number 2 remains present only as the auxiliary K_3 -fibre categorical check $\kappa_{\text{cat}}(K_3) = \chi(\mathcal{O}_{K_3}) = 2$; it is not a $K_3 \times E$ total-space or fibre-rank entry. Two further numerical proxies appear in the $K_3 \times E$ literature but lie *outside* the canonical subscripted quadruple and are distinct with it: the BCOV value $\chi(K_3 \times E)/24 = 0$ and the MacMahon exponent of $\mathcal{M}(-q)^\chi = \mathcal{M}(-q)^0$, both vanishing on $K_3 \times E$ precisely because $\kappa_{\text{cat}}(K_3 \times E) = 0$. These coincide with $\kappa_{\text{ch}} = c/2$ only for the Virasoro algebra; for $K_3 \times E$ the five canonical invariants diverge, and each answers a different categorical, Hodge-supertrace, Koszul, Borchers, or fibrewise question.

Remark 26.29.14 (Shadow depth classification). The chiral algebra $\Omega^{\text{ch}}(K_3 \times E)$ has central charge $c = 6$, multiple generators of varying conformal weight, and an infinite tower of OPE coefficients from the K_3 sigma model. By the shadow depth classification (Vol I, Definition 21.16), $K_3 \times E$ belongs to class M (mixed, shadow depth $r_{\text{max}} = \infty$): the Borchers product formula (26.6) has infinitely many distinct doubled exponents $2c_0(D)$. Its square-root Δ_5 -lane has signed root-character coefficients $c_0(D)$, reflecting an infinite sequence of independent shadow invariants. This is consistent with the operadic complexity principle: the sigma model on a Calabi–Yau target, being a fully interacting CFT, has non-formal E_1 -chiral coassociative structure at all degrees.

Remark 26.29.15 (Genus stratification summary). The bridge between the shadow tower and Siegel modular forms degrades with genus:

Genus	Torelli	Shadow–Siegel relation
1	Isomorphism	$F_1 = 1/8$ matches η^{-6} exactly
2	Birational	$F_2 = 7/1920$ is topological residue of $1/\Phi_{10}^{\text{un}}$
3	Injective, dense	F_3 captures most Siegel data
≥ 4	Schottky obstructed	Shadow sees codim- $\frac{(g-2)(g-3)}{2}$ slice

The genus-2 case is the first one where the Torelli map is birational and Φ_{10}^{un} (the unique genus-2 cusp form of weight 10) enters directly. The four obstructions of Theorem 26.29.8 quantify exactly what the shadow tower captures (the topological skeleton $F_g^{\text{sc}} = \kappa_{\text{ch}} \lambda_g^{\text{FP}}$, exact at $g = 1$; the full coefficient is $F_g = F_g^{\text{sc}} + \delta F_g^{\text{cross}}$ at $g \geq 2$) and what it misses (the analytic, second-quantized, and transverse-Siegel content).

26.30 $K_3 \times E$ SYNTHESIS: BI-BASED FACTORISATION DATUM

Remark 26.30.1 (Bi-based factorisation datum). By Chapter 20, Theorem 20.7.1, the K_3 chiral bialgebra lives on a bi-based Ran-space datum: chiral base $\text{Ran}(E_{24}^{\text{nod,sm}})$ on the smooth locus of the marked reference curve with nearby-cycles $\mathcal{D}$ -modules at the 24 transported Kodaira I_1 -nodes; parameter base $\overline{\mathcal{A}}_2$ with Francis–Gaitsgory factorisation ∞ -category in holonomic $\mathcal{D}$ -modules regular-singular on $H_1 \cup H_4$; averaging correspondence $\text{av} = \pi_{\text{Sp}_4} \circ \mathcal{P}_{K_3}$ on the fixed rank-5 lattice-polarised branch.

Remark 26.30.2 (Δ_5 as 1-loop-forced output). By Chapter 20, Theorem 20.11.1, the Gritsenko–Nikulin Igusa form Δ_5 is the 1-loop-forced output of paramodular anomaly cancellation in twisted 11D supergravity on $K_3 \times T^2$ with 24 M_5 -branes on I_1 Kodaira fibres. Its Borchers weight is the constant-term value $\kappa_{\text{BKM}}(\Delta_5) = c_N(0)/2|_{N=1} = 10/2 = 5$. The monic Borchers determinant used in the denominator algebra is $D_5 = 64^{-1}\Delta_5$, so $\text{den}(\mathfrak{g}_{\Delta_5}) = D_5(2Z) = 64^{-1}\Delta_5(2Z)$. The OP/DT scalar square is

$$\Phi_{10}^{\text{OP}} = D_5^2 = 4096^{-1}\Delta_5^2, \quad Z_{\text{OP/DT}} = -(\Phi_{10}^{\text{OP}})^{-1} = -4096 \Delta_5^{-2}.$$

The theta-normalised square Δ_5^2 spans the classical weight-10 Igusa line; the OP superscript records the monic scalar normalisation. The Fake-Monster lift Φ_{12} is a $d = 5$ Borchers form of weight 12 and does not normalise the $K_3 \times E$ scalar. The aggregate stress-tensor residue $\sum_{i=1}^{24} \text{Res}_{z=z_i} T(z) = -\chi(\mathcal{O}_{K_3}) = -2$ and the Fricke-split residue sector are anomaly-cancellation data for the same output; they are not an additive decomposition of $\kappa_{\text{BKM}}(\Delta_5)$ into $\chi(\mathcal{O}_{K_3})$ plus a Heisenberg contribution, and they do not construct compact Hall brackets or orientation monodromy. Four duality frames (heterotic Harvey–Moore 1996; IIB D1-D5 DVV 1996-97; IIA DMVV 1997; M-theory Witten 1995) produce the same form.

Remark 26.30.3 (4d class-S parent). The 4d $\mathcal{N} = 2$ parent is $\mathcal{T}[A_1, \Sigma_{0,24}]$ with 24 maximal regular $\mathfrak{su}(2)$ punctures preserving the Steiner system $S(5, 8, 24)$ (Conway–Sloane 1988). Chapter 20, Theorem 20.10.2 and Proposition 20.10.3, compute the Chacaltana–Distler pants decomposition with 22 T_2 trinions and 21 $\mathfrak{su}(2)$ tubes:

$$(n_v, n_h) = (63, 88), \quad c_{4d} = \frac{2n_v + n_h}{12} = \frac{107}{6}, \quad c_{2d} = -12c_{4d} = -214.$$

The Coulomb rank is 21 and the flavour algebra is $\mathfrak{su}(2)^{24}$. The Schur-index bridge is the composite of Theorem 20.10.8,

$$\mathcal{I}_{\text{Schur}} \xrightarrow{\text{av}_{M_{24}}} \phi_{0,1}^{K_3} \xrightarrow{\text{Borch}} \Delta_5,$$

not a direct equality $\mathcal{I}_{\text{Schur}} = 1/\Delta_5$.

Remark 26.30.4 (Conditional Heegner classification invariant). Assume the compact Hall source, pairing, comparison maps, PBW/no-extra relations, and inverse-limit condition have been supplied, and assume the resulting source deformation complex carries the Bruinier–Heegner characteristic comparison. Then the paramodular $K(1)$ invariant line of the comparison is generated by the scalar Igusa form:

$$\chi_{\text{Heg}}(\text{Def}_{K_3}^{K(1), \mathbb{Z}/2}) \subset \mathbb{C} \cdot \Delta_5.$$

Here $K(1) = \Gamma_{\text{para}}$ is the level-1 paramodular group introduced above equation (26.9). This is a conditional Heegner characteristic statement; it is not an intrinsic computation of $H^2(\mathfrak{g}_{\Delta_5})$ before the source-recognition datum is constructed.

Remark 26.30.5 (Mukai doubling $K^{\kappa_{\text{ch}}} = 8$). Write $K^{\kappa_{\text{ch}}}$ for the Koszul conductor of the κ_{ch} -graded bar complex (Vol I, Theorem C). Then $K^{\kappa_{\text{ch}}} = 2c_+(\text{Mukai}(K_3)) = 8$ via the Mukai lattice calculation. The order-eight Humbert datum and a Lusztig $\ell = 8$ specialisation are comparison data, not consequences of Bruinier’s Chern-class formula alone. Vol I Theorem C bucket enlarges to $\{0, 8, 13, 250/3, 98/3\}$.

Explicit Stage-2 specialisation and dimension-stratified siblings

Theorem 5.1.58 of Chapter 5 is used here in its conditional form: the Stage-2 specialisation $\text{Sp}_{K_3, E}^{\text{ch}}(\Phi_3^{\text{FA}}(\text{Perf}(K_3 \times E)))$ has target $U^{\text{ch}}(\mathfrak{g}_{\Delta_5})$ only after compact source provenance, source orientation monodromy, finite Hall–Borchers recognition, and completion data are supplied. The following sharpening expresses that conditional identification via Lurie additivity against the Mukai Heisenberg factor, and extends the sibling census to the dimension-stratified list.

COROLLARY 26.30.6 (Explicit $\text{Sp}_{K_3, E}^{\text{ch}}$ via Lurie additivity). Assume the H1–H4 K_3 -fibre specialisation of Theorem 5.11.1, the compact obstruction trivialisation of Definition 26.21.6, the finite Rees gluing of Definition 26.21.7, the compact CY₃ closure input of either $B_{\text{TCFT}}^{(2)}$ or the filtered $HH_{E_1}^{-2}$

theorem, the finite Hall–Borcherds recognition datum of Proposition 26.21.8 with compact source provenance, source orientation monodromy, matrices M, D, B, G, K, Q, A , radical descent, no-extra-relations kernel equality, PBW comparison, centre control, associator control, and strict completion transitions, satisfying the finite-double criterion of Theorem 19.7.13, and the centre/double assembly data of Definition 23.2.4. Under the Dunn–Lurie decomposition $E_3 \simeq E_2 \otimes E_1$ (HA 5.5.3.6), the Stage-2 specialisation of $\Phi_3^{\text{FA}}(\text{Perf}(K_3 \times E))$ along $\Sigma_2 = K_3$ decomposes as

$$\text{Sp}_{K_3, E}^{\text{ch}}(\Phi_3^{\text{FA}}(\text{Perf}(K_3 \times E))) \simeq U^{\text{ch}}(\mathfrak{heis}_{\text{Muk}}) \otimes U^{\text{ch}}(\mathfrak{g}_{K_3}^{\text{BPS}}) \quad (26.10)$$

as E_1 -chiral algebras on E , where $\mathfrak{heis}_{\text{Muk}}$ is the abelian Heisenberg of the Mukai lattice $\Lambda_{\text{Muk}} = \Pi_{4,20}$ of rank 24, whose middle-cohomology summand has signature $(3, 19)$ and rank 22, and $\mathfrak{g}_{K_3}^{\text{BPS}} = \mathfrak{n}_+(\mathfrak{g}_{\Delta_3})$ is the BPS Lie algebra of Theorem 19.8.8 of Chapter 19 equipped with the Maulik–Okounkov R -matrix braiding. The total output is the vertex envelope $U^{\text{ch}}(\mathfrak{g}_{\Delta_3})$ of Theorem 5.1.58.

Proof. Theorem 5.11.1 supplies, on the fixed K_3 -fibre branch and under H1–H4, a framed object-level E_1 -chiral algebra on the elliptic reference curve. Dunn–Lurie additivity separates the local E_3 -observable into a transverse E_2 sector on the K_3 surface and an ordered E_1 sector on E ; it does not by itself prove compact CY₃ closure, which is why the $B_{\text{TCFT}}^{(2)}$ or filtered $HH_{E_1}^{-2}$ input is part of the hypothesis:

$$\int_{K_3 \times E} \Phi_3^{\text{FA}}(-) \simeq \int_E \left(\int_{K_3} \Phi_3^{\text{FA}}(-)_{E_2} \right)_{E_1}.$$

The compact K_3 integral of the abelian Mukai sector is the Heisenberg algebra attached to $\Lambda_{\text{Muk}} \otimes \mathbb{C}$. Its oscillator Fock character contributes the factor $1/\eta^{24}$. The momentum sum over the indefinite Mukai lattice is not a holomorphic theta function before a positive four-plane is chosen; after that choice it is the real-analytic Siegel–Narain factor. The chiral vertex envelope of the oscillator sector is therefore $U^{\text{ch}}(\mathfrak{heis}_{\text{Muk}})$, while the Narain momentum factor belongs to the completed modular trace.

The non-abelian positive-half sector is not obtained by calling the BKM object a Yangian, and not by coefficient projection. The oriented map $\Theta_{\text{hCS} \rightarrow \text{Hall}}^{K_3 \times E}$ produces the compact Hall source; Theorem 19.7.6 records its finite source matrices; the Gritsenko–Nikulin denominator supplies the target Borcherds multiplicity function. The finite radical-quotient Hall–Drinfeld double is constructed window by window in Theorem 19.7.5; only after the defect vanishing of Theorem 19.7.13 does that source quotient identify with $\mathfrak{n}_+(\mathfrak{g}_{\Delta_3})$ and the finite Serre–Borcherds current quotient on the Borcherds charge lattice. If those five vanishings have not been proved, the canonical replacement is the recognition envelope $\mathcal{E}_{\Delta_3}^{\leq H}(K_3 \times E, \sigma)$ of Theorem 19.7.15; when the finite source matrices do prove the five vanishings, Theorem 19.7.16 gives the missing injectivity $\mathfrak{J}_H \cap D_H^X = 0$. The Maulik–Okounkov R -matrix remains the E_2 chamber-braiding datum on the K_3 stable-envelope side; the E_1 output on E acquires its braided representation category only after the Drinfeld-centre passage encoded in the CY-C centre/double assembly data.

Tensor decomposition (26.10) is therefore the explicit form of the fixed K_3 -fibre specialisation: an abelian Mukai–Heisenberg sector tensored with the positive BPS Borcherds sector. The final vertex envelope $U^{\text{ch}}(\mathfrak{g}_{\Delta_3})$ is reached after the finite radical-quotient doubles are recognised at every height, the centre and associator data are compatible in the inverse limit, and the vacuum/VOA envelope data are supplied; before those data are supplied the proved object is the displayed E_1 -chiral positive-half decomposition. $\square$

Remark 26.30.7 (Six (Σ_2, C) -specialisations of $\Phi_3^{\text{FA}}(\text{Perf}(K_3 \times E))$). The Stage-2 specialisation $\text{Sp}_{\Sigma_2, C}^{\text{ch}}$ of Definition 5.1.1 consumes a transverse-surface/boundary-curve pair $(\Sigma_2, C) \subset (K_3 \times E) \times (K_3 \times E)$. The following six rows are comparison targets, not six applications of Φ_3 : R_1 is the fixed K_3 -fibre specialisation constructed by Theorem 5.11.1, while $R_2 - R_6$ are independent construction outputs whose interpretation as Stage-2 shadows requires the CY-C bridge and centre/double data.

R_1 (**canonical K_3 fibration**). $(\Sigma_2, C) = (K_3, E)$; conditional output $U^{\text{ch}}(\mathfrak{g}_{\Delta_5})$ by Corollary 26.30.6; monic denominator $D_5(2Z) = 64^{-1}\Delta_5(2Z)$; Borchers weight $\kappa_{\text{BKM}}(\Delta_5) = c_N(\mathfrak{o})/2|_{N=1} = 5$.

R_2 (**K_3 -orbifold twist ladder**). $(\Sigma_2, C) = (K_3/(\mathbb{Z}/N\mathbb{Z}), E)$ for $N \in \{1, 2, 3, 4, 6\}$ Mukai–Nikulin symplectic denominator lane; output the N -twisted paramodular $U^{\text{ch}}(\mathfrak{g}_{\Phi_N})$ on E ; $\kappa_{\text{BKM}}(\Phi_N) = c_N(\mathfrak{o})/2 \in \{5, 4, 3, 2, 1\}$ in the chiral-half Gritsenko denominator normalisation. Chiral-bialgebra sharpening of Lorgat 2020 Conjecture 1 supplies target comparison invariants for the putative comparison with $\mathbf{H}_{\Delta_5}^{(N)}$: character $\text{ch } \mathbf{H}_{\Delta_5}^{(N)}(Z) = \Phi_N(Z)^{-2}$, root multiplicities $c^{(g_N)}(D, \ell)$, and Borchers weight $c_N(\mathfrak{o})/2$. They do not pin a chiral-bialgebra equivalence. The equivalence

$$\text{Sp}_{K_3/(\mathbb{Z}/N\mathbb{Z}), E}^{\text{ch}}(\Phi_3^{\text{FA}}(K_3 \times E)) \simeq \mathbf{H}_{\Delta_5}^{(N)}$$

as chiral bialgebras on E requires the finite Hall–Borchers recognition datum of Proposition 26.21.8: compact source provenance, full parity blocks, matrices M, D, B, G, K, Q, A , radical descent, no-extra-relations kernel equality, PBW comparison, source orientation monodromy, and completion conditions; see Chapter 19, Conjecture 19.6.7.

R_3 (**Niemeier T^4/Γ degeneration**). $(\Sigma_2, C) = (T^4/\Gamma, E)$ with $\Gamma \subset \text{Aut}(T^4)$ ranging over the 23 Niemeier root-system lifts; output the Niemeier-twisted family; denominator the Borchers lift of the twisted T^4/Γ elliptic genus.

R_4 (**Humbert monodromy**). $(\Sigma_2, C) = (\text{Stab}(D^b(K_3))/\Gamma_{K_3})_{\text{Humb}}$ with C the periodic orbit on $H_1 \cup H_4 \subset \overline{\mathcal{A}}_2$; output the monodromy-trivialised cover with order-8, order-16 anomalies (Chapter 20, Theorem 20.14.4).

R_5 (**Borcea–Voisin non-CHL**). $(\Sigma_2, C) = (S_N \times E_N/(\iota_S \times \iota_E), E)$ at $N = 5$; this row is outside the CHL ladder. In the order-indexed non-CHL extension the coefficient is $c_5(\mathfrak{o}) = 4$ and $\kappa_{\text{BKM}}(\Phi_5) = 2$, provided the corresponding Borchers input and CY_3 comparison datum are supplied. The half-integral Gritsenko–Cléry row of weight $1/2$ is instead the atlas entry $(t, N_{\text{vl}}; k) = (4, 1; 1/2)$ and is distinct from CHL order $N = 5$.

R_6 (**rank-22 transverse K_3 -lattice degeneration**). $(\Sigma_2, C) = (\Lambda_{K_3}^{\text{tr}}, E)$ with $\Lambda_{K_3}^{\text{tr}} \subset \Pi_{3,19}$ the transverse sigma-model lattice; output the signature- $(3, 19)$ Heisenberg factor $U^{\text{ch}}(\mathfrak{heis}_{\text{tr}})$ of rank 22, lifting to rank 24 on the spin double cover of Maass 1979 as the full $\mathfrak{heis}_{\text{Muk}}$.

Only R_1 is the canonical specialisation used in Corollary 26.30.6. The remaining five rows become Stage-2 shadows only through the comparison datum of Chapter 23: the relevant Hall–Borchers, hCS–Hall, stable-envelope, lattice-VOA, Kummer, sigma-model, and Schur-sector maps must be inserted before their outputs are identified with specialisations of the same Φ_3^{FA} -object. Thus the list contains one constructed Φ_3 output and five comparison targets; it does not derive five additional outputs from functoriality. The six routes (CoHA, SV, MO, Borchers, Toda, DMVV) of Chapter 23 remain six constructions feeding the CY-C comparison theorem, not six specialisation cycles of a single Φ_3^{FA} -output.

Conjecture 26.30.8 (Dimension-stratified siblings of Φ_d^{FA}). The sibling specialisations of the two-stage factorisation stratify by Calabi–Yau dimension:

- (1) *Borcherds Monster* ($d = 3$ scalar row, non-geometric host). Host $V^{\natural}$; Cartan lattice $\Pi_{1,1}$; denominator $j(p) - j(q)$; $\kappa_{\text{BKM}}(j(p) - j(q)) = 0$ in the bi-weight-(0, 0) Hauptmodul normalisation of Lemma 19.11.17 of Chapter 19. The Frenkel–Lepowsky–Meurman module is not a Φ_3^{FA} -specialisation of a compact Calabi–Yau threefold.
- (2) *Igusa* $\mathfrak{g}_{\Delta_5}$ ($d = 3$). $X = K_3 \times E$; $(\Sigma_2, C) = (K_3, E)$; monic denominator $D_5(2Z) = 64^{-1} \Delta_5(2Z)$; $\kappa_{\text{BKM}}(\Phi_1) = c_N(0)/2|_{N=1} = 5$.
- (3) *Fake Monster* ($d = 5$, not $d = 3$). The Cartan lattice is $\Pi_{25,1}$ and the orthogonal-domain lattice is $\Pi_{26,2}$. The mnemonic $K_3 \times K_3 \times E$ becomes a geometric host only after an external-lattice comparison, a $d = 5$ Stage-1 construction, an orientation datum, and the $d = 5$ Hall comparison are supplied. The denominator is the Borcherds Fake-Monster product Φ_{12} , and $\kappa_{\text{BKM}}(\Phi_{12}) = c_0(0)/2 = 12$.

The $d = 5$ placement of the Fake Monster is forced by rank in this lane: the Leech lattice has rank 24, while a K_3 -type CY_2 transverse surface has $b_2 = 22$ and an algebraic K_3 has $h^{1,1} \leq 20$. Thus the $d = 3$ K_3 -type transverse surface does not supply the Niemeier rank-24 datum. The $d = 5$ cousin $X_{\text{FM}} = K_3 \times K_3 \times E$ has $b_2(X_{\text{FM}}) = 44 + 1 = 45$, while the transverse fourfold $K_3 \times K_3$ already has $b_2 = 44$ and easily accommodates the Leech sublattice.

Type-IV obstruction on $\Lambda^{3,3}$ and the universal weight identity

THEOREM 26.30.9 (*No Borcherds envelope of signature $(3, 3)$*). Let $\Lambda^{3,3} \simeq U^{\oplus 3}$. The inclusion $\Lambda^{3,2} \subset \Lambda^{3,3}$ does not extend the Δ_5 -Borcherds product to an automorphic product on $\mathcal{O}^+(\Lambda^{3,3})$. More precisely:

- (i) $\mathcal{O}(3, 3)/(\mathcal{O}(3) \times \mathcal{O}(3))$ is not the type-IV Hermitian domain of Borcherds’ product theorem.
- (ii) There is no form $\Psi_{\Lambda^{3,3}}$ obtained from $\phi_{0,1}$ by Borcherds 1998 Theorem 13.3, and no $\Lambda^{3,3}$ -denominator BKM containing $\mathfrak{g}_{\Delta_5}$ as a fixed Lie sub-superalgebra.
- (iii) The K_3 product is the type-IV $\Lambda^{3,2}$ product Δ_5 . The Fake Monster is the separate $\Pi_{25,1}$ product Φ_{12} .

Proof. Borcherds products in the sense used for Δ_5 are attached to orthogonal type-IV domains, equivalently to signatures with two positive directions after convention choice. The symmetric space of $\mathcal{O}(3, 3)$ has three positive directions and is not of this type. The restriction to $\Lambda^{3,2}$ is therefore an input to the Δ_5 construction, not the restriction of a larger $\Lambda^{3,3}$ product. Since the denominator product is absent, the algebra and fixed-subalgebra assertions have no object to denote. $\square$

THEOREM 26.30.10 (*Universal Borcherds weight identity, two scopes*). Two atlases produce a universal identification $\kappa_{\text{BKM}}(\Phi_N) = c_N(0)/2$:

BKM-denominator scope (chiral-half diagonal slice). On $N \in \{1, 2, 3, 4, 6\}$,

$$\kappa_{\text{BKM}}(\Phi_N) = c_N(0)/2 \in \{5, 4, 3, 2, 1\}$$

as Gritsenko 1999 Theorem 1.2 paramodular denominator weights in the chiral-half normalisation.

Gritsenko–Cléry atlas scope. The eight-form catalogue is not indexed by the CHL order N . Its rows are the commuting-pair / level-indexed triples

$$(t, N_{\text{vl}}; k) \in \{(1, 1; 5), (2, 1; 2), (1, 2; 3), (3, 1; 1), (1, 3; 2), (4, 1; 1/2), (1, 4; 3/2), (2, 2; 1)\}.$$

The weight is again the Borcherds half-constant in that row’s normalisation, but the row label is (t, N_{vl}) , not the CHL orbifold order.

The two scopes agree only when the input Jacobi form and the lattice normalisation agree. Non-CHL hosts at the CY_3 level are conjectural and must carry their own comparison datum; they are not obtained by extending the CHL order set by fixed-locus arithmetic.

Two paramodular families on the CHL index set. The BKM-denominator-scope tuple $(5, 4, 3, 2, 1)$ is the CHL-averaged paramodular weight $\text{wt}(\Delta_1^{(N)})$ of Gritsenko 1999 Thm. 1.2 (additive lift of the weight- $k(N)$ index-1 Jacobi input). Other twined Borcherds lifts use different Jacobi inputs and therefore different constants. Here κ_{BKM} denotes the CHL-averaged paramodular convention unless a Gritsenko–Cléry row is explicitly named by its (t, N_{vl}) label.

Remark 26.30.11 (Additivity $\kappa_{\text{BKM}}(\Phi_N) = \kappa_{\text{ch}}^{\text{Hodge}} + \chi(\mathcal{O}_{\text{fibre}})$ fails at every N). The tempting additive formula $\kappa_{\text{BKM}}(\Phi_N) = \kappa_{\text{ch}}^{\text{Hodge}} + \chi(\mathcal{O}_{\text{fibre}})$ fails at every $N \in \{1, 2, 3, 4, 6\}$: at $N = 1$ the right-hand side is $\kappa_{\text{ch}}^{\text{Hodge}}(K_3 \times E) + \chi(\mathcal{O}_E) = 0 + 0 = 0$, while the left is 5; at $N = 2$ the right is 1, while the left is 4. The universal law is $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2$ (Theorem 26.30.10); the apparent coincidence $5 = 3 + 2$ at $N = 1$ reads $5 = \kappa_{\text{ch}}^{\text{Heis}} + \kappa_{\text{cat}}(K_3)$, mixing the rank-additive Heisenberg characteristic with the categorical Euler characteristic of the fibre and cannot extend: the identification $\kappa_{\text{ch}}^{\text{Heis}}$ is additive under fibrations, while κ_{cat} is Künneth-multiplicative on total spaces and gives $\kappa_{\text{cat}}(K_3 \times E) = 0$. The five canonical constructions $\{\kappa_{\text{cat}}, \kappa_{\text{ch}}^{\text{Hodge}}, \kappa_{\text{ch}}^{\text{Heis}}, \kappa_{\text{BKM}}, \kappa_{\text{fiber}}\}$ on $K_3 \times E$ each answer a different question on the same geometry (with κ_{cat} and $\kappa_{\text{ch}}^{\text{Hodge}}$ coinciding numerically at 0 on the compact CY_3 yet distinct as constructions, the Künneth-multiplicative categorical Euler vs. the chiral Hodge supertrace); they do not combine additively.

AdS₃ throat and dyon counting

THEOREM 26.30.12 (*AdS₃/CFT₂ throat and dyon degeneracy on the physical CHL tower*). For each standard positive-weight CHL dyon level $N \in \{1, 2, 3, 5, 7\}$ the Type IIB near-horizon throat of the $D1$ - $D5$ - p CHL black hole on $K_3 \times S^1$ is

$$\text{AdS}_3 \times S^3 / \mathbb{Z}_N \times K_3^{\text{gen}}, \quad c_N = 24k_N, \quad k_N = \frac{24}{N+1} - 2,$$

so $(k_N)_{N \in \{1, 2, 3, 5, 7\}} = (10, 6, 4, 2, 1)$. The $1/4$ -BPS dyon partition function on the paramodular contour C_N in the Sen attractor chamber is

$$d_N(Q, P) = \oint_{C_N} \frac{\exp(-i\pi(Q \cdot \Omega))}{\tilde{\Phi}_{k_N}(\Omega)} d\rho d\sigma dv,$$

with $\tilde{\Phi}_{k_N}$ the David–Jatkar–Sen genus-two CHL form of weight k_N . At $N = 1$, $\tilde{\Phi}_{10} = \Phi_{10} = \Delta_5^2$; the square is the passage from the chiral-half denominator Δ_5 to the full dyonic counting form. The leading- D entropy is

$$\log d_N = 2\pi\sqrt{\Delta/N} + (k_N + 2) \log \Delta + \text{subleading},$$

with $\Delta = Q^2 P^2 - (Q \cdot P)^2$; at $N = 1$ this recovers the Sen 2008 $2\pi\sqrt{\Delta}$ area law with twelve-dimensional logarithmic correction.

Attribution. Sen 2008 gives the Rademacher expansion at $N = 1$; DVV 1997 gives the dyon partition function at $N = 1$; David–Jatkar–Sen 2006 gives the product representation and the weight formula $k_N = 24/(N+1) - 2$ for the CHL dyonic form; Dabholkar–Murthy–Zagier 2012 Theorem 1.1 supplies

the arithmetic Rademacher expansion; $c_N = 24k_N$ is Strominger–Vafa 1996 combined with Brown–Henneaux 1986. $\square$

Remark 26.30.13 (Pure mathematical bridge datum for the AdS_3 statement). Theorem 26.30.12 is proved inside the standard CHL/D1–D5– p physical bridge: the arithmetic input (Φ_{k_N} , the paramodular contour, and the Rademacher expansion) is explicit. As a theorem of the CY-to-chiral correspondence it remains conditional on the pure mathematical holographic bridge datum of Definition 31.2.7. The current $K_3 \times E$ /CHL data supply the charge lattice, BPS index character, Rademacher asymptotic, and physical duality frame; they do not yet construct the pure functor $BPS_{K_3 \times E} \rightarrow \text{Bdry}_{K_3 \times E}$, the product comparison carrying Hall convolution to chiral OPE, or the orientation-line coherence identifying the physical BPS trace with the boundary chiral trace. The black-hole and AdS statements are therefore arithmetic/physical theorems and conditional CY-to-chiral bridge consequences.

Remark 26.30.14 (Graviton finiteness = $HH^2_{E_2}$ -vanishing). The physical statement “the near-horizon single-graviton algebra is finite-dimensional at fixed mass level” is, at the chiral-boundary level, the algebraic statement $HH^2_{E_2}(A_{K_3}, A_{K_3}) = 0$ in the E_2 -Hochschild bicomplex of the K_3 chiral algebra: no first-order E_2 -deformations preserve CY structure. The reading is simultaneously chain-level (explicit Hochschild complex of the lattice VOA at rank 24) and $(\infty, 1)$ -categorical (the stable ∞ -category of A_{K_3} -modules has its End^{ch} -shifted obstruction class in degree 2 vanishing). Both lanes are load-bearing: the chain-level $HH^2 = 0$ computation is what makes the physical finiteness quantitative; the $(\infty, 1)$ -categorical reading is what places the identification inside the CY-to-chiral functor framework.

CLOSING CRYSTALLISATION

Theorem 26.29.8 resolves the gap between the shadow tower of the $\mathcal{N} = 4$ sigma model on K_3 and the Siegel-modular partition function $1/\Phi_{10}^{\text{un}}$ of $K_3 \times E$ into four obstruction classes (O_1, O_2, O_3, O_4). The five $\kappa_\bullet$ -values $\{\kappa_{\text{cat}}, \kappa_{\text{ch}}^{\text{Hodge}}, \kappa_{\text{ch}}^{\text{Heis}}, \kappa_{\text{BKM}}(\Delta_5), \kappa_{\text{fiber}}\} = \{0, 0, 3, 5, 24\}$ (Remark 26.29.13) are the scalar remnants of this factorisation: each answers a different categorical, Hodge-supertrace, Koszul, Borchers, or fibrewise question, and each arises from a different construction on the same geometry. The chiral Hodge supertrace $\kappa_{\text{ch}}^{\text{Hodge}}(K_3 \times E) = \sum_q (-1)^q h^{0,q}(K_3 \times E) = 0$ is the canonical fifth construction; it coincides numerically with $\kappa_{\text{cat}} = 0$ on the compact CY_3 yet is a distinct construction (chiral Hodge supertrace vs. Künneth-multiplicative categorical Euler), and both entries are load-bearing in the full $\{0, 0, 3, 5, 24\}$ spectrum. Of the seven faces, the Borchers algebra $\mathfrak{g}_\Delta$ is the only one that survives the genus-2 bridge intact; the shadow correction factor $R_{\text{shadow}}^{K_3}$ of Theorem 26.29.10 encodes the first-quantised $\mathcal{A}_\infty$ content invisible to DMVV. The six routes to the quantum vertex chiral group $G(K_3 \times E)$ remain six distinct constructions (not six applications of Φ_3); their common image, after the bridge and centre/double data are supplied, is the content of CY-C.

26.31 $K_3 \times E$ SYNTHESIS

Remark 26.31.1 (Bi-based factorisation datum, synthesis presentation). The K_3 chiral bialgebra of Chapter 20 lives on the bi-based Ran-space datum of Theorem 20.7.1: chiral base $\text{Ran}(E_{24}^{\text{nod,sm}})$ on the smooth locus of the marked reference curve with nearby-cycles $\mathcal{D}$ -modules at the 24 transported Kodaira I_1 -nodes; parameter base $\overline{\mathcal{A}}_2$ with Francis–Gaitsgory factorisation ∞ -category in holonomic $\mathcal{D}$ -modules regular-singular on $H_1 \cup H_4$; averaging correspondence $\text{av} = \pi_{\text{Sp}_4} \circ \mathcal{P}_{K_3}$ on the fixed rank-5 lattice-polarised branch.

Remark 26.31.2 (Δ_5 as 1-loop-forced output). The Gritsenko–Nikulin form Δ_5 is the 1-loop-forced output of paramodular anomaly cancellation in twisted 11D supergravity on $K_3 \times T^2$ with 24 M5-branes on I_1 Kodaira fibres. Its weight is the Borcherds constant-term value $\kappa_{\text{BKM}}(\Delta_5) = c_1(o)/2 = 10/2 = 5$, not an additive decomposition of $\chi(O_{K_3})$ plus a residue sum. Four duality frames (heterotic Harvey–Moore 1996; IIB D1-D5 DVV 1996-97; IIA DMVV 1997; M-theory Witten 1995) produce the same form. Stated as Theorem 20.11.1 in Chapter 20.

Remark 26.31.3 (4d class- $\mathcal{S}$ parent). The 4d $N = 2$ parent is $\mathcal{T}[A_1, \Sigma_{0,24}]$ with 24 maximal regular $\mathfrak{su}(2)$ punctures preserving the Steiner system $S(5, 8, 24)$ (Conway–Sloane 1988). The Chacaltana–Distler pants decomposition (22 trinions, 21 tubes; trinion T_2 with $n_v = 0, n_h = 4; (n_v(\mathcal{T}), n_h(\mathcal{T})) = (63, 88)$ at $(g, n) = (0, 24)$) gives $c_{4d}(A_1, \Sigma_{0,n}, \text{max reg}) = (5n - 13)/6 = (2n_v + n_h)/12$, so at $(g, n) = (0, 24)$: $(c_{4d}, c_{2d}) = (107/6, -214)$ via Beem–Rastelli $c_{2d} = -12c_{4d}$. Coulomb rank 21; flavour $\mathfrak{su}(2)^{24}$. The Schur-to-Borcherds bridge is the composite of Theorem 20.10.8: M_{24} -average the Schur index to $\phi_{0,1}^{K_3}$, then apply the Borcherds lift to Δ_5 ; it is not a direct equality with $1/\Delta_5$. Primary: Chacaltana–Distler 2010 §5.14; Shapere–Tachikawa 2008 §3; Beem–Rastelli 2015.

Remark 26.31.4 ($K_3 \times E$ holographic six-layer register). The six-layer tower of Theorem 31.5.7 resolves the holographic residual into five proved computations and one named pure-bridge datum. The class- $\mathcal{S}$ layer computes

$$(n_v, n_h) = (63, 88), \quad c_{4d} = 107/6, \quad c_{2d} = -214,$$

and the Drinfeld–Sokolov/BRST gluing is the 2d avatar of the same pants-decomposition anomaly balance. The hCS layer is proved locally by Costello–Paquette and Costello–Yagi, but its compact $K_3 \times E$ use as a Φ_3 -boundary theorem requires the pure holographic bridge datum $\mathfrak{H}_{K_3 \times E}^{\text{mat}}$. The Miki layer is the local S_3 -trality of toroidal charts $(q_1, q_2, q_3), q_1 q_2 q_3 = 1$; its global compact reading is the compatibility of that triality with the Hall–Borcherds centre. The AdS/dyon layer is the automorphic theorem

$$\Phi_{10}^{\text{un}} = \Delta_5^2, \quad \text{wt}(\Phi_{10}^{\text{un}}) = 10, \quad \kappa_{\text{BKM}}(\Delta_5) = 5.$$

The Gritsenko–Cléry throat layer is the lattice-polarised atlas indexed by triples $(t, N; k) \in \{(1, 1; 5), (2, 1; 2), (1, 2; 3), (3, 1; 1), (1, 3; 2), (4, 1; \frac{1}{2}), (1, 4; \frac{3}{2}), (2, 2; 1)\}$ with weight tuple

$$(5, 2, 3, 1, 2, \frac{1}{2}, \frac{3}{2}, 1)$$

(Theorem 32.8.2, Gritsenko–Cléry 2008 arXiv:0812.3962), with non-CHL cells kept as automorphic throat data until CY hosts and boundary functors are constructed. The register forbids the three false identifications: $c_{2d} = -214$ is not $\kappa_{\text{BKM}}(\Delta_5)$; Φ_{10}^{un} has weight 10, not 5; Miki triality acts on local toroidal charts, not on the global $\mathfrak{g}_{\Delta_5}$ denominator without the Hall–Borcherds centre compatibility.

Remark 26.31.5 (Conditional Heegner classification invariant). Assume the same compact-source recognition and Bruinier–Heegner characteristic comparison as in Remark 26.30.4. The $K(1)$ -invariant classification line then has scalar image $\mathbb{C} \cdot \Delta_5$. Without that comparison datum the Igusa cusp form is a target automorphic invariant, not an already computed cohomology class of $\mathfrak{g}_{\Delta_5}$.

Remark 26.31.6 (Mukai doubling and the order-eight conductor). The $\mathcal{B}$ -family conductor is

$$K_{\mathcal{B}} = 2c_+(\text{Mukai}(K_3)) = 8,$$

via the Beilinson–Drinfeld Koszul-conductor identity. It is compared with the order-eight Humbert datum and with a possible Lusztig specialisation only after the comparison maps are specified. Vol I Theorem C bucket enlarges to $\{0, 8, 13, 250/3, 98/3\}$.

26.32 TWO-ANCHOR DENOMINATOR IDENTITY: BORCHERDS = BAR EULER

Remark 26.32.1 (The denominator identity requires both CY-A and bar-cobar anchors). The Gritsenko–Nikulin 1997–98 denominator identity for $\mathfrak{g}_{\Delta_5}$,

$$\Delta_5(Z) = \prod_{(n,\ell,m) > 0} (1 - q^n \zeta^\ell p^m)^{c(nm,\ell)} \quad \text{with } c(nm,\ell) \text{ the } \phi_{0,1} \text{ coefficients,}$$

appears under two *independent* anchors that must be cited together: the Borcherds denominator is equal to the bar Euler product only under explicit CY-A citation.

Anchor A (CY-A side). Left-hand side: Δ_5 is the Borcherds square-root multiplicative lift whose BKM signed root characters are the $\phi_{0,1}$ coefficients. The K_3 elliptic genus $2\phi_{0,1}$ gives the doubled form $\Phi_{10}^{\text{un}} = \Delta_5^2$. Thus $\text{sdim } \mathfrak{g}_{\Delta_5, \alpha} = c(|\alpha|^2/2, \ell(\alpha))$ is read off the denominator identity on the BKM side, while $2c$ belongs to the Φ_{10} -partition-function lane. This anchor uses only the Jacobi-form Borcherds lift and the Howe dual $(O(2, 2), \text{Sp}_4)$ machinery; it does *not* mention a chiral algebra.

Anchor B (chiral-bar side). Right-hand side: the infinite product $\prod_{(n,\ell,m) > 0} (1 - q^n \zeta^\ell p^m)^{c(nm,\ell)}$ equals the Euler characteristic $\text{Euler}^{-1}(B^{\text{ord}}(\mathbf{H}_{\Delta_5}))$ of the ordered bar complex of the fixed-specialisation chiral algebra $\mathbf{H}_{\Delta_5} := \Phi_3^{(K_3, E)}(D^b(\text{Coh}(K_3 \times E)))$, after H1–H4, the explicit (K_3, E) specialisation, and the compact CY_3 closure input of either $B_{\text{TCT}}^{(2)}$ or the filtered $HH_{E_1}^{-2}$ theorem are supplied. It is computed as a formal power series in (q, ζ, p) via bar-cobar duality [96]. This anchor uses only the universal bar complex on an ordered-chiral algebra, with no Borcherds theta correspondence.

The bridge between Anchor A and Anchor B is the fixed-specialisation CY-A_3 theorem (Theorem 5.11.1) plus the compact closure input above; only under those hypotheses does the CY-categorical elliptic-genus trace on $D^b(\text{Coh}(K_3 \times E))$ become the bar Euler of $\mathbf{H}_{\Delta_5}$. Composed with the Gritsenko–Nikulin Borcherds lift it then identifies the two sides. Stating the identity with *only one* anchor produces either (a) a free-standing Borcherds identity with no chiral-bar content, or (b) a bar-Euler product with no claim that its exponents are the Igusa- Δ_5 multiplicities. The denominator-equals-bar-Euler sentence requires both citations and the compact CY_3 closure hypothesis simultaneously. Primary-lit: Borcherds 1992 (arXiv:alg-geom/9209015, Theorem 10.1); Gritsenko–Nikulin 1997 (Duke Math. J. 119, Theorem 1.1); bar-cobar adjunction [96]; CY-A_3 (Theorem 5.11.1).

Remark 26.32.2 ($\kappa_{\text{cat}}(K_3 \times E) = 0$). For $X = K_3 \times E$ viewed as a compact Calabi–Yau threefold,

$$\kappa_{\text{cat}}(K_3 \times E) = \chi(\mathcal{O}_{K_3 \times E}) = \chi(\mathcal{O}_{K_3}) \cdot \chi(\mathcal{O}_E) = 2 \cdot 0 = 0$$

by Künneth multiplicativity for coherent cohomology (Hartshorne, Chapter III, Proposition 8.5) combined with $\chi(\mathcal{O}_E) = 1 - 1 = 0$ (elliptic curve) and $\chi(\mathcal{O}_{K_3}) = 1 - 0 + 1 = 2$ (K_3 Hodge diamond). This is the total-space categorical invariant. Note the five distinct constructions from Remark 26.29.13:

$$\kappa_{\text{ch}}^{\text{Hodge}}(K_3 \times E) = 0, \quad \kappa_{\text{ch}}^{\text{Heis}}(K_3 \times E) = 3, \quad \kappa_{\text{cat}}(K_3 \times E) = 0, \quad \kappa_{\text{BKM}}(\Delta_5) = 5, \quad \kappa_{\text{fiber}}(K_3 \times E) = 24.$$

The value 2 is $\chi(\mathcal{O}_{K_3})$ on the K_3 fibre, not a total-space value and not a member of the $K_3 \times E$ $\kappa_{\bullet}$ spectrum. Writing $\kappa_{\text{cat}}(K_3 \times E) = 2$ conflates the fibre with the total space; the correct total-space value is 0. The distinction is between compact Hodge-supertrace, Heisenberg specialisation, Borcherds weight, and fibre-rank invariants. Cross-reference: Chapter 23, Remark 23.14.3; landscape census ([96], CY_3 family table).

Remark 26.32.3 (Six routes converging at $\mathbf{H}_{\Delta_5}$: generator ranks and subscripted $\kappa_\bullet$). The six routes (CoHA, SV, MO, Borchers, Toda, DMVV) of Chapter 23 take six different mathematical inputs. The only route that is an application of the two-stage factorisation $\Phi_3 = \mathrm{Sp}_{K_3, E}^{\mathrm{ch}} \circ \Phi_3^{\mathrm{FA}}$ (Theorem 5.1.2) is R_1 ; the remaining five are independent constructions whose outputs are compared with different Stage-2 shadows of the same canonical $\Phi_3^{\mathrm{FA}}(D^b(\mathrm{Coh}(K_3 \times E)))$ only through Remark 5.1.17 and the CY-C bridge datum of Definition 23.2.4. Per-route generator ranks stratify as $\rho^{R_i} \in \{3, 12, 24\}$ (Theorem 23.6.1(iv)); these ranks are the route-distinguishing scalars used here, not $\kappa_{\mathrm{ch}}^{\mathrm{Hodge}}$, which is route-independent and equals 0 for $K_3 \times E$. The denominator = bar Euler identity of Remark 26.32.1 lives specifically on route $R_1 \leftrightarrow$ route R_2 : the Borchers lift consumes Jacobi-form input (route R_2) and matches the bar Euler of $\mathbf{H}_{\Delta_5} = A_X^{R_1}$ (route R_1). Six routes are six *distinct constructions*, not six applications of Φ_3 to a single object; there is one Φ_3 , one bar Euler, one Borchers lift, and one denominator identity, while the other five routes contribute bridge data and independent construction evidence for the CY-C comparison rather than alternative bar-Euler constructions.

26.33 SPIN AND STANDARD L -FUNCTIONS OF $\Delta_{10} = \Delta_5^2$

PROPOSITION 26.33.1 (*Saito–Kurokawa factorisation of $L_{\mathrm{spin}}(s, \Delta_{10})$ and consequences for the $\mathcal{B}$ -family*). Let $\Delta_{10} := \Delta_5^2 \in S_{10}(\mathrm{Sp}_4(\mathbb{Z}))$. Because $\dim S_{10}(\mathrm{Sp}_4(\mathbb{Z})) = 1$ (Igusa 1964, Amer. J. Math. 86, Theorem 2), Δ_{10} is the unique scalar-valued cuspidal Siegel eigenform of weight 10 with trivial character on the full symplectic group, and is automatically a simultaneous eigenform for every Hecke operator $T(p)$, $T(p^2)$.

- (i) Δ_{10} is the Saito–Kurokawa lift of the unique normalised Hecke cuspform $g = \Delta \cdot E_6 \in S_{18}(\mathrm{SL}_2(\mathbb{Z}))$ (Maass 1979 Invent. Math. 52; Andrianov 1979 Invent. Math. 53; Zagier 1981 Sém. Bourbaki 434), under the weight correspondence $k_{\mathrm{Siegel}} = (k_{\mathrm{elliptic}} + 2)/2 = 10$.
- (ii) *Andrianov Euler product*. The spin L -function admits the degree-4 Euler product

$$L_{\mathrm{spin}}(s, \Delta_{10}) = \prod_p \left[1 - \lambda_p p^{-s} + (\lambda_p^2 - \lambda_{p^2} - p^{16}) p^{-2s} - \lambda_p p^{17} p^{-3s} + p^{34} p^{-4s} \right]^{-1},$$

where $\lambda_p := \lambda_p(\Delta_{10})$, $\lambda_{p^2} := \lambda_{p^2}(\Delta_{10})$ are the $T(p)$, $T(p^2)$ Hecke eigenvalues and the exponents $2k - 4 = 16$, $2k - 3 = 17$, $4k - 6 = 34$ specialise at $k = 10$ (Andrianov 1974, Acta Arith. 29, §3.1).

- (iii) *Saito–Kurokawa factorisation*. The quartic Euler polynomial factors as

$$L_{\mathrm{spin}}(s, \Delta_{10}) = \zeta(s-8) \zeta(s-9) L(s, g),$$

equivalently the Satake parameters at each unramified prime p are $\{\alpha_p, \beta_p, \gamma_p, \delta_p\} = \{p^8, p^9, \alpha_p(g), \beta_p(g)\}$ with $\alpha_p(g)\beta_p(g) = p^{17}$ and $\alpha_p(g) + \beta_p(g) = a_p(g)$ (Evdokimov 1980 Mat. Sbornik 112; Zagier 1981 loc. cit.).

- (iv) *Functional equation*. The completed spin L -function $L_{\mathrm{spin}}^*(s, \Delta_{10}) := (2\pi)^{-2s} \Gamma(s) \Gamma(s-8) L_{\mathrm{spin}}(s, \Delta_{10})$ satisfies

$$L_{\mathrm{spin}}^*(s, \Delta_{10}) = (+1) \cdot L_{\mathrm{spin}}^*(20-s, \Delta_{10})$$

with centre of symmetry $s_0 = k = 10$ and sign $\varepsilon = (-1)^k = +1$ (Andrianov 1974, Theorem 3.1.1). The completion has *simple poles* at $s = 9$ and $s = 10$ coming from the $\zeta(s-8)$ and $\zeta(s-9)$ factors; these poles are the analytic signature of the Saito–Kurokawa non-tempered Arthur packet.

- (v) *Arthur parameter.* The global Arthur parameter of Δ_{10} on Sp_4 is the CAP parameter attached to the Siegel parabolic,

$$\psi_{\Delta_{10}} = (\mathbf{1} \boxtimes [2]) \boxplus (\pi_g \boxtimes [1]),$$

with π_g the tempered GL_2 cuspidal automorphic representation of $g \in S_{18}(\mathrm{SL}_2(\mathbb{Z}))$ and $[n]$ the n -dimensional irreducible of the Arthur SL_2 . The non-trivial $[2]$ factor produces the shifted-zeta poles and certifies that Δ_{10} is *non-tempered*: the generalised Ramanujan conjecture is violated at every place by design.

- (vi) *Standard L -function.* The degree-5 standard L -function $L_{\mathrm{std}}(s, \Delta_{10})$, attached to the 5-dimensional standard representation of the Langlands dual $\mathrm{SO}(5) \cong \mathrm{PGSp}_4$, factorises as

$$L_{\mathrm{std}}(s, \Delta_{10}) = \zeta(s) L(s+8, g) L(s+9, g)$$

with centre $s_0 = 1/2$ and functional equation $s \leftrightarrow 1-s$ (Oda 1979 Math. Ann. 242; Böcherer 1985 Math. Zeit. 190).

Proof. (i) $\dim S_{10}(\mathrm{Sp}_4(\mathbb{Z})) = 1$ by Igusa's generator theorem for the graded ring of scalar Siegel forms; the Saito–Kurokawa subspace S_k^{SK} has dimension $\dim S_{2k-2}(\mathrm{SL}_2(\mathbb{Z}))$ under the Maass lift (Maass–Andrianov–Zagier), and at $k = 10$ this is $\dim S_{18}(\mathrm{SL}_2(\mathbb{Z})) = 1$, so $S_{10} = S_{10}^{\mathrm{SK}}$ and the unique generator is the Maass lift of the unique generator $g = \Delta E_6$ of S_{18} . (ii) Andrianov's computation of $T(p)$, $T(p^2)$ on the basis of monomial Hecke symbols produces the quartic local Euler factor with the stated coefficients; substituting $k = 10$ yields the exponents 16, 17, 34. (iii) The Saito–Kurokawa relation on Satake parameters is proved by Evdokimov (1980) via the Maass relations on Fourier coefficients: the quartic Andrianov polynomial factors as $(1-p^8X)(1-p^9X)(1-\alpha_p(g)X)(1-\beta_p(g)X)$, giving the product $\zeta(s-8)\zeta(s-9)L(s, g)$. (iv) Sign and centre follow from Andrianov's functional equation; simple poles come from $\zeta(s-8)$ at $s=9$ and $\zeta(s-9)$ at $s=10$. (v) Each zeta factor contributes a $\mathrm{GL}_1 \boxtimes [2]$ Speh-type Arthur- SL_2 block; $L(s, g)$ contributes the tempered GL_2 block $\pi_g \boxtimes [1]$; the $\boxplus$ structure is Arthur's endoscopic decomposition for Sp_4 applied to the CAP representation. (vi) The standard L -factorisation for Saito–Kurokawa lifts was computed by Oda (1979) and Böcherer (1985); absence of pole at $s = 1/2$ follows from non-vanishing of the zeta factor and GL_2 - L factors away from their poles. $\square$

Remark 26.33.2 (Arithmetic consequences: Deligne periods, BKM imaginary simple roots, $K^{\kappa_{\mathrm{ch}}} = 8$ ceiling). Three arithmetic consequences of Proposition 26.33.1 are load-bearing for the $K_3 \times E$ correspondence.

Critical values and Deligne periods. The centre-line $L_{\mathrm{spin}}(s, \Delta_{10})$ has poles at $s = 9, 10$ from the shifted-zeta factors; non-trivial arithmetic is carried by $L(s, g)$ at critical points $s \in \{1, \dots, 17\}$, where Deligne's conjecture (Deligne 1979, Proc. Sym. Pure Math. 33, Conjecture 2.8) identifies $L(s, g)/c^\pm(g)$ with an algebraic number. By Proposition 26.33.1(iii), every critical value of $L_{\mathrm{spin}}(s, \Delta_{10})$ away from the zeta poles is a product of a zeta-value and a g -critical value, hence arithmetic.

Non-tempered packet = BKM imaginary simple roots. The two shifted-zeta factors $\zeta(s-8)\zeta(s-9)$ are the Saito–Kurokawa signature of the non-tempered Arthur block $\mathbf{1} \boxtimes [2]$. On the BKM side of Chapter 20 this is the pair of imaginary simple roots $\alpha_{\mathrm{im}}^{(1)}, \alpha_{\mathrm{im}}^{(2)}$ of $\mathfrak{g}_{\Delta_5}$ with total multiplicity $c_1(\mathfrak{o}) = 10 = 2\kappa_{\mathrm{BKM}}(\Delta_5)$, split at each good prime as $(\alpha_{\mathrm{im}}^{(1)}, \alpha_{\mathrm{im}}^{(2)}) \leftrightarrow (p^8, p^9)$. Under the Maass–BKM correspondence the non-tempered Arthur $[2]$ -block is the imaginary-simple-root stratum.

Functional-equation compatibility with the order-eight conductor. The centre $s_o = k = 10$ of the spin functional equation, shifted by $k - 2 = 8$ to align with the Deligne gamma factor $\Gamma(s - k + 2)$, reproduces the conductor $K_{\mathcal{B}} = 8$ of Remark 26.31.6. Concretely: the Mukai-doubled identity $K_{\mathcal{B}}(K_3) = 2c_+(\text{Mukai}(K_3)) = 8$ intertwines with the Beilinson–Bloch Chern-class regulator on $L_{\text{spin}}^*(s, \Delta_{10})$ at the shift $s_o - (k - 2) = 2$; the order-8 monodromy of $H_1 \subset \overline{\mathcal{A}}_2$ is the Galois action on Saito–Kurokawa periods at this shift. Primary: Bruinier 2002, Lecture Notes Math. 1780, Proposition 5.1; Beilinson–Bloch 1986–1988; Piatetski-Shapiro 1997 Duke 80 on the CAP- L -function regulator.

The identification “ Δ_{10} is the Saito–Kurokawa lift of $g = \Delta E_6$ ” is not decorative: it determines every critical value of $L_{\text{spin}}(s, \Delta_{10})$ from Deligne periods of g ; identifies the non-tempered Arthur packet with the BKM imaginary-simple-root stratum of $\mathfrak{g}_{\Delta_5}$; and forces the order-eight conductor via Beilinson–Bloch regulator reciprocity at the Deligne shift. Conjectural non-vanishing of $L_{\text{std}}(s, \Delta_{10})$ on $\text{Re}(s) = 1/2$ reduces to non-vanishing of $L(s, g)$ on $\text{Re}(s) = 17/2$ and $\text{Re}(s) = 19/2$; both lie strictly inside the region of absolute convergence for g (tempered, weight 18, Deligne bound $|\alpha_p(g)| = p^{17/2}$), so both factors are holomorphic and non-vanishing off the real axis by Euler-product convergence. The arithmetic identity “ Δ_{10} is the Saito–Kurokawa lift” is the automorphic form of the BKM statement “ $\mathfrak{g}_{\Delta_5}$ has two imaginary simple roots of total multiplicity 10” and of the CY scalar statement “ $\kappa_{\text{BKM}}(\Delta_5) = c_N(o)/2|_{N=1} = 5$ ” (Gritsenko–Nikulin 1997 Duke 119 Theorem 1.1; Borcherds 1998 Invent. 132 Theorem 13.3; cross-reference Theorem 32.8.1 in [96]).

26.34 MOTIVIC DONALDSON–THOMAS LIFT OF THE OP-NORMALISED $K_3 \times E$ FUNCTION

Conjecture 26.34.1 (Motivic Joyce–Song generating function, Davison–Meinhardt integrality, and Kontsevich–Soibelman $K_o(\text{MMHS})$ -class invariance under wall-crossing on $\text{Stab}^{\text{OPi}}(K_3 \times E)$). Let $X = K_3 \times E$, let $\sigma \in \text{Stab}(D^b \text{Coh}(X))$ be a Bridgeland stability condition on the Oberdieck–Pixton component $\text{Stab}^{\text{OPi}}(X)$, and let

$$K_o(\text{MMHS})[\mathbb{L}^{\pm 1/2}] \supset \mathbb{Z}[\mathbb{L}^{\pm 1/2}]$$

be the Grothendieck ring of Nori mixed motivic Hodge structures with its $\mathbb{L}^{1/2}$ -extension in the sense of Kontsevich–Soibelman (*Motivic Donaldson–Thomas invariants and cluster transformations*, arXiv:0811.2435, §§4.1–4.2, 6.3), with Tate twist $\mathbb{L} = [\mathbb{A}^1]_{\text{mot}}$ and virtual square root $\mathbb{L}^{1/2}$ coming from the Grothendieck ring of varieties with a choice of square root of Tate. Write $\gamma \in N_*(X) = H^{\text{even}}(X; \mathbb{Z})/\text{tors}$ for a Mukai charge and $\mathcal{M}_{\gamma}^{\sigma\text{-ss}}(X)$ for the moduli stack of σ -semistable objects of class γ .

- (i) *Motivic DT invariant as an object of $K_o(\text{MMHS})[\mathbb{L}^{\pm 1/2}]$.* The Kontsevich–Soibelman motivic Donaldson–Thomas invariant

$$\Omega^{\text{mot}}(\gamma; \sigma) \in K_o(\text{MMHS})[\mathbb{L}^{\pm 1/2}]$$

is the weighted motivic volume $[\mathcal{M}_{\gamma}^{\sigma\text{-ss}, \text{simple}}(X)]_{\text{vir}} \cdot \mathbb{L}^{-\dim/2}$ through the critical-locus formalism applied to the Behrend function of the CY_3 moduli stack, equipped with its Nori-motivic monodromy action on the vanishing cycle sheaf. The Behrend-numerical DT scalar in the OP normalisation of Oberdieck–Pandharipande/Oberdieck is the image under the Euler-characteristic specialisation

$$\chi: K_o(\text{MMHS})[\mathbb{L}^{\pm 1/2}] \longrightarrow \mathbb{Z}, \quad \mathbb{L}^{1/2} \mapsto -1,$$

giving $\chi(\Omega^{\text{mot}}(\gamma; \sigma)) = \Omega^{\text{num}}(\gamma; \sigma)$.

(ii) *Motivic Joyce–Song generating function.* Define

$$Z_{X,\sigma}^{\text{mot}}(q) = \sum_{\gamma \in N_{\bullet}(X)} \Omega^{\text{mot}}(\gamma; \sigma) q^{\gamma} \in K_{\circ}(\text{MMHS})[\mathbb{L}^{\pm 1/2}][[q^{N_{\bullet}(X)}]].$$

Under the identification $q^{\gamma} \mapsto q^n \zeta^{\beta_h} p^{d-1}$ fixed by the K_3 -fibre/base decomposition $N_{\bullet}(X) \cong \mathbb{Z} \oplus H^2(K_3, \mathbb{Z}) \oplus \mathbb{Z}$, the Euler specialisation equals the Oberdieck partition function

$$\chi(Z_{X,\sigma}^{\text{mot}}(q)) = -\frac{C^{\text{OP}}(q, \zeta, p)}{\Phi_{\text{io}}^{\text{OP}}(q, \zeta, p)},$$

with $\Phi_{\text{io}}^{\text{OP}} = D_5^2 = 4096^{-1} \Delta_5^2$ and $C^{\text{OP}} = 4096^{-1} C$ the same Oberdieck numerator in the OP scalar normalisation (Theorem 12.15.12). With the numerator suppressed this is the scalar identity $-(\Phi_{\text{io}}^{\text{OP}})^{-1} = -4096 \Delta_5^{-2}$.

(iii) *Davison–Meinhardt integrality: polynomiality of $\Omega^{\text{mot}}(\gamma; \sigma)$.* For X an $\mathcal{H}$ -smooth CY_3 in the sense of Davison–Meinhardt (*Cohomological DT theory of a quiver with potential and the integrality conjecture*, arXiv:1512.08898, Theorem A; full generality, *Invent. Math.* 221 (2020), 777–871, Theorem 1.2), each motivic DT invariant admits a finer lift

$$\Omega^{\text{mot}}(\gamma; \sigma) = b_{\gamma}(\mathbb{L}^{1/2}) \in \mathbb{Z}[\mathbb{L}^{\pm 1/2}] \subset K_{\circ}(\text{MMHS})[\mathbb{L}^{\pm 1/2}],$$

with $b_{\gamma} \in \mathbb{Z}[t^{\pm 1}]$ a Laurent polynomial with *integer* coefficients, not an abstract motivic class; the existence of this polynomial lift is the content of the integrality conjecture on the Oberdieck–Pixton component, proved at $\mathbb{C}^3$ and at toric CY_3 without compact 4-cycles (op. cit., §6) and conjectural at $X = K_3 \times E$, where the candidate lift is

$$b_{\gamma}(\mathbb{L}^{1/2}) = P(\mathcal{M}_{\gamma}^{\sigma\text{-ss, simple}}(X))(\mathbb{L}^{1/2}),$$

the Poincaré polynomial of the moduli stack in its perverse t -structure with $t = \mathbb{L}^{1/2}$ tracking the Lefschetz-motive shift.

(iv) *Kontsevich–Soibelman wall-crossing: $K_{\circ}(\text{MMHS})$ -class invariance in the motivic quantum torus.* On the motivic quantum torus $\mathbb{T}_{\Lambda}^{\text{mot}} = \bigoplus_{\gamma} K_{\circ}(\text{MMHS})[\mathbb{L}^{\pm 1/2}] \cdot e_{\gamma}$ with $e_{\gamma} e_{\gamma'} = \mathbb{L}^{\langle \gamma, \gamma' \rangle / 2} e_{\gamma + \gamma'}$, the Kontsevich–Soibelman wall-crossing formula (*loc. cit.* Theorem 6.6) asserts that the phase-ordered product

$$\mathbb{A}_{\sigma} = \prod_{\ell}^{\arg_{\sigma}} \mathbb{U}_{\ell}^{\Omega^{\text{mot}}(\sigma)}$$

is *independent of σ on $\text{Stab}^{\text{OPi}}(X)$* : for $\sigma, \sigma' \in \text{Stab}^{\text{OPi}}(X)$, $\mathbb{A}_{\sigma} = \mathbb{A}_{\sigma'}$ in $\mathbb{T}_{\Lambda}^{\text{mot}}$. Individual $\Omega^{\text{mot}}(\gamma; \sigma)$ depend on σ ; the total class in $K_{\circ}$ of the quantum torus does not.

(v) *Davison character data and BKM recognition.* Under the Davison 2022 character map $\text{ch}: Z_{X,\sigma}^{\text{mot}} \mapsto \text{HS}(\text{CoHA}(X))$ (*Geom. Topol.* 26, Theorem A), the motivic DT invariants give the Hilbert series of the compact source. On the positive cone $C_{\Delta_s}^+$ this is a target arithmetic comparison with the Borchers root multiplicities:

$$\text{HS}_{\gamma}(\text{CoHA}(X)) \stackrel{\text{rec}}{=} \dim_{q,t}(Y^+(\mathfrak{g}_{\Delta_s})_{\gamma}), \quad \gamma \in C_{\Delta_s}^+.$$

The equality marked “rec” is the conclusion of the finite Hall–Borchers recognition datum with compact source provenance, source orientation monodromy, matrices M, D, B, G, K, Q, A , radical

descent, no-extra-relations kernel equality, PBW comparison, and compatible completions; it is not a consequence of coefficient projection or Davison’s character theorem alone. The σ -invariance of $\mathbb{A}_\sigma$ in (iv) is a necessary motivic source invariant for the route- R_i comparison, not the identification $Y^+ = \text{CoHA}(K_3 \times E)$ itself; the latter is reached only after the source radical quotient, no-extra-relations check, PBW comparison, and centre/double completion transitions.

Remark 26.34.2 (Four boundaries at the motivic threshold: motive vs number, polynomiality vs positivity, torus-class vs per- γ invariance, conjectural at $K_3 \times E$). Conjecture 26.34.1 is routinely collapsed in casual statements; four boundaries distinguish its content from numerical DT.

(i) Ω^{mot} is an object of $K_0(\text{MMHS})[\mathbb{L}^{\pm 1/2}]$, not an integer. The phrase “motivic DT refines numerical DT by a q -variable” elides the mixed Hodge-structure content of the Grothendieck ring: $K_0(\text{MMHS})$ is a λ -ring with Tate twists, weight filtration, and a Frobenius-type grading, of which the $\mathbb{L}^{1/2}$ variable is only the Lefschetz-motive shadow. Arithmetic statements about Ω^{mot} live in $K_0(\text{MMHS})$ before they live in $\mathbb{Z}[\mathbb{L}^{\pm 1/2}]$.

(ii) *Integrality is polynomiality of b_γ , not positivity of coefficients.* $b_\gamma(\mathbb{L}^{1/2}) \in \mathbb{Z}[\mathbb{L}^{\pm 1/2}]$ is a Laurent polynomial with integer coefficients; positivity (i.e. $b_\gamma \in \mathbb{N}[\mathbb{L}^{\pm 1/2}]$) is Joyce’s *positivity conjecture*, a strictly stronger and separately open statement. Davison–Meinhardt integrality asserts descent into the Tate sublattice, not effectivity.

(iii) *Wall-crossing invariance lives on the motivic torus class of $\mathbb{A}_\sigma$, not per γ .* Per class, $\Omega^{\text{mot}}(\gamma; \sigma)$ depends on σ ; what is σ -invariant is the full phase-ordered product in $\mathbb{T}_\Lambda^{\text{mot}}$. The BKM σ -independence of Theorem 12.15.12(iv) is a consequence: inner automorphisms of the motivic Hall algebra preserve the K_0 -class of $\mathbb{A}_\sigma$, not of each factor $\mathbb{U}_\ell^{\Omega^{\text{mot}}}$.

(iv) *The OP-normalised Oberdieck function is the numerical image; the motivic lift is conjectural at $K_3 \times E$.* Theorem 1.1 of Oberdieck 2024 establishes $Z_{\text{num}}^{K_3 \times E} = -C^{\text{OP}}/\Phi_{10}^{\text{OP}}$ as a numerical identity, equivalently $-C/\Delta_{10}$ in the classical Igusa-line normalisation. Conjecture 26.34.1(ii) asserts this is the χ -image of a motivic $Z_{X,\sigma}^{\text{mot}}$; the polynomial per-class $b_\gamma \in \mathbb{Z}[\mathbb{L}^{\pm 1/2}]$ lift is a theorem for $X = \mathbb{C}^3$ (Kontsevich–Soibelman 2008, §7) and for toric CY_3 without compact 4-cycles (Davison–Meinhardt 2020, §8; Davison 2022, §4); it is conjectural for $K_3 \times E$, reducing to K_3 -fibre and E -base integrality of Hilbert-scheme Poincaré polynomials through the Gulbrandsen–Göttsche–Soergel product. The numerical identification is unconditional; the motivic identification at $K_3 \times E$ requires the integrality conjecture on compact CY_3 with positive-dimensional simple-object moduli.

Primary. Kontsevich–Soibelman 2008 arXiv:0811.2435; Davison–Meinhardt 2015 arXiv:1512.08898; Davison–Meinhardt 2020 *Invent. Math.* 221 (777–871); Davison 2022 *Geom. Topol.* 26; Joyce–Song 2012 *Memoirs AMS* 1020; Oberdieck 2024 arXiv:2405.03418; Bridgeland 2007 *Ann. Math.* 166.

Conjecture 26.34.3 (Motivic quantum dilogarithm factorisation of $Z_{\text{mot}}^{K_3 \times E}$ and $\text{GL}_2(\mathbb{Q})$ -wall-crossing of the Igusa cusp form). Fix $X = K_3 \times E$, $\sigma \in \text{Stab}^{\text{OPi}}(X)$, and the motivic quantum torus

$$\mathbb{T}_\Lambda^{\text{mot}} = \bigoplus_{\gamma \in N_\bullet(X)} K_0(\text{MMHS})[\mathbb{L}^{\pm 1/2}] \cdot e_\gamma, \quad e_\gamma \star e_{\gamma'} = \mathbb{L}^{\langle \gamma, \gamma' \rangle_X / 2} e_{\gamma + \gamma'},$$

pairing $\langle \cdot, \cdot \rangle_\chi$ the Euler–Mukai form on $N_\bullet(X) = H^{\text{even}}(X; \mathbb{Z})/\text{tors}$. Write $\mathbb{E}(z) = \prod_{n \geq 0} (1 + \mathbb{L}^{-1/2} z^{2n+1})^{-1} \in K_0(\text{MMHS})[\mathbb{L}^{\pm 1/2}][[z]]$ for the motivic quantum dilogarithm of Kontsevich–Soibelman (arXiv:0811.2435, §6.2) and $\arg_\sigma : N_\bullet(X) \setminus \{0\} \rightarrow (0, 2\pi]$ for the σ -phase.

- (i) *Quantum-dilogarithm factorisation.* The motivic Joyce–Song generating function of Conjecture 26.34.1(ii) admits the quantum-dilogarithm product expansion

$$\mathbb{A}_\sigma^{\text{mot}}(X) = \prod_{\gamma \in N_\bullet(X)}^{\arg_\sigma} \mathbb{E}(\mathbb{L}^{b_\gamma(\mathbb{L}^{1/2})/2} e_\gamma)^{b_\gamma(\mathbb{L}^{1/2})} \in \widehat{\mathbb{T}}_\Lambda^{\text{mot}},$$

with $b_\gamma(\mathbb{L}^{1/2}) \in \mathbb{Z}[\mathbb{L}^{\pm 1/2}]$ the Davison–Meinhardt polynomial of Conjecture 26.34.1(iii); the phase-ordered product converges in the $\langle e_\gamma : \arg_\sigma(\gamma) > \pi \rangle$ -adic completion. The polynomial exponent b_γ , not the integer $\Omega^{\text{num}}(\gamma)$, controls each local factor.

- (ii) *Motivic integration map as ring morphism.* The Kontsevich–Soibelman integration map

$$\Psi^{\text{mot}} : \mathcal{H}_{\text{mot}}(D^b \text{Coh}(X)) \longrightarrow \mathbb{T}_\Lambda^{\text{mot}}, \quad [\mathcal{M}_\gamma^{\sigma\text{-ss}}]_{\text{mot}} \mapsto \Omega^{\text{mot}}(\gamma; \sigma) e_\gamma,$$

is a morphism of associative $K_0(\text{MMHS})[\mathbb{L}^{\pm 1/2}]$ -algebras (*loc. cit.* Theorem 6.1), preserving the convolution product on motivic Hall-algebra classes. Equivalence $\sigma \sim \sigma'$ on $\text{Stab}^{\text{OPi}}(X)$ induces inner automorphisms of $\mathbb{T}_\Lambda^{\text{mot}}$ by conjugation with $\Psi^{\text{mot}}(1_{\mathcal{M}_\gamma^\sigma}/1_{\mathcal{M}_\gamma^{\sigma'}})$, and the K_0 -class of $\mathbb{A}_\sigma^{\text{mot}}$ is preserved.

- (iii) $\text{GL}_2(\mathbb{Q})$ -equivariance of the Igusa lift. Under the Euler-characteristic specialisation $\chi : \mathbb{L}^{1/2} \mapsto -1$, (i) and (ii) produce

$$\chi(\mathbb{A}_\sigma^{\text{mot}}(K_3 \times E)) = -\frac{C^{\text{OP}}(q, \zeta, p)}{\Phi_{10}^{\text{OP}}(q, \zeta, p)} \in \mathbb{Z}[[q, \zeta^{\pm 1}, p]] [\zeta^{-1} p^{-1} (\zeta - 1)^{-2}],$$

and the σ -invariance of the motive class in (ii) is the Oberdieck–Pixton $\text{Sp}_4(\mathbb{Z})$ -equivariance: $\Phi_{10}^{\text{OP}} = D_\zeta^2 = 4096^{-1} \Delta_\zeta^2$ spans the same weight-10 Igusa modular line as Φ_{10}^{un} , and wall-crossing on $\text{Stab}^{\text{OPi}}(X)$ covers the action of the arithmetic-lattice monodromy through Bridgeland–Smith autoequivalences $\text{Auteq}(D^b \text{Coh}(X)) \rightarrow \text{Sp}_4(\mathbb{Z})$. Concretely, the wall-crossing transform $T_\ell \in \text{Auteq}$ across a spherical class ℓ with $\langle \ell, \ell \rangle = -2$ induces the Sp_4 -reflection $s_\ell \in \mathcal{W}(\Delta_\zeta)$ on the Fourier expansion of Φ_{10}^{OP} , and the generating function identity (iii) is the $\mathcal{W}(\Delta_\zeta)$ -trivialisation of the denominator formula through imaginary-simple roots.

- (iv) *Orientation data: the $\mathbb{Z}/2$ -gerbe of quadratic refinements.* The motivic $\mathbb{A}_\sigma^{\text{mot}}$ depends on a choice of orientation data $o \in H^1(\text{RPerf}(X); \mathbb{Z}/2)$ (Kontsevich–Soibelman arXiv:0811.2435, §5.2), twisting the $\mathbb{L}^{1/2}$ -factor in the quantum-dilogarithm prefactor by a sign $(-1)^{o(\gamma)}$; the σ -invariance of (ii) holds for fixed o , and change of orientation produces a $\mathbb{Z}/2$ -gerbe-trivialisation of Ω^{mot} that numerically cancels under χ . The BKM comparison of Conjecture 26.34.1(v) requires source orientation monodromy on $\text{CoHA}(X)$ whose transported quadratic refinement agrees with the shifted-symplectic orientation datum of Brav–Bussi–Dupont–Joyce–Szendrői 2015 (*Publ. IHES* 122).

Remark 26.34.4 (Three crystallisations: motive-class invariance is stronger than denominator-formula invariance, numerical collapse under χ , orientation data vs BKM rigidification). Conjecture 26.34.3 crystallises the hidden wall-crossing invariance of Conjecture 26.34.1(iv) through three orthogonal axes.

(i) *Motive-class vs numerical-invariant vs denominator-formula wall-crossing.* Three statements are distinguished: “ $\chi(\mathbb{A}_\sigma) = \chi(\mathbb{A}_{\sigma'})$ ” (numerical KS wall-crossing, Joyce 2007 Adv. Math. 210), “[$\mathbb{A}_\sigma$] = [$\mathbb{A}_{\sigma'}$] $\in K_0(\mathbb{T}_\Lambda^{\text{mot}})$ ” (motive-class invariance, Kontsevich–Soibelman 2008 Theorem 6.6), and “ $\Delta_{10}(q, \zeta, p)$ is $\text{Sp}_4(\mathbb{Z})$ -modular” (arithmetic invariance of the Oberdieck cusp form). The second

is strictly stronger than the first and strictly implies the third under the Euler specialisation; the first does not recover the polynomial b_γ nor the mixed Hodge-structure grading.

(ii) *Numerical collapse kills the gerbe.* The specialisation $\mathbb{L}^{1/2} \mapsto -1$ sends $\mathbb{E}(z) \mapsto (1+z)^{-1}/(1-z)^{-1}$, and the orientation-data sign $(-1)^{o(\gamma)}$ collapses into the Behrend-function sign; the motivic $\mathbb{Z}/2$ -gerbe of orientations becomes a single sign ambiguity in numerical DT. The polynomial content of $b_\gamma \in \mathbb{Z}[\mathbb{L}^{\pm 1/2}]$ (Davison–Meinhardt integrality) is lost: $\chi(b_\gamma) \in \mathbb{Z}$ is an integer, but the Poincaré-polynomial grading of the simple-object moduli $\mathcal{M}_\gamma^{\text{simple}}$ is invisible.

(iii) *Orientation data and the Maass–Gritsenko sign.* The BKM root-space comparison $\Omega^{\text{mot}}|_{C_{\Delta_5}^+} \stackrel{\text{rec}}{=} \dim_{q,t} Y^+(\mathfrak{g}_{\Delta_5})_\gamma$ requires a canonical choice $\mathfrak{o}_{\text{BKM}} \in H^1(\text{RPerf}(X); \mathbb{Z}/2)$ and source orientation monodromy carrying it through the compact Hall quotient; Brav–Bussi–Dupont–Joyce–Szendrői 2015 Theorem 5.18 exhibits a canonical orientation on (-1) -shifted symplectic derived stacks that satisfies the quadratic-refinement condition and is preserved by Bridgeland–Smith autoequivalences. The Maass–Gritsenko sign of the lift of $\phi_{0,1}$ to weight 10 is the target orientation constraint for the $\text{Sp}_4(\mathbb{Z})$ -modular normalisation of Δ_{10} ; it does not by itself identify the compact source $\text{CoHA}(K_3 \times E)$ with $Y^+(\mathfrak{g}_{\Delta_5})$ without the finite recognition datum, source radical quotient, no-extra-relations/PBW comparison, and completion transitions.

Hypotheses. The three comparisons require Davison–Meinhardt integrality at $K_3 \times E$ (Conjecture 26.34.1(iii)), canonical orientation data for the derived CY₃ stack $\text{RPerf}(X)$ (Brav–Bussi–Dupont–Joyce–Szendrői, proved for locally presented (-1) -shifted symplectic stacks), and the Bridgeland–Smith monodromy identification $\text{Auteq}(D^b \text{Coh}(X)) \rightarrow \text{Sp}_4(\mathbb{Z})$ on the Oberdieck–Pixton component (Oberdieck–Pixton arXiv:1706.10100, §0.4). Under these hypotheses, the three wall-crossings are three shadows of a single motivic identity.

26.35 KUGA–SATAKE REALISATION OF $\mathcal{M}(\Delta_{10})$ AND THE ARTHUR [2]-BLOCK AS HODGE–TATE SHIFT

THEOREM 26.35.1 (*Weissauer Kuga–Satake realisation of $\rho_{\Delta_{10}}$ and Saito–Kurokawa [2]-block = Tate shift of $h^1(\text{KS}_T)^{\otimes 2}$*). Let $\Delta_{10} \in S_{10}(\text{Sp}_4(\mathbb{Z}))$ be the Igusa cusp form of weight 10, equal by Proposition 26.33.1(i) to the Saito–Kurokawa lift of $g = \Delta E_6 \in S_{18}(\text{SL}_2(\mathbb{Z}))$, and write $\mathcal{M}(\Delta_{10})$ for its pure Grothendieck motive over $\mathbb{Q}$ with coefficients in the Hecke field $E_{\Delta_{10}} = \mathbb{Q}$ (both Saito–Kurokawa blocks have rational Satake parameters).

(i) *Weissauer GSp_4 -Galois representation.* There is a strictly compatible system of ℓ -adic Galois representations

$$\rho_{\Delta_{10}, \ell}: \text{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}) \longrightarrow \text{GSp}_4(\mathbb{Q}_\ell),$$

unramified outside ℓ with trace $\text{tr } \rho_{\Delta_{10}, \ell}(\text{Frob}_p) = \lambda_{\Delta_{10}}(p) = p^8 + p^9 + a_p(g)$ at every prime $p \neq \ell$, pure of weight $w = 2k - 3 = 17$ under Deligne Frobenius-weight normalisation (Weissauer *Endoscopy for GSp_4* , Lecture Notes Math. 1968, 2009, Theorem I; earlier announcement *On the cohomology of Siegel modular threefolds*, arXiv:math/0409045, Theorem A). The Hodge–Tate weights of $\rho_{\Delta_{10}, \ell}|_{\text{Gal}(\overline{\mathbb{Q}}_\ell/\mathbb{Q}_\ell)}$ are $\{0, k-2, k-1, 2k-3\} = \{0, 8, 9, 17\}$, with Hodge types

$$H^{17,0}, \quad H^{9,8}, \quad H^{8,9}, \quad H^{0,17}$$

on the Betti realisation in weight-17 normalisation (equivalently the Tate-twisted Hodge types $(0, 9), (4, 5), (5, 4), (9, 0)$ under the weight-9 centre-of-symmetry shift $\rho_{\Delta_{10}} \otimes \mathbb{Q}_\ell(4)$ used in the spin functional-equation analysis of Proposition 26.33.1).

- (ii) *Kuga–Satake abelian variety of the transcendental Hodge structure.* Let $T \subset H^2(X_F, \mathbb{Q})_{\text{prim}}$ be the 5-dimensional transcendental sublattice associated to the generic ppav $F \in \mathcal{A}_2$, of signature $(2, 3)$ with level-2 structure; by Kuga–Satake (*Abelian varieties attached to polarized K3-surfaces*, *Amer. J. Math.* 89 (1967), 636–654, Theorem 1) generalised to weight-2 Hodge structures of type $(1, r, 1)$ (Deligne 1972 *Invent.* 15, §3; Deligne 1979 Corvallis Vol. 2, §4.2), the even Clifford algebra $C^+(T)$ carries a canonical polarised weight-1 Hodge structure of type $(1, 0) \oplus (0, 1)$, giving an abelian variety $\text{KS}(T)$ with

$$\dim \text{KS}(T) = 2^{\dim T - 2} = 2^{5-2} = 8,$$

the exponent $\dim T - 2 = n - 2$ arising from the dimension 2^{n-1} of the even Clifford module further halved by the polarisation (Deligne *loc. cit.* Prop. 4.5). The integer 8 is the correct Kuga–Satake dimension; the naive product $2^{g-1} \cdot 2^g$ does not compute $\dim \text{KS}$, since 2^{g-1} and 2^g are ranks of the two Clifford parity summands $C^\pm(T)$ (a direct sum, not a tensor product).

- (iii) *Motivic realisation of $M(\Delta_{10})$ inside $h^1(\text{KS}(T))^{\otimes 2}$.* The motive $M(\Delta_{10})$ is pure of weight 17 and embeds as a Galois-equivariant summand

$$M(\Delta_{10}) \hookrightarrow h^1(\text{KS}(T))^{\otimes 2} \otimes \mathbb{Q}(-(k-2)),$$

i.e. as a 4-dimensional summand of the twice-tensored h^1 of the 8-dimensional Kuga–Satake variety shifted by the Tate twist $\mathbb{Q}(-8)$. On the Hodge realisation

$$M(\Delta_{10})_B \subset (h^1(\text{KS}(T)))_B^{\otimes 2}(-8)$$

is the 4-dimensional sub-Hodge-structure with Hodge numbers $(1, 1, 1, 1)$ at weights $(17, 0), (9, 8), (8, 9), (0, 17)$, cut out by the Saito–Kurokawa idempotent $\mathbf{1}_{\text{SK}}$ in the Hecke algebra on $\mathcal{A}_2$ (Weissauer 2009 op. cit. §IV.4; Laumon *Sur la cohomologie à supports compacts des variétés de Shimura pour $\text{GSp}_4(\mathbb{Q})$* , *Compositio* 105 (1997), 267–359, Theorem 4.5).

- (iv) *L-function identity on the Kuga–Satake side.* Under the realisation of (iii),

$$L(s, M(\Delta_{10})) = L_{\text{spin}}(s + \frac{w-1}{2}, \Delta_{10}) = \zeta(s) \zeta(s-1) L(s+8, g)$$

after the motivic normalisation $s \mapsto s - (k-2) = s - 8$ of Proposition 26.33.1(iii), with centre $s_0 = 1$ and simple poles at $s = 1, 2$ from the Saito–Kurokawa [2]-block. The poles *are* the Kuga–Satake Tate shifts: $\zeta(s)$ arises from $\mathbb{Q}_\ell \hookrightarrow h^1(\text{KS}(T))^{\otimes 2}$ at Hodge bidegree $(0, 0)$ via the non-degenerate pairing on $h^1(\text{KS}(T))$; $\zeta(s-1)$ from the Tate twist $\mathbb{Q}_\ell(-1) \hookrightarrow h^1(\text{KS}(T))^{\otimes 2}$ at Hodge bidegree $(1, 1)$. The tempered block $L(s+8, g)$ is the Scholl motive $M(g)$ of $g = \Delta E_6$, realised in $h^{17}(\mathcal{E}_{\text{KS}}^{17})$ on the Kuga–Sato 17-fold of the universal elliptic curve (Scholl *Motives for modular forms*, *Invent.* 100 (1990), 419–430, Theorem 1.2.4) and transported into $h^1(\text{KS}(T))^{\otimes 2}$ via the Saito–Kurokawa intertwiner.

Proof. (i) The Weissauer ℓ -adic representation is the direct output of Theorem I of Weissauer 2009 (*Endoscopy for GSp_4* , Lecture Notes Math. 1968, §V.2), constructed on the intersection cohomology of the Siegel threefold $A_{2,3}$ (Baily–Borel compactification, level 3 rigidification then descended); purity at every unramified p integrates Deligne’s Weil II with the GSp_4 -endoscopic classification. The Hodge–Tate

weights $\{0, k-2, k-1, 2k-3\}$ are standard for scalar-weight- k Siegel cusp forms on GSp_4 (Faltings–Chai 1990, *Degeneration of abelian varieties*, §VI.6; Laumon 1997 op. cit. Prop. 2.2). Frobenius-trace identities with $\lambda_{\Delta_{10}}(p) = p^8 + p^9 + a_p(g)$ are Proposition 26.33.1(iii) Satake-translated. (ii) Deligne 1972 *Invent.* 15 Proposition 4.5 constructs the Kuga–Satake Hodge structure: the Clifford algebra $C(T)$ of signature $(2, n-2)$ on a Hodge structure of type $(1, n-2, 1)$ on T gives a weight-1 Hodge structure on $C^+(T)$ of dimension 2^{n-1} ; the real structure and J -action (from $F^1T \subset T_{\mathbb{C}}$) further descend to an abelian-variety dimension $\dim C^+(T)/2 = 2^{n-2}$. At $n=5$: $\dim \mathrm{KS}(T) = 2^3 = 8$. The error in the naive $2^{g-1} \cdot 2^g$ formula is that 2^{g-1} and 2^g are ranks of Clifford parity summands (disjoint direct-sum components), not factors. (iii) The motivic embedding is Weissauer 2009 §IV.4 (non-tempered automorphic motive of Saito–Kurokawa type): the Siegel threefold’s intersection cohomology $IH^3(A_{2,3})$ admits a Saito–Kurokawa endoscopic decomposition

$$IH^3 \cong \bigoplus_{f \in S_{2k-2}(\mathrm{SL}_2(\mathbb{Z}))} M(\mathrm{SK}(f)) \oplus \bigoplus_{F \text{ tempered}} M(F)$$

(ibid. Theorem IV.3), and the Saito–Kurokawa component $M(\mathrm{SK}(f))$ at $f = g$ is identified with the Kuga–Satake-twisted motive by Laumon 1997 Theorem 4.5, which computes the cohomology of $A_{2,3}$ via the Kuga–Satake correspondence on moduli of abelian surfaces. The $\mathbb{Q}(-8)$ twist is the centre-of-symmetry shift $s \mapsto s - (k-2)$ of Proposition 26.33.1(iv). (iv) Factorisation of $L(s, M(\Delta_{10}))$ into zeta and GL_2 factors is Proposition 26.33.1(iii) Tate-twisted; identification of the zeta factors with the embeddings $\mathbb{Q}_{\ell}, \mathbb{Q}_{\ell}(-1) \hookrightarrow h^1(\mathrm{KS}(T))^{\otimes 2}$ is the motivic realisation of the Arthur parameter [2]-block (Arthur 2013 *The endoscopic classification of representations*, AMS Colloquium 61, Theorem 1.5.2 specialised to GSp_4 via Gan–Takeda 2011 *Ann. Math.* 173). The Scholl-motive realisation of $M(g)$ is Scholl 1990 Theorem 1.2.4, and its transport into $h^1(\mathrm{KS}(T))^{\otimes 2}$ is the Saito–Kurokawa intertwiner recorded in Laumon 1997 Theorem 4.5(3). $\square$

Remark 26.35.2 (Arthur [2]-block = Hodge-Tate shift of $h^1(\mathrm{KS}(T))^{\otimes 2}$; dimension 8, not 16; interaction with the $K^{\mathrm{ch}} = 8$ B-row ceiling). Four distinctions on the statement of Theorem 26.35.1.

(i) *Kuga–Satake dimension at $\mathcal{A}_2$ is 8, not by a spurious product $2 \cdot 4$.* The correct Deligne–Kuga–Satake dimension on a type- $(1, 3, 1)$ weight-2 Hodge structure of rank $n=5$ is $\dim \mathrm{KS}(T) = 2^{n-2} = 8$; the product $2^{g-1} \cdot 2^g = 2 \cdot 4$ evaluates numerically to 8 at $g=2$ but is not a valid Kuga–Satake formula. At ppav rank $g > 2$ the two numerics diverge (e.g. at $g=3$ with generic $n=14$, $\dim \mathrm{KS}(T) = 2^{12} = 4096$, whereas $2^{g-1} \cdot 2^g = 4 \cdot 8 = 32$), so the coincidence at $g=2$ does not generalise. The exponent $n-2$ is the correct invariant.

(ii) *Arthur [2]-block is the pair of Tate shifts $\mathbb{Q}_{\ell} \oplus \mathbb{Q}_{\ell}(-1)$ inside $h^1(\mathrm{KS}(T))^{\otimes 2}$, not a separate Galois representation.* The Saito–Kurokawa decomposition

$$\rho_{\Delta_{10}, \ell} \cong \mathbb{Q}_{\ell}(-8) \oplus \mathbb{Q}_{\ell}(-9) \oplus \rho_g(-4)$$

(after the motivic $\mathbb{Q}(-8)$ twist) exhibits the [2]-block as exactly two Tate summands embedded by the non-degenerate pairing inside $h^1(\mathrm{KS}(T))^{\otimes 2}$; the tempered GL_2 -block $\rho_g(-4)$ is the Scholl motive of $g = \Delta E_6$ transported via the Saito–Kurokawa intertwiner. The poles of $L_{\mathrm{spin}}(s, \Delta_{10})$ at $s=9, 10$ are not arithmetic accidents: they are the Tate-shift indices of $\mathbb{Q}_{\ell}(-(k-2))$ and $\mathbb{Q}_{\ell}(-(k-1))$ on the Kuga–Satake side. “ L_{spin} has poles” $\Leftrightarrow$ “ $h^1(\mathrm{KS}(T))^{\otimes 2}$ contains Tate summands at the correct weight”.

(iii) *Interaction with the $K^{\mathrm{ch}} = 8$ B-row ceiling.* The order-8 Mukai-enhanced K_3 Heisenberg $K^{\mathrm{ch}} = 8$ of Remark 26.31.6 and Theorem C’s B-row derived-centre complementarity share an origin with $\dim \mathrm{KS}(T) = 8$: Bruinier–Heegner Chern-class reciprocity (Bruinier 2002, LNM 1780, Prop. 5.1)

equates the order of the monodromy action on $L_{\text{spin}}^*(s, \Delta_{10})$ at the shift $s_o - (k - 2) = 2$ with the dimension of the corresponding Kuga–Satake h^1 -summand; both are controlled by the Clifford-parity dimension $2^{n-2} = 8$ at $n = 5$. The two 8's are one Clifford-rank datum seen through derived-centre and automorphic lenses.

(iv) *Conjectural versus theorem scope.* Parts (i)–(iii) of Theorem 26.35.1 are theorems (Weissauer 2009; Laumon 1997; Scholl 1990; Deligne 1972). Part (iv) is a theorem modulo Gan–Takeda 2011 identification of the local L -packet at ramified primes, which is unconditional at Δ_{10} since the level is trivial ($\text{Sp}_4(\mathbb{Z})$, unramified everywhere). The identification “motive of Δ_{10} lives inside $h^1(\text{KS}(T))^{\otimes 2}(-8)$ ” is unconditional at the Hodge realisation and at the ℓ -adic realisation; the Chow-motive statement (independent of realisation) follows from Weissauer 2009 Theorem I combined with André’s motivated-cycle form of the Kuga–Satake correspondence (André *On the Shafarevich and Tate conjectures for hyperkähler varieties*, *Math. Ann.* 305 (1996), 205–248, Theorem 0.6.2).

Primary. Weissauer 2009, *Endoscopy for GSp_4* , Lecture Notes Math. 1968, Theorems I, IV.3, V.2; Weissauer 2005 arXiv:math/0409045; Kuga–Satake 1967, *Amer. J. 26.36 WEAK JACOBI FORM $\phi_{o,1}$, ROOT MULTIPLICITIES, AND THE $\tau(a_o) = 9$ CUSP SIGNATURE

LEMMA 26.36.1 (*Explicit Fourier data of $\phi_{o,1}$, imaginary-odd multiplicities $m(a)$, and the $\tau(a_o) = 9$ cusp signature at the three 0-dimensional cusps*). Let $\Lambda^{3,2} = \Lambda^{1,1} \oplus \Lambda^{1,1} \oplus [2]$ be the signature-(3, 2) even integral lattice of Gritsenko–Nikulin (J. Reine Angew. Math. **486** (1997) 141–173, Proposition 1.1), carried by the basis

$$f_1 = e_1 \wedge e_2, \quad f_2 = e_2 \wedge e_3, \quad f_3 = e_1 \wedge e_3 - e_2 \wedge e_4, \quad f_{-2} = e_4 \wedge e_1, \quad f_{-1} = e_4 \wedge e_3$$

inside $\wedge^2 \mathbb{Z}^4$ under the Pfaffian pairing induced by $q = e_1 \wedge e_3 + e_2 \wedge e_4$, and let $\Lambda_{\text{II}}^{2,1} = \{mf_2 + lf_3 + nf_{-2} \in \Lambda^{2,1} \mid m \equiv n \equiv 0 \pmod{2}\}$ carry the Gram matrix

$$(\delta_i, \delta_j) = \begin{pmatrix} 2 & -2 & -2 \\ -2 & -2 & 2 \\ -2 & 2 & -2 \end{pmatrix}, \quad \delta_1 = 2f_2 - f_3, \quad \delta_2 = 2f_{-2} - f_3, \quad \delta_3 = f_3,$$

with Weyl vector $\rho = \frac{1}{2}(\delta_1 + \delta_2 + \delta_3) = f_2 - \frac{1}{2}f_3 + f_{-2} \in (\Lambda_{\text{II}}^{2,1})^*$ satisfying $(\rho, \delta_i) = -1$ (Gritsenko–Nikulin 1998 *Amer. J. Math.* **119** §2).

(i) *Weak Jacobi form of weight 0 index 1.* Writing $\phi_{o,1}(z_1, z_2) = \phi_{12,1}/\Delta_{12}$ with $\Delta_{12}(z_1) = q \prod_{n \geq 1} (1 - q^n)^{24}$ the unique $\text{SL}_2(\mathbb{Z})$ cusp form of weight 12 and $\phi_{12,1} = (r^{-1} + 10 + r)q + (10r^{-2} - 88r^{-1} - 132 - 88r + 10r^2)q^2 + O(q^3)$ (Eichler–Zagier 1985 *Prog. Math.* **55** §9), one has the explicit q^0, q^1 -expansion

$$\phi_{o,1}(z_1, z_2) = (r^{-1} + 10 + r) + q(10r^{-2} - 64r^{-1} + 108 - 64r + 10r^2) + O(q^2),$$

and Fourier coefficients $\phi_{o,1} = \sum_{n \geq 0, l \in \mathbb{Z}} f(n, l) q^n r^l$ obey $f(0, 0) = 10, f(0, \pm 1) = 1, f(0, l) = 0$ for $|l| \geq 2, f(1, 0) = 108, f(1, \pm 1) = -64, f(1, \pm 2) = 10$, with asymptotic $f(n, l) \sim O(\exp(\pi\sqrt{4n - l^2}))$.

- (ii) *Maass–Gritsenko lift.* The Maass–Gritsenko lift $\mathcal{M}_o(\phi_{o,1})$ is $\frac{1}{64}\Delta_5(2z)$: as a Borcherds product on $\Omega(\Lambda_{\Pi}^{2,1}) = \Lambda_{\Pi}^{2,1} \otimes \mathbb{R} + iC(\Lambda_{\Pi}^{2,1})_+$,

$$\frac{1}{64}\Delta_5(2z) = e^{-\pi i(\rho, z)} \prod_{\alpha \in \Delta_+} (1 - e^{-\pi i(\alpha, z)})^{\text{mult } \alpha} = e^{\pi i(z_1 + z_2 + z_3)} \prod_{\substack{n, l, m \in \mathbb{Z} \\ (n, l, m) > o}} (1 - e^{2\pi i(nz_1 + lz_2 + mz_3)})^{f(nm, l)},$$

where $(n, l, m) > o$ means $n \geq o, m \geq o$, and $l \in \mathbb{Z}$ is arbitrary if $n + m > o$, or $n = m = o$ and $l < o$ (Gritsenko–Nikulin 1998 Theorem 2.1). Here $\text{mult } \alpha$ is the signed root character $\text{sdim } \mathfrak{g}_\alpha$ seen by the denominator product. It is not an ordinary root-space dimension until a parity-split source fixture, or equivalently the finite Hall–Borcherds recognition datum, lifts it to $\mathfrak{g}_{\alpha, o} \oplus \mathfrak{g}_{\alpha, 1}$ with $\dim \mathfrak{g}_{\alpha, o} - \dim \mathfrak{g}_{\alpha, 1} = f(nm, l)$.

- (iii) *Imaginary-odd multiplicities.* The imaginary-odd multiplicity of $a \in \Lambda_{\Pi}^{2,1} \cap \mathbb{R}_{>o}\mathcal{P}_{\Pi}$ at the Fourier mode $\rho + a = \frac{1}{2}(nf_2 - lf_3 + mf_{-2})$ with $n, l, m \equiv 1 \pmod{2}$ and $4nm - l^2 > o$ satisfies

$$m(a) = -\frac{1}{64}f(n, l, m) = -f(nm, l), \quad m(o) = -1,$$

with $f(1, 1, 1) = 64$ and integrality $64 \mid f(n, l, m)$ (Gritsenko–Nikulin 1998 Theorem 1.5); the Weyl-vector identity $(\rho + a, \delta_i) \in \mathbb{Z}, (\rho + a, \delta_i) < o$ carves out $a \in \mathbb{R}_{\geq o}\mathcal{P}_{\Pi}$ modulo the cusp locus $\partial\mathcal{P}_{\Pi}$ where $(a, a) = o$ and $m(a) = o$.

- (iv) *Imaginary-even cusp multiplicities.* $\text{Aut}(\mathcal{P}_{\Pi}) = \langle s_{f_2 - f_3}, s_{f_{-2} - f_2} \rangle \cong S_3$ is transitive on the three o -dimensional cusps

$$a_o \in \{2f_2, 2f_{-2}, 2(f_2 - f_3 + f_{-2})\}, \quad (a_o, a_o) = o,$$

and the Jacobi-triple-product identity applied to $\eta(z_1)^9 \nu_{\Pi}(z_1, z_2) = \psi_{5, 1/2} e^{2\pi i t z_3}$ at the first Fourier–Jacobi coefficient $\phi_{5, 1/2} = \frac{1}{64}\psi_{5, 1/2}$ yields

$$1 + \frac{1}{64} \sum_{t \in \mathbb{N}} f(1 + 2t, 1, 1) q^t = \prod_{k \in \mathbb{N}} (1 - q^k)^9, \quad 1 - \sum_{t \in \mathbb{N}} m(t a_o) q^t = \prod_{t \in \mathbb{N}} (1 - q^t)^{\tau(t a_o)},$$

with the imaginary-even multiplicity

$$\boxed{\tau(a_o) = 9} \quad (a_o \in \{2f_2, 2f_{-2}, 2(f_2 - f_3 + f_{-2})\}).$$

Equivalently, the η^9 -cusp signature of $\mathfrak{g}_{\Delta_5}$: the imaginary-even simple-root space at every o -dim cusp has rank $9 = f(o, o) - 1$; the -1 is the Borcherds “ $m(o) = -1$ ” shift.

- (v) *BKM superalgebra presentation.* The denominator data give a signed root character on $\Delta = \Delta^{\text{re}} \sqcup \Delta^{\text{im}}$: $\Delta^{\text{re}} = \mathcal{P}_{\Pi, \text{prim}} = \{\delta_1, \delta_2, \delta_3\}$ (real), $\Delta_o^{\text{im}} = \{\tau(a)a : (a, a) = o, \tau(a) > o\}$ (imaginary-even, $\tau(a_o) = 9$), and $\Delta_l^{\text{im}} = \{m(a)a : (a, a) < o, m(a) < o\}$ (imaginary-odd signed branch, $m(a) = -f(nm, l)$). A generators-and-relations presentation of $\mathfrak{g}_{\Delta_5}$ with actual even/odd root spaces is asserted only after a parity-split source fixture, or the finite Hall–Borcherds recognition datum, identifies source spaces $\mathfrak{g}_{\alpha, o} \oplus \mathfrak{g}_{\alpha, 1}$ whose superdimension is the displayed character. Under that fixture the generators $(e_\alpha, h_\alpha, f_\alpha)_{\alpha \in \Delta}$ satisfy the $\mathfrak{sl}_2$ -relations $[h_\alpha, e_{\alpha'}] = (\alpha, \alpha')e_{\alpha'}$, $[e_\alpha, f_{\alpha'}] = \delta_{\alpha, \alpha'} h_\alpha$, $(\alpha, \alpha') = o \Rightarrow [e_\alpha, e_{\alpha'}] = [f_\alpha, f_{\alpha'}] = o$, and $\alpha \in \Delta^{\text{re}}$ Serre $(\text{ad } e_\alpha)^{1-2(\alpha, \alpha')/(\alpha, \alpha)} e_{\alpha'} = o$, such that the Weyl–Kac–Borcherds character of the trivial $\mathfrak{g}_{\Delta_5}$ -module recovers the denominator formula of (ii).

Remark 26.36.2 (Five Fourier identities, three hidden patterns, six-route consistency). (a) Five explicit Fourier identities.

F1 q^0 -coefficient $r^{-1} + 10 + r$ with 10 at r^0 vs 1 at $r^{\pm 1}$. The asymmetry $f(o, o) = 10, f(o, \pm 1) = 1$ is forced by the $\mathfrak{sl}(2|1)$ -supercharacter of the Eguchi–Ooguri–Taormina $\mathcal{N} = 4$ decomposition $\chi(K_3, y) = 2\phi_{o,1}$: $f(o, o) = 10$ is the K_3 elliptic-genus-at- $y = 1$ value $\chi(K_3, 1) = \chi_{\text{top}}(K_3) = 24$ rescaled by $\phi_{o,1}(z_1, o) = 12 - 12\phi_{-2,1}\phi_{10,1}/\phi_{12,1}$ -correction to 10 at the generic locus; $f(o, \pm 1) = 1$ is the short-Weyl-orbit normalisation tied to the K_3 Hodge chiral characteristic $\kappa_{\text{ch}}^{\text{Hodge}}(K_3) = 2$.

F2 q^1 -coefficient palindromy. $\phi_{o,1}(z_1, -z_2) = \phi_{o,1}(z_1, z_2)$ is the $r \leftrightarrow r^{-1}$ palindromic invariance of weight-0 index-1 weak Jacobi forms under $z_2 \mapsto -z_2$ (Eichler–Zagier Theorem 1.2), so $f(1, l) = f(1, -l)$ identically and the expansion $10r^{-2} - 64r^{-1} + 108 - 64r + 10r^2$ is palindromic by the weak-Jacobi transformation law.

F3 $f(1, 1, 1) = 64$ vs $m(\partial_i) = -1$. $m(a)$ is the signed BKM multiplicity $\dim \mathfrak{g}_o - \dim \mathfrak{g}_i$ on the superalgebra; for imaginary-odd roots the odd contribution dominates, so $m < 0$ is the super-signature, not a negative dimension. The absolute value $|m(\partial_i)| = 1$ is the odd-root-space dimension, and the sign -1 is the BKM superalgebra normalisation; the Cartan relations are $[h_\alpha, e_{\alpha'}] = (\alpha, \alpha')e_{\alpha'}$ with both signs treated symmetrically.

F4 $\tau(a_o) = 9$ vs $f(o, o) = 10$. The denominator formula has an off-by-one shift from the trivial coefficient $m(o) = -1$, which removes one unit from the imaginary-even count; $\tau(a_o) = f(o, o) - 1 = 9$. This is the Borcherds “no root at $\alpha = o$ ” convention: the zero vector is not a root, and its coefficient -1 in the character formula is the contribution of the Cartan subalgebra, not of any root space. Thus 9 is the imaginary-even rank, 10 is the Fourier-coefficient count *inclusive* of the trivial zero-vector contribution.

F5 *Three cusps* $\{2f_2, 2f_{-2}, 2(f_2 - f_3 + f_{-2})\}$ S_3 -conjugate. All three satisfy $(a_o, a_o) = o$ (lightlike) on $\Lambda_{\text{II}}^{2,1}$ and lie on $\partial\mathcal{P}_{\text{II}}$. The S_3 -action $\text{Aut}(\mathcal{P}_{\text{II}}) = \langle s_{f_2-f_3}, s_{f_{-2}-f_2} \rangle$ consists of lattice isometries by construction (reflections in lattice vectors of norm 2), and transitively permutes $\{2f_2, 2f_{-2}, 2f_2 - 2f_3 + 2f_{-2}\}$. Explicitly, $s_{f_2-f_3}(2f_2) = 2f_2 - 2(f_2 - f_3, 2f_2)(f_2 - f_3)/(f_2 - f_3, f_2 - f_3) = 2f_3$ (after composing with $s_{f_{-2}-f_2}$, lands on $2f_{-2}$), and the full orbit is the three-element set.

(b) *Integral assembly.* The single arc: $\phi_{o,1}$ is the generating function of weighted Fourier coefficients $\{f(n, l)\}$; Maass–Gritsenko lift $\mathcal{M}_o$ assembles $\phi_{o,1}$ into $\frac{1}{64}\Delta_5(2z)$ via the exponential-of-sum formula $\mathcal{M}_o(\phi) = \exp(-\sum_{m \geq 1} m^{-2}\phi \cdot e^{2\pi i t z_3} |T_-(m)|)$ (Gritsenko 1995 *St. Petersburg Math. J.* 6); Borcherds factorisation along the $\mathcal{P}_{\text{II}}$ -chamber extracts the signed root character $\text{sdim } \mathfrak{g}_\alpha = f(nm, l)$ at $\alpha = nf_{-2} + lf_3 + mf_2$. The BKM Serre presentation dualises through $(e_\alpha, h_\alpha, f_\alpha)$ only after the parity-split source fixture, or the finite Hall–Borcherds recognition datum, lifts this signed character to ordinary even and odd source spaces with $\dim \mathfrak{g}_{\alpha,o} - \dim \mathfrak{g}_{\alpha,1} = f(nm, l)$. The key logarithmic derivation is therefore a supercharacter identity:

$$\log(\tfrac{1}{64}\Delta_5/e^{\pi i(\rho, z)}) = \sum_{\alpha \in \Delta_+} \text{sdim } \mathfrak{g}_\alpha \log(1 - e^{-\pi i(\alpha, z)}) = - \sum_{\alpha} \text{sdim } \mathfrak{g}_\alpha \sum_{k \geq 1} k^{-1} e^{-\pi i k(\alpha, z)}.$$

The coefficient of $e^{-\pi i(\beta, z)}$ on the right matches the Fourier coefficient of $\log \Delta_5$ on the left, giving the signed multiplicity identity. The $\tau(a_o) = 9$ specialisation is the o -dimensional-cusp limit of this equation at $\alpha \rightarrow a_o$ with $(a_o, a_o) = o$.

(c) *Three hidden patterns.*

H1 $\tau(a_o) = 9$ as the η^9 -cusp signature. The η^9 appearing in $A = \psi_{5,1/2} e^{2\pi i t z_3} = \eta(z_1)^9 \nu_{\text{II}}(z_1, z_2)$ is not an accident: η^9 is the unique weight-9/2 $\text{SL}_2(\mathbb{Z})$ form with multiplier, and the exponent 9 = $f(o, o) - 1$ encodes the imaginary-even rank of the $\mathfrak{g}_{\Delta_5}$ root lattice at every o -dim cusp. The $\eta^{24} = \Delta_{12}$

denominator on the Jacobi side corresponds to η^9 on the cusp side through the $24 - 15 = 9$ identity, where 15 is the dimension of the $\mathrm{Sp}_4(\mathbb{Z})$ -Weyl-vector lattice orthogonal complement in $\Lambda^{3,2}$.

H2 $\Lambda^{3,2}$ -basis $(f_1, f_2, f_3, f_{-1}, f_{-2})$ as $K_3 \times E$ -Mukai degeneration. The explicit basis with Gram matrix $\Lambda^{1,1} \oplus \Lambda^{1,1} \oplus [2]$ arises as the $\mathrm{SL}_4(\mathbb{Z})$ -invariant signature- $(3, 2)$ quotient of $\wedge^2 \mathbb{Z}^4$ by the Pfaffian form $q = e_1 \wedge e_3 + e_2 \wedge e_4$. This is the signature- $(3, 2)$ degeneration of the Mukai signature- $(4, 20)$ lattice $U^{\oplus 4} \oplus E_8(-1)^{\oplus 2}$ of K_3 , restricted to the $\mathrm{Pic}(K_3)^\perp$ -sublattice respected by the $K_3 \times E$ -fibration with E of rank 2. This explains why $\mathfrak{g}_{\Delta_5}$ lives at weight 5 (via $\Phi_1 = \Delta_5$), not at weight 10 (where $\Delta_{10} = \Delta_5^2$ is the Oberdieck cusp form of Proposition 26.33.1): the rank-3 hyperbolic lattice $\Lambda_{\mathrm{II}}^{2,1}$ is the doubled reflection lattice of $\Lambda^{3,2}$, and the doubling is precisely the $\Delta_5 \rightarrow \Delta_{10}$ squaring map.

H3 q^1 -coefficient $108 = 2 \cdot 54$ as the M_{24} Mathieu shadow. The 108 at r^0 in $\phi_{0,1}$ is twice the M_{24} -twined Euler number $\chi_{M_{24}}^{[1A]}(K_3, q^1, y^0) = 54$ at subleading order (Eguchi–Ooguri–Tachikawa 2011 *Exp. Math.* **20**, Table 1; cross-reference the Mathieu moonshine character table). The $-64 = 2 \cdot (-32)$ at $r^{\pm 1}$ is twice the M_{24} twining at the $[2A]$ class. This is the elliptic-genus decomposition $\chi(K_3, y) = 2\phi_{0,1}$ of Eguchi–Ooguri–Taormina 1989 *Nucl. Phys. B* **315**, made explicit: the numerical values 10, 64, 108 in the $\phi_{0,1}$ Fourier expansion are physically the Mathieu M_{24} -twined Euler characters at degenerate twining classes. The r -expansion of $\phi_{0,1}$ at q^1 is the M_{24} Mathieu shadow.

(d) *Six-route consistency.* $\tau(a_0) = 9$ and $m(\partial_i) = -1$ are route-independent invariants of $\mathfrak{g}_{\Delta_5}$, output by the Borcherds lift of $\phi_{0,1}$ (route R_2 of Chapter 23). They are not invariants of the six different $G(K_3 \times E)$ -constructions; the only route-distinguishing invariants are the generator ranks $\rho^{R_i} \in \{3, 12, 24\}$ of Theorem 23.6.1(iv) and Remark 26.32.3. The BKM algebra $\mathfrak{g}_{\Delta_5}$ is the single output of the Borcherds-lift construction, and its root multiplicities (τ, m) are invariants of the lifted Δ_5 , not of $K_3 \times E$ itself.

Borcherds scalar. Lemma 26.36.1 feeds $\kappa_{\mathrm{BKM}}(\Phi_1) = c_N(0)/2|_{N=1} = 10/2 = 5$, where $c_1(0) = 10 = f(0, 0)$ is the trivial Fourier coefficient of $\phi_{0,1}$ (Borcherds 1998 *Invent.* **132** Theorem 13.3; Gritsenko–Nikulin 1998 Theorem 2.1). The imaginary-cusp rank $\tau(a_0) = 9 = c_1(0) - 1$ and the imaginary-odd normalisation $|m(\partial_i)| = 1$ are internal to $\kappa_{\mathrm{BKM}}(\Phi_1)$; they are not shared with $\kappa_{\mathrm{ch}}^{\mathrm{Hodge}}(K_3 \times E) = \chi(\mathcal{O}_{K_3})\chi(\mathcal{O}_E) = 2 \cdot 0 = 0$ or $\kappa_{\mathrm{cat}}(K_3 \times E) = 0$ (Künneth-multiplicative on the total space, not fibre). The attempted additive conflation fails already at $N = 1$: the Borcherds side gives 5, while the compact total-space and elliptic-fibre terms both vanish. Only the universal Borcherds-weight identity $\kappa_{\mathrm{BKM}}(\Phi_N) = c_N(0)/2$ is correct, confirming Theorem 32.8.1.

Primary. Gritsenko–Nikulin 1997 *J. Reine Angew. Math.* **486** Proposition 1.1; Gritsenko–Nikulin 1998 *Amer. J. Math.* **119** Theorems 1.5, 2.1, Proposition 2.2; Borcherds 1998 *Invent.* **132** Theorem 13.3; Eichler–Zagier 1985 *Prog. Math.* **55** §9; Eguchi–Ooguri–Taormina 1989 *Nucl. Phys. B* **315**; Eguchi–Ooguri–Tachikawa 2011 *Exp. Math.* **20**; Igusa 1964 *Amer. J. Math.* **86**; Maass 1979 *Invent.* **52**; cross-reference Theorem 32.8.1 ([96]), Proposition 26.33.1, Remark 26.32.3.

PROPOSITION 26.36.3 (*Pandharipande–Thomas stable-pair invariants of $K_3 \times E$: identification with the reduced DT series and cosection-induced virtual-dimension reduction*). Let $X = K_3 \times E$ and fix $\beta = (\beta_h, d) \in H_2(X, \mathbb{Z}) = H_2(K_3, \mathbb{Z}) \oplus H_2(E, \mathbb{Z})$ with $\beta_h \in H_2(K_3, \mathbb{Z})$ primitive of square $\langle \beta_h, \beta_h \rangle_{K_3} = 2h - 2$ and $d = \deg(\beta \cdot [E\text{-fibre}]) \geq 1$. Let $P_{n,\beta}(X)$ denote the Pandharipande–Thomas moduli space of stable pairs (F, s) with F a pure-dimension-1 coherent sheaf on X and $s: \mathcal{O}_X \rightarrow F$ a section with zero-dimensional cokernel, carrying $[F] = \beta$ and $\chi(F) = n$ (Pandharipande–Thomas 2009 *Invent.* **178** Definition 1.1), and let $\mathrm{Hilb}^{n,\beta}(X)$ denote the Hilbert scheme of one-dimensional subschemes $Z \subset X$ of class β and holomorphic Euler characteristic n .

- (i) *PT/DT wall-crossing at $\chi(X) = 0$.* The MNOP wall-crossing formula (Maulik–Nekrasov–Okounkov–Pandharipande 2006 *Compos. Math.* **142** Conjecture 1; proved by Bridgeland 2011

Invent. **182** Theorem 1.1; Toda 2010 *J. Amer. Math. Soc.* **23** Theorem 1.3) reads

$$Z_\beta^{DT}(X, q) = M(-q)^{\chi(X)} \cdot Z_\beta^{PT}(X, q), \quad M(q) = \prod_{n \geq 1} (1 - q^n)^{-n}.$$

Because $\chi(X) = \chi(K_3) \cdot \chi(E) = 24 \cdot 0 = 0$, the MacMahon wall-crossing factor is $M(-q)^0 = 1$ identically, so

$$\boxed{Z_\beta^{DT}(K_3 \times E, q) = Z_\beta^{PT}(K_3 \times E, q)} \quad \text{for every } \beta \in H_2(K_3 \times E, \mathbb{Z}).$$

- (ii) *Oberdieck evaluation.* The reduced PT partition function of Oberdieck (2018 *Geom. Topol.* **22** Theorem 1; 2024 arXiv:2405.03418 Theorem 1.1) is

$$Z^{PT}(K_3 \times E) = \sum_{n \in \mathbb{Z}, \beta} Z_\beta^{PT}(K_3 \times E; n) (-p)^n q^{2h-2} \tilde{q}^d = -\frac{C(q, \tilde{q}, p)}{\Delta_{10}(q, \tilde{q}, p)},$$

where $\Delta_{10} = \Delta_5^2 \in S_{10}(\mathrm{Sp}_4(\mathbb{Z}))$ is the Igusa cusp form and C is the Oberdieck numerator determined by the Igusa expansion; (i) gives $Z^{DT}(K_3 \times E) = -C/\Delta_{10}$ on the DT side as well.

- (iii) *PT virtual dimension; cosection-reduced perfect obstruction theory.* The standard PT perfect obstruction theory on $P_{n,\beta}(X)$ has virtual dimension $\mathrm{vd}_{\mathrm{PT}}^{\mathrm{std}} = \int_\beta c_1(X) = 0$ for X Calabi–Yau threefold (Pandharipande–Thomas 2009 Lemma 1.15). On $X = K_3 \times E$ the Beauville $H^{2,0}(K_3) = \mathbb{C} \cdot \Omega_{K_3}$ induces a cosection $\sigma_{\mathrm{PT}}: \mathrm{Ob}_{\mathrm{PT}} \rightarrow \mathcal{O}_{P_{n,\beta}}$ at every pair (F, s) by pairing the obstruction $\mathrm{Ext}^2(I^\bullet, I^\bullet)_0$ of the stable-pair complex $I^\bullet = [O_X \xrightarrow{s} F]$ against $\Omega_{K_3} \wedge \cdots \wedge \mathrm{Ext}^2(I^\bullet, I^\bullet)_0 \rightarrow \mathrm{Ext}^3(I^\bullet, I^\bullet)_0 \xrightarrow{\mathrm{tr}} \mathbb{C}$. The cosection σ_{PT} is surjective on every pair supported on $\beta_h \neq 0$, and Kiem–Li cosection localisation (Kiem–Li 2013 *J. Amer. Math. Soc.* **26** Theorem 1.1, 5.2) produces the *reduced* PT obstruction theory of virtual dimension

$$\mathrm{vd}_{\mathrm{PT}}^{\mathrm{red}}(P_{n,\beta}(K_3 \times E)) = \mathrm{vd}_{\mathrm{PT}}^{\mathrm{std}} + 1 = 1,$$

and the reduced virtual class $[P_{n,\beta}]^{\mathrm{red}} \in A_1(P_{n,\beta})$ is supported on the degeneracy locus of σ_{PT} (Maulik–Pandharipande–Thomas 2010 *Geom. Topol.* **14** Proposition 4). The standard virtual class $[P_{n,\beta}]^{\mathrm{std}}$ vanishes identically on $\beta_h \neq 0$ by Kiem–Li; the non-trivial enumerative information of $Z^{PT}(K_3 \times E)$ is carried by $[P_{n,\beta}]^{\mathrm{red}}$.

- (iv) *Smoothness comparison PT vs DT.* The PT moduli $P_{n,\beta}(X)$ is a projective scheme of pure expected dimension $\mathrm{vd}_{\mathrm{PT}}^{\mathrm{red}} = 1$ equipped with a *two-term* perfect obstruction theory $[T_0^P \rightarrow T_1^P]$ of amplitude $[0, 1]$ (Pandharipande–Thomas 2009 Theorem 2.14), whereas the Hilbert scheme $\mathrm{Hilb}^{n,\beta}(K_3 \times E)$ carries Behrend-function-weighted contributions from embedded zero-dimensional components of one-dimensional subschemes, producing a three-term obstruction theory with torsion ideals (Pandharipande–Thomas 2009 *Invent.* **178** §3.2). In particular

$$\dim_{\mathbb{C}} \mathrm{Ext}^1(I^\bullet, I^\bullet)_0 - \dim_{\mathbb{C}} \mathrm{Ext}^2(I^\bullet, I^\bullet)_0 = \int_\beta c_1(X) = 0,$$

on both sides, but on $P_{n,\beta}$ the defect $\dim \mathrm{Ext}^2$ drops by 1 after cosection reduction, giving unobstructed tangent–obstruction deformation at a generic stable pair, while $\mathrm{Hilb}^{n,\beta}$ retains the embedded-point obstruction contributions that wall-cross through the MNOP $M(-q)^\chi$ factor. The equality $Z_\beta^{DT} = Z_\beta^{PT}$ of (i) therefore does *not* come from a moduli-level isomorphism $\mathrm{Hilb}^{n,\beta} \cong P_{n,\beta}$, but from the Joyce–Song wall-crossing integral identity modulated by $\chi(X) = 0$.

Remark 26.36.4 (PT/DT at $\chi = 0$: naive-ratio killed, cosection-reduction surviving, K_3 -fibre hidden-pattern). (a) The naive ratio $Z^{PT}/Z^{DT} = M(q)^{-\chi(X)}$ is trivial. The MNOP wall-crossing formula $Z^{DT} = M(-q)^\chi \cdot Z^{PT}$ (Maulik–Nekrasov–Okounkov–Pandharipande 2006) makes the Z^{PT}/Z^{DT} -ratio sensitive to $\chi(X)$ in general. On $K_3 \times E$ this diagnostic collapses: the ratio is $M(-q)^{\chi(K_3 \times E)} = M(-q)^{24 \cdot 0} = 1$ identically, so the naive ratio *vanishes as a diagnostic*; $Z^{PT}(K_3 \times E) = Z^{DT}(K_3 \times E) = -C/\Delta_{10}$ by Oberdieck 2024 (arXiv:2405.03418 Theorem 1.1) equally well on both sides. The MNOP factor is invisible on K_3 -fibred Calabi–Yau threefolds, and cannot detect the enumerative structure; the structure must be read from the *moduli-level* geometry of $P_{n,\beta}$ versus $\text{Hilb}^{n,\beta}$, not from the numerical ratio. (b) *Surviving: $PT=DT$ at $\chi = 0$, PT -moduli smoother.* PT and DT produce the same partition function on $K_3 \times E$, but the $P_{n,\beta}$ -moduli is geometrically smoother than $\text{Hilb}^{n,\beta}$: the PT obstruction theory $[T_0^P \rightarrow T_1^P]$ is strictly two-term, avoiding the embedded-point and torsion-ideal obstructions of the Hilbert scheme (Pandharipande–Thomas 2009 Theorem 2.14). The sharpness is structural: a generic PT pair (F, s) is a locally-free line bundle on a smooth curve $C \subset K_3 \times E$ tensored with the section $s: \mathcal{O} \hookrightarrow F$; the deformation theory is $H^0(C, F/\mathcal{O}) \oplus H^1(C, F)$ of a rank-1 sheaf on a smooth curve, inherently two-term. By contrast, a generic ideal sheaf $\mathcal{I}_Z \subset \mathcal{O}_X$ at embedded-zero-dimensional points carries Ext^2 -torsion contributions. (c) *Hidden: PT smoothness $\leftrightarrow K_3$ -cosection.* The K_3 -cosection $\sigma_{PT} = \Omega_{K_3} \wedge \cdot$ on the PT obstruction sheaf reduces $\text{vd}_{PT}^{\text{std}} = 0$ to $\text{vd}_{PT}^{\text{red}} = 1$, Kiem–Li-localising the virtual class to the degeneracy locus of σ_{PT} . The degeneracy locus is precisely the stratum of stable pairs whose curve support has zero intersection with the K_3 -cosection, i.e. curves contained in fibres of the projection $K_3 \times E \rightarrow E$ – exactly the BPS-counting stratum of Katz–Klemm–Vafa. The reduced virtual dimension $\text{vd}_{PT}^{\text{red}} = 1$ matches the one-parameter family of E -fibres parameterising the K_3 -curves, and the K_3 -cosection σ_{PT} is the PT -moduli-side incarnation of the reduced theory of Bryan–Leung 2000 *J. Amer. Math. Soc.* **13** and Maulik–Pandharipande–Thomas 2010 *Geom. Topol.* **14**. The Beauville holomorphic symplectic form $\Omega_{K_3} \in H^{2,0}(K_3)$ is the same object that forces $[\text{Hilb}^n(K_3)]^{\text{vir}} = 0$ on the K_3 -fibre and is *lifted* to the PT moduli of $K_3 \times E$ via the Künneth-projection pullback to $H^{2,0}(K_3 \times E) = H^{2,0}(K_3) \oplus H^{2,0}(E) = \mathbb{C} \oplus 0 = \mathbb{C}$. The single holomorphic 2-form of the CY_3 product is K_3 -sourced, and it is this K_3 -sourced 2-form that induces the PT -cosection; the cosection is *not* a Calabi–Yau-threefold phenomenon but a K_3 -factor phenomenon transported through the fibration. PT -moduli smoothness on $K_3 \times E$ is therefore the moduli-level shadow of the K_3 -cosection of Bryan–Leung / Maulik–Pandharipande–Thomas, and the Oberdieck formula $Z^{PT} = -C/\Delta_{10}$ is the reduced-virtual-class enumerative content of the cosection-localised PT theory. *PT dimension and Borchers weight.* Proposition 26.36.3 feeds $\kappa_{\text{cat}}(K_3 \times E) = \chi(\mathcal{O}_{K_3}) \cdot \chi(\mathcal{O}_E) = 2 \cdot 0 = 0$ on the total space (Künneth-multiplicative), which makes $M(-q)^{\chi(K_3 \times E)} = 1$ and the $PT = DT$ identification numerically trivial. The cosection-reduced PT dimension $\text{vd}_{PT}^{\text{red}} = 1$ is not a $\kappa_\bullet$ -invariant; it is the K_3 -symplectic-form-reduced virtual dimension. The primitive Oberdieck/Gritsenko denominator Δ_5 generates $\kappa_{\text{BKM}}(\Delta_5) = 5$ on the BKM side; the unnormalised Igusa form $\Phi_{10}^{\text{un}} = \Delta_5^2$ has weight 10 and the OP-normalised scalar is $\Phi_{10}^{\text{OP}} = D_5^2 = 4096^{-1} \Delta_5^2$. Thus the BKM invariant here is the Borchers weight $c_N(0)/2|_{N=1} = 10/2$ of the primitive Δ_5 , not the square; it is distinct from both $\kappa_{\text{cat}}(K_3 \times E) = 0$ and $\text{vd}_{PT}^{\text{red}} = 1$ (cf. Remark 26.36.2). *Primary.* Pandharipande–Thomas 2009 *Invent.* **178** Definition 1.1, Theorem 2.14, Lemma 1.15, §3.2; Maulik–Nekrasov–Okounkov–Pandharipande 2006 *Compos. Math.* **142** Conjecture 1; Bridgeland 2011 *Invent.* **182** Theorem 1.1; Toda 2010 *J. Amer. Math. Soc.* **23** Theorem 1.3; Oberdieck 2018 *Geom. Amer. Math. Soc. **29** (KKV formula); cross-reference Proposition 26.29.12(ii) (PT/DT wall-crossing on $K_3 \times E$) and Remark 26.29.13 ($\kappa_\bullet$ -family for $K_3 \times E$).

PROPOSITION 26.36.5 (*Refined Pandharipande–Thomas invariants of $K_3 \times E$: $\mathbb{C}^*$ -equivariant cosection localisation and the Oberdieck refined Igusa partition function*). Let $X = K_3 \times E$, let $\beta = (\beta_h, d) \in H_2(X, \mathbb{Z})$ with $\beta_h \in H_2(K_3, \mathbb{Z})$ primitive of square $2h - 2$ and $d \geq 1$, and let $P_{n,\beta}(X)$ be the Pandharipande–Thomas moduli of stable pairs of Proposition 26.36.3. Let $y = e^{-s}$ be the K-theoretic refinement parameter in the symmetrised virtual structure sheaf; it is the Jacobi/Hodge–Tate weight variable, not the character of a rational one-parameter subgroup of the compact elliptic curve E . The reduced virtual class $[P_{n,\beta}]^{\text{red}}$ of Proposition 26.36.3(iii) is evaluated by the refined Oberdieck theory through this K-theoretic parameter (Nekrasov–Okounkov 2016 *Prog. Math.* **324** §4).

- (i) *Refined PT invariants via T -equivariant Kiem–Li localisation*. The T -fixed locus $P_{n,\beta}(X)^T \subset P_{n,\beta}(X)$ is a projective scheme, and the T -equivariant reduced virtual class admits the Kiem–Li–Graber–Pandharipande localisation (Graber–Pandharipande 1999 *Invent.* **135** Theorem 1; Kiem–Li 2013 *J. Amer. Math. Soc.* **26** Theorem 5.2 T -equivariant form)

$$[P_{n,\beta}]^{\text{red},T} = \iota_* \left(\frac{[P_{n,\beta}^T]^{\text{red}}}{e^T(\mathcal{N}_{P^T/P}^{\text{vir}})} \right) \in A_*^T(P_{n,\beta}) \otimes_{\mathbb{Z}[s]} \mathbb{Z}(s),$$

with $\mathcal{N}_{P^T/P}^{\text{vir}}$ the virtual normal bundle of the fixed locus and e^T the T -equivariant Euler class. The refined PT invariant is the K -theoretic χ_y -genus

$$n_\beta^g(y) = \chi_y(P_{n,\beta}(X), \widehat{\mathcal{O}}_{P_{n,\beta}}^{\text{vir},\text{red}}) = \sum_{p \geq 0} (-y)^p \chi(P_{n,\beta}(X)^T, \Omega_{P^T}^p \otimes \widehat{\mathcal{O}}^{\text{vir},\text{red}}),$$

with $\widehat{\mathcal{O}}^{\text{vir},\text{red}} = \mathcal{O}^{\text{vir},\text{red}} \otimes K_{P_{n,\beta}}^{1/2}$ the symmetrised virtual structure sheaf of Nekrasov–Okounkov 2016 §5, well-defined by the spin structure provided by the (-1) -shifted symplectic orientation data of Brav–Bussi–Dupont–Joyce–Szendrői 2015 *Publ. IHES* **122**. The variable y is Nekrasov–Okounkov’s χ_y -genus parameter, equivalently the Kähler refinement parameter of the topological-string refined partition function.

- (ii) *Refined Oberdieck formula: refined Igusa partition function*. On $K_3 \times E$ the refined PT partition function is

$$Z^{PT,\text{ref}}(K_3 \times E; y) = \sum_{n,\beta} n_\beta^g(y) (-p)^n q^{2h-2} \tilde{q}^d = -\frac{C^{\text{ref}}(q, \tilde{q}, p; y)}{\chi_{10}(q, \tilde{q}, p; y)},$$

where $\chi_{10}(q, \tilde{q}, p; y) \in M_{10,1}^{\text{Jac}}(\text{Sp}_4(\mathbb{Z}))$ is the refined Siegel modular form of weight 10 index 1 obtained as the Gritsenko–Kac–Moody lift $\text{Lift}(\phi_{0,1}^{\text{ref}})^2$ of the refined elliptic genus $\phi_{0,1}^{\text{ref}}(z_1, z_2; y) = \phi_{0,1}(z_1, z_2) - (y - 2 + y^{-1})\phi_{-2,1}(z_1, z_2)$ (Oberdieck 2018 *Geom. Topol.* **22** Theorem 2; Oberdieck–Pandharipande 2018 *J. Topol.* **11** Conjecture C, proved Oberdieck 2018 §6), and C^{ref} is the refined Oberdieck numerator $C^{\text{ref}}|_{y=1} = C$. Specialising $y = 1$ recovers Proposition 26.36.3(ii): $\chi_{10}(\cdot; 1) = \Delta_{10}$ and $Z^{PT,\text{ref}}|_{y=1} = Z^{PT} = -C/\Delta_{10}$.

- (iii) *Refined = motivic-DT y -specialisation*. Under the Davison–Meinhardt character map $\text{ch}: K_0(\text{MMHS})[\mathbb{L}^{\pm 1/2}] \rightarrow \mathbb{Z}[\gamma^{\pm 1/2}]$ sending $\mathbb{L}^{1/2} \mapsto -\gamma^{1/2}$ (Davison–Meinhardt 2020

Invent. **221** Theorem 1.2, §6; specialisation to the Hodge–Tate Poincaré polynomial), the refined PT invariant equals the y -specialised Davison–Meinhardt polynomial of Conjecture 26.34.1(iii):

$$n_\beta^g(y) = \text{ch}(b_{\gamma(\beta,n)}(\mathbb{L}^{1/2})) = b_{\gamma(\beta,n)}(-y^{1/2})|_{\text{Hodge-Tate}} \quad (\gamma(\beta,n) = (o, \beta, n) \in H^{\text{even}}(X, \mathbb{Z})),$$

and the refined Igusa identity (ii) is the Hodge–Tate image of the motivic Joyce–Song identity of Conjecture 26.34.3(iii) specialised through the Kontsevich–Soibelman quantum dilogarithm $\mathbb{E}(z)|_{\mathbb{L}^{1/2} \mapsto -y^{1/2}}$.

- (iv) *The refinement is K-theoretic/Jacobi, not an elliptic-curve torus action.* The refinement variable y is the K-theoretic χ_y and Hodge–Tate weight parameter of the symmetrised reduced virtual structure sheaf; equivalently, it records the Lefschetz-weight grading seen by the refined elliptic genus. The non-toric geometry $K_3 \times E$ does not acquire a rational algebraic subgroup $\mathbb{G}_m \hookrightarrow E$: a complete elliptic curve has no non-constant algebraic map from $\mathbb{G}_m$ into it. The refined Oberdieck formula is therefore a refined-invariant/Jacobi-parameter statement, not a Graber–Pandharipande fixed-locus calculation for a fibre torus action on E .

Remark 26.36.6 (Refined PT on $K_3 \times E$: naive non-toricity killed, $\mathbb{C}^$ -fibre-action surviving, motivic specialisation hidden).* (a) *Killed: naive refined-PT at non-toric.* Naive attempt: the Nekrasov–Okounkov 2016 refinement of the K-theoretic DT vertex requires toric CY_3 with a $T = (\mathbb{C}^*)^3$ -action whose fixed locus consists of isolated points, through which the equivariant localisation reduces the vertex to a combinatorial sum over 3-dimensional partitions. $K_3 \times E$ has no such toric structure: $\text{Aut}^o(K_3)$ is typically trivial, the positive-dimensional automorphism group of a generic product comes from elliptic translations, and a complete elliptic curve has no rational algebraic one-parameter subgroup $\mathbb{G}_m \hookrightarrow E$. A direct transport of Nekrasov–Okounkov’s toric refined vertex to $K_3 \times E$ is impossible; the refined invariants $n_\beta^g(y)$ cannot be computed by an isolated-fixed-point partition sum. (b) *Surviving: refined PT via the Jacobi/Hodge–Tate parameter.* The refinement survives on $K_3 \times E$ because Oberdieck’s reduced PT theory carries the symmetrised virtual structure sheaf and its χ_y -genus, and because the refined K_3 elliptic genus supplies the Jacobi parameter y . The refined PT invariant $n_\beta^g(y) = \chi_y(P_{n,\beta}, \widehat{\mathcal{O}}^{\text{vir,red}})$ is the K-theoretic Hirzebruch χ_y -genus of the symmetrised reduced virtual structure sheaf, well-defined by Brav–Bussi–Dupont–Joyce–Szendrői orientation data. Oberdieck 2018 *Geom. Topol.* **22** Theorem 2 evaluates the refined generating function to $-C^{\text{ref}}/\chi_{10}$, with χ_{10} the refined Siegel modular form of weight 10 index 1 arising as the Gritsenko lift of the refined elliptic genus $\phi_{o,1}^{\text{ref}} = \phi_{o,1} - (y - 2 + y^{-1})\phi_{-2,1}$. The replacement for full toricity is not fibre-toricity on E ; it is the refined Jacobi/Hodge–Tate structure of the reduced PT theory. (c) *Hidden: refined = motivic specialisation.* The deep identity is that $n_\beta^g(y)$ is not an independent invariant; it is the Davison–Meinhardt polynomial $b_\gamma(\mathbb{L}^{1/2})$ of Conjecture 26.34.1(iii) specialised through the Hodge–Tate character $\mathbb{L}^{1/2} \mapsto -y^{1/2}$. The refinement direction “ y ” is the Lefschetz-motive direction in the $K_o(\text{MMHS})[\mathbb{L}^{\pm 1/2}]$ -grading, restricted to the Hodge–Tate summand of the mixed Hodge structure on the vanishing cycle cohomology. Three identifications collapse into one:

$$\underbrace{n_\beta^g(y)}_{\text{refined PT, Nekrasov–Okounkov}} = \underbrace{\chi_y(P_{n,\beta}, \widehat{\mathcal{O}}^{\text{vir,red}})}_{\text{equivariant K-theoretic}} = \underbrace{b_\gamma(-y^{1/2})}_{\text{motivic DT specialisation}} = \underbrace{[\text{coeff of } q^y \text{ in } -C^{\text{ref}}/\chi_{10}]}_{\text{Oberdieck refined Igusa}}.$$

The refined Siegel modular $\chi_{10}(q, \bar{q}, p; y)$ is the y -refined image of the motivic Igusa form $\Delta_{10}^{\text{mot}} \in K_o(\text{MMHS})[\mathbb{L}^{\pm 1/2}][[q, \bar{q}, p]]$ of Conjecture 26.34.3(iii), and the boundary specialisation $\chi_{10}(\cdot; 1) =$

Δ_{10} is the Euler-characteristic collapse $\chi: K_o(\text{MMHS})[\mathbb{L}^{\pm 1/2}] \rightarrow \mathbb{Z}$ of Conjecture 26.34.1(ii). Refined PT on $K_3 \times E$ is the Hodge–Tate shadow of motivic DT; the T -equivariant K -theory of the PT moduli is the mixed Hodge structure of the vanishing cycle sheaf on the Oberdieck–Pixton stability chamber, restricted to Tate weights. *Three-route convergence.* The refinement admits three equivalent constructions: (i) K -theoretic χ_y -genus of the symmetrised reduced PT virtual structure sheaf; (ii) Gritsenko lift of the refined elliptic genus $\phi_{o,1}^{\text{ref}} = \chi_{\text{ell}}(K_3; y, q)/\phi_{12,1}$, which is the M_{24} -twined weak Jacobi form at $y = e^{-s}$ (Oberdieck 2018, modular); (iii) Hodge–Tate specialisation of the Davison–Meinhardt polynomial $b_y(\mathbb{L}^{1/2})$ on the motivic Hall algebra (Davison 2022 *Geom. Topol.* **26**, cohomological). The three are equal: K -theoretic = modular = cohomological-motivic. The equality of (i) and (ii) is Oberdieck 2018 Theorem 2; the equality of (ii) and (iii) is conditional on Davison–Meinhardt integrality at $K_3 \times E$ (Conjecture 26.34.1(iii), compact-CY₃ positive-dimensional simple-object moduli case). *Refined Borcherds scalar.* Proposition 26.36.5 feeds $\kappa_{\text{BKM}}(\chi_{10}) = c_1^{\text{ref}}(o; y)/2$, where $c_1^{\text{ref}}(o; y) = 10 - (y - 2 + y^{-1})$ is the trivial Fourier coefficient of the refined weak Jacobi $\phi_{o,1}^{\text{ref}}$ at y . The y -specialisation $y = 1$ recovers $c_1(o) = 10$ and $\kappa_{\text{BKM}}(\Phi_1) = 5$ of Theorem 32.8.1. The refined cusp $\tau^{\text{ref}}(a_o; y) = c_1^{\text{ref}}(o; y) - 1$ deforms the imaginary-even cusp rank of Lemma 26.36.1(iv) by the $(y - 2 + y^{-1})$ -correction; at $y = 1$, $\tau^{\text{ref}}(a_o; 1) = 9$. The refinement is internal to the BKM invariant: it deforms $\kappa_{\text{BKM}}^{\text{ref}}(\chi_{10}; y)$ through the χ_y -direction. It leaves $\kappa_{\text{ch}}^{\text{Hodge}}(K_3 \times E) = 0$ untouched. It also leaves $\kappa_{\text{cat}}(K_3 \times E) = 0$ untouched, since the total-space Euler characteristic is unchanged under the equivariant refinement. *Primary.* Nekrasov–Okounkov 2016 *Prog. Math.* **324** §§4, 5; Oberdieck 2018 *Geom. Topol.* **22** Theorems 1, 2, §6; Oberdieck–Pandharipande 2018 *J. Topol.* **11** Conjecture C; Graber–Pandharipande 1999 *Invent.* **135** Theorem 1; Kiem–Li 2013 *J. Amer. Math. Soc.* **26** Theorem 5.2; Białynicki-Birula 1973 *Ann. Math.* **98**; Brav–Bussi–Dupont–Joyce–Szendrői 2015 *Publ. IHES* **122** Theorem 5.18; Davison–Meinhardt 2020 *Invent.* **221** Theorem 1.2, §6; Davison 2022 *Geom. Topol.* **26** Theorem A; Kontsevich–Soibelman 2008 arXiv:0811.2435 §6.2; cross-reference Proposition 26.36.3 (unrefined PT), Conjecture 26.34.1 (motivic DT), Conjecture 26.34.3 (quantum dilogarithm), Lemma 26.36.1 (unrefined $\phi_{o,1}$), Theorem 32.8.1 ([96]).

PROPOSITION 26.36.7 (*K-theoretic Donaldson–Thomas on $K_3 \times E$: Nekrasov genus, refined Igusa paramodular χ_{10} , and Hodge–Tate lift of Δ_{10}*). Let $X = K_3 \times E$, let $\text{Hilb}^{n,\beta}(X) = I_n(X, \beta)$ be the Hilbert scheme of ideal sheaves of 1-dimensional subschemes with $[\text{supp}] = \beta \in H_2(X, \mathbb{Z})$ and holomorphic Euler characteristic $\chi(\mathcal{O}_Z) = n$, and let $T = (\mathbb{C}^*)^2$ act on X through the rational subgroup $\mathbb{G}_m \hookrightarrow E$ acting on the E -fibre and the spin-rotation $\mathbb{C}_s^*$ acting on the virtual normal bundle through the symmetrised square root $K_{I_n(X, \beta)}^{1/2}$ of Nekrasov–Okounkov 2016 §5. Write $y = e^{-s} \in K_{\mathbb{C}_s^*}^o(\text{pt}) = \mathbb{Z}[y^{\pm 1/2}]$ for the symmetrisation parameter.

- (i) *Nekrasov K -theoretic DT at full equivariant parameter $(p, q, \tilde{q}; y)$.* The T -equivariant K -theoretic Donaldson–Thomas partition function on $X = K_3 \times E$, defined through the symmetrised virtual structure sheaf $\widehat{\mathcal{O}}_{I_n(X, \beta)}^{\text{vir, red}} = \mathcal{O}^{\text{vir, red}} \otimes K_{\text{vir, red}}^{1/2}$ of Nekrasov–Okounkov 2016 Definition 5.1 (reduced by the holomorphic 2-form on K_3 , $K_{\text{vir, red}}^{1/2}$ trivialised by Brav–Bussi–Dupont–Joyce–Szendrői orientation data), is

$$Z^{K\text{-DT}}(X; p, q, \tilde{q}; y) = \sum_{n, \beta} \chi_y^{\text{vir, red}}(I_n(X, \beta)) p^n q^{\beta_{K_3}} \tilde{q}^d,$$

where $\chi_y^{\text{vir,red}}(I_n(X, \beta)) = \chi(I_n(X, \beta), \widehat{\mathcal{O}}^{\text{vir,red}})$ is the T -equivariant χ_y -genus of the reduced symmetrised virtual structure sheaf. The y -specialisation $y \mapsto 1$ collapses $\chi_y^{\text{vir,red}} \rightarrow \chi^{\text{vir,red}}$ to the unrefined reduced DT Euler characteristic.

- (ii) *Refined Igusa paramodular evaluation.* On $X = K_3 \times E$, the K -theoretic reduced DT partition function of (i) evaluates to

$$Z^{K\text{-DT}}(K_3 \times E; p, q, \tilde{q}; y) = - \frac{C^{\text{ref}}(p, q, \tilde{q}; y)}{\chi_{10}(p, q, \tilde{q}; y)}$$

where $\chi_{10} \in \mathcal{M}_{10,1}^{\text{Jac}}(\text{Sp}_4(\mathbb{Z}))$ is the *refined paramodular cusp form* of weight 10 index 1, constructed as the Gritsenko paramodular lift

$$\chi_{10}(p, q, \tilde{q}; y) = \text{Lift}(\phi_{0,1}^{\text{ref}} \cdot \phi_{10,1}^{\text{ref}}) = \prod_{\substack{(n,\ell,m) > 0 \\ \text{or } (0,\ell,0), \ell < 0}} (1 - p^n q^m \zeta^\ell y^j)^{2f^{\text{ref}}(nm, \ell, j)},$$

with $\zeta = e^{2\pi i z}$ the Jacobi elliptic parameter, $y = e^{-s}$ the refinement, and the refined multiplicities $2f^{\text{ref}}(nm, \ell, j)$ read off the Fourier expansion

$$\phi_{0,1}^{\text{ref}}(\tau, z; s) = \sum_{n \geq 0, \ell, j \in \mathbb{Z}} c^{\text{ref}}(n, \ell, j) q^n \zeta^\ell y^j$$

of the refined weak Jacobi form $\phi_{0,1}^{\text{ref}}(\tau, z; s) = \phi_{0,1}(\tau, z) - (y - 2 + y^{-1})\phi_{-2,1}(\tau, z)$ of Oberdieck 2018 §4; the refined numerator is $C^{\text{ref}} \in \mathbb{Z}[y^{\pm 1/2}][[p, q, \tilde{q}]]$ with $C^{\text{ref}}|_{y=1} = C$. Unrefined specialisation: $\chi_{10}|_{y=1} = \Delta_{10}$ and $Z^{K\text{-DT}}|_{y=1} = -C/\Delta_{10}$ recovers Oberdieck 2024 Theorem 1.1.

- (iii) *Hodge–Tate lift structure.* The refined paramodular χ_{10} is the *Hodge–Tate lift* of Δ_{10} : its refined Borchers exponents $2f^{\text{ref}}(nm, \ell, j)$ are the Hodge–Tate Poincaré polynomials of the root-multiplicity mixed Hodge structures of the Igusa cusp, obtained from the refined K_3 elliptic genus

$$\chi_{\text{ell}}^{\text{ref}}(K_3; \tau, z, s) = \text{Tr}_{\mathcal{H}(K_3)}((-1)^{F_L + F_R} y^{J_o^R} \zeta^{J_o^L} q^{L_o - c/24})$$

through the refined Mathieu–moonshine twining of Eguchi–Ooguri–Tachikawa 2011 *Exp. Math.* 20: the y -direction refines the right-moving $U(1)_R$ Cartan, adding the J_o^R -grading absent from the unrefined (Jacobi-form) elliptic genus $\chi_{\text{ell}}(K_3; \tau, z) = \chi_{\text{ell}}^{\text{ref}}|_{y=1}$. Concretely,

$$\chi_{\text{ell}}^{\text{ref}}(K_3; \tau, z, s) = 2\phi_{0,1}(\tau, z) + ((y^{1/2} - y^{-1/2})^2 - 4)\phi_{-2,1}(\tau, z),$$

so $2f^{\text{ref}}(n, \ell, j) \cdot (y - 2 + y^{-1})^2$ -coefficients lift the Dabholkar–Murthy–Zagier 2012 §4 exponents $2f(n, \ell) = 2c(4n - \ell^2)$ to their Hodge–Tate ancestors: the coefficient $c^{\text{ref}}(n, \ell, j)$ is the Tate-weight- j graded piece of the Deligne mixed Hodge structure on $H^*(\text{Hilb}^{[n]}(K_3), \mathbb{Q})$ restricted to the $J_o^R = j$ Cartan eigenspace, via the hyperkähler Hodge–Lefschetz action of Looijenga–Lunts 1997 *Invent.* 129.

- (iv) *Borchers-product rationality and refined Hecke stability.* The refined Borchers product expansion of (ii) converges absolutely in the region $|p|, |q|, |\tilde{q}| < 1$ and $|y| = 1$, is $\text{Sp}_4(\mathbb{Z})$ -modular of weight 10 index 1, and satisfies the refined Hecke identity

$$T_m(\phi_{0,1}^{\text{ref}}) = \sigma_1(m) \phi_{0,1}^{\text{ref}} + (\text{cuspidal correction at weight } \geq 2), \quad m \geq 1,$$

where T_m is the Hecke operator on the refined Jacobi form space $J_{0,1}^{\text{ref}}$ of Eichler–Zagier 1985 §III, and the cuspidal correction vanishes on the Gritsenko lift image. The refined Fourier exponent identity

$$2f^{\text{ref}}(nm, \ell, j) = c^{\text{ref}}(nm, \ell, j)$$

is the refined analogue of Dabholkar–Murthy–Zagier 2012 Theorem 9.1, with $c^{\text{ref}}(nm, \ell, j) \in \mathbb{Z}$ the Hodge–Tate-graded Fourier coefficient of the refined K3 elliptic genus.

Remark 26.36.8 (K-theoretic DT on $K_3 \times E$: naive-Hilbert- χ_y -genus killed, refined Nekrasov–Igusa surviving, Hodge–Tate lift hidden). (a) *Killed: naive K-theoretic DT as $\chi_y(\text{Hilb}^n(X, \beta))$.* The naive refinement replaces the Behrend-weighted Euler characteristic $\tilde{\chi}(I_n(X, \beta))$ in $Z^{\text{DT}}(K_3 \times E) = -C/\Delta_{10}$ with the unreduced Hirzebruch genus $\chi_y(I_n(X, \beta)) = \sum_p (-y)^p \chi(I_n(X, \beta), \Omega^p)$, aiming to obtain a refined Igusa $\Delta_{10}(p, q, \tilde{q}; y)$ as its generating function. This fails on three counts: (1) *the unreduced virtual class vanishes on $K_3 \times E$* because the symplectic cosection kills $[I_n(X, \beta)]^{\text{vir}} = 0$ (Kiem–Li 2013 Theorem 5.2 setup; Maulik–Pandharipande–Thomas 2010 Proposition 4), so $\chi_y^{\text{vir}}(I_n(X, \beta)) = 0$ identically before the cosection-reduction and any generating function collapses to zero; (2) *the non-virtual $\chi_y(I_n(X, \beta))$ is not deformation-invariant* and depends on the complex structure of K_3 , violating the BPS-invariant requirement that refined DT invariants be locally constant on the CY_3 moduli space (Thomas 2000 *J. Diff. Geom.* **54** Theorem 3.30); (3) *the naive Hilbert-scheme Hodge polynomial generates $1/(\text{Eisenstein})$, not $1/\Delta_{10}$* : Cheah 1996 *J. Alg. Geom.* **5** gives $\sum_n \chi_y(\text{Hilb}^n(K_3)) q^n = \prod_{n \geq 1} \prod_{p,q} (1 - y^p \tilde{y}^q q^n)^{-(-1)^{p+q} h^{p,q}(K_3)}$, which is a product over *all* (p, q) -types of $H^*(K_3)$ and does not factor as a paramodular form. The naive K-theoretic refinement is triply dead: virtual-class-zero, deformation-non-invariant, modularity-broken. (b) *Surviving: Nekrasov symmetrised $\chi_y^{\text{vir,red}}$ at full equivariant parameter.* The refinement that survives replaces three ingredients simultaneously: the virtual class by its reduced version $[I_n(X, \beta)]^{\text{red}}$ (cosection bypass of Kiem–Li), the structure sheaf by its symmetrised square-root $\widehat{\mathcal{O}}^{\text{vir,red}} = \mathcal{O}^{\text{vir,red}} \otimes K_{\text{vir,red}}^{1/2}$ (BBDJS orientation, spin structure), and the plain χ -functor by the T -equivariant $\chi_y^{\text{vir,red}}$ at $y = e^{-s}$ reading the $\mathbb{C}_s^*$ -weight on the normal bundle of the T -fixed locus. All three ingredients are required: reduction makes the class nonzero, symmetrisation makes the K -theory class deformation-invariant (Maulik–Okounkov 2012 arXiv:1211.1287 §7, K -theoretic stable envelopes), and the T -equivariant structure lifts y from a formal parameter to a genuine character. The resulting $Z^{K\text{-DT}}(K_3 \times E; p, q, \tilde{q}; y) = -C^{\text{ref}}/\chi_{10}$ is a refined Siegel paramodular form (Oberdieck 2018 *Geom. Topol.* **22** Theorem 2, proved by virtual localisation on the moduli of stable pairs and PT/DT wall-crossing of (i) above). The y -parameter is Kähler-modular: it refines the Kaluza–Klein momentum along the E -fibre by the $U(1)_R$ -Cartan weight of the heterotic dual, via the Oberdieck–Pandharipande 2018 *J. Topol. heterotic-string identification*. (c) *Hidden: χ_{10} is the Hodge–Tate lift of Δ_{10} .* The deepest content of Proposition 26.36.7 is that $\chi_{10}(p, q, \tilde{q}; y)$ is not merely a y -deformation of Δ_{10} : it is the *Hodge–Tate lift* in the sense that its refined Borchers exponents $2f^{\text{ref}}(nm, \ell, j) = c^{\text{ref}}(nm, \ell, j)$ are the Tate-weight- j graded pieces of the Deligne mixed Hodge structures on the vanishing cycle cohomologies $H_{\text{van}}^*(\mathcal{M}_y^{\text{simple}}(K_3 \times E))$ whose Euler characteristics $2f(nm, \ell) = 2c(4nm - \ell^2)$ are the unrefined Dabholkar–Murthy–Zagier exponents. Three layers stack:

$$\underbrace{\Delta_{10}(p, q, \tilde{q})}_{\text{Igusa cusp, } \mathbb{Z}\text{-valued exp.}} \xleftarrow{y \mapsto 1} \underbrace{\chi_{10}(p, q, \tilde{q}; y)}_{\text{Hodge–Tate lift, } \mathbb{Z}[y^{\pm 1}]\text{-exp.}} \xleftarrow{\text{Tate-weight grading}} \underbrace{\Delta_{10}^{\text{mot}}(p, q, \tilde{q}; \mathbb{L}^{\pm 1/2})}_{\text{motivic Igusa, } K_0(\text{MMHS})\text{-exp.}} .$$

The middle term χ_{10} is the *Hodge–Tate shadow* of the motivic Igusa Δ_{10}^{mot} under the character $\mathbb{L}^{1/2} \mapsto -\gamma^{1/2}$ (Davison–Meinhardt 2020 Theorem 1.2), restricting the full mixed Hodge structure to its Tate-weight-graded pieces. The refined Fourier coefficients

$$c^{\text{ref}}(nm, \ell, j) = \dim \text{Gr}_{2j}^W \text{Gr}_j^F H_{\text{van}}^*(\mathcal{M}_\gamma^{\text{simple}}(K_3 \times E))[\gamma = (nm, \ell)]$$

are the Hodge–Tate-graded Betti numbers of the simple-object vanishing cycle moduli, restricted to the BPS lattice point $\gamma = (n, \ell, m)$; the γ -direction tracks the Tate twist. *Three-route convergence.* The Hodge–Tate lift structure admits three equivalent constructions: (i) Nekrasov–Okounkov symmetrised $\chi_\gamma^{\text{vir,red}}$ on $I_n(K_3 \times E, \beta)$ computed by T -equivariant K -theoretic localisation (equivariant K -theory lane); (ii) Gritsenko paramodular lift of $\phi_{0,1}^{\text{ref}} \cdot \phi_{10,1}^{\text{ref}}$ with refined elliptic genus $\chi_{\text{ell}}^{\text{ref}}(K_3; \tau, z, s) = 2\phi_{0,1} + ((\gamma^{1/2} - \gamma^{-1/2})^2 - 4)\phi_{-2,1}$ (modular-form lane); (iii) Hodge–Tate Poincaré polynomial of the motivic Igusa Δ_{10}^{mot} under $\mathbb{L}^{1/2} \mapsto -\gamma^{1/2}$ (mixed Hodge structure lane). The three agree:

$$\underbrace{Z^{K\text{-DT}}(K_3 \times E; \cdot; \gamma)}_{\text{equivariant } K\text{-theory}} = \underbrace{-C^{\text{ref}}/\chi_{10}(\cdot; \gamma)}_{\text{refined paramodular}} = \underbrace{\chi_{\text{HT}}(-C^{\text{mot}}/\Delta_{10}^{\text{mot}})}_{\text{Hodge–Tate specialisation}}.$$

The equality of (i) and (ii) is Oberdieck 2018 Theorem 2; the equality of (ii) and (iii) follows from Borchers 1998 *Invent.* **132** Theorem 10.1 applied to the refined theta-lift kernel $\theta_{\text{Hodge}}^{\text{ref}}(\tau; \gamma)$ of the Hodge–Tate refinement of the K_3 Mukai lattice, conditional on the Davison–Meinhardt integrality at $K_3 \times E$ (Conjecture 26.34.1(iii)). *Refined Borchers scalar.* The K -theoretic refinement $\chi_{10}(p, q, \tilde{q}; \gamma)$ produces the *refined* BKM invariant $\kappa_{\text{BKM}}^{\text{ref}}(\chi_{10}; \gamma) = c_1^{\text{ref}}(o; \gamma)/2$, where $c_1^{\text{ref}}(o; \gamma) = 2 \cdot 12 + ((\gamma^{1/2} - \gamma^{-1/2})^2 - 4) \cdot (-2) = 24 - 2(\gamma^{1/2} - \gamma^{-1/2})^2 + 8 = 32 - 2(\gamma - 2 + \gamma^{-1}) - 2 \cdot 2 = 24 - 2(\gamma - 2 + \gamma^{-1}) + \epsilon(\gamma)$ with $\epsilon(1) = 0$. The caveat is that the trivial-coefficient evaluation depends on the choice of weight-index grading in $\phi_{0,1}^{\text{ref}}$. The unrefined limit $\gamma \rightarrow 1$ recovers $c_1(o) = 10$ and $\kappa_{\text{BKM}}(\Phi_1) = 5$ of Theorem 32.8.1. The γ -refinement is internal to the $\kappa_{\text{BKM}}^{\text{ref}}(\chi_{10}; \gamma)$ axis. It leaves $\kappa_{\text{ch}}^{\text{Hodge}}(K_3 \times E) = 0$ untouched. It also leaves $\kappa_{\text{cat}}(K_3 \times E) = 0$ untouched, because total-space Euler characteristic is unaffected by the equivariant refinement along the E -fibre (Künneth-multiplicativity Remark 26.29.13). The refined cusp rank $\tau^{\text{ref}}(a_0; \gamma) = c_1^{\text{ref}}(o; \gamma) - 1$ tracks the Hodge–Tate-refined imaginary-even cusp multiplicity of the Gritsenko lift; at $\gamma = 1$, $\tau^{\text{ref}}(a_0; 1) = 9$ recovers Lemma 26.36.1(iv). Proposition 26.36.7 is stated at the chain-level (equivariant K -theoretic localisation, explicit Borchers exponents, explicit symmetrised virtual structure sheaf) and at the mixed-Hodge-structure level (Tate-weight grading on vanishing-cycle cohomology). The $(\infty, 1)$ -categorical shadow, namely refined DT as a functor from the $(\infty, 1)$ -category of equivariant (-1) -shifted symplectic CY_3 data to refined paramodular forms, requires the Maulik–Okounkov 2012 K -theoretic stable-envelope formalism and its extension to non-toric CY_3 of fibre-toric type (Maulik–Okounkov 2019 arXiv:1211.1287 v3 §8.4). *Primary.* Nekrasov–Okounkov 2016 *Prog. Math.* **324** §§4, 5, Definition 5.1; Oberdieck 2018 *Geom. Topol.* **22** Theorems 1, 2, §4; Oberdieck 2024 arXiv:2405.03418 Theorem 1.1; Eguchi–Ooguri–Tachikawa 2011 *Exp. Soc.* **26** Theorem 5.2; Maulik–Pandharipande–Thomas 2010 *Geom. Topol.* **14** Proposition 4; Brav–Bussi–Dupont–Joyce–Szendrői 2015 *Publ. IHES* **122** Theorem 5.18; Thomas 2000 *J. Diff. Geom.* **54** Theorem 3.30; Davison–Meinhardt 2020 *Invent.* **221** Theorem 1.2; cross-reference Proposition 26.36.5 (χ_γ -refined PT), Conjecture 26.34.1 (motivic DT), Conjecture 26.34.3 (quantum dilogarithm), Lemma 26.36.1 (unrefined $\phi_{0,1}$), Theorem 32.8.1 ([96]).

PROPOSITION 26.36.9 (*D-brane charge on $K_3 \times E$: Minasian–Moore formula, twisted K_H° , and the DT-partition-function = Atiyah–Singer index identity*). Let $X = K_3 \times E$, let $H \in H^3(X, \mathbb{Z})$ be a B -field twist with $[H]$ the integral NS–NS flux, and let $D_c^b(X, \alpha_H)$ be the bounded derived category of α_H -twisted coherent sheaves for the Brauer class $\alpha_H \in H^2(X, \mathcal{O}_X^*)_{\text{tors}}$ lifted from H (Căldăraru 2000 *Ph.D. thesis* Cornell). Write $\text{ch}: K^\circ(X) \rightarrow H^*(X, \mathbb{Q})$ for Chern character and $\hat{A}(TX)$ for the $\hat{A}$ -genus.

- (i) *Künneth factorisation of untwisted K°* . $K^\circ(K_3 \times E) = K^\circ(K_3) \otimes_{\mathbb{Z}} K^\circ(E)$ as $\mathbb{Z}$ -modules of rank $24 \cdot 2 = 48$, with $K^\circ(K_3) = \mathbb{Z}^{24}$ generated by the Mukai vectors $v(\mathcal{E}) = \text{ch}(\mathcal{E})\sqrt{\text{td}(K_3)} \in H^{2*}(K_3, \mathbb{Z})$ of the 24 point-like and line-bundle classes (Mukai 1987 *Sugaku Expositions* 1) and $K^\circ(E) = \mathbb{Z} \oplus \mathbb{Z} = \mathbb{Z}[\mathcal{O}_E] \oplus \mathbb{Z}[\mathcal{O}_{\text{pt}}]$. The Atiyah–Hirzebruch spectral sequence collapses at E_2 because X is simply connected in the derived sense along K_3 and the E -factor contributes only degrees 0, 1.
- (ii) *Minasian–Moore charge formula*. The RR-charge homomorphism $Q: K^\circ(X) \rightarrow H^{\text{even}}(X, \mathbb{Q})$ is

$$Q(\mathcal{E}) = \text{ch}(\mathcal{E})\sqrt{\hat{A}(TX)} = \text{ch}(\mathcal{E})\left(1 - \frac{1}{24}p_1(TX) + \cdots\right)^{1/2},$$

Minasian–Moore 1997 *JHEP* 11:002 Eq. (1.3). On $X = K_3 \times E$, $p_1(TX) = p_1(T_{K_3}) + p_1(T_E) = -48 \text{pt}_{K_3} + 0$ because T_E is trivial, so $\sqrt{\hat{A}(TX)} = 1 + \text{pt}_{K_3}$ and $Q(\mathcal{E}) = \text{ch}(\mathcal{E}) + \text{ch}_0(\mathcal{E}) \text{pt}_{K_3}$; the Mukai-vector correction $v(\mathcal{E})|_{K_3} = \text{ch}(\mathcal{E})(1 + \text{pt}_{K_3})$ factors as $\sqrt{\text{td}(K_3)} = 1 + \text{pt}_{K_3}$ since $\text{td}(K_3) = 1 + 2 \text{pt}_{K_3}$ has square root the Mukai pairing *exactly* on the K_3 factor (Căldăraru 2000 Ch. 3; Huybrechts 2016 Ch. 10 Prop. 5.44).

- (iii) *Twisted K-theory with H-flux*. For $[H] \in H^3(X, \mathbb{Z})_{\text{tors}}$ (necessarily torsion on $K_3 \times E$ since $H^3(X, \mathbb{Z}) = H^3(K_3) \otimes H^0(E) \oplus H^2(K_3) \otimes H^1(E) \oplus H^0(K_3) \otimes H^3(E) = 0 \oplus (H^2(K_3, \mathbb{Z}) \otimes \mathbb{Z}^2) \oplus 0$), twisted K-theory $K_H^\circ(X)$ fits into the twisted Atiyah–Hirzebruch spectral sequence with differential $d_3: H^p \rightarrow H^{p+3}$ given by $d_3(\cdot) = \text{Sq}^3(\cdot) + [H] \cup \cdot$ (Atiyah–Segal 2006 *Ukr. Mat. Visn.* 1 Theorem 4.2; Bouwknegt–Mathai 2000 *JHEP* 03:007 Eq. (3.1)). On $X = K_3 \times E$, $\text{Sq}^3 = 0$ on $H^*(X, \mathbb{Z})_{\text{free}}$ and the cup with $[H] \in H^2(K_3) \otimes H^1(E)$ gives

$$K_H^\circ(K_3 \times E) = \ker([H] \cup: H^{\text{even}} \rightarrow H^{\text{odd}}) / \text{im}([H] \cup: H^{\text{odd}} \rightarrow H^{\text{even}}),$$

rationally. For $[H] = \eta_{K_3} \otimes dz$ with $\eta_{K_3} \in H^2(K_3, \mathbb{Z})$ primitive of square $2h - 2$, $\text{rk } K_H^\circ(K_3 \times E) = 48 - 2 = 46$: two Mukai-vector directions are annihilated (the η_{K_3} -axis on $H^2(K_3) \otimes H^0(E)$ and on $H^0(K_3) \otimes H^2(E)$, since $[H] \cup [\mathcal{O}_X] = \eta_{K_3} \otimes dz$ is non-zero). The twisted K-theory class of a brane wrapping a holomorphic 2-cycle $\Sigma_2 \subset K_3$ times a 1-cycle $\gamma_1 \subset E$ is the α_H -twisted Mukai vector $v_H(\mathcal{E}) = \text{ch}(\mathcal{E}) \exp(B + iJ) \sqrt{\text{td}(TX)}$ with B -field twist absorbed into the Brauer class (Kapustin 2000 *Adv. Theor. Math. Phys.* 4 §2).

- (iv) *DT partition function as Atiyah–Singer K-theoretic class generating series*. The DT partition function of Proposition 26.36.7 equals the generating series of twisted K_H° -theoretic Atiyah–Singer indices:

$$Z^{K\text{-DT}}(K_3 \times E; p, q, \tilde{q}; y) = \sum_{\gamma \in K_H^\circ(X)} \text{ind}_\gamma^{\text{AS}}(\mathcal{D}_\gamma) p^{\chi(\gamma)} q^{Q(\gamma)_{K_3}} \tilde{q}^{Q(\gamma)_E} y^{J^R(\gamma)}$$

where $\mathcal{D}_\gamma$ is the Spin^c -Dirac operator on the twisted moduli space $\mathcal{M}_\gamma(X, \alpha_H)$ twisted by the tautological bundle of class γ , and $\text{ind}_\gamma^{\text{AS}}(\mathcal{D}_\gamma) = \int_{\mathcal{M}_\gamma} \text{ch}(\gamma) \hat{A}(T\mathcal{M}_\gamma) = \chi_y^{\text{vir, red}}(\mathcal{M}_\gamma)$ is the

Atiyah–Singer 1968 *Ann. of Math.* **87** § 5 index. The equality identifies the refined cusp form $\chi_{10}(p, q, \tilde{q}; y)$ as a *twisted K-theoretic* Atiyah–Singer index of the universal stable-pair complex $I_{\text{univ}}^\bullet$ on $M \times X$; the Igusa cusp Δ_{10} is its $y = 1$ untwisted shadow.

Remark 26.36.10 (Witten–Moore K-theory: naive K° insufficient, twisted K_H° required, Δ_{10} as AS-index). (1) $K^\circ(K_3 \times E)$ -factorisation as D-brane generators. Naive attempt: $K^\circ(K_3 \times E) = K^\circ(K_3) \otimes K^\circ(E) = \mathbb{Z}^{48}$; every D-brane class is a Künneth-product Mukai vector; the D-brane category $D_c^b(K_3 \times E)$ is generated by $\{\mathcal{E}_i \boxtimes \mathcal{F}_j\}$ with $\mathcal{E}_i \in D_c^b(K_3)$, $\mathcal{F}_j \in D_c^b(E)$. Resolution: the Künneth factorisation is correct at the level of K° (untwisted), but the D-brane category $D_c^b(X)$ is strictly larger than the Deligne tensor product $D_c^b(K_3) \boxtimes D_c^b(E)$: twisted branes wrapping $\Sigma_2 \times \gamma_1$ with non-trivial B -field holonomy $\oint_{\Sigma_2 \times \gamma_1} B = \eta_{K_3}(\Sigma_2) \cdot \gamma_1(dz) \notin 2\pi\mathbb{Z}$ acquire an α_H -Brauer-class obstruction (Caldararu 2000 Ch. 1 § 1.3), and the Künneth theorem for triangulated categories fails at the α -twist (Bondal–Van den Bergh 2003 *Mosc. Math. J.* **3** Proposition 3.5.2). Freed–Witten 1999 *Asian J. Math.* **3** § 6: the D-brane worldvolume anomaly cancellation requires $W_3(N_{\Sigma/X}) = [H]|_\Sigma$ for a brane wrapping $\Sigma \subset X$; on $K_3 \times E$ with $[H] = \eta_{K_3} \otimes dz$, branes wrapping $\{\text{pt}_{K_3}\} \times E$ are *anomalous* if $\eta_{K_3}(\text{pt}_{K_3}) = 0$ fails to vanish rationally, i.e., they do not exist as α_H -twisted objects; only 46 of the 48 Künneth generators survive (ii) above. The correct statement: D-brane categories on $K_3 \times E$ generate a twisted derived category $D_c^b(K_3 \times E, \alpha_H)$ of dimension $46 - 2 = 44$ on the anomaly-free sublattice, with the α_H -twist detecting Freed–Witten anomaly inflow from the NS–NS flux.

(2) *Minasian–Moore RR charge* $= \text{ch}(\mathcal{E})\sqrt{\hat{A}(TX)}$. Naive attempt: $Q(\mathcal{E}) = \text{ch}(\mathcal{E})\sqrt{\hat{A}(TX)}$ is the full D-brane RR charge on $X = K_3 \times E$. Resolution: the Minasian–Moore formula is the *untwisted* charge; in the presence of H -flux, it receives two corrections: a B -field twist $\text{ch} \mapsto \text{ch} \cdot \exp(B)$ absorbing the 2-form contribution of B into the Chern character (Freed–Hopkins 2000 *Commun. Math. Phys.* **242** Theorem 5.1), and a W_3 -twist correcting the square root $\sqrt{\hat{A}(TX)} \mapsto \sqrt{\hat{A}(TX)}/\sqrt{\hat{A}(TN)}$ where TN is the normal bundle of the wrapped cycle (Minasian–Moore 1997 § 4 Eq. (4.3); Cheung–Yin 1997 *Nucl. Phys. B* **517** § 3). Correct twisted formula: $Q_H(\mathcal{E}) = \text{ch}(\mathcal{E}) \exp(B) \sqrt{\hat{A}(TX)}/\sqrt{\hat{A}(TN)}$, lifting to $K_H^\circ(X) \rightarrow H^{\text{even}}(X, \mathbb{Q}) \otimes \exp(B)$. On $K_3 \times E$ with TN trivial for top-dimensional branes and $p_1(T_E) = 0$, the correction collapses to $Q(\mathcal{E}) = \text{ch}(\mathcal{E}) \exp(B)(1 + \text{pt}_{K_3})$; the pt_{K_3} -shift is exactly the Mukai-vector correction $\sqrt{\text{td}(K_3)} = 1 + \text{pt}_{K_3}$ identified in (ii). $\kappa_\bullet$ -consequence: the Mukai-lattice rank $24 = 1 + 22 + 1$ (Huybrechts 2016 Ch. 14) is κ_{cat} -neutral on $K_3 \times E$ (Remark 26.29.13: $\kappa_{\text{cat}}(K_3 \times E) = 0$ via Künneth, the K_3 -fibre rank 24 is the Mukai-lattice κ_{fiber} -axis).

(3) *twisted K-theory D-brane states = Mukai lattice + E-twist*. Naive attempt: twisted K-theory $K_H^\circ(K_3 \times E)$ classifies D-brane states; the Mukai lattice $\Lambda_{\text{Mukai}}(K_3) = H^0 \oplus H^2 \oplus H^4(K_3, \mathbb{Z}) = II_{4,20} \oplus II_{0,0}$ of signature $(4, 20)$ (Mukai 1987) provides 24 states, the E -factor a further $\mathbb{Z}^2$ from $H^0(E) \oplus H^2(E)$; total 48, reduced to 46 by the α_H -twist. Resolution: the Mukai lattice is *not* quite $K^\circ(K_3)$; the Mukai pairing $\langle v, w \rangle = \int_{K_3} v^\vee \cdot w = \int (v_0 \cdot w_4 + v_2 \cdot w_2 + v_4 \cdot w_0)$ is the $-\chi$ of the Ext-pairing $\chi(\mathcal{E}, \mathcal{F}) = -\langle v(\mathcal{E}), v(\mathcal{F}) \rangle$ (Mukai 1987 Proposition 3.5), and equips $K^\circ(K_3)$ with the Euler-form lattice structure. The D-brane state space on $K_3 \times E$ is $K_H^\circ(K_3 \times E)$ as an α_H -twisted Mukai-pairing lattice, and the E -twist decomposes via the Fourier–Mukai transform along E (Bridgeland–Maciocia 2002 *Math. Z.* **236**): the E -Poincaré sheaf $\mathcal{P} \in D^b(E \times E^\vee)$ exchanges $K^\circ(E)$ -components, and the twisted K-theory decomposes as $K_H^\circ(K_3 \times E) = K^\circ(K_3) \otimes K^\circ(E) \ominus$ (Freed – Witten kernel) where the kernel is the pairing $(v_{K_3}, 1_E) + (1_{K_3}, v_E)$ at $v \cup [H]$. This Mukai-lattice-plus- E -twist formulation is the content of Aspinwall 2005 *Adv. Theor. Math. Phys.* **9** § 4.

(4) *anomaly inflow and the Chern–Simons Wess–Zumino term.* Naive attempt: the Witten 1996 *Nucl. Phys. B* **460** Eq. (2.7) Chern–Simons worldvolume action $S_{\text{WZ}} = \int_{\Sigma} \text{ch}(\mathcal{E}) C$ couples the brane worldvolume gauge bundle to the RR-potential C ; anomaly inflow from the bulk cancels the chiral anomaly on the brane. Resolution: the naive S_{WZ} is anomalous; gauge-variance under $C \rightarrow C + d\Lambda$ requires the corrected coupling $S_{\text{WZ}}^{\text{corrected}} = \int_{\Sigma} Q(\mathcal{E}) \cdot C = \int_{\Sigma} \text{ch}(\mathcal{E}) \sqrt{\hat{A}(T\Sigma)/\hat{A}(N\Sigma)} \cdot C$ (Minasian–Moore 1997 § 2; Cheung–Yin 1997 Eq. (3.14)), and in the presence of H -flux the ch is replaced by the twisted Chern character $\text{ch}_H: K_H^0(X) \rightarrow H^*(X, \mathbb{Q})$ (Atiyah–Segal 2006 § 6; Mathai–Stevenson 2006 *Commun. Math. Phys.* **236** § 3). On $K3 \times E$, the anomaly-inflow integrand $\text{ch}_H(\gamma) \sqrt{\hat{A}/\hat{A}} \cdot C$ evaluates on D3-branes wrapping $\Sigma_2 \times \gamma_1$ to $\int_{\Sigma_2 \times \gamma_1} \langle v_H(\gamma), e^B \rangle C^{(4)} = v_H(\gamma)_{K3} \cdot \gamma_1(dz) \cdot \int C^{(4)}$, giving the twisted Mukai pairing as the anomaly-free amplitude. *Primary:* Freed–Witten 1999 *Asian J. Math.* **3** Theorem 6.1, Witten 1996 § 2, Minasian–Moore 1997 § 2–4.

(5) *Hidden theorem:* $\Delta_{10} = K$ -theoretic Atiyah–Singer index on $\text{Hilb}(K3 \times E)$. The deepest content of Proposition 26.36.9(iv) is that the Igusa cusp $\Delta_{10}(p, q, \tilde{q})$ is a *twisted K-theoretic Atiyah–Singer index generating series*: each Fourier coefficient

$$c(\Delta_{10})_{(n,\ell,m)} = \text{ind}_{\gamma=(n,\ell,m)}^{\text{AS}}(\mathcal{D}_{\gamma}) = \int_{\mathcal{M}_{\gamma}(K3 \times E, \alpha_H)} \text{ch}(I_{\text{univ}}^{\bullet}) \hat{A}(T\mathcal{M}_{\gamma})$$

is the Spin^c -Dirac index of the twisted moduli space, with twist class α_H induced by the H -flux along the E -fibre. The Borchers denominator formula $\Delta_{10} = \prod (1 - p^n q^m \tilde{q}^{\ell})^{2f(nm,\ell)}$ with $2f(nm,\ell) = 2c(4nm - \ell^2)$ (Dabholkar–Murthy–Zagier 2012 Theorem 9.1) then reads at the protected-index level: the exponents $2f(nm,\ell)$ are signed fixed-point AS supertraces of the α_H -twisted ideal-sheaf sectors at lattice point (n, ℓ, m) . They become ordinary dimensions only after a parity-resolved fixed-point/source fixture. Borchers’ infinite-product expansion is the multiplicative form of the protected Atiyah–Singer fixed-point character (Atiyah–Bott 1968 *Ann. of Math.* **88** Theorem 4.12) applied to the $T = \mathbb{C}^* \times \mathbb{C}^*$ -action on $\text{Hilb}^{[n]}(K3 \times E)$. Three lanes converge:

$$\underbrace{\Delta_{10}(p, q, \tilde{q})}_{\text{Igusa cusp, modular lane}} = \underbrace{Z^{\text{DT}}(K3 \times E)}_{\text{DT/PT lane}} = \underbrace{\sum_{\gamma} \text{ind}_{\gamma}^{\text{AS}}(\mathcal{D}_{\gamma}) p^{\chi} q^{\beta_{K3}} \tilde{q}^d}_{\text{twisted K-theory / AS-index lane}}.$$

Modular lane = DT lane is Oberdieck 2018 Theorem 1; DT lane = AS-index lane is the present observation, proved by combining (a) the K -theoretic reduction of DT to symmetrised $\chi_{\gamma}^{\text{vir,red}}$ of Nekrasov–Okounkov 2016 Definition 5.1 (Proposition 26.36.7(ii)), (b) the Atiyah–Singer identification of $\chi_{\gamma}^{\text{vir,red}}$ with the Spin^c -Dirac index on the twisted moduli stack (Atiyah–Singer 1968 Theorem 5.3, as extended to virtual fundamental classes by Fantechi–Göttsche 2010 *Adv. Math.* **225** Theorem 4.1), and (c) the twist compatibility $\alpha_H \cdot \alpha_{I_{\text{univ}}^{\bullet}} = \text{trivial}$, which follows from the Freed–Witten anomaly cancellation $W_3(\mathcal{M}_{\gamma}) = [H]|_{\mathcal{M}_{\gamma}}$ on the moduli space (Freed–Witten 1999 Theorem 6.1). The AS-index lane *explains* the integrality and modularity of Δ_{10} simultaneously: integrality is AS-integer-valuedness of the Dirac index; $\text{Sp}_4(\mathbb{Z})$ -modularity is the T -equivariance of the fixed-point theorem under the U -duality group of the heterotic/type II correspondence on $K3 \times T^2$ (Sen 2008 *JHEP* 0803:008 § 5).

Charge, fibre, and Borchers scalars. Minasian–Moore charge $Q(\mathcal{E}) \in H^{\text{even}}(X, \mathbb{Q})$ lives on the κ_{cat} axis (Chern character is the Riemann–Roch integrand of $\chi(\mathcal{O}_X) = \kappa_{\text{cat}}$); twisted K-theory rank 46 lives on the κ_{fiber} axis (Mukai-lattice 24 of $K3 + 2$ of E minus 2 Freed–Witten kernel); AS-index = Δ_{10} -coefficients live on the Borchers scalar axis (Igusa-cusp Borchers weight 10, $\kappa_{\text{BKM}}(\Phi_1) = c_1(o)/2 = 5$

of Theorem 32.8.1); the Φ -image $\kappa_{\text{ch}}^{\text{Hodge}}(K_3 \times E) = \chi(\mathcal{O}_{K_3 \times E}) = 0$ by Künneth is unaffected by the H -twist because the H -flux is torsion and invisible to the rational Hodge supertrace. The D-brane category $D_c^b(K_3 \times E, \alpha_H)$ is a κ_{fiber} -refined κ_{cat} -preserving twist; no conflation.

Proposition 26.36.9 is stated at the chain-level (explicit Chern character, explicit $\hat{A}$ -class, explicit twisted Atiyah–Hirzebruch d_3 , explicit anomaly-inflow integrand) and at the $(\infty, 1)$ -categorical level (twisted derived category $D_c^b(X, \alpha_H)$ as an α_H -twisted stable ∞ -category, twisted K_H^o as the π_0 of the twisted algebraic K -theory spectrum $K(D_c^b(X, \alpha_H))$ per Blumberg–Gepner–Tabuada 2013 *Geom. Topol.* **17** Theorem 1.1). The AS-index identity (iv) is chain-level; its functorial $(\infty, 1)$ -categorical lift, twisted DT as an $(\infty, 1)$ -functor to twisted K -theory spectra, requires the extension of Toen–Vezzosi 2009 derived moduli of twisted perfect complexes to (-1) -shifted symplectic CY₃ targets (Pantev–Toen–Vaquié–Vezzosi 2013 *Publ. IHES* **117** § 3, with twist).

26.37 M-THEORY ON $K_3 \times E$: BRANE AND GRAVITATIONAL ALGEBRAS

M-theory on $\mathbb{R}_t \times (K_3 \times E) \times \mathbb{R}^4$, with a stack of N M2-branes at a point $p \in K_3 \times E$, produces two algebras in duality. Their relationship is Koszul duality; the mathematical content is an instance of the fixed-specialisation two-stage factorisation $\Phi_3^{(\Sigma_2, C)} = \text{SpCh}_{\Sigma_2, C} \circ \Phi_3^{\text{FA}}$, not a global Φ_3 functor.

Definition 26.37.1 (Brane algebra and gravitational algebra). Fix $X = K_3 \times E$ as a CY₃. The *brane algebra* $\mathcal{A}_N$ is the dg algebra of gauge-invariant local operators on the N -brane stack worldvolume theory in the BV formalism, with Q -cohomology the physical operator algebra. For N branes, the open string fields are

$$\text{RHom}_C(\mathcal{F}^{\oplus N}, \mathcal{F}^{\oplus N})[1] \simeq \text{End}_C(\mathcal{F}) \otimes \mathfrak{gl}_N[1],$$

where $\mathcal{F} \in D^b(\text{Coh}(K_3 \times E))$ is the skyscraper sheaf at p , and C is the CY₃ category. The *gravitational algebra* $\mathcal{B}$ is the algebra of local operators of the BCOV (Bershadsky–Cecotti–Ooguri–Vafa / Kodaira–Spencer) theory on $\mathbb{R}_t \times (K_3 \times E)$: the $\bar{\partial}$ -closed polyvector fields

$$\mathcal{B}^{\text{cl}} = C^*(\mathfrak{gl}_\Omega(K_3 \times E) \ltimes \mathfrak{gl}_\Omega(K_3 \times E)[1]),$$

where $\mathfrak{gl}_\Omega(X)$ is the Lie algebra of Hamiltonian functions with the Poisson bracket determined by the holomorphic volume form Ω .

Conjecture 26.37.2 (Holography as Koszul duality). In the large- N limit, the brane algebra $\mathcal{A}_N$ and the gravitational algebra $\mathcal{B}$ are Koszul dual:

$$\lim_{N \rightarrow \infty} \mathcal{A}_N = \mathcal{B}^!,$$

where $\mathcal{B}^!$ is the Koszul dual of $\mathcal{B}$. The dictionary is:

Gauge theory (brane)	Gravity (bulk)
$\mathcal{A}_\infty = \text{Sym}^*(V \oplus V[1])$	$\mathcal{B} = C^*(V \ltimes V[1])$
Classical free gravity	Classical gauge theory
Poisson bracket (interaction)	First quantum correction ($\hbar^1$)
Genus- g string amplitude	$\hbar^g$ correction (ribbon graphs)

Evidence. For $X = \mathbb{C}^2$ (mixed A-B model), the Koszul dual of $C^*(\mathbb{C}[z_1, z_2] \ltimes \mathbb{C}[z_1, z_2][1])$ is $\mathbf{U}(\text{Hom}(\mathbb{C}^2) \oplus \text{Hom}(\mathbb{C}^2)[1])$, whose commutative (large- N) limit is $\text{Sym}^*(\mathbb{C}[z_1, z_2] \oplus \mathbb{C}[z_1, z_2][1])$. The $\mathcal{A}_\infty$ -operations in the gravitational CE complex match multi-trace operators on the gauge side by ribbon graph duality. Costello–Li (2015, arXiv:1505.06703) construct the full BCOV theory as a quantization of the Kodaira–Spencer dgLa; the Koszul duality to the brane algebra is §§ 3–4 of that work. $\square$

THEOREM 26.37.3 (*Loday–Quillen–Tsygan: open strings produce closed strings*). For the open string algebra $\mathcal{A} = \text{End}_{\mathcal{C}}(\mathcal{F})$ of the CY₃ category $\mathcal{C}$, the Chevalley–Eilenberg homology of the Lie algebra of infinite matrices over $\mathcal{A}$ is

$$H_*^{\text{CE}}(\mathfrak{gl}_\infty(\mathcal{A})) \simeq \bigwedge \text{HC}_*(\mathcal{A}).$$

The left side is the gauge-invariant (single-trace) closed string Hilbert space; the right side is an exterior algebra on the cyclic homology of $\mathcal{A}$.

Attribution. Loday–Quillen 1984, *Comment. Math. Helv.* **59** Theorem 3.4; Tsygan 1983, *Uspekhi Mat. Nauk* **38** (3). Physical interpretation: each cyclic homology class $\text{HC}_k(\mathcal{A})$ is one single-string mode; $\bigwedge^m \text{HC}_*(\mathcal{A})$ is the m -string sector; the exterior algebra encodes bosonic string statistics. $\square$

PROPOSITION 26.37.4 (*Closed strings equal the chiral derived center*). The closed string algebra of Theorem 26.37.3 is the chiral derived center of the CY-to-chiral image:

$$H_*^{\text{CE}}(\mathfrak{gl}_\infty(\mathcal{A})) \simeq \bigwedge \text{HC}_*(\mathcal{A}) = Z_{\text{ch}}^{\text{der}}(\Phi_3^{(\Sigma_2, C)}(\mathcal{C})).$$

The Drinfeld centre of the E_1 -representation category determines a braided monoidal (E_2) category:

$$\mathcal{Z}(\text{Rep}^{E_1}(\Phi_3^{(\Sigma_2, C)}(\mathcal{C}))) \simeq \text{Rep}^{E_2}(Z_{\text{ch}}^{\text{der}}(\Phi_3^{(\Sigma_2, C)}(\mathcal{C}))).$$

This is the categorical content of the closed-sector identification; its identification with a *physical bulk* requires the OCA arrow $\text{OCA} : \mathcal{O}_{\text{bulk}}^{\text{phys}}(\mathcal{T}) \xrightarrow{\sim} Z_{\text{ch}}^{\text{der}}(\mathcal{A})$ of Definition 5.0.5.

The identification connects to the two-stage factorisation (Theorem 5.1.2): Φ_3^{FA} produces the E_1 -chiral algebra $\Phi_3^{(\Sigma_2, C)}(\mathcal{C})$ from the CY₃ data, and $\text{SpCh}_{\Sigma_2, C}$ specialises it to a chiral algebra on the boundary curve C ; the Drinfeld centre of the result is the universal closed-sector algebra $\mathcal{B}^!$ in the large- N limit, gated by OCA for any physical-bulk interpretation.

M-theory parent of the conifold quiver Yangian: stratification

The physics claim that “M-theory on the resolved conifold produces $Y(\widehat{\mathfrak{gl}}(1|1))$ as the algebra of protected local operators at the tip” is a synthesis of four statements living at four distinct epistemic levels. The stratification below separates proved character identities, heuristic reductions, metaphors, and conjectural bialgebra claims; conflating them produces an apparent theorem whose proof has a physics gap.

THEOREM 26.37.5 (*Character-level M-theory parent: $Z_Y^{\text{top,B}} = \chi_{\text{CoHA}(Y)}$*). Let Y be a toric CY_3 with resolved conifold as the basic local model. The B-model topological string partition function $Z_Y^{\text{top,B}}$ equals the graded character of the cohomological Hall algebra $\text{CoHA}(Y)$ as a $\mathbb{Z}^{\text{rk } K_0(Y)}$ -graded vector space:

$$Z_Y^{\text{top,B}}(Q_1, \dots, Q_r; q) = \sum_{\gamma \in K_0(Y)^+} \chi_{\text{CoHA}(Y)_\gamma}(q) Q^\gamma,$$

with Q_i the Kähler parameters and $q = e^{-\hbar}$ the refinement. For the resolved conifold $Y = \mathcal{O}(-1)^{\oplus 2} \rightarrow \mathbb{P}^1$, this reduces to the PT/DT refined partition function

$$Z_{\text{PT}}^{\text{ref}}(Y) = \prod_{k \geq 0} (1 - Qq^{k+1/2})^{-1} \cdot (1 - Qq^{-k-1/2})^{-1},$$

identified with the graded character of the positive half $Y^+(\widehat{\mathfrak{gl}}(1|1))^{\text{conifold}}$.

Character-level chain. Kontsevich–Soibelman 2008 (*Publ. Math. IHÉS* 108, §4–5) prove the CoHA partition function equals the motivic DT generating function for toric CY_3 s; Maulik–Nekrasov–Okounkov–Pandharipande 2006 (MNOP I/II) prove the DT/GW correspondence, identifying motivic DT with the topological string after the PT/DT change of variables. Szendrői 2008 (*Geom. Topol.* 12) computes the non-commutative DT character of the resolved conifold explicitly as the pentagon identity refined product. The character equality is then three applications of primary-literature theorems; no physics synthesis enters. $\square$

THEOREM 26.37.6 (*Toric $\mathbb{C}^2$: Ω -deformed Coulomb = quiver Yangian*). For the toric CY_2 $\mathbb{C}^2$ with Ω -background (ϵ_1, ϵ_2) and $U(1)$ gauge theory coupled to one adjoint hypermultiplet, the Ω -deformed Coulomb branch algebra is canonically isomorphic to the quiver Yangian $Y(\widehat{\mathfrak{gl}}_1)$ (affine Yangian of $\mathfrak{gl}_1$) with parameters $(\epsilon_1, \epsilon_2, -\epsilon_1 - \epsilon_2)$:

$$\text{Coulomb}^\Omega(\mathbb{C}^2; \epsilon_1, \epsilon_2) \simeq Y(\widehat{\mathfrak{gl}}_1).$$

Attribution. Schiffmann–Vasserot 2013 (*Publ. Math. IHÉS* 118, Theorem 8.1) prove the $\text{Coulomb}^\Omega(\mathbb{C}^2) \simeq Y(\widehat{\mathfrak{gl}}_1)$ isomorphism; Maulik–Okounkov 2012 (arXiv:1211.1287) independently derive the same isomorphism via stable envelopes and the RTT relations. The $\text{CoHA}(\mathbb{C}^2) = Y^+(\widehat{\mathfrak{gl}}_1)$ positive-half identification is Schiffmann–Vasserot 2012 (*Duke* 161). The toric $\mathbb{C}^2$ statement is proved end-to-end; no gap. $\square$

Remark 26.37.7 (*Physics heuristic: M-theory on $\mathbb{R}_t \times Y \times \mathbb{R}^4 \rightarrow 5D \mathcal{N} = 2$*). The statement “M-theory on $\mathbb{R}_t \times Y \times \mathbb{R}^4$ at low energies reduces to a $5D \mathcal{N} = 2$ superconformal theory on $\mathbb{R}_t \times \mathbb{R}^4$ whose Coulomb branch is determined by Y ” is *heuristic*: derived from 11D supergravity classical equations of motion plus supersymmetry algebra. The $5D \mathcal{N} = 2$ SCFT is conjectural as a quantum theory (no rigorous construction exists beyond the $\mathcal{A}_n$ -type cases); the Coulomb-branch identification rests on brane-web duality (Aharony–Hanany–Kol 1997; Aharony–Hanany 1997). Call this the *M-theory heuristic*; it motivates but does not prove the M-theory parent.

Remark 26.37.8 (Metaphor: the $(0, 4)$ sigma-model on the wrapped M_5 -brane). The statement “the BPS states of M-theory on Y are counted by the $(0, 4)$ -supersymmetric sigma-model on the M_5 -brane worldvolume wrapping a divisor” is a *metaphor*: it names the physical target space for intuition while the mathematical construction is supplied by automorphic, DT, and stable-envelope data. Maldacena–Strominger–Witten 1997 and Vafa 1997 use this metaphor to relate M_5 -brane BPS indices to automorphic forms; each such relation is independently checkable by direct computation on the automorphic side. The proved conclusions are recovered by independent constructions such as Maulik–Okounkov stable envelopes or Kontsevich–Soibelman DT.

Remark 26.37.9 (Glue across the heuristic–metaphor bridge). The assertion “M-theory on the resolved conifold produces $Y(\widehat{\mathfrak{gl}}(1|1))^{\text{conifold}}$ as the Hopf superalgebra of Ω -protected local operators” is the composite of four different constructions: the character identity of Theorem 26.37.5, the toric $\mathbb{C}^2$ theorem of Theorem 26.37.6, the 5D $\mathcal{N} = 2$ physical reduction of Remark 26.37.7, and the M_5 -brane $(0, 4)$ sigma-model target of Remark 26.37.8. The Hopf-superalgebra equality is therefore the conjecture below; its proved reduction is the character identity.

Conjecture 26.37.10 (Full bialgebra-level M-theory parent of the conifold quiver Yangian). The Ω -deformed algebra of protected local operators at the tip of the resolved conifold in M-theory is $Y(\widehat{\mathfrak{gl}}(1|1))^{\text{conifold}}$ as a Hopf superalgebra, not merely as a graded vector space. The Drinfeld double of the positive half $Y^+(\widehat{\mathfrak{gl}}(1|1))^{\text{conifold}} = \text{CoHA}(Y_{\text{con}})$ is the full R -matrix bialgebra

$$Y(\widehat{\mathfrak{gl}}(1|1))^{\text{conifold}} \cong D(\text{CoHA}(Y_{\text{con}}))$$

with coproduct given by the MNOP-decorated localisation on $\text{Hilb}(\text{conifold}) \times \text{Hilb}(\text{conifold}) \rightarrow \text{Hilb}(\text{conifold})$. The character-level shadow is Theorem 26.37.5; the full bialgebra statement requires a gauge-theoretic construction of the M-theory protected sector that does not yet exist.

Remark 26.37.11 (Construction types in the conifold parent). The five statements above separate by construction type. Theorem 26.37.5 is a character identity proved by composition of primary-literature theorems (KS 2008, MNOP 2006, Szendrői 2008). Theorem 26.37.6 is the toric $\mathbb{C}^2$ theorem of Schiffmann–Vasserot and Maulik–Okounkov. Remark 26.37.7 supplies the physical 5D reduction. Remark 26.37.8 supplies the M_5 target space. Remark 26.37.9 is their composite. Conjecture 26.37.10 is the full bialgebra claim: the equality $Y(\widehat{\mathfrak{gl}}(1|1))^{\text{conifold}} = D(\text{CoHA}(Y_{\text{con}}))$ as Hopf superalgebras, with the character identity as its proved reduction.

26.38 THE BCOV HOLOMORPHIC ANOMALY AS MAURER–CARTAN EQUATION

The B-model holomorphic anomaly equation of Bershadsky–Cecotti–Ooguri–Vafa 1994 is identified with the Maurer–Cartan equation of the shadow obstruction tower.

PROPOSITION 26.38.1 (*BCOV = MC, schematic*). Let $X^\vee$ be the mirror CY_3 with complex structure moduli space $\mathcal{M}$. The genus- g free energy F_g satisfies

$$\partial_{\bar{i}} F_g = \frac{1}{2} \bar{C}_{\bar{i}}^{jk} \left(D_j D_k F_{g-1} + \sum_{r=1}^{g-1} D_j F_r D_k F_{g-r} \right), \quad g \geq 2,$$

where $D_i = \nabla_i + (2 - 2g) \partial_i K$ and $\bar{C}_{\bar{i}}^{jk}$ is the anti-holomorphic Yukawa coupling. This is the Maurer–Cartan equation

$$D\Theta + \frac{1}{2}[\Theta, \Theta] = 0$$

in the dgLa $\mathcal{L}_X = \text{PV}^{\bullet,\bullet}(X^\vee)$ of polyvector-valued $(0, q)$ -forms, expanded at order $\hbar^2 g^{-2}$. The total free energy $\Theta = \sum_g \hbar^2 g^{-2} \Theta^{(g)}$ (with $\Theta^{(g)} \sim F_g$) is a MC element; the propagator S^{ij} of special geometry is the Lie bracket contraction kernel; the Yukawa coupling C_{ijk} is the Schouten–Nijenhuis structure constant; holomorphic ambiguity of F_g is MC gauge freedom. In particular, $\mathcal{L}_X$ is quasi-isomorphic to the dgLa $C^\bullet(B(A_X))$ governing deformations of the bar complex of $G(X)$: the BCOV MC element Θ is the shadow obstruction tower Θ_{A_X} .

Attribution. BCOV 1994, *Nucl. Phys. B* **405** Eq. (3.22), gives the anomaly equation. Costello–Li 2015 arXiv:1505.06703 § 3 gives the MC interpretation in $\mathcal{L}_X$. The Hochschild/bar comparison identifies $\mathcal{L}_X$ with $C^\bullet(B(A_X))$, carrying the BCOV MC element into the chiral shadow complex. $\square$

Remark 26.38.2 (Genus-one anomaly and chiral scalars). At genus $g = 1$, the anomaly is $\partial_i \partial_j F_1 = \frac{1}{2} C_{jkl} \tilde{C}_i^{kl} - (\chi(X)/24 - 1) G_{j\bar{i}}$, where $\chi(X)$ is the topological Euler characteristic. The coefficient $\chi(X)/24$ governs the genus-one gravitational anomaly; it need not equal a chiral modular characteristic. For $K_3 \times E$, $\chi = 0$ and $\kappa_{\text{cat}} = 0$ by Künneth. The compact total-space Hodge supertrace is $\kappa_{\text{ch}}^{\text{Hodge}}(K_3 \times E) = 0$, the Heisenberg Stage-2 branch has $\kappa_{\text{ch}}^{\text{Heis}} = 3$, and the Borchers denominator has the separate weight $\kappa_{\text{BKM}}(\Delta_5) = c_N(0)/2|_{N=1} = 5$ by Theorem 32.8.1. The shared value 0 on the BCOV and Hodge lanes is a coincidence of this product, not an identification of the Heisenberg branch or the BKM weight.

26.39 THE TOPOLOGICAL VERTEX AS LOCAL ROOT DATUM

For toric CY_3 , the A-model partition function factorizes over trivalent vertices of the toric diagram. Each vertex carries the positive-half local CoHA datum $Y^+(\widehat{\mathfrak{gl}}_1)$; the Drinfeld double gives the affine Yangian, and the $\mathcal{W}_{1+\infty}$ object appears only after the centre/vacuum evaluation.

Construction 26.39.1 (AKMV topological vertex and local root datum). The A-model partition function on any toric CY_3 X is

$$Z(X) = \sum_{\{\lambda_e\}} \prod_v C_{\lambda_{e_1} \lambda_{e_2} \lambda_{e_3}}(q) \cdot \prod_e (-Q_e)^{|\lambda_e|} f_{\lambda_e}(q), \quad (26.11)$$

where the sum is over assignments of partitions to internal edges, $C_{\lambda\mu\nu}(q)$ is the topological vertex

$$C_{\lambda\mu\nu}(q) = q^{\kappa_\mu/2} s_{\nu^t}(q^\rho) \sum_\eta s_{\lambda^t/\eta}(q^{\nu+\rho}) s_{\mu/\eta}(q^{\nu^t+\rho}),$$

and $Q_e = e^{-t_e}$ is the Kähler parameter of the edge. The local root datum at vertex v is the positive-half CoHA datum of $\mathbb{C}^3$: the lattice is $\mathbb{Z}$ (dimension vectors), root multiplicities are $\text{mult}(n) = p(n)$ (plane partitions), and $C_{\lambda\mu\nu}(q)$ is the matrix element of the topological-vertex intertwiner on Fock spaces. Passing from this positive half to the full quantum vertex chiral group requires the Drinfeld double/centre construction. With that extra datum, the global root datum $\mathcal{R}(X)$ is assembled by tensor product (factorization product over the toric diagram): the edge sum (26.11) is the trace over $\otimes_e \mathcal{F}_e$ with insertion of vertex operators and Kähler weights.

Remark 26.39.2 (MacMahon function and the denominator identity). The MacMahon function $M(q) = \prod_{n \geq 1} (1 - q^n)^{-n}$ is the DT partition function of $\mathbb{C}^3$ and the vacuum character obtained from the Drinfeld-double/centre evaluation of the affine-Yangian side. It is not a statement that the positive CoHA itself is $\mathcal{W}_{1+\infty}$: the positive half is $Y^+(\widehat{\mathfrak{gl}}_1)$, the full double is $Y(\widehat{\mathfrak{gl}}_1)$, and the vertex-algebra vacuum character is the centre/vacuum shadow. For $K_3 \times E$ (non-toric), the denominator identity is

the Igusa cusp form Δ_5 , and the appropriate analogue of the topological vertex is the BKM denominator product form.

26.40 CELESTIAL HOLOGRAPHY AND QUANTUM VERTEX CHIRAL GROUPS

The Mellin transform of 4d massless scattering amplitudes in $\mathbb{R}^{1,3}$ yields 2d celestial amplitudes on the celestial sphere $S^2 \cong \mathbb{P}^1$. The holomorphic sector is a vertex algebra whose OPE encodes collinear singularities of the S-matrix. For 4d $\mathcal{N} = 2$ theories arising from Type IIB on a CY_3 X , identifying this celestial chiral algebra with a genus-0 sector of $G(X)$ requires both a constructed $G(X)$ and the pure mathematical holographic bridge datum.

THEOREM 26.40.1 (*Triple identification for flat space*). There is a canonical positive-half/double/vacuum chain

$$\mathcal{W}_{1+\infty\text{-vac}} \curvearrowright Y(\widehat{\mathfrak{gl}}_1) = D(Y^+(\widehat{\mathfrak{gl}}_1)) \simeq G(\mathbb{C}^3), \quad (26.12)$$

where $\mathcal{W}_{1+\infty}$ is the unique one-parameter family of vertex algebras freely generated by one current in each spin $s \geq 1$, $Y(\widehat{\mathfrak{gl}}_1) = D(Y^+(\widehat{\mathfrak{gl}}_1))$ is the Drinfeld double of the positive half, and $G(\mathbb{C}^3)$ is the quantum vertex chiral group of the toric CY_3 $\mathbb{C}^3$.

Attribution. The affine Yangian action on the $\mathcal{W}_{1+\infty}$ vacuum module is the Maulik–Okounkov/Schiffmann–Vasserot construction on equivariant cohomology of $\text{Hilb}^n(\mathbb{C}^2)$. Theorem 34.3.1 identifies the critical CoHA of the Jordan quiver with cubic potential $W = \text{tr}(XYZ - XZY)$ as $Y^+(\widehat{\mathfrak{gl}}_1)$; the full affine Yangian, hence $G(\mathbb{C}^3)$, is the Drinfeld double $D(Y^+)$, not the CoHA itself. $\square$

The physical content of (26.12): the celestial symmetry algebra of 4d gravity ($\mathcal{W}_{1+\infty}$, established by Guevara–Himwich–Pate–Strominger 2021) is the quantum vertex chiral group of flat space ($G(\mathbb{C}^3)$). The infinite tower of higher-spin celestial symmetries $\mathcal{W}^{(s)}$ for $s \geq 1$ is the tower of BPS states in the DT theory of $\mathbb{C}^3$.

Conjecture 26.40.2 (*CY_3 celestial chiral algebra*). Assume $G(X)$ has been constructed from a framed CY-to-chiral datum and the pure mathematical holographic bridge datum is supplied. For a 4d $\mathcal{N} = 2$ theory T_X from Type IIB on a CY_3 X , the celestial chiral algebra is then expected to be

$$\mathcal{A}_{\text{cel}}(T_X) \simeq G(X)^{g=0},$$

the genus-0 (tree-level) sector of $G(X)$, with higher-genus corrections from the shadow obstruction tower Θ_{A_X} .

PROPOSITION 26.40.3 (*Soft theorems and the shadow filtration*). Assume $G(X)$ has been constructed and the pure mathematical holographic bridge datum has been supplied. The soft graviton theorems are identified with the degree filtration of the shadow obstruction tower only after the celestial algebra is matched with the constructed boundary chiral algebra. Under that bridge, the sub k -leading soft theorem at $\mathcal{O}(\omega^{k-1})$ is the Ward identity of the degree- $(k+2)$ shadow $\Theta_{A_X}^{(k+2)}$:

$$\text{Sh}_{0,n}(\Theta_{A_X}^{(k+2)}) \cdot \Phi = 0 \quad (\text{degree-}(k+2) \text{ soft Ward identity}).$$

The dictionary is:

Degree	Shadow	Soft theorem	Celestial current
$r = 2$	$\kappa_{\text{ch}}(\mathcal{A}_X)$	Weinberg leading	Supertranslation
$r = 3$	$\mathfrak{C}(\mathcal{A}_X)$	Cachazo–Strominger subleading	Superrotation (Virasoro)
$r = 4$	$\mathfrak{Q}(\mathcal{A}_X)$	Sub-subleading	Spin-3 $\mathcal{W}$ -current
r	$\Theta_{\mathcal{A}_X}^{(r)}$	Sub $^{r-2}$ -leading	Spin- $(r-1)$ $\mathcal{W}$ -current

For $X = \mathbb{C}^3$ with $r_{\max} = \infty$, the full tower generates $\mathcal{W}_{1+\infty}$, recovering Guevara–Himwich–Pate–Strominger 2021.

Attribution and bridge condition. Leading soft graviton: Weinberg 1965. Subleading: Cachazo–Strominger 2014. Celestial algebra: Strominger 2014; He–Lysov–Mitra–Strominger 2015. The shadow tower identification follows only after the pure bridge identifies the celestial Ward algebra with the boundary chiral algebra; inside that conditional target, the degree decomposition of the modular shadow connection gives the displayed filtration. $\square$

Conjecture 26.40.4 (Celestial OPE as collision r -matrix). When $G(X)$ is constructed, the celestial OPE of the 4d theory T_X is determined by its collision r -matrix:

$$\mathcal{O}_{\Delta_1}(z_1) \cdot \mathcal{O}_{\Delta_2}(z_2) \sim r_{G(X)}(z_1 - z_2) \cdot (\mathcal{O}_{\Delta_1} \otimes \mathcal{O}_{\Delta_2})(z_2),$$

where $r_{G(X)}(z) = \text{Res}_{0,2}^{\text{coll}}(\Theta_{\mathcal{A}_X})$ is the degree-2 genus-0 projection of $\Theta_{\mathcal{A}_X}$. The number of singular terms in the OPE equals $r_{\max}(G(X)) - 1$; the leading simple pole coefficient is proportional to $\kappa_{\text{ch}}(\mathcal{A}_X)$; the Yang–Baxter equation for $r_{G(X)}(z)$ is the associativity of the celestial OPE.

26.41 3D MIRROR SYMMETRY AND CY_2 QUANTUM VERTEX CHIRAL GROUPS

A 3d $\mathcal{N} = 4$ gauge theory T has two hyperkähler branches of vacua: the Higgs branch $\mathcal{M}_H(T) = T^*R \amalg G$ (exact, non-renormalized) and the Coulomb branch $\mathcal{M}_C(T)$ (quantum-corrected). Both are CY_2 (hyperkähler of complex dimension 2): the functor Φ (at $d = 2$) produces E_2 -chiral algebras from their derived categories. Mirror symmetry exchanges the two branches and, conjecturally, their quantum vertex chiral groups.

THEOREM 26.41.1 (Hyperkähler branches are CY_2). Both $\mathcal{M}_H(T)$ and $\mathcal{M}_C(T)$ carry hyperkähler metrics. A hyperkähler surface (complex dimension 2, holonomy $\subseteq \text{Sp}(1) \cong \text{SU}(2)$) is a CY_2 space. Consequently $D^b(\text{Coh}(\mathcal{M}_H))$ and $D^b(\text{Coh}(\mathcal{M}_C))$ are both CY_2 categories; the $\mathbb{S}^2$ -framing of $\text{HH}_\bullet$ provides the E_2 -algebra structure on their Φ -images.

Attribution. Higgs branch: hyperkähler quotient theorem of Hitchin–Karlhede–Lindström–Roček 1987. Coulomb branch: Seiberg–Witten 1996 analysis of the 3d low-energy effective action; Braverman–Finkelberg–Nakajima 2016–2019 rigorous construction via convolution on the affine Grassmannian. $\square$

Definition 26.41.2 (BFN Coulomb branch algebra). For a complex reductive group G and representation R , the Coulomb branch algebra is

$$\mathcal{A}_{G,R} = H_\bullet^{G((t))}(\mathcal{R}), \quad \mathcal{R} = \{(g, s) \mid g \in \text{Gr}_G, s \in R[[t]], g \cdot s \in R[[t]]\},$$

with convolution product. The Coulomb branch is $\mathcal{M}_C(G, R) = \text{Spec}(\mathcal{A}_{G,R})$. Its quantization $\mathcal{A}_{G,R}^{\hbar} = K_\bullet^{G[[t]]}(\mathcal{R})$ is a filtered associative algebra.

THEOREM 26.41.3 (*CoHA = Yangian positive half*). For a quiver Q without potential (the pre-projective algebra case), the cohomological Hall algebra of the Higgs branch Nakajima quiver variety is

$$\mathrm{CoHA}(Q) \cong Y^+(\mathfrak{g}_Q),$$

the positive half of the Yangian of the Kac–Moody algebra $\mathfrak{g}_Q$. The passage from the associative (E_1) CoHA to the braided monoidal (E_2) full quantum vertex chiral group $G(\mathcal{M}_H)$ requires the stable-envelope wall-crossing operators together with the negative half, Hopf pairing, Drinfeld double, and centre comparison.

Attribution. $\mathrm{CoHA}(\widehat{\mathfrak{gl}}_1) \cong Y^+(\widehat{\mathfrak{gl}}_1)$: Schiffmann–Vasserot 2013. General quivers: Maulik–Okounkov 2019; Davison 2021 (critical CoHA). Stable envelopes and R -matrix: Maulik–Okounkov 2019 § 4. $\square$

Conjecture 26.41.4 (*Mirror symmetry for quantum vertex chiral groups*). Let T and $T^\dagger$ be 3d $\mathcal{N} = 4$ mirrors (Intriligator–Seiberg 1996). The quantum vertex chiral groups of their branches are exchanged:

$$G(\mathcal{M}_H(T)) \cong G(\mathcal{M}_C(T^\dagger)), \quad G(\mathcal{M}_C(T)) \cong G(\mathcal{M}_H(T^\dagger)).$$

Equivalently, there is an equivalence of E_2 -chiral algebras

$$\Phi(D^b(\mathrm{Coh}(\mathcal{M}_H(T)))) \simeq \Phi(D^b(\mathrm{Coh}(\mathcal{M}_C(T^\dagger))))$$

preserving braided monoidal structure, modular characteristic, and root datum. At the positive-half level, this is Yangian duality: $Y^+(\mathfrak{g}_Q) = \mathrm{CoHA}(\mathcal{M}_H(T)) \cong \mathcal{A}_{G^\dagger, R^\dagger}^\hbar = Y^+(G(\mathcal{M}_C(T^\dagger)))$ where $(G^\dagger, R^\dagger)$ is the mirror gauge theory data.

The non-trivial content of Conjecture 26.41.4: the Higgs side produces a CoHA by convolution on quiver representations, while the Coulomb side produces a BFN algebra by convolution on the affine Grassmannian. The conjecture identifies the positive halves and their root data; the braided E_2 structure is recovered on the representation category through the Drinfeld-centre or stable-envelope construction, not on the bare CoHA product. For type A quivers, the BFN algebra is a truncated shifted Yangian (Kamnitzer–Webster–Weekes–Yacobi 2021), and the isomorphism $Y^+(\widehat{\mathfrak{sl}}_n) \cong$ (truncated shifted Yangian for $\mathfrak{gl}_N$) is the mathematical incarnation of 3d mirror symmetry.

Remark 26.41.5 (*Hitchin moduli and geometric Langlands*). For pure G -gauge theory on a curve C (no matter), the Higgs branch is the Hitchin moduli space $\mathcal{M}_H = T^*\mathrm{Bun}_G(C) = \mathrm{Higgs}(C, G)$, a CY_2 space. The quantum vertex chiral group $G(\mathcal{M}_H) = G(\mathrm{Higgs}(C, G))$ connects to geometric Langlands via Kapustin–Witten 2006: S-duality exchanges G and $G^\vee$, which at the level of quantum vertex chiral groups should exchange $G(\mathrm{Higgs}(C, G))$ and $G(\mathrm{Higgs}(C, G^\vee))$. This is the conjectural quantum vertex chiral group incarnation of geometric Langlands (the Hitchin-mirror conjecture for CY_2 targets).

Part IV

The Seven Faces of $r_{\text{CY}}(z)$

The seven faces of $r_{CY}(z)$ are the level-2 cross-axis structure of the two-stage factorisation $\Phi_d = \mathrm{Sp}_{\Sigma_{d-1}, C}^{\mathrm{ch}} \circ \Phi_d^{\mathrm{FA}}$. A single chosen Stage-1 datum $\mathcal{F}_X = \Phi_d^{\mathrm{FA}}(C) \in E_d\text{-HolFA}(X)$ admits two orthogonal seven-fold decompositions: the *three-tier vertical* stratification along the universal-arrow levels 0, 1, 2, and the *seven-presentation horizontal* slicing by algebraic language at level 2. The R-matrix $r_{CY}(z) \in \mathcal{A}_C \otimes \mathcal{A}_C((z))$ is the binary collision residue of the universal Maurer–Cartan element of the Stage-2 chiral algebra; it organises the entire output side.

Three tiers along the universal-arrow vertical. Each face occupies one tier of the two-stage factorisation:

- *Tier (i), CY-datum intrinsic* (level 0, chart-free, ambient ordinary): invariants of (X, C, Ω_C) alone. The Mukai pairing on $\tilde{H}^*(K_3) = \Pi_{4,20}$, the Hodge supertrace $\kappa_{\mathrm{ch}}^{\mathrm{Hodge}}(X) = \sum_q (-1)^q h^{0,q}(X)$, the holomorphic volume class $[\Omega_C]$, the $\mathcal{A}_\infty$ -coassociator $\delta^{(3)}$ at degree 3 of the shadow tower. Read directly off C_X .
- *Tier (ii), Stage-1 invariant of $\mathcal{F}_X$* (level 1, before the chart (Σ_{d-1}, C) , ambient $E_d\text{-HolFA}(X)$): properties of the canonical $\Phi_d^{\mathrm{FA}}(C) \in E_d\text{-HolFA}(X)$ before any specialisation. The K_3 -fibre rank $\kappa_{\mathrm{fiber}}(K_3 \times E) = 24$, the Atiyah class $\mathrm{At}(T_X)$, the Yukawa $Y_3 \in H^{0,3}(X)$, the Costello–Li BCOV curving $\alpha_{\mathrm{BCOV}} = (\chi(X)/24) \cdot [\Omega_X]^{\mathrm{ol}}$, the Maulik–Okounkov stable envelope on the derived moduli of the CY_{*d*} target, the Costello $\mathfrak{z}$ d hCS tree amplitude on the $4d$ twistor background of the CY₃ target.
- *Tier (iii), (Σ_{d-1}, C) -specialisation* (level 2, chart-dependent, ambient $E_n\text{-HolFA}(C)$ at the recalled depth $n(d)$): the genuine Stage-2 siblings, all distinct $\mathrm{Sp}_{\Sigma_{d-1}, C}^{\mathrm{ch}}$ -evaluations of the same $\mathcal{F}_X$. The BKM face $(K_3, E) \mapsto \mathfrak{g}_{\Delta_5}$ with $\kappa_{\mathrm{BKM}}(\Delta_5) = 5$; the Niemeier 23-twist family indexed by Conway–Norton root data; the Humbert boundary-monodromy limit at $H_1 \cup H_4$; the CHL twined $\mathbb{Z}/N$ family at $N \in \{1, 2, 3, 4, 6\}$ with universal Borcherds weight $\kappa_{\mathrm{BKM}}(\Phi_N) = c_N(o)/2$.

On $K_3 \times E$ the spectrum $\kappa_\bullet \in \{0, 0, 3, 5, 24\}$ sorts one value per tier: $\kappa_{\mathrm{cat}} = 0$ via Künneth and $\kappa_{\mathrm{ch}}^{\mathrm{Hodge}} = 0$ at tier (i); $\kappa_{\mathrm{fiber}} = 24$ and $\kappa_{\mathrm{ch}}^{\mathrm{Heis}} = 3$ at tier (ii); $\kappa_{\mathrm{BKM}}(\Delta_5) = 5$ at tier (iii). Only tier-(iii) faces are $\mathrm{Sp}_{\Sigma_{d-1}, C}^{\mathrm{ch}}$ -siblings; tier-(i) and tier-(ii) faces are pre-specialisation invariants visible without any curve-specialisation.

Seven algebraic presentations along the level-2 horizontal. The Stage-2 output $\mathcal{A}_C = \mathrm{Sp}_{\Sigma_{d-1}, C}^{\mathrm{ch}}(\mathcal{F}_X)$ admits seven distinct algebraic presentations of one binary residue $r_{CY}(z)$:

- | | |
|---|--|
| (i) Yangian coproduct twist: | $r_{CY}(z) = \Delta_u(x) - \Delta_u^{\mathrm{op}}(x),$ |
| (ii) Drinfeld-centre half-braiding: | $r_{CY}(z) = \sigma_V(\mathcal{Z}(\mathrm{Rep}^{E_1}(\mathcal{A}_C))),$ |
| (iii) Knizhnik–Zamolodchikov monodromy: | $r_{CY}(z) = \lim_{z' \rightarrow z} \mathrm{Hol}_{\nabla_{\mathrm{KZ}}}(z' \rightarrow z),$ |
| (iv) BKM vertex-operator exchange: | $r_{CY}(z) = V_\alpha(z)V_\beta(o) - (\alpha \leftrightarrow \beta),$ |
| (v) Maulik–Okounkov stable envelope: | $r_{CY}(z) = \mathrm{Stab}_{\mathcal{K}} \circ \mathrm{Stab}_{\mathcal{K}}^{-1},$ |
| (vi) $\mathcal{A}_\infty$ -coassociator: | $r_{CY}(z) = \delta^{(3)}$ (shadow tower at degree 3), |
| (vii) Costello $\mathfrak{z}$ d hCS tree amplitude: | $r_{CY}(z) = \mathrm{Tree}_z^{\mathrm{hCS}}[\mathfrak{gl}_1].$ |

The seven-presentation slicing is orthogonal to the three-tier vertical: faces (i)–(iv) are tier-(iii) Stage-2 outputs on the chosen chart; faces (v) and (vii) are tier-(ii) Stage-1 invariants of $\mathcal{F}_X$; face (vi) is the tier-(i) intrinsic shadow of the cyclic $\mathcal{A}_\infty$ structure on C . The seven-face master agreement (Theorem 31.9.2) is the statement that all twenty-one (tier, presentation) cells extract the same algebraic element $r_{CY}(z)$.

Maulik–Okounkov as gluing-cocycle residue. Face (v) admits the sharpest geometric realisation. Let $\mathcal{M}_{\mathrm{eff}}^+(C)$ be the moduli of effective objects in the CY_{*d*} category C , T the torus preserving the

CY structure, and $\mathcal{W} \subset \mathfrak{t}_{\mathbb{C}}^*$ the equivariant wall arrangement. The *UV positive-half gluing cocycle* is the meromorphic $\text{End}(Y^+ \otimes Y^+)$ -valued 1-form ϕ_{UV}^+ on $\mathfrak{t}_{\mathbb{C}}^*$ whose chamber-by-chamber data is the Maulik–Okounkov stable envelope and whose wall residues are the hyperbolic-restriction r_{α} . The Maulik–Okounkov R -matrix is the residue of this cocycle across an equivariant chamber wall:

$$R^{\text{MO}}(u) = \text{Res}_{u=u_{\star}} \phi_{UV}^+(u), \quad u = u_1 - u_2,$$

at any chamber wall $u_{\star}$, independent of the chamber choice up to unitarity (Construction 10.5.5, Theorem 10.5.6). The Maulik–Okounkov axiom $R_{12}(u_1 - u_2)R_{13}(u_1 - u_3)R_{23}(u_2 - u_3) = R_{23}(u_2 - u_3)R_{13}(u_1 - u_3)R_{12}(u_1 - u_2)$ is the Čech-cocycle condition for ϕ_{UV}^+ on the codimension-two wall triple-intersection; unitarity $R_{21}(-u)R_{12}(u) = \text{id}$ is the cocycle-reversal identity; the hexagon axioms of the braided monoidal structure on $\text{Rep}^{E_2}(\mathfrak{Z}_C) = \mathcal{Z}(\text{Rep}^{E_1}(A_C))$ are the codimension-three coherence relations of ϕ_{UV}^+ .

The level-2 cross-axis crystallisation. The R -matrix $r_{CY}(z)$ is the bar-of- Φ shadow at level 2 of the universal arrow. Its three-tier vertical exposes where each invariant is read; its seven-presentation horizontal exposes which algebraic language is appropriate. The two orthogonal sevens are not rival presentations of seven objects; they are two organising principles applied to one Stage-1 holomorphic factorisation algebra, intersecting along tier (iii) where Sp^{ch} -siblinghood is the common structural content (Remark 31.0.2). Two scalar-complementarity identities accompany the crystallisation,

$$\kappa_{\text{ch}}(A) + \kappa_{\text{ch}}(A^!) = \varrho_A \cdot K(A), \quad A^! = D_{\text{Ran}}(B^{\text{ord}}(A)),$$

with prefactor $\varrho_A = H_N - 1$ for principal $\mathcal{W}_N$, $\varrho_A = 0$ for class G/L (free / affine Kac–Moody; complementarity vanishes), $\varrho_{\text{BP}} = 1/6$ for Bershadsky–Polyakov; and the Trinity invariant $K(A) = c(A) + c(A^!) = -c_{\text{ghost}}(\text{BRST})$ takes values $K(V_k(\mathfrak{g})) = 2 \dim \mathfrak{g}$, $K(\mathcal{W}_N) = 4N^3 - 2N - 2 \in \{26, 100, 246, 488, \dots\}$ at $N = 2, 3, 4, 5$, $K(\text{BP}) = 196$. At K_3 with $\mathfrak{g}_{K_3} = H_{\text{Muk}}^*$ both sides vanish (class G).

Shadow–Feynman dictionary. At the bar-cobar bridge to Volume I,

$$L\text{-loop Feynman amplitude} = S_{L+1} = \delta^{(L+1)}\text{-coefficient of the } A_{\infty}\text{-coproduct correction tower.}$$

Class M: the finite-mode E_3 bar page after the quartic shadow differential has dimension 6^g ; it equals E_{∞} for $g \leq 3$, while for $g \geq 4$ the first possible further operator is d_g . The ordinary PBW bar complex is infinite-dimensional; the finite spectral sequence is the weight-completed one.

Chapter dependencies. Chapter 27 constructs the modular trace on CY chiral algebras and is the first place where the seven realisations of $r_{CY}(z)$ are read as one modular observable. Chapter 28 proves the Koszul conductor formula at $d = 2$ via Serre duality $\mathbb{S}_C = [2]$. Chapter 29 installs the shadow–Feynman dictionary and the class M Borel summability result. Chapter 31 executes the full synthesis of the seven faces in the CY setting, with explicit (level, chart, ambient) declarations per face and the two-orthogonal-sevens stratification table.

Into Part V. The seven-face crystallisation organises the level-2 chart classification of the Calabi–Yau landscape: each example occupies one (chart class) $\times$ (tier-(iii) face) cell, with toric T^d , reduced $\mathbb{C}^{\times} + \text{Aut}$, orbifold inertia $I(X/G)$, and lattice-polarised period domain as the four equivariance strata.

THE MODULAR TRACE

Remark 27.0.1 (Stage-1 $\leftrightarrow$ Stage-2 bridge). The modular trace connects the Stage-2 chiral-algebra character to the Stage-1 reduced Donaldson–Thomas generating function. On $K_3 \times E$ at $(\Sigma_2, C) = (K_3, E)$, the Stage-2 E_1 -chiral-algebra character equals the Stage-1 reduced Donaldson–Thomas partition function

$$Z_{\text{DT}}^{\text{red}}(K_3 \times E) = -(\Phi_{10}^{\text{OP}})^{-1} = -D_5^{-2} = -4096 \Delta_5^{-2}$$

on K_3 -primitive classes, where $D_5 = 64^{-1} \Delta_5$ and $\Phi_{10}^{\text{OP}} = D_5^2 = 4096^{-1} \Delta_5^2$ (Pandharipande–Oberdieck, *Invent. Math.* **222** (2017)). The modular-trace constraint discussed in this chapter is the shadow of this Stage-1 $\leftrightarrow$ Stage-2 correspondence.

A chiral algebra carries a modular characteristic κ_{ch} ; a Calabi–Yau category carries a categorical trace $\text{Tr}: \text{HH}_d(C) \rightarrow k$; a Calabi–Yau manifold carries a holomorphic Euler characteristic $\chi(\mathcal{O}_X)$. The CY-invariant target of κ_{ch} on compact CY_d is the Hodge-supertrace $\kappa_{\text{ch}}^{\text{Hodge}} = \chi(\mathcal{O}_X)$ on the slice ($d = 2$, $h^{1,0} = 0$); the topological Euler density $\chi_{\text{top}}/24$ is the genus-1 BCOV reading $\kappa_{\text{ch}}^{\text{BCOV}}$, a separate construction layer.

The two readings differ across the CY landscape. For the elliptic curve, $\chi_{\text{top}} = 0$ while $\kappa_{\text{ch}}^{\text{Heis}}(H_1) = 1$. For K_3 , $\chi_{\text{top}}/24 = 1$ while $\kappa_{\text{ch}}^{\text{Hodge}}(\mathcal{A}_{K_3}) = 2 = \chi(\mathcal{O}_{K_3})$. For $K_3 \times E$, multiple modular characteristics coexist on distinct construction layers: $\kappa_{\text{ch}}^{\text{Heis}} = 3$ from the Heisenberg-level chiral de Rham complex (cf. Remark 5.3.27) and $\kappa_{\text{BKM}}(\Delta_5) = 5$ from the Borchers lift weight. For the resolved conifold, $\chi_{\text{top}}/24 = 1/12$ while $\kappa_{\text{ch}}^{\text{loc}}(\text{conifold}) = 1$ via direct McKay.

This chapter develops the chain-level identifications. The CY trace, refined to negative cyclic homology $\text{HC}_d^-(C)$, determines $\kappa_{\text{ch}}(\mathcal{A}_C)$ through the two-stage factorisation $\Phi_d = \text{Sp}_{\Sigma_{d-1}, C}^{\text{ch}} \circ \Phi_d^{\text{FA}}$ of Chapter 9 (Theorem 5.1.2): the modular trace lives on the specialisation shadow $\text{Sp}_{\Sigma_{d-1}, C}^{\text{ch}}(\Phi_d^{\text{FA}}(C))$, the E_1 - or E_2 -chiral algebra on the reference curve C cut out by the cycle Σ_{d-1} . At $d = 2$, the resulting equality $\kappa_{\text{ch}}(\mathcal{A}_C) = \chi^{\text{CY}}(C) = \chi(\mathcal{O}_X)$ is proved (Proposition 5.3.13). At $d \neq 2$, κ_{ch} and $\chi(\mathcal{O}_X)$ differ in general: the Heisenberg-level characteristic $\kappa_{\text{ch}}^{\text{Heis}}$ is additive under products while $\chi(\mathcal{O}_X)$ is multiplicative (Künneth), so $\kappa_{\text{ch}}^{\text{Heis}}(K_3 \times E) = 3 \neq 0 = \chi(\mathcal{O}_{K_3 \times E})$ (cf. Remark 5.3.27). The corrected $d = 3$ formula is dimension-stratified (Conjecture 5.3.25). The genus- g obstruction tower $\text{obs}_g(\mathcal{A}_C) = \kappa_{\text{ch}}(\mathcal{A}_C) \cdot \lambda_g$ then encodes the higher-genus CY invariants on the uniform-weight lane, with the multi-weight cross-channel correction $\partial F_g^{\text{cross}}$ from Vol I appearing at $g \geq 2$ for families with fields of distinct conformal weights.

27.1 CY TRACE AS MODULAR CHARACTERISTIC

The CY trace $\text{Tr}: \text{HH}_d(C) \rightarrow k$ determines the modular characteristic $\kappa_{\text{ch}}(\mathcal{A}_C)$.

THEOREM 27.1.1 (CY modular characteristic: Theorem CY-D). Fix the Vol III convention that the Künneth-additive Heisenberg branch is written with its own superscript

$$\kappa_{\text{ch}}^{\text{Heis}}(X),$$

while the Hodge comparator is written separately as

$$\kappa_{\text{ch}}^{\text{Hodge}}(X) := \sum_{q=0}^d (-1)^q h^{\circ, q}(X) = \chi(\mathcal{O}_X).$$

Let $\mathcal{C}$ be a smooth proper CY category and let $\mathcal{A}_{\mathcal{C}} = \Phi(\mathcal{C})$.

- (i) If $d = 2$ and $\text{HH}_{-1}(\mathcal{C}) = 0$ (equivalently, for $\mathcal{C} = D^b \text{Coh}(X)$, $h^{1,0}(X) = 0$), then

$$\kappa_{\text{ch}}(\mathcal{A}_{\mathcal{C}}) = \chi^{\text{CY}}(\mathcal{C}) = \chi(\mathcal{O}_X).$$

This is the proved CY- D_2 slice: the Serre-duality parity argument kills the one-loop correction.

- (ii) For compact CY input of dimension $d \geq 3$, the comparison between κ_{ch} and $\kappa_{\text{ch}}^{\text{Hodge}}$ is stratified by the Beauville–Bogomolov holonomy type:

- (a) if d is odd, then $\kappa_{\text{ch}}^{\text{Hodge}}(X) = 0$ by Serre cancellation, but $\kappa_{\text{ch}}(\mathcal{A}_X)$ need not vanish;
- (b) if d is even and X is strict CY, then the Hodge comparator is the genuine Serre-duality endpoint contribution $\kappa_{\text{ch}}^{\text{Hodge}}(X) = 2$;
- (c) if $d = 2n$ and X is irreducible holomorphic-symplectic, then $\kappa_{\text{ch}}^{\text{Hodge}}(X) = n + 1$, generated by $1, \sigma, \dots, \sigma^n$.

- (iii) The product $K3 \times E$ is the basic obstruction to the naive identity $\kappa_{\text{ch}} = \chi(\mathcal{O}_X)$:

$$\kappa_{\text{ch}}^{\text{Hodge}}(K3 \times E) = \chi(\mathcal{O}_{K3 \times E}) = 0, \quad \kappa_{\text{ch}}^{\text{Heis}}(K3 \times E) = 3.$$

The left-hand side is Künneth-multiplicative; the right-hand side is Künneth-additive.

- (iv) On the uniform-weight lane, the genus- g scalar obstruction satisfies $\text{obs}_g^{\text{sc}}(\mathcal{A}_{\mathcal{C}}) = \kappa_{\text{ch}}(\mathcal{A}_{\mathcal{C}}) \cdot \lambda_g$. For a multi-weight algebra this is only the scalar trace. At genus $g \geq 2$ the full coefficient is

$$F_g(\mathcal{A}_{\mathcal{C}}) = F_g^{\text{sc}}(\mathcal{A}_{\mathcal{C}}) + \partial F_g^{\text{cross}}(\mathcal{A}_{\mathcal{C}}), \quad F_g^{\text{sc}}(\mathcal{A}_{\mathcal{C}}) = \kappa_{\text{ch}}(\mathcal{A}_{\mathcal{C}}) \lambda_g \quad \text{on the uniform-weight lane.}$$

The nonvanishing witness is Vol I op:multi-generator-universality, resolved negatively: $\partial F_2(\mathcal{W}_3) = (c+204)/(16c) > 0$. The shadow obstruction tower of $\mathcal{A}_{\mathcal{C}}$ encodes the higher-genus CY invariants of $\mathcal{C}$ only after this scalar/full-coefficient distinction is kept.

27.2 CY EULER CHARACTERISTIC VERSUS MODULAR CHARACTERISTIC

The modular characteristic κ_{ch} is an invariant of the quantum chiral algebra $\mathcal{A}_{\mathcal{C}}$, not of the underlying topology. It differs from the topological Euler characteristic χ in every known case.

PROPOSITION 27.2.1 ($\chi/24 \neq \kappa_{\text{ch}}$ in general). The ratio $\chi_{\text{top}}/24$ and the modular characteristic κ_{ch} disagree for most CY threefolds. The following table records all cases where both are known.

X	$\chi_{\text{top}}(X)$	$\chi_{\text{top}}/24$	κ_{ch}	Source
Elliptic curve E	0	0	1	$\kappa_{\text{ch}}(H_1) = 1$
$K3$ surface	24	1	2	$\kappa_{\text{ch}}^{\text{Hodge}}(\mathcal{A}_{K3}) = 2$ (Prop. 26.22.2)
$K3 \times E$	0	0	$3^{\text{Heis}}/5^*$	$\kappa_{\text{ch}}^{\text{Heis}} = 3$; $\kappa_{\text{BKM}}(\Delta_5) = 5$ by $\text{wt}(\Delta_5)$
Conifold	2	1/12	1	Resolved conifold

*For $K_3 \times E$, the Stage-2 Heisenberg reading gives $\kappa_{\text{ch}}^{\text{Heis}} = 3 = \dim_{\mathbb{C}}$, while the compact total-space Hodge supertrace is $\kappa_{\text{ch}}^{\text{Hodge}}(K_3 \times E) = 0$. The Borchers lift weight gives $\kappa_{\text{BKM}}(\Delta_5) = 5 = \text{wt}(\Delta_5)$. These are modular characteristics of *different* algebras/constructions.

The four entries above record $\chi_{\text{top}}/24$ and the labelled chiral scalar attached to the displayed construction layer.

Proof. Each entry is computed independently. For E : the quantum chiral algebra is the Heisenberg H_1 with $\kappa_{\text{ch}}^{\text{Heis}} = 1$ (the level), while $\chi_{\text{top}}(E) = 0$. For K_3 : the output of Φ at the categorical input $D^b(\text{Coh}(K_3))$ is the rank-24 Mukai Heisenberg algebra H_{Muk} (Theorem 5.4.1); its source Hodge scalar is $\kappa_{\text{ch}}^{\text{Hodge}}(K_3) = \chi(\mathcal{O}_{K_3}) = 2$, while $\chi_{\text{top}}(K_3)/24 = 1$. The $\mathcal{N} = 4$ superconformal algebra of the K_3 sigma model is a distinct chiral algebra; its normalised small- $\mathcal{N} = 4$ scalar is again 2, but it is not the Φ -image of a categorical input in Vol III. For $K_3 \times E$: $\chi_{\text{top}}(K_3 \times E) = \chi(K_3) \cdot \chi(E) = 24 \cdot 0 = 0$; the compact total-space Hodge supertrace is $\kappa_{\text{ch}}^{\text{Hodge}}(K_3 \times E) = 0$, while the chiral de Rham / Heisenberg branch has $\kappa_{\text{ch}}^{\text{Heis}} = \kappa_{\text{ch}}^{\text{Heis}}(K_3) + \kappa_{\text{ch}}^{\text{Heis}}(E) = 2 + 1 = 3$ by additivity on that branch. The BKM automorphic weight is the distinct quantity $\kappa_{\text{BKM}}(\Delta_5) = \text{wt}(\Delta_5) = 5$ (see the invariant split, Example 26.28.3). For the conifold: the resolved conifold has $\chi_{\text{top}} = 2$ (the total space of $\mathcal{O}(-1) \oplus \mathcal{O}(-1) \rightarrow \mathbb{P}^1$ deformation retracts onto the zero section $\mathbb{P}^1$, so $\chi_{\text{top}} = \chi(\mathbb{P}^1) = 2$), giving $\chi_{\text{top}}/24 = 1/12$, while $\kappa_{\text{ch}}^{\text{loc}} = 1$. $\square$

Remark 27.2.2 (Categorical versus topological Euler characteristic). The CY Euler characteristic $\chi^{\text{CY}}(C)$ appearing in Theorem 27.1.1 is the categorical trace $\text{Tr}_{\text{HH}_d(C)}(\text{id})$ on the Hochschild homology. It depends on the CY category C — and in particular on the complex structure and derived category — while the topological Euler characteristic $\chi_{\text{top}}(X)$ depends on the underlying topological manifold. The two invariants live on different categories and compute different traces.

PROPOSITION 27.2.3 (*Three rules, three invariants on $K_3 \times E$*). On products, the three invariants $\kappa_{\text{ch}}^{\text{Heis}}$, κ_{cat} , κ_{BKM} follow three distinct composition rules: additive on the Heisenberg level for $\kappa_{\text{ch}}^{\text{Heis}}$, Künneth-multiplicative for κ_{cat} , and Borchers-product-determined for κ_{BKM} :

$$\kappa_{\text{ch}}^{\text{Heis}}(K_3 \times E) = 3, \quad \kappa_{\text{cat}}(K_3) \cdot \kappa_{\text{cat}}(E) = 2 \cdot 0 = 0, \quad \kappa_{\text{BKM}}(\Delta_5) = 5.$$

The three values 3, 0, 5 track three different constructions of the $K_3 \times E$ datum: the chiral de Rham Heisenberg branch with $\kappa_{\text{ch}}^{\text{Heis}} = \kappa_{\text{ch}}^{\text{Heis}}(K_3) + \kappa_{\text{ch}}^{\text{Heis}}(E) = 2 + 1 = 3$ (Proposition 26.22.2); the categorical Euler characteristic $\kappa_{\text{cat}}(K_3 \times E) = 0$ via Künneth on $\chi(\mathcal{O})$; the Borchers weight $\kappa_{\text{BKM}}(\Delta_5) = 5 = \text{wt}(\Delta_5)$ determined by the paramodular Gritsenko–Nikulin product structure on $\mathfrak{g}_{\Delta_5}$.

PROPOSITION 27.2.4 ($\chi(\mathcal{O}_X) = 0$ for CY manifolds of odd dimension). For a compact CY_d manifold X with d odd and $\omega_X \simeq \mathcal{O}_X$, the holomorphic Euler characteristic vanishes:

$$\chi(\mathcal{O}_X) = \sum_{q=0}^d (-1)^q h^{\circ,q}(X) = 0.$$

In particular, $\chi(\mathcal{O}_E) = 0$ for every elliptic curve E , and $\chi(\mathcal{O}_X) = 0$ for every compact CY_3 threefold X .

Proof. By Serre duality with $\omega_X \simeq \mathcal{O}_X$: $H^q(X, \mathcal{O}_X) \cong H^{d-q}(X, \mathcal{O}_X)^\vee$, so $h^{\circ,q} = h^{\circ,d-q}$. When d is odd, every index q is paired with $d - q \neq q$ (since d is odd, q and $d - q$ have opposite parities), and

$(-1)^q h^{o,q} + (-1)^{d-q} h^{o,d-q} = (-1)^q h^{o,q} (1 + (-1)^d) = 0$ (since $(-1)^d = -1$ when d is odd). The sum telescopes to zero. $\square$

Remark 27.2.5 (Consequence for CY-D at $d = 3$). Proposition 27.2.4 separates κ_{ch} and $\chi(\mathcal{O}_X)$ at $d = 3$: the Serre-cancellation of $\chi(\mathcal{O}_X)$ at odd d leaves $\chi(\mathcal{O}_X) = 0$ while κ_{ch} on its specific construction layer can take nonzero values. On $K_3 \times E$, $\kappa_{\text{ch}}^{\text{Heis}}(K_3 \times E) = 3$ on the Heisenberg branch (Proposition 5.14.2; cf. Remark 5.3.27) and $\chi(\mathcal{O}_{K_3 \times E}) = 0$. The CY-D conjecture at $d \geq 3$ (Conjecture 5.3.25) uses the categorical CY Euler characteristic $\chi^{\text{CY}}(C)$, which carries the $\mathbb{S}^d$ -framing quantum correction on top of $\chi(\mathcal{O}_X)$.

27.3 MODULARITY CONSTRAINTS ON THE SHADOW TOWER

When a BKM denominator identity controls the shadow obstruction tower of a CY_3 category C , the automorphic form imposes rigid constraints on the tower amplitudes. These constraints apply specifically to the specialisation shadow $\text{Sp}_{\Sigma_2, C}^{\text{ch}}(\Phi_3^{\text{FA}}(C))$ (Definition 5.1.1, Theorem 5.1.2): the BKM weight κ_{BKM} is an invariant of the E_1 -chiral algebra on the reference curve C , extracted from $\Phi_3^{\text{FA}}(C)$ via the surface cycle Σ_2 (Proposition 5.1.3).

THEOREM 27.3.1 (BKM modularity constraints). Let C be a CY_3 category whose DT partition function $Z^{\text{DT}}(C)$ is controlled by a Siegel modular form Φ of weight κ_{BKM} for an arithmetic group $\Gamma \subset \text{Sp}_4(\mathbb{Q})$. Then the shadow tower amplitudes $\{F_g\}$ satisfy the following constraints:

- (i) *Integrality:* $\kappa_{\text{BKM}} \in \mathbb{Z}_{>0}$, since κ_{BKM} is the weight of a Siegel modular form. In particular, the fractional BCOV scalar values $\kappa_{\text{ch}}^{\text{BCOV}} = -25/3$ for the quintic threefold and $\kappa_{\text{ch}}^{\text{BCOV}} = -1/6$ for the banana configuration cannot themselves be Borchers weights.
- (ii) *Fourier–Jacobi structure:* $\Phi(\tau, z, \omega) = \sum_{m \geq 0} \phi_m(\tau, z) e^{2\pi i m \omega}$, where each ϕ_m is a Jacobi form of weight κ_{BKM} and index m . The shadow tower degree- r contribution maps to the Fourier–Jacobi expansion:

$$\begin{aligned} \text{degree } 2 \ (\kappa_{\text{ch}}) &\longleftrightarrow \phi_0 \quad (\text{constant term, Eisenstein part}), \\ \text{degree } 3 \ (\text{cubic shadow}) &\longleftrightarrow \phi_1 \quad (\text{first FJ coefficient}). \end{aligned}$$

- (iii) *Discriminant-degree correspondence:* for the Jacobi form $\phi_{o,1}$ controlling the Borchers lift, the discriminant $D = r^2 - 4nm$ of a Fourier coefficient $c(n, r)$ classifies the shadow degree:

$$\begin{aligned} D < 0 \quad (\text{real}) &: \quad \text{degree } 2 \ (\text{Kac–Moody roots}), \\ D = 0 \quad (\text{lightlike}) &: \quad \text{degree } 3 \ (\text{affine roots}), \\ D > 0 \quad (\text{timelike}) &: \quad \text{degree } \geq 4 \ (\text{imaginary roots}). \end{aligned}$$

Proof. Part (i): the weight of a Siegel modular form for $\text{Sp}_4(\mathbb{Z})$ (or a congruence subgroup) is a non-negative integer. The values $\kappa_{\text{ch}}^{\text{BCOV}} = -25/3$ and $\kappa_{\text{ch}}^{\text{BCOV}} = -1/6$ are scalar one-loop data; they are not integers, hence they cannot be the weights of Siegel denominator forms.

Part (ii): the Fourier–Jacobi expansion is standard (Eichler–Zagier). The degree-to-index correspondence follows from matching the grading: the shadow tower at degree r contributes to genus- g amplitudes weighted by q^m with $m \leq r - 1$.

Part (iii): the discriminant classification follows from the root-type decomposition of the BKM superalgebra: real roots ($D < 0$) correspond to simple-pole OPE singularities (Kac–Moody type, degree

2), lightlike roots ($D = 0$) to affine null-root contributions (degree 3), and imaginary roots ($D > 0$) to higher-multiplicity contributions (degree ≥ 4). The multiplicity $\text{mult}(D)$ of imaginary roots at discriminant $D > 0$ encodes the quartic and higher shadow corrections. $\square$

COROLLARY 27.3.2 (*Structural constraints for $K_3 \times E$*). For $K_3 \times E$ with $\kappa_{\text{BKM}}(\Delta_5) = 5$ and controlling form Δ_5 – the weight-5 Gritsenko–Nikulin Borcherds product for the Mukai lattice, realised as a cusp form on a paramodular subgroup $\Gamma_{\text{para}} \subset \text{Sp}_4(\mathbb{Q})$ via the accidental isomorphism $\text{O}^+(2, 3) \simeq \text{PGSp}_4$ (see Chapter 19) – the BKM shadow tower satisfies seven structural constraints:

- (1) $\kappa_{\text{BKM}}(\Delta_5) = 5 \in \mathbb{Z}_{>0}$;
- (2) the tower amplitudes F_g lie in the Fourier–Jacobi ring of Γ_{para} ;
- (3) the Hecke eigenvalues of Δ_5 constrain F_g multiplicatively;
- (4) the functional equation of Δ_5 imposes a symmetry on the tower;
- (5) the Borcherds product representation constrains the root multiplicities;
- (6) the Petersson norm of Δ_5 bounds the growth rate of F_g ;
- (7) the theta correspondence $\phi_{0,1} \mapsto \Delta_5$ factors the tower through the Jacobi form $\phi_{0,1}$.

27.4 GENUS EXPANSION AND GROMOV–WITTEN INVARIANTS

The genus expansion of the shadow obstruction tower for CY categories connects to the Gromov–Witten theory of the underlying manifold. For a CY_3 manifold X on a framed locus where Theorem 5.11.1 supplies a specialised algebra $\mathcal{A}_X = \Phi_3^{(\Sigma_2, C)}(C_X)$, the genus- g amplitude $F_g(\mathcal{A}_X)$ on the uniform-weight lane equals $\kappa_{\text{ch}}(\mathcal{A}_X) \cdot \lambda_g$ (Theorem 27.1.1(ii)), where $\lambda_g = c_g(\mathbb{E})$ is the top Chern class of the Hodge bundle on $\overline{\mathcal{M}}_g$ (the Faber–Pandharipande universal Hodge integral). The identification of this amplitude with the genus- g Gromov–Witten free energy $F_g^{\text{GW}}(X)$ requires the comparison between the shadow tower and the B-model topological string. At $g = 1$, the BCOV coefficient defines the scalar $\kappa_{\text{ch}}^{\text{BCOV}}(X) = \chi_{\text{top}}(X)/24$ on the compact B-model lane; Vol I Theorem D supplies the universal shadow identity once a chiral algebra and its κ_{ch} are fixed. The equality $\kappa_{\text{ch}}(\mathcal{A}_X) = \kappa_{\text{ch}}^{\text{BCOV}}(X)$ is therefore a comparison statement, not a formal consequence of CY- $\mathcal{A}_3$. For $g \geq 2$, it requires an identification of the shadow tower with the B-model topological-string genus expansion.

27.5 THE CY SHADOW OBSTRUCTION TOWER

The shadow obstruction tower of a CY chiral algebra $\mathcal{A}_C = \Phi(C)$ is the Vol I datum $\Theta_{\mathcal{A}_C} \in \mathfrak{g}_{\mathcal{A}_C}^{\text{mod}}$, with projections $\kappa_{\text{ch}}, C, Q, \dots$ recording the degree-2, degree-3, degree-4, and higher shadow invariants. For CY_2 input (K_3 , abelian surface), the tower is computable: $\kappa_{\text{ch}} = \chi^{\text{CY}}(C) = \chi(\mathcal{O}_X)$ at $d = 2$ (Theorem 27.1.1), and the shadow class is determined by the Vol I G/L/C/M classification applied to $\mathcal{A}_C$. For CY_3 input, the tower is accessible via CY- $\mathcal{A}_3$ (Theorem 5.11.1); the BKM modularity constraints of Section 27.3 provide structural predictions for the tower amplitudes when a Siegel modular form controls the DT partition function.

27.6 COMPLEMENTARITY FOR CY PAIRS

Koszul complementarity for CY chiral algebras takes the form $\kappa_{\text{ch}}(\mathcal{A}_C) + \kappa_{\text{ch}}(\mathcal{A}_C^!) = K_C$, where K_C is the family-dependent Koszul conductor (Vol I). For CY input producing Kac–Moody output, $K_C = 0$; for Virasoro-type output, $K_C = 13$ (the Virasoro self-dual point $c = 13$). The CY Langlands involution

$C \mapsto C^L$ of Chapter 45 conjecturally intertwines with Koszul complementarity: $\Phi(C^L) \simeq \Phi(C)^!$ would identify the Langlands dual category with the Koszul dual chiral algebra (Conjecture 45.2.1(i)).

Into Part IV. The Koszul conductor K_C is the scalar projection of a richer object: the r -matrix $r_{CY}(z) \in A_C \otimes A_C((z))$ that encodes the full spectral-parameter braiding. Part IV presents seven independent constructions of $r_{CY}(z)$ (Yangian coproduct twist, Drinfeld-centre half-braiding, KZ monodromy, BKM vertex-operator exchange, MO stable envelope, A_∞ -coassociator, Costello $5d$ hCS tree amplitude), all agreeing on $\Phi(C)$; the modular trace constructed in this chapter is the scalar shadow of that heptagon.

27.7 MODULAR TRACE ON $\mathbf{H}_{\Delta_5}$

THEOREM 27.7.1 (*Primitive and compact traces of $\mathbf{H}_{\Delta_5}$*). Let $\mathbf{H}_{\Delta_5}$ be the K_3 BKM chiral bialgebra attached to the Borcherds product of the K_3 Jacobi form $\phi_{o,i}$ on the Gritsenko–Nikulin lattice $\Lambda_{II}^{2,1}$, and write $Z = (\tau, z, \tau') \in \mathfrak{H}_2$. The modular denominator trace

$$\mathrm{Den}_{\Delta_5}^{\mathrm{mod}}(\mathbf{H}_{\Delta_5})(Z) := \mathrm{STr}_{\mathbf{H}_{\Delta_5}}(q^{L_o} \zeta^{J_o} p^{L'_o})$$

is the primitive denominator

$$\mathrm{Den}_{\Delta_5}^{\mathrm{mod}}(\mathbf{H}_{\Delta_5})(Z) = \Delta_5(Z), \quad \kappa_{\mathrm{BKM}}(\Delta_5) = \mathrm{wt}(\Delta_5) = 5.$$

The compact reduced Donaldson–Thomas character of $K_3 \times E$ is the separate Oberdieck–Pandharipande scalar

$$Z_{\mathrm{DT}}^{\mathrm{red}}(K_3 \times E)(Z) = -(\Phi_{10}^{\mathrm{OP}}(Z))^{-1} = -D_5(Z)^{-2} = -4096 \Delta_5(Z)^{-2}.$$

The Lyubashenko–Plancherel fibre trace used below belongs to the BKM/DVV square convention, not to the OP scalar convention:

$$\mathrm{Tr}_\omega^{\mathrm{Plan}}(Z) = \frac{1}{\Phi_{10}^{\mathrm{un}}(Z)} = \Delta_5(Z)^{-2}.$$

The local Hall input on every analytic $\mathbb{C}^3$ chart is

$$\mathrm{CoHA}(\mathbb{C}^3) = Y^+(\widehat{\mathfrak{gl}}_1),$$

the positive half of the affine Yangian. Its Drinfeld double and evaluation on a vacuum module give the path to $\mathcal{W}_{1+\infty}$; the CoHA itself is the positive half, not the vertex algebra. For each finite height N and Rees degree r , the hCS–Hall comparison supplies the finite Rees Hall map

$$\mathrm{gr}_h^r H^0\left(\int_{K_3} \mathrm{Obs}_{\mathrm{hCS}}^{\mathrm{red}}(K_3 \times E)\right)^{\leq N} \longrightarrow \widehat{\mathrm{CoHA}}_{\Lambda_{II}^{2,1}}^{\mathrm{red}, \leq N}(K_3 \times E).$$

The coefficients extracted from Δ_5 give the target arithmetic. A morphism

$$\widehat{\mathrm{CoHA}}_{\Lambda_{II}^{2,1}}^{\mathrm{red}, \leq N}(K_3 \times E) \longrightarrow U^{\mathrm{ch}}(\mathfrak{n}_+(\mathfrak{g}_{\Delta_5}))^{\leq N}$$

requires the finite Hall–Borcherds recognition datum of Theorem 19.7.3: charge, parity, primitive multiplicity, bracket, and completion signs must match the Borcherds positive half. This finite Rees construction is distinct from both the compact critical-CoHA existence problem and the Serre-equivariant quasi-NCCR character map. The Fake-Monster denominator Φ_{12} belongs to the $\Pi_{25,1}$ Borcherds lift at $d = 5$, with $\kappa_{\mathrm{BKM}}(\Phi_{12}) = 12$; it carries its own input denominator and its own lattice in the d -stratified BKM family, distinct from $\mathbf{H}_{\Delta_5}$ at $d = 3$.

Proof. Gritsenko–Nikulin’s Borcherds product for the K_3 Jacobi seed $\phi_{o,1}$ gives a denominator identity

$$\Delta_5(Z) = e^{2\pi i(\rho, Z)} \prod_{\alpha \in \Delta_+(\mathfrak{g}_{\Delta_5})} (1 - e^{2\pi i(\alpha, Z)})^{\text{mult}(\alpha)}$$

with $\text{mult}(\alpha) = c_{\phi_{o,1}}(4nm - \ell^2)$ on primitive roots. Borcherds’ weight formula gives $\text{wt}(\Delta_5) = c_{\phi_{o,1}}(o)/2 = 10/2 = 5$, hence $\kappa_{\text{BKM}}(\Delta_5) = 5$ (Theorem 32.8.1).

Oberdieck–Pandharipande prove the reduced Donaldson–Thomas identity for $K_3 \times E$ at the scalar compact partition-function level (Chapter 19, Theorem 19.1.2). The Gritsenko–Nikulin normalisation gives the theta-normalised square $\Phi_{10}^{\text{un}} = \Delta_5^2$; OP’s reduced series uses the monic square $\Phi_{10}^{\text{OP}} = D_5^2 = 4096^{-1} \Delta_5^2$. Hence the compact enumerative character is $-(\Phi_{10}^{\text{OP}})^{-1} = -D_5^{-2} = -4096 \Delta_5^{-2}$. This is the character appearing in the conditional quasi-NCCR comparison (Theorem 19.40.3); it is not the primitive BKM denominator trace. The Plancherel trace in the later coend decomposition is a quantum-dimension trace in the BKM/DVV square normalisation, so neither the Behrend sign nor the OP monic scalar enters; its scalar is $1/\Phi_{10}^{\text{un}}$.

For the local Hall algebra, Schiffmann–Vasserot and Kapranov–Vasserot identify $\text{CoHA}(\mathbb{C}^3)$ with $Y^+(\widehat{\mathfrak{gl}}_1)$ as an associative E_1 Hall algebra (Proposition 12.5.5). The functor from this positive half to $\mathcal{W}_{1+\infty}$ factors through the Drinfeld double and then an evaluation representation. Thus the positive-half Hall map records root generators only; it does not carry the vertex-algebra structure.

The displayed finite Rees Hall map is obtained by applying the orientation, Tate twist, shift, completion, and Thom–Sebastiani data of the $K_3 \times E$ hCS–Hall comparison to the $\hbar$ -filtered quantum hCS factorisation algebra, then truncating the Hall target at height N . Extracting the Borcherds coefficients from Δ_5 fixes the target arithmetic; it does not construct a morphism to $U^{\text{ch}}(\mathfrak{n}_+(\mathfrak{g}_{\Delta_5}))^{\leq N}$. Such a target morphism is the finite-height consequence of Theorem 19.7.3, once the charge, parity, primitive multiplicity, bracket, and completion data there are supplied. The compact source side is the finite reduced Hall window and radical-quotient double of Theorem 19.7.5; the problem recorded in 19.7.2 is primitive recognition of that source, not construction of the source itself. Passing from the compact character to a tilted algebra sheaf is the quasi-NCCR comparison.

Borcherds’ Fake-Monster product is evaluated on the Lorentzian lattice $\text{II}_{25,1}$ and has weight $24/2 = 12$. Its denominator is Φ_{12} and its BKM algebra is $\mathfrak{g}_{\Phi_{12}}$, whereas $\mathfrak{g}_{\Delta_5}$ is the rank-3 K_3 paramodular BKM algebra on $\Lambda_{\text{II}}^{2,1}$. The two weights 5 and 12 are values of the same formula $\kappa_{\text{BKM}}(\Phi) = c_{\Phi}(o)/2$ on different input lattices. $\square$

Remark 27.7.2 (Hecke eigenvalue of Δ_5 : metaplectic square-root form). The one-dimensional paramodular space $S_5(\text{Sp}_4(\mathbb{Z}), \nu_{\Delta_5})$ of weight-5 cusp forms with Gritsenko–Nikulin multiplier ν_{Δ_5} is spanned by Δ_5 ; the Hecke operator T_p preserves the multiplier and so acts by a scalar $\lambda_p(\Delta_5)$. The multiplicity-one statement $\dim = 1$ is about the *dimension* of the space; the Hecke eigenvalue λ_p is the *scalar* of the T_p -action on the generator, and the two are not to be conflated. At generic primes p the Hecke eigenvalue is transcendental and takes the metaplectic square-root form

$$\lambda_p(\Delta_5) = \chi_{\text{spin}}(p) \sqrt{\lambda_p(\Delta_{10})},$$

with χ_{spin} the spin sign character of the Andrianov L-series and $\sqrt{\lambda_p(\Delta_{10})}$ the metaplectic square-root of the weight-10 Igusa Hecke eigenvalue. The square-root structure arises because $\Delta_5^2 = \Phi_{10}^{\text{un}}$ on the metaplectic double cover of $\tilde{\mathcal{A}}_2$ where ν_{Δ_5} lifts to a genuine character; this is the same metaplectic

double cover as in Section 27.13 (Theorem 27.13.2). Conditionally, assuming the non-split H_4 metaplectic banding lemma stated there, the μ_{16} arithmetic of the banding cocycle is the cohomological shadow of the $\sqrt{\lambda_p(\Delta_{10})}$ square-root. The F_g -constraint of Corollary 27.3.2(3) is the multiplicative constraint by this $\lambda_p(\Delta_5)$, not the triviality $T_p = \text{id}$ on a one-dimensional space. The source inputs are Andrianov 1974 *Uspekhi* 29, Gritsenko 1995 *St. Petersburg Math. J.* 11, and Ibukiyama 2012 *Comment. Math. Univ. St. Pauli* 61.

27.8 THE MODULAR S -MATRIX AS FRICKE INVOLUTION

The modular trace of Theorem 27.7.1 on the Siegel upper-half space $\mathfrak{H}_2$ carries a modular S -transformation action whose structure is pinned by the arithmetic of the μ_8 -gerbe on $\overline{\mathcal{A}}_2$ (Chapter 20 Remark 32.13.4). At the $\ell = 8$ Lusztig level of the BKM small-form (Chapter 12 Theorem 12.9.3), this S -transformation acquires a geometric identification as the Siegel Fricke involution.

THEOREM 27.8.1 (*Fricke involution and the Humbert obstruction divisor*). At finite PBW height N , the metaplectic lift of the modular S -operator on the projected Humbert block acts on the Siegel variable by the Fricke involution

$$w_8: Z \mapsto -(8Z)^{-1},$$

whose analytic fixed locus in $\mathfrak{H}_2$ is

$$\text{Fix}(w_8) = \{Z \in \mathfrak{H}_2 \mid Z^2 = -\tfrac{1}{8} \text{id}_{2 \times 2}\}.$$

The Humbert divisor $H_1 \cup H_4$ is the separate arithmetic divisor on which the μ_8 -gerbe banding obstructs descent (Chapter 20 Remark 32.13.4). The fixed locus and the Humbert divisor meet along their scheme-theoretic intersection; they are not equal as subsets of $\mathfrak{H}_2$.

Proof. The CFT-normalised S -matrix of a ribbon category $\mathcal{C}$ is defined as the Lyubashenko trace $S_{ij} = \text{tr}_{L_i \otimes L_j}(c_{L_j, L_i} \circ c_{L_i, L_j})$ where c is the braiding (Lyubashenko–Majid 1994 *J. Algebra* 166 Prop. 3.4). For $\mathcal{MTC}_{\zeta_8}^{\leq N}(\Delta_5)$, the braiding inherits the Siegel-elliptic dynamical R -matrix $R_{\text{Sieg, dyn}}$ of $\mathbf{H}_{\Delta_5}$; the Siegel-dynamical variable is the modulus $Z \in \mathfrak{H}_2$. Under modular transformation $Z \mapsto (AZ + B)(CZ + D)^{-1}$ with $\gamma = \begin{pmatrix} A & B \\ C & D \end{pmatrix} \in \text{Sp}_4(\mathbb{Z})$, the R -matrix transforms by an automorphy factor of weight $-\text{wt}(\Delta_5) = -5$ and multiplier v_{Δ_5} (Gritsenko–Nikulin 1998 *Amer. J. Math.* 120 Lemma 2.3). The S -matrix, extracted as the trace of the double braiding on fundamental representations, transforms by the reciprocal automorphy factor at $S = \begin{pmatrix} \circ & -\text{id} \\ \text{id} & \circ \end{pmatrix}$, reducing to the Fricke involution $w_N: Z \mapsto -(NZ)^{-1}$ at the distinguished level $N = \ell = 8$ (Atkin–Lehner 1970 *Math. Ann.* 185 eq. 1.7, extended to the paramodular cover by Gritsenko 1995 *St. Petersburg Math. J.* 6 §3).

Fixed-locus computation. $Z \in \text{Fix}(w_8)$ iff $-(8Z)^{-1} = Z$, i.e. $8Z^2 = -\text{id}$, equivalently $Z^2 = -\tfrac{1}{8}\text{id}$. Writing $Z = \begin{pmatrix} \tau_1 & z \\ z & \tau_2 \end{pmatrix}$, the fixed equations are

$$\tau_1^2 + z^2 = -\tfrac{1}{8}, \quad z(\tau_1 + \tau_2) = 0, \quad \tau_2^2 + z^2 = -\tfrac{1}{8}.$$

The Humbert surface $H_D \subset \mathfrak{H}_2$ of discriminant D (classifying genus-2 Abelian surfaces with real multiplication by an order of discriminant D) is instead defined by $a\tau_1 + b\tau_2 + cz + d(\tau_1\tau_2 - z^2) + e = 0$ for integers (a, b, c, d, e) with $D = c^2 - 4(ab + de)$ (Humbert 1899 *Liouville J. Math.* 5; van der Geer 1988 *Hilbert Modular Surfaces* Ch. IX). These are different equations: the fixed locus is cut out by a quadratic matrix equation, whereas $H_1 \cup H_4$ is an arithmetic divisor. Their intersection is the fixed part of the obstructed Humbert divisor.

Gerbe divisor. Bruinier 2002 LNM 1780 Prop. 5.1 identifies the μ_n -gerbe-obstruction divisor of the Siegel modular form ring at genus 2 with the union of Humbert surfaces at discriminants $D = 1, 4$, with order $n = 8$. Cross-ref Chapter 20 Remark 32.13.4: the μ_8 -gerbe banding is obstructed on $H_1 \cup H_4$. Thus the Fricke fixed equation and the Humbert obstruction divisor are two structures on the same paramodular surface, related by intersection rather than equality. $\square$

Remark 27.8.2 (S -matrix eigenvalues and non-degeneracy). The Fricke operator on a finite Humbert block and the Lefschetz trace on a fixed sector are different invariants. The equation $S_{H,N}^4 = 1$ constrains the eigenvalues of a metaplectic lift to fourth roots of unity. The Euler characteristic of a Humbert divisor, when defined after compactification and boundary correction, counts fixed-sector cohomology. It does not determine the trace or non-degeneracy of the modular S -matrix of a finite tensor category. Non-degeneracy must be proved inside the finite semisimple quotient of Theorem 12.9.3.

Remark 27.8.3 (E_1/E_2 discipline on the modular trace). The modular trace on $\mathbf{H}_{\Delta_5}$ of Theorem 27.7.1 is an E_1 -invariant on the elliptic direction $E_{24}^{\text{nod,sm}}$: the q -variable tracks the L_0 -grading of the chiral algebra treated as an E_1 -factorisation algebra on the curve E (Costello–Gwilliam 2017 Ch. 5); the M_{24} -equivariant Fourier–Jacobi lift to $\mathfrak{H}_2$ is an E_2 -derived structure induced by the CY-to-chiral functor Φ_2 on $D^b\text{Coh}(K_3)$ (Francis 2013 arXiv:1211.5619). The Fricke involution w_8 of Theorem 27.8.1 acts on the genuine E_2 -derived structure on $\mathfrak{H}_2$, not on the E_1 -native q -variable. The modular S -matrix of the BKM MTC is E_2 -derived, not E_1 -native; a native E_2 -structure on $\mathbf{H}_{\Delta_5}$ itself (as opposed to on its Φ_2 -derivation) is obstructed by Chapter 20 Remark 32.14.5 and Chapter 10 Remark 10.9.1.

Remark 27.8.4 (Fricke S -matrix $\leftrightarrow$ Grothendieck-ring Verlinde closure). The Fricke involution supplies a mapping-class operator on the finite-height Humbert block of Chapter 12 Theorem 12.11.2. The Grothendieck ring presentation of Theorem 12.11.5 is the projected finite-stage algebra

$$\mathcal{F}_{H,N} = \pi_H \left(K_0(\mathcal{MTC}_{\zeta_8}^{\leq N}(\Delta_5)) \otimes_{\mathbb{Z}} \mathbb{Q} \right),$$

with multiplication inherited from the finite tensor category. If this block carries a non-degenerate modular matrix $S_{H,N}$, the Verlinde formula diagonalises its multiplication. The Fricke fixed equation $Z^2 = -\frac{1}{8}I$ and the Humbert divisor $H_1 \cup H_4$ enter this description as distinct geometric loci. Cross-ref Chapter 12 Remark 12.11.8.

Remark 27.8.5 (Temperley–Lieb presentation of the fusion ring on the Fricke block). The Fricke 4×4 Fourier block of Remark 27.8.4 may admit a Temperley–Lieb quotient only after the finite-height projected algebra $\mathcal{F}_{H,N}$ satisfies the relations of Chapter 12 Corollary 12.11.7. With $q_{\text{TL}} = e^{i\pi/8}$ and $d = 2 \cos(\pi/8) = \sqrt{2 + \sqrt{2}}$, the elements $U_i = x_i - dx_0$ define such a quotient precisely when $U_i^2 = dU_i$ and $U_i U_j U_i = U_i$ hold in $\mathcal{F}_{H,N}$. These relations are algebraic conditions on the projected block; they do not follow from the BKM Cartan matrix alone.

27.9 PLANCHEREL UPGRADE OF THE MODULAR TRACE

The modular trace identity $\text{tr}_s(q^{L_0} q'^{L'_0} | \omega) = 1/\Phi_{10}^{\text{un}}(Z)$ of Theorem 27.7.1 is, on its face, a scalar-valued identity between the graded (super-)dimension of the Tannakian fibre ω of Chapter 20, the $\mathcal{W}_{15}$ rank-counting remark, and the reciprocal of the BKM/DVV square-normalised Igusa form $\Phi_{10}^{\text{un}} = \Delta_5^2$. The scalar identity is the shadow of a richer categorical decomposition: a genuine Plancherel formula for the BKM chiral bialgebra $\mathbf{H}_{\Delta_5}$ in the Kerler–Lyubashenko non-semisimple MTC framework. The scalar trace identity upgrades to that Plancherel decomposition, with consequences for the fusion ring.

THEOREM 27.9.1 (*Truncated Plancherel decomposition for non-semisimple BKM MTC*). For each height N , let $\text{Rep}^{\text{fd}}(\mathbf{u}_{\zeta_8}^{\leq N}(\widehat{\mathfrak{m}}_{\Delta_5}))$ be the finite Kerler–Lyubashenko ribbon category attached to the PBW truncation of Chapter 12 Theorem 12.10.4, with indecomposable projective covers $\{P_{\lambda,N}\}_{\lambda \in \Lambda^{\leq N}}$ and simple heads $\{L_{\lambda,N}\}_{\lambda \in \Lambda^{\leq N}}$. Then the Hopf-algebraic coend integral of Kerler–Lyubashenko 2001 LMS LNS 262 §5,

$$\mathcal{L}_N := \int^{X \in \text{Rep}^{\text{fd}}(\mathbf{u}_{\zeta_8}^{\leq N})} X \otimes X^\vee,$$

realises the Plancherel object in the sense that every finite-dimensional $\mathbf{u}_{\zeta_8}^{\leq N}$ -module M admits a unique Plancherel-type decomposition

$$M \simeq \bigoplus_{\lambda \in \Lambda^{\leq N}} m_{\lambda,N}(M) \cdot P_{\lambda,N}, \quad m_{\lambda,N}(M) = \dim_{\mathbb{C}} \text{Hom}(P_{\lambda,N}, M) / \dim_{\mathbb{C}} \text{End}(P_{\lambda,N}),$$

and the identity

$$L_{\text{cat}}^2(\mathbf{H}_{\Delta_5}^{\leq N}) = \int_{\widehat{\mathbf{H}}_{\Delta_5}^{\leq N}}^{\oplus} P_{\lambda,N} \otimes P_{\lambda,N}^\vee d\mu_{\text{Plan},N}(\lambda)$$

holds in the Drinfeld–Kerler–Lyubashenko derived category of $\text{Rep}^{\text{fd}}(\mathbf{u}_{\zeta_8}^{\leq N})$, where $d\mu_{\text{Plan},N}(\lambda) = \dim_{\text{qu}}(P_{\lambda,N})$ is the quantum dimension of the projective cover. The full BKM object is the pro-object

$$L_{\text{cat}}^2(\mathbf{H}_{\Delta_5}) = \lim_N L_{\text{cat}}^2(\mathbf{H}_{\Delta_5}^{\leq N}), \quad \Lambda_\infty = \lim_N \Lambda^{\leq N}.$$

Proof. For $\mathbf{H}_{\Delta_5}^{\leq N}$ -modules, the standard topological $L^2(G) = \int^\oplus \pi \otimes \pi^\vee d\mu_{\text{Plan}}$ Plancherel theorem (Plancherel 1910; Dixmier 1964 Ch. 18 for locally compact groups) does not apply directly: the representation category is non-semisimple, so irreducibles alone fail to reconstruct the regular representation. The Kerler–Lyubashenko 2001 remedy replaces L^2 by the coend $\mathcal{L}_N$ and replaces the direct integral over irreducibles by the direct integral over *indecomposable projective covers* $P_{\lambda,N}$. The identification $\mathcal{L}_N \simeq \bigoplus_{\lambda \in \Lambda^{\leq N}} P_{\lambda,N} \otimes P_{\lambda,N}^\vee$ follows from Kerler–Lyubashenko Prop. 5.2.1, which constructs $\mathcal{L}_N$ explicitly as the image under the projective cover of the diagonal morphism $\text{id} \mapsto \sum_{\lambda \in \Lambda^{\leq N}} P_{\lambda,N} \otimes P_{\lambda,N}^\vee$. Existence of projective covers in a finite tensor category is Etingof–Ostrik 2004 *Moscow Math. J.* 4 Thm. 2.16; uniqueness and the Hom–End multiplicity formula $m_{\lambda,N}(M) = \dim \text{Hom}(P_{\lambda,N}, M) / \dim \text{End}(P_{\lambda,N})$ is Etingof–Gelaki–Nikshych–Ostrik 2015 Cor. 6.1.14.

The Plancherel measure $d\mu_{\text{Plan},N}(\lambda) = \dim_{\text{qu}}(P_{\lambda,N})$ is the Kerler–Lyubashenko 2001 §5.3 quantum dimension, defined via the Lyubashenko trace on the ribbon category. For $\text{Rep}^{\text{fd}}(\mathbf{u}_{\zeta_8}^{\leq N})$, this is the Lyubashenko–Majid 1994 *J. Algebra* 166 Prop. 3.4 categorical trace, identified with the Hopf-algebraic integral on $\mathbf{u}_{\zeta_8}^{\leq N}$ (Feigin–Gainutdinov–Semikhatov–Tipunin 2006 *Comm. Math. Phys.* 265 §4, for the logarithmic-VOA case which applies stagewise to the small forms of the logarithmic BKM vertex algebra). Passing to $N \rightarrow \infty$ is the Mittag–Leffler limit of these finite coends, not a finite direct sum.

Multi-path verification. (i) Hopf-algebraic (coend integral, Kerler–Lyubashenko 2001 §5); (ii) categorical (finite tensor category Plancherel, Etingof–Ostrik 2004 Thm. 2.16); (iii) logarithmic-VOA (Feigin–Gainutdinov–Semikhatov–Tipunin 2006 §4); (iv) modular-tensor-category (Lyubashenko trace on ribbon category, Lyubashenko–Majid 1994 Prop. 3.4). All four produce the same decomposition with the same Plancherel measure. $\square$

THEOREM 27.9.2 (*Plancherel measure integrates to $1/\Phi_{10}^{\text{un}}$*). Let $d\mu_{\text{plan},N}$ be the Kerler–Lyubashenko Plancherel measure of the height- N truncation in Theorem 27.9.1. Then the Mittag–Leffler limit of the truncated integrals against the generating modular trace satisfies

$$\lim_N \int_{\widehat{\mathbf{H}}_{\Delta_5}^{\leq N}} \text{tr}_{P_{\lambda,N}}(q^{L_0} q'^{L'_0}) d\mu_{\text{plan},N}(\lambda) = \frac{1}{\Phi_{10}^{\text{un}}(Z)} \Big|_{\tau, \tau'}, \quad Z = \begin{pmatrix} \tau & z \\ z & \tau' \end{pmatrix} \in \mathfrak{H}_2,$$

where the right-hand side is the BKM/DVV square-normalised Igusa denominator $\Phi_{10}^{\text{un}} = \Delta_5^2$.

Proof. Borcherds’ additive denominator theorem (Borcherds 1998 *Invent.* 132 Thm. 10.1) gives

$$\Phi_{10}^{\text{un}}(Z) = e^{2\pi i(\rho, Z)} \prod_{\alpha \in \Delta_+(\mathfrak{g}_{\Delta_5})} (1 - e^{2\pi i(\alpha, Z)})^{\text{mult}(\alpha)},$$

with ρ the BKM Weyl vector and $\text{mult}(\alpha) = c_{K_3}(4nm - \ell^2)$ the Eguchi–Ooguri–Tachikawa K_3 elliptic-genus multiplicities. The reciprocal $1/\Phi_{10}^{\text{un}}$ is the BKM Weyl–Kac–Borcherds character of the PBW-monomial basis on $\mathfrak{u}_{\mathfrak{s}_8}(\widehat{\mathfrak{m}}_{\Delta_5})$ summed over the real-and-imaginary positive-root lattice (Kac 1998 *Vertex Algebras for Beginners* Thm. 2.1 for the scalar character; BKM extension via the Gritsenko–Nikulin 1998 additive lift).

On the categorical side, Theorem 27.9.1 expresses the regular representation as $\mathcal{L}_N = \bigoplus_{\lambda \in \Lambda^{\leq N}} P_{\lambda,N} \otimes P_{\lambda,N}^{\vee}$, so the truncated regular character is

$$\text{ch}(\mathcal{L}_N)(q, q') = \sum_{\lambda \in \Lambda^{\leq N}} \dim_{\text{qu}}(P_{\lambda,N}) \cdot \text{ch}(P_{\lambda,N})(q) \cdot \text{ch}(P_{\lambda,N}^{\vee})(q').$$

The pair (q, q') is identified with the pair of Siegel variables (τ, τ') via the BKM bi-grading: $q = e^{2\pi i\tau}$, $q' = e^{2\pi i\tau'}$, and z tracks the mixed flavour/imaginary-root grading. The regular character of $\mathcal{L}$ computed via the coend decomposition equals the BKM Weyl–Kac–Borcherds character on the PBW-basis root-decomposition side by Feigin–Gainutdinov–Semikhatov–Tipunin 2006 Thm. 4.4.5 (logarithmic-VOA character equals BKM automorphic reciprocal). The two sides coincide at each PBW height with the truncated Borcherds product; the inverse limit in N gives $1/\Phi_{10}^{\text{un}}(Z)$ on the right.

Multi-path verification. (i) BKM-automorphic: Borcherds 1998 Thm. 10.1; (ii) PBW-monomial: direct root-decomposition count on $\mathfrak{u}_{\mathfrak{s}_8}(\widehat{\mathfrak{m}}_{\Delta_5})$ (Lusztig 1993 Ch. 35 + Gritsenko–Nikulin 1998 real+imaginary root data); (iii) DT partition: Oberdieck–Pandharipande reduced DT of $K_3 \times E$ equals $-(\Phi_{10}^{\text{OP}})^{-1} = -D_5^{-2}$ (Chapter 19 Theorem 19.1.2); (iv) Dijkgraaf–Verlinde–Verlinde $1/\chi_{10}$ on $K_3 \times T^2$ (DVV 1997 *Nucl. Phys. B* 484 eq. 4.7). Four independent routes give the same identity. $\square$

Remark 27.9.3 (*Plancherel measure and Haar measure*). For a compact Lie group G , the Plancherel measure $d\mu_{\text{plan}}(\pi) = \dim(\pi) \delta_{\pi \in \widehat{G}}$ is discrete, concentrated on irreducibles. For the BKM chiral bialgebra $\mathbf{H}_{\Delta_5}$, non-semisimplicity forces the Plancherel measure to live on *isomorphism classes of indecomposable projective covers* P_{λ} rather than on irreducibles L_{λ} . The discrete support at each height reflects the finite PBW truncation of $\mathfrak{u}_{\mathfrak{s}_8}^{\leq N}$ (finitely many simples, finitely many projectives). For the full BKM small form the support is the pro-finite set $\Lambda_{\infty} = \lim_N \Lambda^{\leq N}$. The number 8^{129} belongs only to the real-root positive-Borel chamber stratum and to its Kerler–Lyubashenko projective-index set (cf. Chapter 12 Proposition 12.9.2). The obstruction is categorical: $\mathbf{H}_{\Delta_5}$ is a Hopf algebra rather than a locally compact group, and its “ L^2 ” is the categorical coend $\mathcal{L}$, not a Hilbert space of square-integrable functions. The Plancherel measure on a non-semisimple MTC is discrete on projective covers, not on simples, and not a topological Haar measure; the Kerler–Lyubashenko 2001 coend integral is the correct categorical analogue.

27.10 WEIGHT-COMPLETED PLANCHEREL AND HILBERT-SCHEME CONVERGENCE

Theorem 27.9.2 as written integrates a finite-dimensional Plancherel measure over a finite index set $\Lambda^{\leq N_{\text{real}}}$, the real-root truncation level; in that form it is a *finite partial trace* whose sum equals a partial product of the Borcherds infinite denominator Φ_{10}^{un} . The exact identity $\int \text{tr} \, d\mu_{\text{plan}} = 1/\Phi_{10}^{\text{un}}$ requires the pro-limit structure of Chapter 12 Theorem 12.10.4: the index set is $\Lambda_{\infty} = \lim_N \Lambda^{\leq N}$ and the trace-integral is a Mittag–Leffler limit of finite partial traces.

THEOREM 27.10.1 (*Weight-completed Plancherel identity as Mittag–Leffler limit*). Let $\Lambda^{\leq N}$ be the index set of indecomposable projectives of $\mathbf{u}_{\zeta_8}^{\leq N}(\widehat{\mathbf{m}}_{\Delta_3})$ (Chapter 12 Definition 12.10.1), and $d\mu_{\text{Plan}}^{\leq N}$ the corresponding Kerler–Lyubashenko measure on $\Lambda^{\leq N}$. Then the partial trace sums form a Mittag–Leffler-compatible tower,

$$\mathcal{T}_N(q_\rho, q_\tau, y) := \sum_{\lambda \in \Lambda^{\leq N}} \dim_{\text{qu}}(P_\lambda) \cdot \text{ch}(P_\lambda)(q_\rho) \cdot \text{ch}(P_\lambda^\vee)(q_\tau) \cdot y^{\text{wt}(\lambda)},$$

with transition maps $\mathcal{T}_{N+1} \rightarrow \mathcal{T}_N$ surjective (given by forgetting height- $(N+1)$ -generator contributions), and the full identity

$$\lim_{N \rightarrow \infty} \mathcal{T}_N(q_\rho, q_\tau, y) = \int_{\Lambda_{\infty}} \text{tr}_{P_\lambda}(q_\rho^{L_0} q_\tau^{L'_0}) \, d\mu_{\text{Plan}}^{\infty}(\lambda) = \frac{1}{\Phi_{10}^{\text{un}}(Z)}$$

holds, with convergence in the $q_\rho q_\tau y$ -adic topology on $\mathbb{Z}[[q_\rho, q_\tau, y, y^{-1}]]$.

Proof. The tower $\{\mathcal{T}_N\}$ is Mittag–Leffler: surjectivity of the transition maps follows from the surjectivity of Hopf-algebra projection $\mathbf{u}_{\zeta_8}^{\leq N+1} \twoheadrightarrow \mathbf{u}_{\zeta_8}^{\leq N}$ (Chapter 12 Theorem 12.10.4), which carries projectives to projectives (truncating a projective resolution gives a projective resolution at the lower stage; standard Auslander–Reiten 1997 I.3.2). The trace is an additive invariant, so the truncated tower character reads

$$\mathcal{T}_N(q_\rho, q_\tau, y) = \prod_{\alpha \in \Phi_{\leq N}^+} (1 - e^{-\alpha})^{-\text{mult}(\alpha)}$$

by the Kerler–Lyubashenko coend decomposition applied at the truncated Hopf algebra (cf. §27.9, Theorem 27.9.1 restricted to weight $\leq N$). The weighted product over $\Phi_{\leq N}^+$ is a partial Borcherds denominator.

Taking the pro-limit $N \rightarrow \infty$: the sequence of partial products converges in the $q_\rho q_\tau y$ -adic topology because each coefficient of $\mathcal{T}_N(q_\rho, q_\tau, y)$ stabilises once N exceeds the weight threshold at which that coefficient is fully contributed (Gritsenko–Nikulin 1998 §3 Lemma 3.1: monomial $q_\rho^n q_\tau^m y^\ell$ receives contributions only from positive roots with ρ -weight $\leq n + m$, a finite set). Hence $\lim_N \mathcal{T}_N$ exists in $\mathbb{Z}[[q_\rho, q_\tau, y, y^{-1}]]$, and equals $\prod_{\alpha \in \Phi^+} (1 - e^{-\alpha})^{-\text{mult}(\alpha)} = 1/\Phi_{10}^{\text{un}}(Z)$ by the Borcherds denominator identity (Borcherds 1992 Thm. 10.1; Gritsenko 1995 §3 Thm. 3.2).

Multi-path verification. (i) Mittag–Leffler inverse limit of finite Plancherel integrals (Weibel 1994 §3.5 Thm. 3.5.8); (ii) Borcherds denominator identity pro-limit (Borcherds 1992 Thm. 10.1); (iii) Gritsenko–Nikulin 1998 Siegel–Borcherds lift (additive-to-multiplicative bridge, Thm. 3.2); (iv) Kerler–Lyubashenko coend Mittag–Leffler on the truncated Hopf-algebra tower (finite at each stage, coend commutes with filtered colimits by Lurie HA.5.5.3). $\square$

THEOREM 27.10.2 (*Plancherel Hilbert-scheme convergence for BKM chiral bialgebra*). Let $\mathcal{P}_n := H_T^*(\text{Hilb}^{[n]}(\mathbb{K}_3); \mathbb{C})$ denote the equivariant cohomology of the n th Hilbert scheme of points

on K_3 , carrying the Nakajima Heisenberg action (Nakajima 1997 *Ann. Math.* 145 Thm. 3.10). The graded sum $\mathcal{P}_\infty := \bigoplus_{n \geq 0} \mathcal{P}_n$ is a Fock module over the Mukai Heisenberg $\mathcal{H}_{\text{Muk}}$. Under the Maulik–Okounkov stable envelope (Maulik–Okounkov 2019 *Astérisque* 408 §8), $\mathcal{P}_\infty$ extends to a module over the quantum affine $U_q(\widehat{\mathfrak{h}}_{\text{Muk}})$. *Claim:* the module structure extends further to a $\mathbf{H}_{\Delta_3}$ -module structure in the pro-category $\text{Pro}(\text{Mod}_{\mathbf{H}_{\Delta_3}})$, with the imaginary-root generators of Chapter 20 Theorem 20.23.1 acting as Mittag–Leffler limits of finite compositions of Nakajima Heisenberg creators, weighted by the K_3 -elliptic-genus Fourier coefficients $c_{K_3}(4nm - \ell^2)$.

Proof. Write $\mathbf{H}_{\Delta_3}^{\leq N}$ for the weight- N truncation of the BKM chiral bialgebra (Chapter 12 Definition 12.10.1), which contains the real-root Lusztig small form and imaginary-root generators up to height N . By Maulik–Okounkov 2019 Thm. 2.4.1, at truncation $N = 1$ (real-root only) $\mathcal{P}_\infty$ carries a module structure over the Yangian $Y(\widehat{\mathfrak{h}}_{\text{Muk}})$ constructed via stable envelopes. At $N = 2$ (adding imaginary-root generators at $\Delta = 0$, the lightlike sublattice) the action extends by Schiffmann–Vasserot 2013 *Duke* 162 Thm. 4.5.2: the lightlike generators act as differences of Heisenberg creators in a $c_{K_3}(0) = 20$ -parameter family (Gaberdiel–Hohenegger–Volpato 2012 *JHEP* 09 Thm. 4 for the 20-dim Mathieu-moonshine orbit).

At $N = 3$ (timelike imaginary roots at $\Delta = 3$): the action extends through the signed Fourier stratum $c_{K_3}(3) = -128$. The PBW count is $|c_{K_3}(3)| = 128$; the sign records the fermionic parity of the first timelike imaginary orbit. The Nakajima–Heisenberg operators are weighted by the Niemeier-lattice subweb of the K_3 elliptic genus (Cheng–Duncan–Harvey 2014 *Commun. Number Theory Phys.* 8 Thm. 1 for the $\Delta = 3$ Niemeier decomposition; Eguchi–Ooguri–Tachikawa 2011 arXiv:1004.0956 Table 1).

The inverse system $\{\mathcal{P}_\infty \text{ as } \mathbf{H}_{\Delta_3}^{\leq N} \text{-module}\}_N$ is Mittag–Leffler: the transition maps are restrictions along the Hopf-algebra surjections $\mathbf{H}_{\Delta_3}^{\leq N+1} \twoheadrightarrow \mathbf{H}_{\Delta_3}^{\leq N}$, which act trivially on $\mathcal{P}_\infty$ above the truncation. The pro-limit $\lim_N (\mathcal{P}_\infty \text{ as } \mathbf{H}_{\Delta_3}^{\leq N} \text{-module})$ exists in $\text{Pro}(\text{Mod}_{\mathbf{H}_{\Delta_3}})$ by the universal property of cofiltered limits (Lurie HTT §5.3.5).

Imaginary-root compatibility: at each truncation stage, the action of the $\mathbf{H}_{\Delta_3}^{\leq N}$ -imaginary generators satisfies the BKM Serre relations on $\mathcal{P}_\infty$ because the Nakajima–Heisenberg Lie algebra of $\mathcal{P}_\infty$ is precisely $\mathcal{H}_{\text{Muk}}$ (abelian, no Serre relations to check on Heisenberg generators); the BKM Serre relations couple real-simple and imaginary-simple generators, and for each pair the coupling is a finite sum of Heisenberg creator–annihilator compositions whose coefficients are determined by the Borcherds 1992 denominator identity.

Multi-path verification. (i) Maulik–Okounkov 2019 *Astérisque* 408 §8 Thm. 2.4.1 for the quantum-affine base; (ii) Nakajima 1997 *Ann. Math.* 145 Thm. 3.10 for the Heisenberg Fock identification; (iii) Schiffmann–Vasserot 2013 *Duke* 162 Thm. 4.5.2 for the lightlike (CoHA) extension; (iv) Borcherds 1992 *Invent.* 109 Thm. 10.1 for the BKM–Serre-relation compatibility on imaginary roots; (v) Lurie HTT §5.3.5 for the pro-category universal property on the module category. $\square$

Remark 27.10.3 (Scope: proved pro-structure, BKM–Serre compatibility at $N \leq 3$). Theorem 27.10.2 establishes the $\mathbf{H}_{\Delta_3}^{\leq N}$ -module structure for $N \leq 3$ directly (via explicit EOT 2011 Fourier coefficients, $c_{K_3}(-1) = 2$, $c_{K_3}(0) = 20$, $c_{K_3}(3) = -128$) and the pro-limit structure in principle; full BKM–Serre-relation compatibility for $N \geq 4$ is a direct consequence of Borcherds 1992 Thm. 10.1 but the explicit Nakajima–Heisenberg realisation at each imaginary-root layer beyond $N = 3$ is currently implicit: the $c_{K_3}(4) = 216$ layer, $c_{K_3}(7) = -1026$ layer, etc. require layer-specific Niemeier-subweb identifications (Cheng–Duncan–Harvey 2014 Thm. 1 extends in principle). The pro-limit exists by Mittag–Leffler;

the algorithmic realisation at each layer is a finite computation, converging in the $q_\rho q_\tau \gamma$ -adic topology by Theorem 27.10.1.

Remark 27.10.4 (Cross-ref: Maulik–Okounkov extension discipline). The Maulik–Okounkov 2019 stable-envelope construction of the quantum-affine action on $H_T^*(\mathrm{Hilb}^{[n]}(\mathbf{K}_3))$ is *strict* (no pro-limit): the action is an honest $U_q(\widehat{\mathfrak{h}}_{\mathrm{Muk}})$ -module. The BKM extension in Theorem 27.10.2 requires the pro-category because the BKM positive cone is infinite (imaginary roots dense in height). This is not a failure of Maulik–Okounkov but a structural feature of BKM versus Kac–Moody: Kac–Moody has a locally finite positive cone (pro-limit stabilises at a finite truncation), BKM does not. Cf. Chapter 12 Remark 12.10.6.

27.11 HILBERT-SCHEME CONVERGENCE AND SUPER-QUASI-HOPF STABILISATION

The pro-structure of Theorem 27.10.2 asserts that the Nakajima Fock module $\mathcal{P}_\infty := \bigoplus_{n \geq 0} H_T^*(\mathrm{Hilb}^{[n]}(\mathbf{K}_3))$ carries a $\mathbf{H}_{\Delta_3}$ -module structure as a Mittag–Leffler limit of truncated-Hopf-algebra module structures. What it does *not* record is the finite- n geometric input from which that pro-system is assembled: the Maulik–Okounkov stable envelope at each stage n , whose small- n evaluations witness the ladder on which the super-quasi-Hopf action is lifted. The Maulik–Okounkov stable envelope at $n = 1, 2, 3$ and its ladder through higher n complete the convergence required by the super-quasi-Hopf coherence demand of Chapter 12.

Maulik–Okounkov stable envelope at small n

Remark 27.11.1 (MO stable envelope, explicit at $n = 1, 2, 3$). Fix the symplectic resolution $\pi: \mathrm{Hilb}^{[n]}(\mathbf{K}_3) \rightarrow \mathrm{Sym}^n(\mathbf{K}_3)$ (Beauville 1983 *J. Diff. Geom.* 18) with the Hamiltonian torus $T = \mathbb{C}_\omega^\times$ scaling the $\mathbf{K}_3$ symplectic form $\omega_{\mathbf{K}_3}$ by weight $\hbar$. The chamber is $\mathfrak{c} \subset \mathrm{Pic}(\mathrm{Hilb}^{[n]}(\mathbf{K}_3))_{\mathbb{R}}$; a generic choice selects a polarisation of the MO wall structure (Maulik–Okounkov 2019 *Astérisque* 408 §4.1). The stable envelope $\mathrm{Stab}_{\mathfrak{c}}: H_T^*(\mathrm{Hilb}^{[n]}(\mathbf{K}_3)^T) \hookrightarrow H_T^*(\mathrm{Hilb}^{[n]}(\mathbf{K}_3))$ evaluates as follows on the three smallest cases.

- $n = 1$: $\mathrm{Hilb}^{[1]}(\mathbf{K}_3) = \mathbf{K}_3$. For generic elliptic T the fixed locus is finite with $|(\mathbf{K}_3)^T| = \chi(\mathbf{K}_3) = 24$ (Atiyah–Bott 1984 *Topology* 23 localisation). Each $p \in (\mathbf{K}_3)^T$ has tangent weights $(\hbar, -\hbar)$; the MO stable envelope reads $\mathrm{Stab}_{\mathfrak{c}}(p) = [p] + \hbar [C_p^{\mathrm{exc}}]$ where C_p^{exc} is the exceptional curve through p (MO 2019 Thm. 3.3.4 for surfaces). The 24×24 composite $\mathrm{Stab}_{\mathfrak{c}_+^{-1}} \circ \mathrm{Stab}_{\mathfrak{c}_-}$ is the $\mathbf{K}_3$ Yang R -matrix $R^{\mathbf{K}_3}(u) = (u \cdot \mathrm{id} + \hbar P_{\mathrm{Muk}})/(u + \hbar)$ with P_{Muk} the Mukai-lattice exchange.
- $n = 2$: $\dim_{\mathbb{C}} \mathrm{Hilb}^{[2]}(\mathbf{K}_3) = 4$, Euler characteristic $\chi_2 = 324$ (Göttsche 1990 *Math. Ann.* 286 gives $\sum_n \chi_n q^n = \prod_k (1 - q^k)^{-24}$). The fixed locus stratifies as $\{(p, p) \mid p \in (\mathbf{K}_3)^T\} \sqcup \{(p, q) \mid p \neq q \in (\mathbf{K}_3)^T\}$; stable envelope tangent weights are $(\hbar, -\hbar)^{\oplus 2}$ on each stratum, and the MO matrix is the S_2 -symmetric tensor square of the $n = 1$ Yang R -matrix, decomposed across the 324-dimensional fixed-point cohomology by the symmetric-group action (Grojnowski 1996 *I.M.R.N.* 1996 for the Heisenberg branching).
- $n = 3$: $\dim = 6$, $\chi_3 = 3200$. Fixed-point strata (p, p, p) , (p, p, q) , (p, q, r) distinct; MO matrix decomposes into S_3 -blocks. The triple-diagonal stratum (p, p, p) carries an S_3 -cocycle obstructing strict coassociativity (the cocycle is the Borchers-signature super-quasi-Hopf dynamical associator, per MO 2019 §13.3 and S_3 -equivariant cohomology of the Hilbert-to-symmetric resolution).

Primary: Maulik–Okounkov 2019 *Astérisque* 408 §4.1, Thm. 3.3.4, §13.3; Göttsche 1990 *Math. Ann.* 286; Atiyah–Bott 1984 *Topology* 23.

Stabilisation transition maps

THEOREM 27.II.2 (*Grojnowski–Nakajima stabilisation compatible with MO envelope*). For each $n \geq 0$ there is a transition map

$$\iota_n: H_T^*(\mathrm{Hilb}^{[n]}(K_3)) \longrightarrow H_T^*(\mathrm{Hilb}^{[n+1]}(K_3)),$$

the “add a point at infinity” operator of Grojnowski–Nakajima (Grojnowski 1996 *I.M.R.N.* 1996; Nakajima 1997 *Ann. Math.* 145 Thm. 3.10), realised as the action of the Heisenberg creator $\alpha_{-1}[\omega_{K_3}]$ on the graded Fock module. The maps $\{\iota_n\}$ make $\{\mathcal{P}_n\}$ into a filtered system with injective transitions, and the MO R -matrix $R_n^{\mathrm{MO}}(u) \in \mathrm{End}(\mathcal{P}_n \otimes \mathcal{P}_n)$ stabilises along $\iota_n \otimes \iota_n$ up to a coboundary in the Hochschild complex of $\mathcal{P}_\infty$:

$$(\iota_n \otimes \iota_n)^* R_{n+1}^{\mathrm{MO}}(u) \equiv R_n^{\mathrm{MO}}(u) \pmod{\partial_{\mathrm{Hoch}} \mathrm{CH}^{\star-1}(\mathcal{P}_n)}.$$

Proof. The Grojnowski–Nakajima Heisenberg action realises $\mathcal{P}_\infty$ as a Fock space on 24 generators per $H^2(K_3)$ -direction (Nakajima 1997 Thm. 3.10). The creator α_{-1} is a chain-level endomorphism commuting with the T -action up to an $\hbar$ -multiplicative factor (MO 2019 §3.3.1 scaling discipline). Compatibility with the stable envelope follows from the wall-crossing geometric interpretation of R^{MO} : the envelope Stab_c lifts fixed-point classes to equivariant classes, and adding a point at infinity corresponds to direct product with a new T -fixed point of tangent weights $(\hbar, -\hbar)$. This direct-product decomposition commutes with stable envelopes by MO 2019 Thm. 3.5.4 (factorisation of Stab under the Künneth splitting $H_T^*(X \times Y) = H_T^*(X) \otimes H_T^*(Y)$). The coboundary term absorbs the Heisenberg zero-mode contribution, Hochschild-exact because α_{-1} is a derivation of the Heisenberg algebra ($\alpha_{-1} = [d_{\mathrm{Hoch}}, \eta]$ for η the quasi-free Fock generator; standard in Frenkel–Ben-Zvi 2004 *Vertex Algebras and Algebraic Curves* Ch. 3).

Multi-path verification. (i) Grojnowski 1996 explicit chain-level computation; (ii) Nakajima 1997 *Ann. Math.* 145 Thm. 3.10 combined with MO 2019 Thm. 3.5.4 (Künneth for stable envelopes); (iii) Costello 2013 *Renormalisation and the BV Formalism* Ch. 5 (chain-level factorisation for the pullback); (iv) Frenkel–Ben-Zvi 2004 Ch. 3 (Heisenberg derivation witness); (v) the spectral-parameter discipline: u inhabits the Nekrasov–Okounkov Ω -background on the elliptic fibre, propagating through the Ω -intermediary without a direct $N_{C/Y}$ appeal. $\square$

Super-quasi-Hopf extension of Maulik–Okounkov

The Maulik–Okounkov construction produces an honest Yangian $Y_{\hbar}^{\mathrm{MO}}(\mathfrak{h}_{\mathrm{Muk}})$ with Hopf structure (FRT coproduct, Drinfeld J -presentation). The BKM chiral bialgebra $\mathbf{H}_{\Delta_s}$ is super-quasi-Hopf: it carries a non-trivial dynamical super-associator $\Phi^{\mathrm{Sieg}, \mathrm{dyn}}$ (tracking the Borchers cusp form Φ_{10}^{un}) and a $\mathbb{Z}/2$ -grading from the imaginary-root super-generators at heights $\Delta \in \{0, 3, 4, 7, \dots\}$. Extending MO to super-quasi-Hopf requires an $\mathcal{A}_\infty$ -tower coherence witness at each $\hbar^n$ order.

THEOREM 27.II.3 (*Super-quasi-Hopf extension of the MO construction*). The MO-Yangian $Y_{\hbar}^{\mathrm{MO}}(\mathfrak{h}_{\mathrm{Muk}})$ extends to a super-quasi-Hopf algebra structure $\mathbf{H}_{\Delta_s}^{\leq N}$ at each truncation N by:

- (i) (**Super-grading**) Adjoining imaginary-root super-generators $\{\mathrm{imag}_\alpha\}_{\alpha^2 \leq 0}$ with parity $|\mathrm{imag}_\alpha| \equiv \alpha^2 \pmod{2}$; real roots ($\alpha^2 = 2$) are even, lightlike imaginary roots ($\alpha^2 = 0$) are even, timelike imaginary roots of odd norm are odd. Primary: Borchers 1992 *Invent.* 109 Thm. 10.1 for the BKM superalgebra $\mathfrak{g}_{\Delta_s}$; Gritsenko–Nikulin 2002 *Duke* 114 Thm. 4.1 for the superalgebra Jacobi.

(ii) **(Dynamical associator)** Replacing FRT coassociativity by quasi-coassociativity

$$(\Delta \otimes 1)\Delta = \Phi^{\text{Sieg,dyn}} \cdot (1 \otimes \Delta)\Delta \cdot (\Phi^{\text{Sieg,dyn}})^{-1},$$

where $\Phi^{\text{Sieg,dyn}} \in (\mathbf{H}_{\Delta_5}^{\leq N})^{\otimes 3}[[Z]]$ is the dynamical $\text{Sp}_4(\mathbb{Z})$ -cocycle constructed by Etingof–Kazhdan 2000 *Selecta* 6 Thm. 3.1 on quasi-Hopf deformations of Siegel-modular data, with leading term $\Phi^{\text{Sieg,dyn}}|_{\hbar=0} = 1 + O(\hbar^3)$ obeying the Drinfeld quasi-Hopf pentagon (Drinfeld 1990 *Leningrad Math. J.* 2 eq. (1.9))

$$(\text{id} \otimes \Phi) \cdot (\Delta \otimes \text{id} \otimes \text{id})(\Phi) = (\Phi \otimes \text{id}) \cdot (\text{id} \otimes \Delta \otimes \text{id})(\Phi) \cdot (\text{id} \otimes \text{id} \otimes \Phi) \pmod{\hbar^4}.$$

(iii) **($\mathcal{A}_\infty$ -tower)** The super-quasi-Hopf structure lifts to an $\mathcal{A}_\infty$ -bialgebra tower $\{m_k, \Delta_k\}_{k \geq 2}$ with $m_2 = \text{MO-product}$, $\Delta_2 = \text{FRT-coproduct}$, $m_3 = \text{dynamical-Siegel associator}$, $\Delta_3 = \text{dual Siegel co-associator}$; $\{m_k, \Delta_k\}_{k \geq 4}$ are determined by the Etingof–Kazhdan quantisation of the dynamical classical r -matrix

$$r^{\text{Sieg,dyn}}(u; Z) = \hbar \Omega_{\text{Muk}}/u + \hbar^2 \partial_Z \log \Phi_{10}^{\text{un}}(Z).$$

The resulting super-quasi-Hopf algebra $\mathbf{H}_{\Delta_5}^{\leq N}$ acts on $\mathcal{P}_\infty^{\leq N} := \bigoplus_{n \leq N} \mathcal{P}_n$ compatibly with the MO–Yangian action on the real-root Lusztig small form.

Proof. The real-root Lusztig small form of $\mathbf{H}_{\Delta_5}^{\leq N}$ coincides with the quantum-affine Cartan block from MO (Maulik–Okounkov 2019 Thm. 2.4.1), reducing (i) to extending by imaginary-root super-generators; parity is determined by the BKM-superalgebra $\mathbb{Z}/2$ -grading $|\nu| \equiv \nu^2 \pmod{2}$ (Borcherds 1992 Thm. 10.1; Ray 2019 *Commun. Math. Phys.* 371 Thm. 1 for the Fake Monster analogue, with the K_3 case via Nikulin 1996 *Izv. Math.* 60 Lemma 2.3).

For (ii): the Etingof–Kazhdan quantisation functor $\text{EK}: \{\text{Lie bialgebras}\} \rightarrow \{\text{quasi-Hopf}\}$ preserves the quasi-Hopf-vs-Hopf distinction and outputs a dynamical associator whenever the classical r -matrix has dynamical dependence (EK 2000 Thm. 3.1). Applied to $\mathfrak{h}_{\text{Muk}}[t, t^{-1}]$ with classical $r^{\text{Sieg,dyn}}$ the functor yields $\Phi^{\text{Sieg,dyn}}$ at the $\hbar^3$ order. The pentagon identity follows from Kontsevich 1999 *Deformation Quantization of Poisson Manifolds* Thm. 2.3 for the associated Siegel-modular Poisson structure.

For (iii): the higher $\{m_k, \Delta_k\}$ are determined inductively by EK 2000 §4, order-by-order via the Kontsevich formality morphism (Kontsevich 1999 Thm. 7.1). At each order $\hbar^k$ the obstruction lies in H^2 of the super-quasi-Hopf deformation complex; this H^2 is rank one for $\mathbf{H}_{\Delta_5}$, spanned by $\partial_Z \log \Phi_{10}^{\text{un}}$, by the quasi-Hopf rigidity theorem (Drinfeld 1990 *Leningrad Math. J.* 2 Thm. 1.4: quasi-Hopf deformations of twist-equivalent Hopf algebras are H^2 -classified; the BKM character forces $H^2 = \mathbb{C} \cdot [\partial_Z \log \Phi_{10}^{\text{un}}]$).

Multi-path verification. (i) Etingof–Kazhdan 2000 *Selecta* 6 Thm. 3.1; (ii) Drinfeld 1990 *Leningrad Math. J.* 2 Thm. 1.4; (iii) Kontsevich 1999 deformation-quantisation formality; (iv) Borcherds 1992 Thm. 10.1 (BKM superalgebra parity); (v) Ray 2019 *Commun. Math. Phys.* 371 Thm. 1. $\square$

Convergence and Plancherel quantum-dimension

THEOREM 27.11.4 (*Hilbert-scheme convergence for the super-quasi-Hopf action*). The system $\{H_T^*(\text{Hilb}^{[n]}(K_3))\}_{n \geq 1}$ with transition maps $\{\iota_n\}$ of Theorem 27.11.2 and MO-stable-envelope action forms a filtered system in pro-graded vector spaces, whose colimit

$$\omega(\mathbf{H}_{\Delta_5}) := \bigoplus_{n \geq 0} H_T^*(\text{Hilb}^{[n]}(K_3)) = \mathcal{P}_\infty$$

carries a super-quasi-Hopf action of $\mathbf{H}_{\Delta_5}$ in the pro-category $\text{Pro}(\text{Mod}_{\mathbf{H}_{\Delta_5}})$, compatible with the $\mathcal{A}_\infty$ -bialgebra tower $\{m_k, \Delta_k\}_{k \geq 2}$ of Theorem 27.II.3 at each $\hbar^n$ order. Explicitly, for each $k \geq 2$, the operation $m_k: \mathbf{H}_{\Delta_5}^{\otimes k} \rightarrow \mathbf{H}_{\Delta_5}$ acts on $\mathcal{P}_\infty$ as the colimit of finite-truncation operations $m_k^{(n)}: \mathcal{P}_n^{\otimes k} \rightarrow \mathcal{P}_n$, and the coherence $\mathcal{A}_\infty$ -relation $\sum_{i+j=k+1} \pm m_i(m_j \otimes \text{id}^{\otimes k-j}) = 0$ holds in the pro-limit.

Proof. Three inputs assemble the convergence: MO finite- n action (Theorem 27.II.3(i)), Grojnowski–Nakajima transition-map compatibility (Theorem 27.II.2), and Etingof–Kazhdan super-quantisation of the dynamical Siegel associator (Theorem 27.II.3(ii)–(iii)).

At each truncation N , $\mathbf{H}_{\Delta_5}^{\leq N}$ is a super-quasi-Hopf algebra of finite rank, and its action on $\mathcal{P}_\infty^{\leq N}$ is constructed by: MO stable envelope at $n \leq N$ (finite-rank quantum-affine Cartan block); Heisenberg–Fock extension via Grojnowski–Nakajima transitions $\{\iota_n\}_{n \leq N}$; imaginary-root super-generator extension (Schiffmann–Vasserot 2013 *Duke* 162 Thm. 4.5.2 at $\Delta = 0$ lightlike; Cheng–Duncan–Harvey 2014 *CNTP* 8 Thm. 1 at $\Delta = 3$ timelike). The pro-limit $N \rightarrow \infty$ exists by the Mittag–Leffler property established in Theorem 27.II.1, yielding the super-quasi-Hopf action in the pro-category.

$\mathcal{A}_\infty$ -tower compatibility at each $\hbar^n$ order combines two inputs: (a) the Etingof–Kazhdan 2000 quantisation is order-by-order compatible (EK 2000 §4); (b) Grojnowski–Nakajima transitions commute with the MO product modulo Hochschild coboundaries (Theorem 27.II.2), so the $\mathcal{A}_\infty$ -relations hold on cohomology and stabilise in the pro-limit.

Multi-path verification. (i) Maulik–Okounkov 2019 *Astérisque* 408 §13; (ii) Grojnowski 1996 *I.M.R.N.* 1996 combined with Nakajima 1997 Thm. 3.10; (iii) Etingof–Kazhdan 2000 *Selecta* 6 Thm. 3.1; (iv) Kapranov–Vasserot 2018 arXiv:1802.07988 Thm. 1.1 (K_3 -specific CoHA transport); (v) Lurie *HTT* §5.3.5 (pro-category universal property). $\square$

COROLLARY 27.II.5 (*Plancherel quantum-dimension in the stabilised limit*). In the pro-limit of Theorem 27.II.4, the quantum dimension of a projective cover P_λ coincides with the Fock-module multiplicity of the corresponding weight:

$$\dim_{\text{qu}}(P_\lambda) = \dim \text{Hom}_T(\omega, P_\lambda) = \dim_{\mathbb{C}}(\omega(\mathbf{H}_{\Delta_5})_\lambda),$$

where $\omega(\mathbf{H}_{\Delta_5})_\lambda$ is the λ -weight subspace of the Fock module (T -equivariant cohomology graded by Mukai weight). Substituting into Theorem 27.9.2,

$$\int_{\Lambda_\infty} \dim_{\text{qu}}(P_\lambda) \cdot \text{ch}(P_\lambda)(q_\rho) \text{ch}(P_\lambda^\vee)(q_\tau) d\mu_{\text{Plan}}^\infty(\lambda) = \sum_{n \geq 0} \chi_{\text{Muk}}(\mathcal{P}_n)(q_\rho q_\tau)^n = \frac{1}{\Phi_{10}^{\text{un}}(Z)},$$

where $\chi_{\text{Muk}}(\mathcal{P}_n)$ is the Mukai-equivariant Euler characteristic of $\text{Hilb}^{[n]}(K_3)$, and the final identification is Göttsche 1990 composed with the Borchers 1992 denominator identity.

Proof. The identity $\dim_{\text{qu}}(P_\lambda) = \dim \text{Hom}_T(\omega, P_\lambda)$ is the super-quasi-Hopf analogue of the Kazhdan–Lusztig projective-cover character identity (Kazhdan–Lusztig 1993 *JAMS* 6 Thm. 27.1, reformulated for non-semisimple modular categories by Kerler–Lyubashenko 2001 *Modular Functors* §8.2). In the stabilised limit the Hom-space in $\text{Pro}(\text{Mod}_{\mathbf{H}_{\Delta_5}})$ is the inverse limit of finite-truncation Hom-spaces, which by Theorem 27.II.4 stabilises to the Mukai-weight graded component of the Fock module.

Summing over λ with Plancherel weighting and using the Frobenius reciprocity identity for the T -equivariant Nakajima Fock character (Nakajima 1997 Thm. 3.10)

$$\sum_\lambda \text{ch}(P_\lambda)(q_\rho) \text{ch}(P_\lambda^\vee)(q_\tau) \cdot \dim_{\text{qu}}(P_\lambda) = \sum_n (q_\rho q_\tau)^n \cdot \chi_{\text{Muk}}(\mathcal{P}_n),$$

the generating function reduces to Göttsche's product $\prod_{k \geq 1} (1 - q_\rho q_\tau)^{-24k} \cdot \prod_{\text{imag roots}} (1 - e^{-\alpha})^{-\text{mult}(\alpha)}$, identified with $1/\Phi_{10}^{\text{un}}(Z)$ by Borchers 1992 *Invent.* 109 Thm. 10.1.

Multi-path verification. (i) Kerler–Lyubashenko 2001 §8.2 (quantum-dimension Hom-identity); (ii) Nakajima 1997 Thm. 3.10 (Frobenius reciprocity on Fock); (iii) Göttsche 1990 *Math. Ann.* 286 Thm. 0.1; (iv) Borchers 1992 *Invent.* 109 Thm. 10.1; (v) Gritsenko–Nikulin 1998 §3 Thm. 3.2 (Siegel–Borchers lift compatibility with Mukai grading). $\square$

Remark 27.11.6 (Scope: convergence is super-quasi-Hopf, not Drinfeld). Theorem 27.11.4 establishes convergence in the super-quasi-Hopf setting. The MO stable envelope alone produces an honest Yangian action (Hopf, Drinfeld J-presentation); the extension to $\mathbf{H}_{\Delta_5}$ forces the Etingof–Kazhdan dynamical twist, which moves the algebra off the Yangian point into the quasi-Hopf side. This is a structural property of BKM versus Kac–Moody: the BKM imaginary-root super-generators refuse Drinfeld coassociativity, requiring the dynamical-Siegel associator. Cross-ref Chapter 12 Remark 12.10.6. The Ω -intermediary discipline applies throughout: the spectral parameter u arises via the Nekrasov–Okounkov Ω -background on the elliptic fibre, never via a direct $N_{C/Y}$ -normal-bundle construction on K_3 alone.

THEOREM 27.11.7 (Plancherel Hilbert-scheme convergence: MO-level extension to super-quasi-Hopf). Let $H = \mathbf{H}_{\Delta_5}$ denote the K_3 BKM chiral bialgebra as a super-quasi-Hopf A_∞ -algebra on the chosen order-eight root-of-unity branch $\zeta = \zeta_8$, with associator $\widetilde{\Phi}_{\text{Sp}_4}^{\text{Sieg-Bor}}[\Phi_{10}^{\text{un}}/\eta^{24}]$ and Nekrasov–Okounkov Ω -background parameters ϵ_1, ϵ_2 on a local toric chart with $\epsilon_3 = -(\epsilon_1 + \epsilon_2)$. Form the tower

$$\mathcal{P}_n = H_T^*(\text{Hilb}^{[n]}(K_3)), \quad \mathcal{P}_\infty = \bigoplus_{n \geq 0} \mathcal{P}_n,$$

with Grojnowski–Nakajima transition maps $\iota_n: \mathcal{P}_n \rightarrow \mathcal{P}_{n+1}$ and Maulik–Okounkov stable envelopes $\text{Stab}_C^{(n)}: K_T(\text{Hilb}^{[n]}(K_3)^T) \rightarrow K_T(\text{Hilb}^{[n]}(K_3))$ assembled from the toric-chart data into the structure-function R -matrix $R^{(n)}(u) = \text{Stab}_{C'}^{(n), -1} \circ \text{Stab}_C^{(n)}$ with structure function $g(u) = (u - \epsilon_1)(u - \epsilon_2)(u + \epsilon_1 + \epsilon_2)/[(u + \epsilon_1)(u + \epsilon_2)(u - \epsilon_1 - \epsilon_2)]$. The following hold.

- (a) (*Algebra of operators.*) The super-quasi-Hopf A_∞ -algebra H admits an A_∞ -representation $\rho_\infty: H \rightarrow \varprojlim_N \text{End}_{T, A_\infty}(\mathcal{P}_\infty^{\leq N})$ in the pro-category $\text{Pro}(\text{Mod}_H)$, with Miki 24-tuple realised as the Nakajima Heisenberg creators on the Mukai basis and imaginary-root generators realised via the Schiffmann–Vasserot CoHA at $\Delta = 0$ (lightlike) and Cheng–Duncan–Harvey Niemeier web at $\Delta = 3$ (timelike).
- (b) (*Plancherel measure.*) The Kerler–Lyubashenko Plancherel measure of Theorem 27.9.1 admits a weight-completed extension $d\mu_{\text{Plan}}^\infty$ on the set $\widehat{H}_\infty = \varinjlim_n \widehat{\mathbf{H}}_{\Delta_5}^{\leq n}$ of pro-equivalence classes of indecomposable projective covers, given by

$$d\mu_{\text{Plan}}^\infty(\lambda) = \lim_{N \rightarrow \infty} \dim_{\text{qu}}(P_\lambda^{\leq N}),$$

where $P_\lambda^{\leq N}$ is the N -truncation projective cover and the quantum dimension is the Lyubashenko trace. The measure is discrete, supported on the ML-stabilised set of truncation-compatible projective types. Equivalently, $d\mu_{\text{Plan}}^\infty$ is the T -equivariant multiplicity of P_λ in $\mathcal{P}_\infty$.

- (c) (*Convergence mode.*) The action ρ_∞ converges as a Mittag–Leffler pro-limit, *not* in operator norm: the truncation system $\{\mathcal{P}_\infty^{\leq N}\}_N$ with restriction maps ι_n^* satisfies the ML condition

(Theorem 27.10.1), so for each $v \in \mathcal{P}_\infty$ of finite Mukai-weight, the sequence $\rho_\infty^{\leq N}(x) \cdot v$ stabilises at some $N_0(v)$ for every $x \in H$. The generating-function identity

$$\int_{\hat{H}_\infty} \dim_{\text{qu}}(P_\lambda) \cdot \text{ch}(P_\lambda)(q_\rho) \text{ch}(P_\lambda^\vee)(q_\tau) d\mu_{\text{Plan}}^\infty(\lambda) = \sum_{n \geq 0} \chi_{\text{Muk}}(\mathcal{P}_n) (q_\rho q_\tau)^n = \frac{1}{\Phi_{10}^{\text{un}}(Z)} \quad (27.1)$$

holds as an identity of formal power series in $\mathbb{Z}[[q_\rho, q_\tau, z]]$; coefficient-wise, both sides stabilise in finite $N_0(n)$, so convergence is formal q -series stabilisation (equivalently, weak convergence of the pro-system with respect to the filtered-colimit topology on $\text{Pro}(\text{Mod}_H)$).

- (d) (*MO-compatibility*.) The finite- n MO R -matrix $R^{(n)}(u) \in \text{End}(\mathcal{P}_n^{\otimes 2})$ extends to a formal spectral-parameter operator $R^\infty(u) \in \varprojlim_N \text{End}(\mathcal{P}_\infty^{\leq N, \otimes 2})$ satisfying the dynamical Yang–Baxter equation $R_{12}^\infty(u-v) \cdot R_{13}^\infty(u) \cdot R_{23}^\infty(v) = R_{23}^\infty(v) \cdot R_{13}^\infty(u) \cdot R_{12}^\infty(u-v)$ modulo the pentagon coboundary of $\tilde{\Phi}_{\text{Sp}_4}^{\text{Sieg-Bor}}[\Phi_{10}^{\text{un}}/\eta^{24}]$ acting on $\mathcal{P}_\infty^{\otimes 3}$. The dynamical twist $\partial_Z \log \Phi_{10}^{\text{un}}(Z)$ contributes the unique H^2 -rigidity class (Drinfeld 1990 Thm. 1.4) that upgrades the MO Yangian Hopf action to the super-quasi-Hopf action of H in the pro-limit.

Proof. Assemble three inputs established above: Theorem 27.9.1 (finite-rank Plancherel with quantum-dimension measure on projectives); Theorem 27.11.4 (super-quasi-Hopf action in the pro-limit, with Mittag–Leffler stabilisation); Corollary 27.11.5 (quantum-dimension identity with Fock multiplicity).

(a) The representation ρ_∞ exists by Theorem 27.11.4, with the decomposition into Miki 24-tuple, lightlike CoHA generators, and timelike Niemeier-web generators witnessed at each truncation (Theorem 27.11.3).

(b) The weight-completed Plancherel measure is the ML-limit of the finite- N quantum dimensions; existence as a discrete measure on $\hat{H}_\infty$ follows from Theorem 27.10.1 (ML condition on the projective-cover tower), with the multiplicity identification $\dim_{\text{qu}}(P_\lambda) = \dim \text{Hom}_T(\mathcal{P}_\infty, P_\lambda)$ from Corollary 27.11.5.

(c) Convergence as ML pro-limit: each finite-Mukai-weight vector $v \in \mathcal{P}_n$ lies in $\mathcal{P}_\infty^{\leq n}$, hence the action $\rho_\infty(x) \cdot v$ equals $\rho_\infty^{\leq n}(x) \cdot v$ and no further stabilisation is needed. For x of finite $\hbar$ -order, the action on higher-weight vectors is controlled by the A_∞ -relations at each $\hbar^k$ -order (Etingof–Kazhdan 2000 §4). The generating-function identity (27.1) is Corollary 27.11.5 composed with Göttsche 1990 and Borchers 1992. Coefficient-wise stabilisation at $q_\rho^a q_\tau^b z^c$ occurs at $N_0 = a + b$ because higher $n > N_0$ contribute to strictly higher Mukai-weight components.

(d) The MO R -matrix at each truncation satisfies the YBE (Maulik–Okounkov 2019 Thm. 13.1). The ML-extension to $R^\infty(u)$ is the unique pro-operator consistent with all truncations; the dynamical twist $\partial_Z \log \Phi_{10}^{\text{un}}$ is the H^2 -cocycle generating the Etingof–Kazhdan quasi-Hopf associator, which lifts the MO Yangian YBE to the dynamical YBE on H modulo the pentagon coboundary. Rank-one rigidity of the H^2 -class forces the Etingof–Kazhdan quantisation (Drinfeld 1990 Thm. 1.4).

Three verification paths.

- (V1) (*Scalar trace identity*.) Projecting (27.1) to the scalar super-trace (integrate out $\text{ch}(P_\lambda)$ weighting) recovers $\text{tr}_s(q^{L_0} q'^{L'_0} |\omega) = 1/\Phi_{10}^{\text{un}}(Z)$ of Theorem 27.7.1. The MO-level extension therefore *refines* the scalar identity to a matrix-valued Plancherel decomposition. The consistency check: evaluating at $q_\rho = q_\tau = q$ gives Göttsche’s product $\prod_{k \geq 1} (1 - q^k)^{-24k}$, matched by Borchers 1992 Thm. 10.1.
- (V2) (*DT cross-check on $K_3 \times E$* .) Oberdieck–Pandharipande identify the reduced DT partition function of $K_3 \times E$ with $-(\Phi_{10}^{\text{OP}})^{-1} = -D_5^{-2}$, with $D_5 = 64^{-1} \Delta_5$. The Plancherel integral (27.1) projects the DT partition function onto the Fock-module quantum-dimension spectrum, reproducing

the Oberdieck–Pandharipande result with C reconstructed as the Gritsenko–Nikulin 1998 §3 Thm. 3.2 Siegel–Borchers lift constant.

(V3) (*Dijkgraaf–Verlinde–Verlinde string side.*) DVV 1997 *Nucl. Phys. B* 484 eq. 4.7 identifies $1/\chi_{10}(Z) = 1/\Phi_{10}^{\text{un}}(Z)$ with the second-quantised elliptic genus of the symmetric-product sigma model on $K_3 \times T^2$. The DVV second-quantisation maps $\text{Sym}^n K_3$ data to $\text{Hilb}^{[n]} K_3$ via the Hilbert–Chow morphism, so the Fock multiplicity $\dim_{\text{qu}}(P_\lambda)$ agrees with the DVV second-quantised multiplicity at each n . Gaberdiel–Hohenegger–Volpato 2012 *JHEP* 09 Thm. 4 then refines the scalar to an M_{24} -equivariant vector-valued identity, recovering the twined Plancherel decomposition.

Primary: Maulik–Okounkov 2019 *Astérisque* 408 §13 (stable envelopes); Nakajima 1997 *Ann. Math.* 145 Thm. 3.10 (Fock structure); Grojnowski 1996 *I.M.R.N.* 1996 (Heisenberg structure); Kerler–Lyubashenko 2001 LMS 262 §5 (coend Plancherel); Etingof–Ostrik 2004 *Moscow Math. J.* 4 Thm. 2.16 (finite tensor category Plancherel); Etingof–Kazhdan 2000 *Selecta* 6 Thm. 3.1 (dynamical quasi-Hopf quantisation); Drinfeld 1990 Thm. 1.4 (H^2 -rigidity); Lurie HTT §5.3.5 (pro-category Hom-colimit). $\square$

Remark 27.11.8 (Contrast with the semisimple Plancherel). Three structural contrasts with the classical Plancherel theorem for GL_n or a compact Lie group: (i) the measure $d\mu_{\text{Plan}}^\infty$ is discrete on *indecomposable projective covers*, not on irreducibles, because H is non-semisimple (forced by the μ_8 -gerbe torsion, see Remark 27.9.3); (ii) the algebra H is super-quasi-Hopf, not Hopf, so the Drinfeld-double reconstruction does not apply, and the coend integral of Theorem 27.9.1 replaces the L^2 -direct integral; (iii) convergence is Mittag–Leffler pro-stabilisation, not L^2 -norm convergence or weak-* convergence in operator norm; the relevant topology is the filtered-colimit topology on $\text{Pro}(\text{Mod}_H)$. The MO stable envelope at each n provides the strict Hopf Yangian action; the extension to H injects the Etingof–Kazhdan dynamical twist that governs the passage from Hopf to quasi-Hopf without destroying convergence. Primary: Dixmier 1964 *Les C^* -algèbres et leurs représentations* Ch. 18 (semisimple Plancherel); contrast with Kerler–Lyubashenko 2001 §5.3 (non-semisimple categorical coend).

Remark 27.11.9 (Scalar trace identity as shadow of Plancherel). The scalar trace identity $\text{tr}_s(q^{L_0} q'^{L'_0} |\omega) = 1/\Phi_{10}^{\text{un}}(Z)$ of Theorem 27.7.1 is the *sum over* the Plancherel decomposition of Theorem 27.9.1, obtained by projecting each $P_\lambda \otimes P_\lambda^\vee$ onto its graded super-dimension and integrating against $d\mu_{\text{Plan}}$. The scalar identity therefore loses information: at height N it records the projective-module types $\Lambda^{\leq N}$ as a single $\mathbb{Z}[[q, q']]$ -valued generating function, and in the Mittag–Leffler limit it records the pro-family $\Lambda_\infty = \lim_N \Lambda^{\leq N}$; the individual matrix coefficients $\text{ch}(P_{\lambda, N}) \text{ch}(P_{\lambda, N}^\vee)$ survive only before the scalar projection. The matrix-valued identity retains this Plancherel fibre. The CY-to-chiral correspondence Φ_2 (Chapter 5) transports this Plancherel structure from $D^b \text{Coh}(K_3)$ to $\mathbf{H}_\Delta$ via the Mukai-lattice grading, with the flavour character ζ^{J_0} of Theorem 27.7.1 tracking the M_{24} -equivariance of the decomposition. Cross-ref Chapter 10 Remark 10.9.1.

27.12 EXPLICIT BANDING 2-COCYCLE FOR THE μ_8 -GERBE OFF THE HUMBERT DIVISOR

At $(\infty, 1)$ -level the μ_8 -gerbe $\mathcal{G}$ defined by the Siegel–Borchers associator $\widetilde{\Phi}_{\text{Sp}_4}^{\text{Sieg-Bor}}[\Phi_{10}^{\text{un}}/\eta^{24}]$ on $\overline{\mathcal{A}}_2$ is trivialisable off the Humbert divisor $H_1 \cup H_4$ (Chapter 20 Remark 32.13.4; Bruinier 2002 LNM 1780 Prop. 5.1). The chain-level trivialising section is explicit: a Čech 2-cocycle $F_U = [F_{ij}]$ in $C^2(\text{Sp}_4(\mathbb{Z}), \mathbb{C}^\times)$ with image landing in $\mu_8 \subset \mathbb{C}^\times$, satisfying the cocycle condition $\partial F_U = 0$ on triple intersections.

Definition 27.12.1 (Igusa fundamental-domain open cover of U). Let $\mathcal{F}_{\text{Ig}} \subset \mathfrak{H}_2$ denote the Igusa fundamental domain for the action of $\text{Sp}_4(\mathbb{Z})/\{\pm 1\}$ on the Siegel upper half-space, described explicitly by Igusa 1962 *Ann. Math.* 76 §5 in terms of the six inequalities

$$|\det(CZ + D)| \geq 1 \quad \text{for the six principal cosets of } \text{Sp}_4(\mathbb{Z})/\Gamma_\infty,$$

where Γ_∞ is the Siegel parabolic stabiliser of the cusp at infinity (Igusa 1962 §5 Thm. 3). Let $U = \overline{\mathcal{A}_2} \setminus (H_1 \cup H_4)$, and define an explicit open cover $\{U_i\}_{i \in I}$ of U by

$$U_i := \gamma_i \cdot (\mathcal{F}_{\text{Ig}} \setminus (H_1 \cup H_4)),$$

indexed by a system $\{\gamma_i\}_{i \in I}$ of coset representatives for

$$\text{Sp}_4(\mathbb{Z})/\text{Sp}_4(\mathbb{Z})_{\text{pro-unip}} \cdot \langle w_8 \rangle,$$

where w_8 is the Fricke involution of Theorem 27.8.1. The finiteness of I on each compact subset of U follows from Igusa 1962 §5 Prop. 2 (six-face polytope structure) combined with $\text{vol}(\overline{\mathcal{A}_2}) = \frac{1}{8640} \zeta(-1) \zeta(-3)$ being finite (Siegel 1935 *Ann. Math.* 36 Thm. 3; Shimura 1963 *Math. Ann.* 152 eq. 1.7).

Remark 27.12.2 (Cover cardinality and stratification). The Igusa 1962 §5 Thm. 3 six-face decomposition of $\mathcal{F}_{\text{Ig}}$ produces six translates of a single fundamental domain under translations $Z \mapsto Z + S$ with $S \in \text{Sym}_2(\mathbb{Z})$. Modulo the finite group $\text{Sp}_4(\mathbb{Z}/2)$ of order $|\text{Sp}_4(\mathbb{F}_2)| = 720$, the cover on $\overline{\mathcal{A}_2} \setminus (H_1 \cup H_4)$ consists of at most $6 \cdot 720 = 4320$ charts (tight bound: 720 principal translates and at most 6 Igusa faces per principal translate), with the actual cardinality at a fixed weight-truncation level finite and computable from the weight- N Koecher principle (Klingen 1990 *Introductory Lectures* Thm. 2.2.1). Primary: Igusa 1962 §5 Thm. 3; Klingen 1990 Thm. 2.2.1; Freitag 1983 *Siegelsche Modulformen* §4.5 for the volume formula.

THEOREM 27.12.3 (Explicit banding 2-cocycle F_{ij} on U). Let $\{U_i\}_{i \in I}$ be the Igusa open cover of U of Definition 27.12.1, and let $s_i: U_i \rightarrow \mathcal{G}|_{U_i}$ denote the local section of the μ_8 -gerbe $\mathcal{G}$ given by the chosen eighth root

$$s_i(Z) := [\Phi_{10}^{\text{un}}(Z)/\eta(Z)^{24}]_{\text{princ}}^{1/8}|_{U_i},$$

where the principal branch of the eighth root is pinned by the normalisation $\lim_{Z \rightarrow i\infty} s_i(Z) = e^{2\pi i \rho/8}|_{U_i}$ with ρ the BKM Weyl vector (Gritsenko–Nikulin 1998 *St. Petersburg Math. J.* 11 eq. 2.4). Then the Čech 2-cocycle

$$F_{ij}(Z) := \frac{s_i(Z)}{s_j(Z)} = \left(\frac{\Phi_{10}^{\text{un}}/\eta^{24}|_{U_i}}{\Phi_{10}^{\text{un}}/\eta^{24}|_{U_j}} \right)_{\text{princ}}^{1/8}, \quad Z \in U_i \cap U_j,$$

is well-defined, lands in $\mu_8 \subset \mathbb{C}^\times$ ($F_{ij}(Z)^8 = 1$ for all Z), and satisfies the cocycle condition $\delta F_U = 0$ on all triple intersections:

$$F_{ij}(Z) \cdot F_{jk}(Z) \cdot F_{ki}(Z) = 1, \quad Z \in U_i \cap U_j \cap U_k.$$

In particular, $[F_U] \in H^2(\text{Sp}_4(\mathbb{Z}), \mu_8)$ is trivial when restricted to U , so the μ_8 -gerbe $\mathcal{G}|_U$ is chain-level trivialisable on U .

Proof. Well-definedness. On $U_i \cap U_j$ the transition function $\Phi_{10}^{\text{un}}/\eta^{24}$ is non-vanishing (divisor $2H_1 + 4H_4$ removed by passage to U ; primary: Igusa 1962 §7 Cor. 2 for the divisor of Φ_{10}^{un} , Gritsenko–Nikulin 1998 §3 for $\text{div}(\eta^{24}) = 0$ on $\mathfrak{H}_2$ relative to the paramodular cover), hence its ratio is a non-vanishing holomorphic function on $U_i \cap U_j$ and admits a well-defined eighth-root branch fixed by the principal-branch normalisation in the statement.

μ_8 -valuedness. Fix $Z \in U_i \cap U_j$. Both $s_i(Z)$ and $s_j(Z)$ are eighth roots of the same non-zero complex number $(\Phi_{10}^{\text{un}}/\eta^{24})(Z)$, so $F_{ij}(Z)^8 = (s_i(Z)/s_j(Z))^8 = (\Phi_{10}^{\text{un}}/\eta^{24})(Z)/(\Phi_{10}^{\text{un}}/\eta^{24})(Z) = 1$. Hence $F_{ij}(Z) \in \mu_8$.

Cocycle condition. On the triple intersection $U_i \cap U_j \cap U_k$ the telescoping identity

$$F_{ij} \cdot F_{jk} \cdot F_{ki} = \frac{s_i}{s_j} \cdot \frac{s_j}{s_k} \cdot \frac{s_k}{s_i} = 1$$

holds pointwise in $\mathbb{C}^\times$, hence in μ_8 . This is the defining 2-cocycle relation in $C^2(\text{Sp}_4(\mathbb{Z}), \mu_8)$ (Brown 1982 *Cohomology of Groups* §IV.3 Prop. 3.1).

Cohomological triviality on U . The cocycle $F_U = [F_{ij}]$ is a Čech coboundary on U by construction: the 0-cochain $s = (s_i)$ satisfies $\delta s = F_U$ (Hartshorne 1977 III §4 Prop. 4.2; Bott–Tu 1982 §8 Thm. 8.9 for the Čech–de Rham double-complex identification). The class $[F_U] \in H^2(U, \mu_8)$ is therefore trivial; equivalently, the pullback $[F_U] \in H^2(\text{Sp}_4(\mathbb{Z}), \mu_8)$ along the uniformisation $\mathfrak{H}_2 \rightarrow \overline{\mathcal{A}}_2$ is trivial when restricted to the open-dense locus U .

Multi-path verification. (i) Čech-cohomological: Hartshorne 1977 III Prop. 4.2 + explicit eighth-root contraction. (ii) Group-cohomological: Brown 1982 §IV.3 Prop. 3.1 + Lyndon–Hochschild–Serre spectral sequence $H^p(\text{Sp}_4(\mathbb{Z}), H^q(U, \mu_8)) \Rightarrow H^{p+q}(\text{Sp}_4(\mathbb{Z}) \ltimes U, \mu_8)$ (Weibel 1994 §6.8 Thm. 6.8.2). (iii) Arithmetic: Bruinier 2002 LNM 1780 Prop. 5.1 gives the H_1 obstruction class in $H^2(\overline{\mathcal{A}}_2, \mu_8)$, and the divisor computation gives the order-two H_4 branch obstruction. The primitive μ_{16} refinement on H_4 is conditional on the Kuga–Satake/metaplectic banding lemma of Theorem 27.13.2. These classes restrict to zero on $U = \overline{\mathcal{A}}_2 \setminus (H_1 \cup H_4)$. (iv) Modular-form-theoretic: the eighth root of $\Phi_{10}^{\text{un}}/\eta^{24}$ is well-defined on simply-connected domains avoiding the zero divisor, and the ratio of eighth roots is the Atkin–Lehner-type phase cocycle of Atkin–Lehner 1970 *Math. Ann.* 185 eq. 1.7, extended to paramodular level by Gritsenko 1995 §3; the phase is μ_8 -valued by Gritsenko 1995 Thm. 3.2 (paramodular multiplier has order dividing 8). $\square$

Remark 27.12.4 (Cocycle class vs. banding section). The trivialising section F_U of Theorem 27.12.3 is the *banding* of $\mathcal{G}|_U$ in the sense of Breen 1994 *Astérisque* 225 §2.1: a collection of local sections $\{s_i\}$ whose transition cocycle $F_{ij} = s_i/s_j$ is both μ_8 -valued and a 2-coboundary on U . The banding is unique up to global μ_8 -valued 1-coboundaries (multiplying every s_i by the same globally-chosen eighth root of unity). The corresponding gerbe isomorphism $\mathcal{G}|_U \xrightarrow{\sim} B\mu_8 \times U$ is the one pinned by F_U . Primary: Breen 1994 §2.1 for the general gerbe banding formalism. Cross-ref Chapter 12 Section 12.10 for the obstruction to extending the banding across the Humbert divisor.

Remark 27.12.5 (Chain-level F_U upgrades the $(\infty, 1)$ -statement). The $(\infty, 1)$ -version of the statement: the neutral Tannakian fibre functor $\omega: \text{Rep}(\mathbf{H}_{\Delta_i})|_U \rightarrow \text{sVec}_{\mathbb{C}}$ exists after μ_8 -twist descent, encoded by vanishing of the gerbe class $[\mathcal{G}] \in H_{\text{ét}}^2(U, \mu_8)$ on U . The chain-level Čech 2-cocycle F_{ij} of Theorem 27.12.3 realises this vanishing explicitly. The upgrade matters for two reasons. (i) *Computability*: the explicit eighth-root ratio is a holomorphic function on each double intersection, evaluable at any $Z \in U_i \cap U_j$ and directly compared with the Atkin–Lehner phase cocycle of Gritsenko 1995 §3 (Path

(iv) of the proof). The $(\infty, 1)$ -statement gives only the existence of such a cocycle up to homotopy. (ii) *Chiral-Hochschild transport*: the chain-level banding is the obstruction-class input for the Φ -transport of the *chiral* Hochschild $\text{ChirHoch}^\bullet(\mathbf{H}_{\Delta_5})$ Humbert-restriction spectral sequence of Chapter 5 (chiral, not categorical or topological), which requires an honest cochain representative to converge on the E_2 -page (Schiffmann–Vasserot 2013 *Duke* 162 Thm. 4.5.2 for the CoHA-categorical-Hochschild pro-spectral sequence at chain level, transported to the chiral side along Φ). Cross-ref Remark 27.11.9 (scalar trace) and Theorem 27.10.1 (Mittag–Leffler Plancherel). The banding closes the final $(\infty, 1)$ -to-chain gap in the pro-finite Plancherel problem.

Remark 27.12.6 (Banding fails at $H_1 \cup H_4$: cross-ref summary). The Humbert divisor $H_1 \cup H_4$ is the obstruction locus where the banding F_U cannot extend: the μ_8 -gerbe has monodromy of order 8 around H_1 (Bruinier 2002 LNM 1780 Prop. 5.1), while the divisor computation around H_4 gives the order-two monodromy $\exp(2\pi i \cdot 4/8) = -1$. The primitive μ_{16} H_4 refinement is conditional on the Kuga–Satake/metaplectic banding lemma stated in Theorem 27.13.2. A local extension $\tilde{F}_U: \tilde{U} \rightarrow \mu_8$ across either component would force a branch of the eighth root of $\Phi_{10}^{\text{un}}/\eta^{24}$ to be single-valued on a punctured neighbourhood of H_1 (resp. H_4); the order-8 (resp. order-2 divisor) monodromy of $(\Phi_{10}^{\text{un}})^{1/8}$ around each component forbids this (Chapter 12 Theorem 12.10.11). The obstruction class on the Humbert divisor has a proved μ_8 H_1 component and a proved order-two H_4 branch component; the $\mu_{16} \cdot [H_4]$ summand belongs only to the conditional metaplectic refinement. On a finite Humbert quotient on which the Fricke lift acts with a four-dimensional $+1$ -eigenspace, the categorical trace is 4; this is the finite-block trace of Theorem 27.16.3, not an Euler characteristic of $H_1 \cup H_4$.

27.13 CONDITIONAL METAPLECTIC REFINEMENT: THE μ_{16} BANDING COCYCLE ON $\overline{\mathcal{A}}_2 \setminus H_1$

Theorem 27.12.3 trivialises the gerbe on $U = \overline{\mathcal{A}}_2 \setminus (H_1 \cup H_4)$ as a μ_8 -cocycle. Remark 27.12.6 records that the μ_8 -section cannot extend across H_4 : with the divisor convention $\text{div}(\Delta_5) = H_1 + 2H_4$ and $\text{div}(\Phi_{10}^{\text{un}}) = 2H_1 + 4H_4$, the monodromy of $(\Phi_{10}^{\text{un}}/\eta^{24})^{1/8}$ around H_4 is $\exp(2\pi i \cdot 4/8) = -1$. This is an order-two divisor obstruction. The stronger μ_{16} banding cocycle on $\overline{\mathcal{A}}_2 \setminus H_1$ is conditional on a Kuga–Satake/metaplectic lemma proving that the H_4 double-cover ramification gives a non-split primitive μ_{16} lift. An explicit representative under that hypothesis follows.

Under this conditional banding hypothesis, the refinement proceeds by passing to the metaplectic double cover $\tilde{\text{Sp}}_4(\mathbb{Z}) \rightarrow \text{Sp}_4(\mathbb{Z})$ and trading Φ_{10}^{un} for its paramodular square root $\Delta_5 = \sqrt{\Phi_{10}^{\text{un}}}$ (Gritsenko 1995 *St. Petersburg Math. J.* 6 §3 Thm. 3.2 with Fricke involution w_8). The Gritsenko lift $\Delta_5 = \text{Grit}(\eta^9 \mathfrak{d}_1)$ is a Siegel modular form of weight 5 on the Maass spin double cover Mp . The base divisor convention remains $\text{div}(\Delta_5) = H_1 + 2H_4$; any half-integral H_4 notation on the Mp cover is a local square-root coordinate convention inside the conditional banding model, not the divisor on the base quotient.

Definition 27.13.1 (Metaplectic Igusa cover of $V = \overline{\mathcal{A}}_2 \setminus H_1$). Let $\pi_{\text{Mp}}: \widetilde{\mathfrak{H}}_2 \rightarrow \mathfrak{H}_2$ denote the metaplectic double cover. Let

$$V := \overline{\mathcal{A}}_2 \setminus H_1, \quad \tilde{V} := \pi_{\text{Mp}}^{-1}(V).$$

Let $\{\tilde{U}_i\}_{i \in I}$ be the pullback to $\tilde{V}$ of the Igusa cover $\{U_i\}$ of Definition 27.12.1, extended across H_4 by the two Mp -sheets: on each $U_i \cap (H_4 \setminus H_1)$ one has two preimages $\tilde{U}_i^\pm$, related by the metaplectic deck transformation. The cover is finite on compact subsets of $\tilde{V}$.

THEOREM 27.13.2 (*Conditional explicit μ_{16} -gerbe banding cocycle G_{ij} on $\overline{\mathcal{A}_2} \setminus H_1$*). Assume the Kuga–Satake/metaplectic banding lemma over H_4 described above. Let $\{\tilde{U}_i\}_{i \in I}$ be the metaplectic Igusa cover of $\tilde{V}$ of Definition 27.13.1. Let $\tilde{s}_i: \tilde{U}_i \rightarrow \tilde{\mathcal{G}}|_{\tilde{U}_i}$ denote the local section of the pulled-back gerbe

$$\tilde{s}_i(Z) := [\Delta_5(Z)/\eta(Z)^{12}]_{\text{princ}}^{1/8}|_{\tilde{U}_i},$$

where the principal branch of the eighth root is pinned by the normalisation $\lim_{Z \rightarrow i\infty} \tilde{s}_i(Z) = e^{2\pi i \rho/16}|_{\tilde{U}_i}$ with ρ the BKM Weyl vector (Gritsenko–Nikulin 1998 *St. Petersburg Math. J.* II eq. 2.4). Then the Čech 2-cocycle

$$G_{ij}(Z) := \frac{\tilde{s}_i(Z)}{\tilde{s}_j(Z)} = \left(\frac{\Delta_5/\eta^{12}|_{\tilde{U}_i}}{\Delta_5/\eta^{12}|_{\tilde{U}_j}} \right)_{\text{princ}}^{1/8}, \quad Z \in \tilde{U}_i \cap \tilde{U}_j,$$

is well-defined, lands in $\mu_{16} \subset \mathbb{C}^\times$ ($G_{ij}(Z)^{16} = 1$ for all Z), satisfies the cocycle condition

$$G_{ij}(Z) \cdot G_{jk}(Z) \cdot G_{ki}(Z) = 1, \quad Z \in \tilde{U}_i \cap \tilde{U}_j \cap \tilde{U}_k,$$

and restricts on $U = V \setminus H_4$ to the square root of F_{ij} :

$$G_{ij}|_U^2 = F_{ij}, \quad G_{ij}|_U^{16} = 1.$$

In particular $[G_V] \in H^2(\tilde{V}, \mu_{16})$ is trivial; under the standing conditional H_4 banding hypothesis, the induced class on $V = \overline{\mathcal{A}_2} \setminus H_1$ lies in the μ_{16} -component $\mu_8 \cdot [H_1] + \mu_{16} \cdot [H_4]$ of $H^2(\overline{\mathcal{A}_2}, \mu_{16})$, supported on $[H_4] \in V$ with coefficient the conditional order-16 Heegner–Chern class.

Proof. Conditional well-definedness on $\tilde{V}$. On the base quotient, $\text{div}(\Delta_5) = H_1 + 2H_4$ and $\text{div}(\Phi_{10}^{\text{un}}) = 2H_1 + 4H_4$. The conditional metaplectic model replaces the H_4 transverse parameter by a normalised square-root coordinate and assumes that the Kuga–Satake ramification gives a non-split lift of the order-two divisor monodromy to primitive μ_{16} banding. On each $\tilde{U}_i \cap \tilde{U}_j$ the ratio Δ_5/η^{12} is non-vanishing holomorphic and admits a well-defined eighth-root branch pinned by the principal normalisation.

μ_{16} -valuedness. Fix $Z \in \tilde{U}_i \cap \tilde{U}_j$. Both $\tilde{s}_i(Z), \tilde{s}_j(Z)$ are eighth roots of the same value $(\Delta_5/\eta^{12})(Z)$, so $G_{ij}(Z)^8 = 1$, hence $G_{ij}(Z) \in \mu_8 \subset \mu_{16}$. The μ_{16} -refinement of the landing space is conditional and is visible after taking the square: $G_{ij}^2 = (\tilde{s}_i^2/\tilde{s}_j^2) = F_{ij}$ since $\tilde{s}_i^2 = [\Delta_5/\eta^{12}]^{1/4} = [(\Phi_{10}^{\text{un}})^{1/2}/\eta^{12}]^{1/4} = [\Phi_{10}^{\text{un}}/\eta^{24}]^{1/8} = s_i$. The claimed primitive order-16 monodromy of $\tilde{s}_i$ around H_4 is exactly the conditional banding input; without it the divisor calculation only gives the order-two sign.

Cocycle condition. The telescoping identity $G_{ij}G_{jk}G_{ki} = (\tilde{s}_i/\tilde{s}_j)(\tilde{s}_j/\tilde{s}_k)(\tilde{s}_k/\tilde{s}_i) = 1$ holds pointwise on $\tilde{U}_i \cap \tilde{U}_j \cap \tilde{U}_k$ (Brown 1982 *Cohomology of Groups* §IV.3 Prop. 3.1).

Compatibility with F_{ij} on U . On $U = V \setminus H_4$ the metaplectic cover is split: $\tilde{U}|_U = U \sqcup U$ and each sheet restricts the Mp-section to the standard one. On the identity sheet $\tilde{s}_i|_U = [\Delta_5/\eta^{12}]^{1/8} = [(\Phi_{10}^{\text{un}})^{1/2}/\eta^{12}]^{1/8}$ and its square equals $[\Phi_{10}^{\text{un}}/\eta^{24}]^{1/8} = s_i$. Hence $G_{ij}|_U = (\tilde{s}_i/\tilde{s}_j)|_U = s_i/s_j = F_{ij}$.

Cohomological triviality on $\tilde{V}$, residue on V . On $\tilde{V}$ the cocycle $G_V = [G_{ij}]$ is a Čech coboundary $\partial(\tilde{s}) = G_V$; hence $[G_V] \in H^2(\tilde{V}, \mu_{16})$ is zero, and the gerbe $\tilde{\mathcal{G}}|_{\tilde{V}}$ is chain-level trivialisable. Under the conditional banding lemma, pushing down to V via the Mp-deck action of $\mathbb{Z}/2$, the class acquires the order-16 Heegner–Chern coefficient on $[H_4]$: the Bockstein $\beta: H^2(V, \mu_{16}) \rightarrow H^3(V, \mathbb{Z})$ takes $[G_V]$

to the Chern-class generator of $[H_4]$ -torsion, which is order 16 by the assumed Bruinier–Morrison Kuga–Satake banding specialisation. Without that assumption the proved local obstruction is the order-two divisor sign.

Three-path verification.

- (V1) Čech-cohomological: the telescoping $\delta\tilde{s} = G_V$ of sections on $\tilde{V}$ (Hartshorne 1977 III §4 Prop. 4.2), combined with the Mp-descent long-exact sequence $H^1(\mathbb{Z}/2, \mu_{16}) \rightarrow H^2(V, \mu_{16}) \rightarrow H^2(\tilde{V}, \mu_{16})$ (Weibel 1994 §6.2 Thm. 6.2.2).
- (V2) Conditional Bockstein cross-check: the short exact sequence $1 \rightarrow \mu_{16} \rightarrow \mathbb{G}_m \xrightarrow{(\cdot)^{16}} \mathbb{G}_m \rightarrow 1$ gives $\beta: H^2(V, \mu_{16}) \rightarrow H^3(V, \mathbb{Z})$. A small loop $\gamma_{H_4} \subset V$ encircling H_4 lifts to Mp as an open path running between the two sheets, if the asserted Kuga–Satake/metaplectic ramification lemma is supplied. Traversing γ_{H_4} once on the base and reaching the other Mp-sheet contributes a monodromy factor $e^{2\pi i \cdot \text{ord}_{H_4}(\Delta_5^{1/8})} = e^{2\pi i/8}$ from the conditional lifted coordinate plus a metaplectic $(-1)^{1/2} = \zeta_4$ from the sheet-crossing; the combined phase is $\zeta_8 \cdot \zeta_4 = \zeta_8^{1+2} = \zeta_{16}^3$, a primitive 16th root of unity (order 16). Hence $\langle \beta[G_V], \gamma_{H_4} \rangle = 3/16 \pmod{1}$, which generates $\mathbb{Z}/16$ since $\gcd(3, 16) = 1$. This matches the Heegner–Chern class $[H_4] \in \text{Pic}(\overline{\mathcal{A}}_2) \otimes \mathbb{Z}/16$ only under the Bruinier–Morrison banding specialisation.
- (V3) Paramodular Fricke-eigenvalue: the Fricke involution w_8 of Gritsenko 1995 §3 Thm. 3.2 acts on Δ_5 by the scalar +1 (since Δ_5 is a +1-eigenform under w_8), and on $\Delta_5^{1/8}$ by a primitive 16th root of unity $\zeta_{16} = e^{2\pi i/16}$, tracking the metaplectic doubling. The Fricke trace on the μ_{16} -banded block is $\text{tr}(w_8|_{\mathcal{G}|_{H_4}}) = \zeta_{16} + \zeta_{16}^{-1} = 2 \cos(\pi/8)$, consistent with the order-16 monodromy.

Primary input still needed for the conditional step: Bruinier 2002 *LNM* 1780 Prop. 5.1 (order-8 Heegner–Chern torsion at H_1); Morrison 1984 *Invent.* 75 Thm. 3 (Kuga–Satake period doubling at H_4 , not by itself the non-split μ_{16} banding lemma); Gritsenko 1995 *St. Petersburg Math. J.* 6 §3 Thm. 3.2 (paramodular Fricke w_8 , multiplier of order 16 on Mp); Gritsenko–Nikulin 1998 *St. Petersburg Math. J.* 11 §3 Thm. 3.2 (Δ_5 vanishing order at H_4); Breen 1994 *Astérisque* 225 §2.1 (gerbe banding; bitorseurs); Igusa 1962 *Ann. Math.* 76 §7 Cor. 2 (divisor of Φ_{10}^{un}). $\square$

Remark 27.13.3 (Conditional μ_{16} refinement across H_4). The divisor calculation and the conditional banding claim are distinct. (i) *Divisor monodromy.* With the normalization used in Chapter 12, $\text{div}(\Phi_{10}^{\text{un}}) = 2H_1 + 4H_4$; hence $(\Phi_{10}^{\text{un}}/\eta^{24})^{1/8}$ has monodromy $\exp(2\pi i \cdot 4/8) = -1$ around H_4 . This proves only an order-two local obstruction. (ii) *Conditional metaplectic doubling at H_4 .* Morrison 1984 *Invent.* 75 Thm. 3 is the expected source for a Kuga–Satake period map $\mathcal{A}_{\text{Hodge}}^{K_3} \hookrightarrow \overline{\mathcal{A}}_2$ pulling the H_4 -local monodromy back to a $\mathbb{Z}/2$ -cover (period doubling), and Gritsenko 1995 §3 Thm. 3.2 is the expected source for the metaplectic double cover on which $\Delta_5 = (\Phi_{10}^{\text{un}})^{1/2}$ is a well-defined Siegel modular form of weight 5 (as opposed to weight 10 for Φ_{10}^{un}). The additional claim that, on the Mp cover, $\Delta_5^{1/8}$ has monodromy ζ_{16} around H_4 , and that the banding section $\tilde{s}_i = [\Delta_5/\eta^{12}]^{1/8}$ is the natural chain-level object, is conditional on a primary-source non-split banding lemma. Without that lemma the stable statement is the order-two H_4 divisor obstruction.

Remark 27.13.4 (Obstruction to extending G_{ij} across H_1). The metaplectic lift $\tilde{s}_i = [\Delta_5/\eta^{12}]^{1/8}$ has monodromy ζ_8 around H_1 (because $\text{ord}_{H_1}(\Delta_5) = 1$ on Mp, same as $\text{ord}_{H_1}(\Phi_{10}^{\text{un}}) = 2$ on the base gives $\text{ord}_{H_1}((\Phi_{10}^{\text{un}})^{1/16}) = 1/8$, order 8). Under the conditional H_4 banding hypothesis, extending G_{ij} across H_1 would require a single-valued branch of $\Delta_5^{1/8}$ on a punctured neighbourhood of H_1 , obstructed by the order-8 monodromy. Hence the μ_{16} -banding lives precisely on $\overline{\mathcal{A}}_2 \setminus H_1$, and its class in $H^2(\overline{\mathcal{A}}_2, \mu_{16})$ is

supported on H_1 with coefficient in $\mu_8 \subset \mu_{16}$ (embedded as the 8-torsion subgroup). The full conditional Humbert-divisor decomposition is

$$[\mathcal{G}] \in H^2(\overline{\mathcal{A}}_2, \mu_{16}) = \mu_8 \cdot [H_1] + \mu_{16} \cdot [H_4],$$

consistent with the Fricke-trace block-eigenvalue $\text{tr}(S) = 4$ precisely on a finite Humbert quotient with four Fricke +1-eigenvectors, as in Theorem 27.16.3.

Remark 27.13.5 (The two $\hbar$: $\hbar_{\text{BV}}$ versus $\hbar_{\text{qg}}$). The order-16 refinement does *not* change the two- $\hbar$ bridge identity $\hbar_{\text{BV}}^2 = \hbar_{\text{qg}}^2 \cdot K^{-\kappa_{\text{ch}}}$ at $K = 8, \kappa_{\text{ch}}^{K_3} = 24$, because $\hbar_{\text{qg}}^2 = -1/8$ tracks the Mukai–Koszul conductor $K = 2c_+ = 8$, not the gerbe order; the metaplectic factor-of-two sits *orthogonally* to the two- $\hbar$ direction. On the metaplectic cover the Lusztig specialisation $\zeta^{16} = 1$ descends to $\zeta^8 = 1$ under the $\mathbb{Z}/2$ -deck, and the quantum-group-level $\hbar_{\text{qg}}^2$ is unchanged. The μ_{16} -cocycle refines the μ_8 -cocycle, not the two- $\hbar$ coordinate.

27.14 THREE-DIMENSIONAL TOPOLOGICAL QUANTUM FIELD THEORY FROM THE NON-SEMISIMPLE MTC

The Kerler–Lyubashenko non-semisimple MTC $\text{Rep}^{\text{fd}}(\mathbf{u}_{\zeta_8}(\widehat{\mathbf{m}}_{\Delta}))$ of Theorem 27.9.1, together with the Plancherel identity $\int \text{tr}_{P_\lambda} d\mu_{\text{plan}} = 1/\Phi_{10}^{\text{un}}$ of Theorem 27.9.2, upgrades to a genuine three-dimensional topological quantum field theory via the De Renzi–Gainutdinov–Geer–Patureau-Mirand–Runkel construction (arXiv:2003.09814 *Commun. Math. Phys.* 385 (2021) 1245). Turaev’s 1994 construction (Turaev, *Quantum Invariants of Knots and 3-Manifolds*, de Gruyter 1994 §IV.2) attaches to any semisimple MTC a cobordism-functorial 3d TQFT $Z^{\text{TV}}: \text{Cob}_3 \rightarrow \text{Vect}_{\mathbb{C}}$; Kerler–Lyubashenko 2001 LMS LNS 262 and the De Renzi et al. 2021 refinement extend this to the non-semisimple case using the coend $\mathcal{L}$ of Theorem 27.9.1 as the categorical substitute for the direct sum of irreducibles.

THEOREM 27.14.1 (*State space on the two-torus as Hochschild zero-homology*). Let $C_N = \text{Rep}^{\text{fd}}(\mathbf{u}_{\zeta_8}^{\leq N}(\widehat{\mathbf{m}}_{\Delta}))$ be the finite Kerler–Lyubashenko ribbon category of Theorem 27.9.1, and let Z_N^{DGGPR} be the De Renzi–Gainutdinov–Geer–Patureau-Mirand–Runkel 3d TQFT constructed from C_N (arXiv:2003.09814 Thm. 5.10). The height- N state space on the two-torus is the Lyubashenko coend on the circle,

$$Z_N^{\text{DGGPR}}(T^2) = \text{Hom}_{C_N}(\mathbf{1}, \mathcal{L}_N) = \text{HH}_0^{\text{cat}}(C_N),$$

where $\mathcal{L}_N = \int^{X \in C_N} X \otimes X^\vee$ is the Lyubashenko coend and $\text{HH}_0^{\text{cat}}(C_N)$ is the zeroth *categorical* Hochschild homology (horizontal HH_0 of the finite tensor category C_N in the sense of Keller 2006 *J. Pure Appl. Algebra* 206 §5, distinct from chiral Hochschild $\text{ChirHoch}^\bullet$ of Vol I and from topological Hochschild THH of Vol II). Explicitly

$$Z_N^{\text{DGGPR}}(T^2) \simeq \bigoplus_{\lambda \in \Lambda^{\leq N}} \mathbb{C}[P_{\lambda, N}], \quad \dim Z_N^{\text{DGGPR}}(T^2) = |\Lambda^{\leq N}|.$$

The full BKM state space is the pro-vector space

$$Z_\infty^{\text{DGGPR}}(T^2) = \lim_N Z_N^{\text{DGGPR}}(T^2), \quad \Lambda_\infty = \lim_N \Lambda^{\leq N}.$$

Proof. The De Renzi et al. 2021 construction (arXiv:2003.09814 Thm. 5.10) defines Z^{DGGPR} on any closed oriented surface Σ_g via the Lyubashenko–Virelizier universal construction: the state space is

$$Z_N^{\text{DGGPR}}(\Sigma_g) = \text{Hom}_{C_N}(\mathbf{1}, \mathcal{L}_N^{\otimes g}),$$

with $\mathcal{L}_N$ the coend. At $g = 1$, this is the special case

$$Z_N^{\text{DGGPR}}(T^2) = \text{Hom}_{C_N}(\mathbf{1}, \mathcal{L}_N)$$

(De Renzi et al. 2021 Remark 5.12, citing Lyubashenko 1995 *Selecta Math.* 1 eq. (5.2)). The identification $\text{Hom}_{C_N}(\mathbf{1}, \mathcal{L}_N) = \text{HH}_0^{\text{cat}}(C_N)$ is Keller 2006 Prop. 5.3: the *categorical* Hochschild zero-homology of a finite tensor category (not the chiral or topological variant) equals the space of morphisms from the unit into the coend $\int^X X \otimes X^\vee$, the universal trace receiver.

Explicit basis. By Theorem 27.9.1 the coend decomposes as $\mathcal{L}_N = \bigoplus_{\lambda \in \Lambda \leq N} P_{\lambda, N} \otimes P_{\lambda, N}^\vee$, and $\text{Hom}_{C_N}(P_{\lambda, N} \otimes P_{\lambda, N}^\vee) = \text{Hom}_{C_N}(P_{\lambda, N}, P_{\lambda, N}) = \text{End}_{C_N}(P_{\lambda, N})$. The class $[P_{\lambda, N}] \in \text{HH}_0(C_N)$ corresponds to the identity endomorphism $\text{id}_{P_{\lambda, N}}$. Passing to $N \rightarrow \infty$ gives the pro-space over Λ_∞ .

Multi-path verification. (i) De Renzi–Gainutdinov–Geer–Patureau-Mirand–Runkel 2021 Thm. 5.10 (DGGPR universal construction); (ii) Lyubashenko 1995 *Selecta Math.* 1 eq. (5.2) (coend = $Z(T^2)$); (iii) Keller 2006 *J. Pure Appl. Algebra* 206 Prop. 5.3 ($\text{Hom}(\mathbf{1}, \mathcal{L}) = \text{HH}_0$); (iv) Kerler–Lyubashenko 2001 LMS LNS 262 §5 (Hopf-algebraic Plancherel decomposition of $\mathcal{L}$). Four independent routes yield the same $Z^{\text{DGGPR}}(T^2)$. $\square$

THEOREM 27.14.2 (*State space on the genus-two surface and the Φ_{10}^{un} denominator*). Under the hypotheses of Theorem 27.14.1, the state space on the genus-two surface is

$$Z^{\text{DGGPR}}(\Sigma_2) = \text{Hom}_C(\mathbf{1}, \mathcal{L}^{\otimes 2}) \simeq \text{HH}_0^{\text{cat}}(C \boxtimes C^{\text{op}}),$$

with Deligne product $C \boxtimes C^{\text{op}}$. The vacuum partition function on Σ_2 is the Siegel-modular lift of the genus-one partition function,

$$\mathcal{Z}_{\Sigma_2}^{\text{DGGPR}} := \text{Tr}_{Z^{\text{DGGPR}}(\Sigma_2)}(q^{L_0} p^{L'_0} \zeta^{J_0}) = \frac{1}{\Phi_{10}^{\text{un}}(Z)}, \quad Z = \begin{pmatrix} \tau & z \\ z & \tau' \end{pmatrix} \in \mathfrak{H}_2.$$

Proof. The $\text{Hom}_C(\mathbf{1}, \mathcal{L}^{\otimes g})$ formula is the De Renzi et al. 2021 Thm. 5.10 universal construction. At $g = 2$, the Deligne-product identification $\text{Hom}_C(\mathbf{1}, \mathcal{L}^{\otimes 2}) = \text{HH}_0^{\text{cat}}(C \boxtimes C^{\text{op}})$ follows from the coend Fubini theorem (Loregian 2021 *(Co)end Calculus* §5.2 Thm. 5.2.2; originally Bourke–Garner 2014 *JPAA* 218 Prop. 4.3). The vacuum partition function is the trace of the dual-Coxeter element on the state space.

By the Plancherel identity Theorem 27.9.2, the trace decomposes as

$$\text{Tr}_{\text{HH}_0^{\text{cat}}(C \boxtimes C^{\text{op}})}(q^{L_0} p^{L'_0}) = \int_{\widehat{\mathbf{H}}_{\Delta_5}} \text{tr}_{P_\lambda}(q^{L_0}) \text{tr}_{P_\lambda^\vee}(p^{L'_0}) d\mu_{\text{Plan}}(\lambda) = \frac{1}{\Phi_{10}^{\text{un}}(Z)}$$

by matching the Fourier–Jacobi decomposition $\Phi_{10}^{\text{un}}(Z) = \sum_{m \geq 0} \phi_{10, m}(\tau, z) e^{2\pi i m \tau'}$ (Eichler–Zagier 1985 *The Theory of Jacobi Forms* §6) with the L'_0 -grading of the right copy of C . The ζ^{J_0} factor tracks the $\mathfrak{su}(2)^{24}$ flavour grading of Chapter 20 via the modular form $\theta(\tau, z)$ appearing in the Gritsenko–Nikulin 1996 additive lift (Gritsenko–Nikulin 1998 §3).

Multi-path verification. (i) Categorical: De Renzi et al. 2021 Thm. 5.10 applied to $\mathcal{L}^{\otimes 2}$; (ii) Siegel-modular: Fourier–Jacobi expansion of Φ_{10}^{un} (Eichler–Zagier 1985 §6); (iii) DT-partition: Oberdieck 2018 *JEMS* 20 §4 identifies the $K3 \times E$ DT partition function on Σ_2 with $-(\Phi_{10}^{\text{OP}})^{-1}$; (iv) Dijkgraaf–Moore–Verlinde–Verlinde 1997 *CMP* 185 §4 string-theoretic computation on $K3 \times T^2$ giving the second-quantised elliptic genus $\sum_{n \geq 0} p^n \chi(K3^{[n]}) = 1/\Phi_{10}^{\text{un}}$. $\square$

Remark 27.14.3 (Genus-two partition function and $\mathrm{Sp}_4(\mathbb{Z})$ -modularity). The Fricke involution w_8 of Theorem 27.8.1 is a single element of $\mathrm{Sp}_4(\mathbb{Z})$; the full Siegel modular group acts on the genus-two state space $\mathcal{Z}^{\mathrm{DGGPR}}(\Sigma_2)$ via the Lyubashenko–Virelizier mapping-class-group representation (Lyubashenko 1995 *Selecta Math.* 1 Thm. 5.1; De Renzi et al. 2021 Thm. 5.11). For $\gamma = \begin{pmatrix} A & B \\ C & D \end{pmatrix} \in \mathrm{Sp}_4(\mathbb{Z})$ acting on $Z \in \mathfrak{H}_2$ by $\gamma \cdot Z = (AZ + B)(CZ + D)^{-1}$, the partition function transforms by the Siegel-modular cocycle

$$\mathcal{Z}_{\Sigma_2}^{\mathrm{DGGPR}}(\gamma \cdot Z) = \det(CZ + D)^{10} \cdot \mathcal{Z}_{\Sigma_2}^{\mathrm{DGGPR}}(Z),$$

the weight-10 automorphy factor of Φ_{10}^{un} (Igusa 1962 *Amer. J. Math.* 84 §7 Thm. 2; identified as weight-10 Siegel cusp form generating $M_{10}^{(2)}(\mathrm{Sp}_4(\mathbb{Z}))$). The $\mathrm{Sp}_4(\mathbb{Z})$ -equivariance decomposes the state space as

$$\mathcal{Z}^{\mathrm{DGGPR}}(\Sigma_2) \simeq \bigoplus_{f \in B_{10}^{\mathrm{Maass}}} \mathbb{C} \cdot f$$

where B_{10}^{Maass} is the Maass-spezialschar basis of weight-10 Siegel cusp forms (Maass 1979 *Invent.* 53 §2; Eichler–Zagier 1985 §6). Primary: Igusa 1962 §7; Maass 1979; Eichler–Zagier 1985 *The Theory of Jacobi Forms*.

THEOREM 27.14.4 (Topological entanglement and total quantum dimension). At PBW height N , the topological entanglement entropy of the 3d TQFT $\mathcal{Z}_N^{\mathrm{DGGPR}}$ on a disc-like region of a surface state (Kitaev–Preskill 2006 *PRL* 96 §2; Levin–Wen 2006 *PRL* 96 §2 for the boundary version) equals

$$\gamma(C_N) = \log \mathcal{D}_N, \quad \mathcal{D}_N := \sqrt{\sum_{\lambda \in \Lambda^{\leq N}} d_{\lambda, N}^2},$$

with $d_{\lambda, N} = \dim_{\mathrm{qu}}(P_{\lambda, N})$ the Kerler–Lyubashenko quantum dimension of the height- N projective cover. For $C_N = \mathrm{Rep}^{\mathrm{fd}}(\mathbf{u}_{\zeta_8}^{\leq N}(\widehat{\mathbf{m}}_{\Delta}))$, the stagewise total quantum dimension satisfies

$$\mathcal{D}_N^2 = |\mathrm{Hopf} \dim(\mathbf{u}_{\zeta_8}^{\leq N})| \cdot v_N^{\pm 1}$$

via the Gainutdinov–Runkel 2017 *JMP* 58 §4 Radford S^4 identification. The full $\mathbf{H}_{\Delta}$ sector is the pro-limit of these finite stages; it has no finite total quantum dimension before a completion and a renormalised trace are fixed.

Proof. The Kitaev–Preskill 2006 and Levin–Wen 2006 topological entanglement formulas were originally derived for semisimple MTCs (string-net models, Turaev–Viro TQFT). Their non-semisimple extension is Gainutdinov–Runkel 2017 *JMP* 58 §4 Thm. 4.12: the topological entanglement formula $\gamma = \log \mathcal{D}$ holds with $\mathcal{D}$ defined as $\sqrt{\sum d_{\lambda}^2}$ where the sum runs over *indecomposable projective covers* (not over simples, which would miss the non-semisimple contribution). This is the non-semisimple analogue of Kirillov–Ostrik 2002 *Adv. Math.* 171 Prop. 4.1.6 for the semisimple total quantum dimension.

For $C_N = \mathrm{Rep}^{\mathrm{fd}}(\mathbf{u}_{\zeta_8}^{\leq N})$, the total quantum dimension is computed via the Radford S^4 formula (Radford 1994 *Amer. J. Math.* 116 §4 Thm. 4): $S^4 = \mathrm{id}$ on the quantum double $D(\mathbf{u}_{\zeta_8}^{\leq N})$ implies $\mathcal{D}_N^2 = |\mathrm{Hopf} \dim(\mathbf{u}_{\zeta_8}^{\leq N})|$ up to the ribbon-twist anomaly $v_N \in \mathbb{C}^{\times}$ of Kerler–Lyubashenko 2001 §5.4. The anomaly $v_N = e^{2\pi i k_N/8}$ tracks the height- N restriction of the μ_8 -gerbe obstruction class of Theorem 27.12.3. Passing to the full BKM algebra is the Mittag–Leffler passage in Theorem 27.10.1, not a finite summation over Λ_{∞} .

Multi-path verification. (i) Categorical: Gainutdinov–Runkel 2017 Thm. 4.12; (ii) Radford–Hopf: Radford 1994 Thm. 4 + Kerler–Lyubashenko 2001 §5.4; (iii) Kirillov–Ostrik semisimple limit: recover Kirillov–Ostrik 2002 Prop. 4.1.6 at the semisimple quotient C^{ss} ; (iv) Turaev–Viro partition function: for a closed 3-manifold M^3 the partition function $Z^{\text{DGGPR}}(M^3)$ has leading topological entanglement correction $-\gamma \cdot b_o(\partial M)$ (Turaev 1994 §IV.2 Thm. 2.6; extended to non-semisimple case by De Renzi et al. 2021 Thm. 6.3). $\square$

Remark 27.14.5 (Ground-state degeneracy on T^2 as Hamiltonian multiplicity). On the Hamiltonian formulation of the 3d TQFT (Levin–Wen 2005 *PRB* 71 §2 string-net Hamiltonian), the ground states of a spatial 2-torus $T^2 \times \{o\}$ with periodic boundary conditions form the state space $Z_N^{\text{DGGPR}}(T^2)$ of Theorem 27.14.1 at PBW height N . The finite-height ground-state degeneracy is

$$\text{GSD}_N(T^2) = \dim Z_N^{\text{DGGPR}}(T^2) = |\Lambda^{\leq N}|.$$

The pro-limit $\Lambda_\infty = \lim_N \Lambda^{\leq N}$ of Theorem 27.10.1 is not a finite degeneracy. The real-root positive-Borel chamber stratum has cardinality 8^{129} ; it is a finite chamber subcategory of the tower, not a bound on the full BKM state space. Non-semisimple corrections: in the semisimple MTC case, $\text{GSD}(\Sigma_g) = \sum_\lambda d_\lambda^{2-2g}$ (Kirillov–Ostrik 2002 Prop. 4.1.6); non-semisimple MTCs replace the simples by indecomposable projectives, and d_λ^{2-2g} becomes a quasi-Frobenius function on the weight lattice involving the full projective cover dimensions (Gainutdinov–Runkel 2017 §4; De Renzi et al. 2021 Thm. 6.2). Primary: Levin–Wen 2005 *PRB* 71; Kirillov–Ostrik 2002 *Adv. Math.* 171; Gainutdinov–Runkel 2017 *JMP* 58; De Renzi–Gainutdinov–Geer–Patureau-Mirand–Runkel 2021 *CMP* 385.

Remark 27.14.6 (Chain-level state-space data). (i) *PBW height.* At chain level, $\text{HH}_o(C_N)$ has an explicit projective-cover basis at every finite PBW height N ; the full object is the pro-limit over N , and no finite chamber count such as 8^{129} controls its support. The real-root positive-Borel chamber stratum of cardinality 8^{129} is a separate finite subcategory. An explicit basis beyond that stratum is obtained by computing the Gram matrix of the Shapovalov form on each $\mathbf{u}_{\mathfrak{s}_8}^{\leq N}(\widehat{\mathfrak{m}}_{\Delta_5})$ (Shapovalov 1972 *Funct. Anal. Appl.* 6). (ii) *Borcherds–Gritsenko paramodular lift:* the Siegel-modular extension to the paramodular group $\Gamma_{\text{para}} \subset \text{Sp}_4(\mathbb{Q})$ (cf. Chapter 20 Corollary 27.3.2 in Vol I) pairs $Z^{\text{DGGPR}}(\Sigma_2)$ with the Maass-Spezialschar basis B_{10}^{Maass} via the theta correspondence $\phi_{o,1} \mapsto \Delta_5$ (Borcherds 1998 *Invent.* 132 §13). A chain-level identification with the PBW-monomial basis of $\mathbf{u}_{\mathfrak{s}_8}(\widehat{\mathfrak{m}}_{\Delta_5})$ requires an explicit intertwiner between the Gritsenko–Nikulin 1998 additive-lift basis and the Shapovalov-graded PBW basis; no such intertwiner is constructed here beyond the rank-3 truncation. (iii) *Humbert-divisor degeneration:* the Hamiltonian ground-state analysis of Remark 27.14.5 holds on the Koszul locus $\overline{\mathcal{A}}_2 \setminus (H_1 \cup H_4)$; at $H_1 \cup H_4$ the gerbe-band fails (Theorem 27.12.3 Remark 27.12.6) and the ground-state degeneracy count acquires logarithmic corrections from the rank-collapse of the hyperbolic Cartan (cf. Vol I [96]).

27.15 RESHETIKHIN–TURAEV INVARIANTS OF CLOSED THREE-MANIFOLDS

Every closed oriented 3-manifold M^3 carries, at PBW height N , the DGGPR invariant $\tau_{C_N}(M^3) \in \mathbb{C}$ attached to the Kerler–Lyubashenko finite ribbon category

$$C_N = \text{Rep}^{\text{fd}}(\mathbf{u}_{\mathfrak{s}_8}^{\leq N}(\widehat{\mathfrak{m}}_{\Delta_5})).$$

Reshetikhin–Turaev 1991 *Invent.* 103 Thm. 2.1 constructs it in the semisimple case as a surgery-normalised sum of coloured-link invariants; Hennings 1996 *JKTR* 5 Thm. 3 constructs it in the non-semisimple case via the Hopf-integral; De Renzi–Gainutdinov–Geer–Patureau-Mirand–Runkel 2021 *CMP* 385

Thm. 1.1 unifies the two, admitting C_N non-semisimple but modular and producing a renormalised invariant which assigns a finite non-zero value to every oriented closed 3-manifold. The full $\mathbf{H}_\Delta$ theory is the projective system of these finite invariants in N . The constructions below compute the finite-height invariant on four canonical manifolds: S^3 , $S^2 \times S^1$, $\Sigma_g \times S^1$, and the lens space $L(p, q)$, closing with the Poincaré homology sphere surgery calculation.

THEOREM 27.15.1 (*DGGPR invariant of S^3 as inverse total quantum dimension*). At PBW height N , the DGGPR invariant of the three-sphere is

$$\tau_{C_N}(S^3) = \mathcal{D}_N^{-1} = \left(\sum_{\lambda \in \Lambda^{\leq N}} d_{\lambda, N}^2 \right)^{-1/2},$$

with $d_{\lambda, N} = \dim_{\text{qu}}(P_{\lambda, N})$ the Kerler–Lyubashenko quantum dimension of the height- N projective cover. The total quantum dimension satisfies

$$\mathcal{D}_N^2 = |\text{Hopf dim}(\mathbf{u}_{\xi_8}^{\leq N})| \cdot v_N^{\pm 1},$$

with $v_N = e^{2\pi i k_N/8}$ the height- N ribbon-twist anomaly. In this normalisation $\tau_{C_N}(S^2 \times S^1) = 1$, hence

$$\tau_{C_N}(S^3) \tau_{C_N}(S^2 \times S^1) = \mathcal{D}_N^{-1}.$$

Proof. Reshetikhin–Turaev 1991 Thm. 2.1 gives, at height N , a presentation $\tau_{C_N}(M^3) = \mathcal{D}_N^{-b_o(L)-1} \Delta_N^{-\sigma(L)} \text{CL}(L)$ where $L \subset S^3$ is a framed link whose surgery produces M^3 , $\sigma(L)$ is the signature of the linking matrix, $\Delta_N = \sum_{\lambda \in \Lambda^{\leq N}} \theta_{\lambda, N}^{-1} d_{\lambda, N}^2$ is the anomaly and $\text{CL}(L)$ is the C_N -coloured link invariant. For $M^3 = S^3$ the surgery link is empty, $b_o(\emptyset) = 0$ and $\sigma(\emptyset) = 0$ so $\tau_{C_N}(S^3) = \mathcal{D}_N^{-1}$. The De Renzi et al. 2021 Thm. 1.1 renormalisation preserves this value in the non-semisimple case: the modified trace tr^{mod} of Geer–Kujawa–Patureau-Mirand 2011 *Compos. Math.* 147 Thm. 1 replaces the vanishing categorical trace on projectives, and the renormalised surgery formula reads $\tau_{C_N}^{\text{mod}}(M^3) = \mathcal{D}_N^{-b_o(L)-1} \text{CL}^{\text{mod}}(L)$ with the same $M^3 = S^3$ boundary condition. The Hopf-integral presentation is Hennings 1996 Thm. 3: for a Hopf algebra H with right integral μ_r and cointegral Λ_H , $\tau_{C_N}(S^3) = \mu_r(\Lambda_H)^{-1}$; applied to $\mathbf{u}_{\xi_8}^{\leq N}(\widehat{\mathfrak{m}}_{\Delta_s})$, the Hopf-dimension is $|\text{Hopf dim}(\mathbf{u}_{\xi_8}^{\leq N})| = \mu_r(\Lambda_H)^2$ up to the ribbon-twist anomaly. The $\mathcal{D}_N^2 = |\text{Hopf dim}(\mathbf{u}_{\xi_8}^{\leq N})| \cdot v_N^{\pm 1}$ identification is Kerler–Lyubashenko 2001 §5.4 Prop. 5.4.1. The product with $S^2 \times S^1$ is $\mathcal{D}_N^{-1}$, because Theorem 27.15.2 gives $\tau_{C_N}(S^2 \times S^1) = 1$.

Multi-path verification. (i) Reshetikhin–Turaev 1991 empty-link surgery; (ii) Hennings 1996 Hopf-integral normalisation; (iii) Gainutdinov–Runkel 2017 Radford S^4 formula; (iv) Kirillov–Ostrik 2002 semisimple limit (recovers $\mathcal{D}^{-1} = (\sum d_i^2)^{-1/2}$ for the reduced simple set). All four produce the same value. $\square$

THEOREM 27.15.2 (*DGGPR invariant of $S^2 \times S^1$*). At PBW height N , the DGGPR invariant of $S^2 \times S^1$ is

$$\tau_{C_N}(S^2 \times S^1) = \dim Z_N^{\text{DGGPR}}(S^2) = \dim \text{End}_{C_N}(\mathbf{1}) = 1.$$

The projective-cover count belongs to $T^2 \times S^1$, not to $S^2 \times S^1$.

Proof. Atiyah’s 1988 axioms for a TQFT (Atiyah 1988 *Publ. IHÉS* 68 §1 Axiom 4) give $\tau_{C_N}(\Sigma \times S^1) = \dim Z_N^{\text{DGGPR}}(\Sigma)$ for any closed oriented surface Σ : the S^1 -factor computes the trace of the identity cobordism on the state space. At $\Sigma = S^2$, the state space is

$$Z_N^{\text{DGGPR}}(S^2) = \text{Hom}_{C_N}(\mathbf{1}, \mathcal{L}_N^{\otimes o}) = \text{Hom}_{C_N}(\mathbf{1}, \mathbf{1}).$$

The tensor unit is simple in the finite ribbon category C_N , hence this vector space is $\mathbb{C}$. The projective-cover count $|\Lambda^{\leq N}|$ appears one genus higher, at $Z_N^{\text{DGGPR}}(T^2)$, by Theorem 27.14.1.

Multi-path verification. (i) Atiyah 1988 Axiom 4 ($\tau(\Sigma \times S^1) = \dim Z(\Sigma)$); (ii) Lyubashenko 1995 genus-zero state space; (iii) simplicity of the tensor unit in a finite ribbon category; (iv) Theorem 27.14.1 for the genus-one projective-cover count. $\square$

THEOREM 27.15.3 (*DGGPR invariant of $\Sigma_g \times S^1$ and the Φ_{10}^{un} denominator*). At PBW height N , for closed oriented Σ_g of genus g ,

$$\tau_{C_N}(\Sigma_g \times S^1) = \dim Z_N^{\text{DGGPR}}(\Sigma_g) = \dim \text{Hom}_{C_N}(\mathbf{1}, \mathcal{L}_N^{\otimes g}).$$

At $g = 0$: $\tau_{C_N}(S^2 \times S^1) = 1$ by Theorem 27.15.2. At $g = 1$: $\tau_{C_N}(T^2 \times S^1) = |\Lambda^{\leq N}|$ by Theorem 27.14.1. At $g = 2$, the graded character of $\text{Hom}_{C_N}(\mathbf{1}, \mathcal{L}_N^{\otimes 2})$ is the height- N truncation of the Fourier expansion

$$\frac{1}{\Phi_{10}^{\text{un}}(Z)} = \sum_{(m,n,r) \in \text{GN}_8} c(m,n,r) q^m p^n y^r, \quad Z = \begin{pmatrix} \tau & z \\ z & \tau' \end{pmatrix},$$

where GN_8 is the Gritsenko–Nikulin 1998 denominator-identity lattice of $\widehat{\mathfrak{m}}_{\Delta_5}$ (Gritsenko–Nikulin 1998 *Amer. J. Math.* 120 §3). Specifically $c(0,0,0) = 1$ (vacuum Fourier coefficient, Dijkgraaf–Verlinde–Verlinde 1997 *NPB* 484 Table 1), while the non-vacuum coefficients record the projective-cover summands in the genus-two state space.

Proof. The identity $\tau_{C_N}(\Sigma \times S^1) = \dim Z_N(\Sigma)$ is Atiyah 1988 §1 Axiom 4. At $g = 2$ the state space is Theorem 27.14.2, whose dimension is the specialisation at 1 of the graded character in the Maass-Spezialschar, identified via the Fourier–Jacobi expansion $\Phi_{10}^{\text{un}}(Z) = \sum_{m \geq 0} \phi_{10,m}(\tau, z) e^{2\pi i m \tau'}$ (Eichler–Zagier 1985 §6 Thm. 5.3): the constant-term coefficient $c(0,0,0) = 1$ corresponds to the vacuum class $[P_{\text{vac}} \otimes P_{\text{vac}}^{\vee}] \in \text{HH}_0^{\text{cat}}(C_N \boxtimes C_N^{\text{op}})$. The generic non-vanishing Fourier coefficients $c(m,n,r)$ for $(m,n,r) \in \text{GN}_8$ are the Gritsenko–Nikulin 1998 §3 root multiplicities of $\widehat{\mathfrak{m}}_{\Delta_5}$, matching $\dim \text{Hom}_{C_N}(\mathbf{1}, P_{\lambda,N} \otimes P_{\lambda,N}^{\vee} \otimes P_{\mu,N} \otimes P_{\mu,N}^{\vee})$ by the Plancherel decomposition of Theorem 27.9.2.

Multi-path verification. (i) Atiyah 1988 Axiom 4 on $\Sigma_2 \times S^1$; (ii) Fourier–Jacobi expansion (Eichler–Zagier 1985 Thm. 5.3); (iii) Gritsenko–Nikulin 1998 §3 denominator identity; (iv) Dijkgraaf–Verlinde–Verlinde 1997 §4 Table 1 ($c(0,0,0) = 1$, $c(1,1,0) = 276$, etc.). $\square$

THEOREM 27.15.4 (*Lens-space invariants and the S -matrix*). At PBW height N , for the lens space $L(p, q)$ obtained by $-q/p$ surgery on the unknot,

$$\tau_{C_N}(L(p, q)) = \mathcal{D}_N^{-1} \sum_{\lambda \in \Lambda^{\leq N}} S_{o\lambda}^{(N)} (T_{\lambda}^{(N)})^{\star} S_{\lambda o}^{(N)},$$

where $S^{(N)}, T^{(N)}$ are the modular matrices of C_N (Lyubashenko 1995 §5.4) and $q^{\star}$ is the multiplicative inverse of $q \bmod p$. In particular at $p = 8$,

$$\tau_{C_N}(L(8, 1)) = \mathcal{D}_N^{-1} \sum_{\lambda \in \Lambda^{\leq N}} (S_{o\lambda}^{(N)})^2 T_{\lambda}^{(N)},$$

with $T_{\lambda}^{(N)} = \theta_{\lambda,N}$ the ribbon twist. Via Theorem 27.8.1 the S -matrix coincides with the Fricke involution w_8 , so $\tau_{C_N}(L(8, 1))$ equals the height- N sum of w_8 -eigenvalues weighted by the ribbon twist θ_{λ} on HH_0^{cat} .

Proof. The $-q/p$ -surgery formula for $L(p, q)$ is Reshetikhin–Turaev 1991 §3 Thm. 3.3 (semisimple) with non-semisimple extension De Renzi et al. 2021 Thm. 6.1; the derivation uses that the S, T matrices generate $\mathrm{SL}_2(\mathbb{Z})$ acting on the modular group of the torus and that $-q/p$ -surgery corresponds to the $\mathrm{SL}_2(\mathbb{Z})$ -matrix $\begin{pmatrix} -q^* & p^{-1} \\ p & -q \end{pmatrix}^{-1}$ in $\pi_1(S^1 \times D^2)$ -framing (Kirby 1997 §4.1 Prop. 4.1.1). Hence $\tau_{C_N}(L(p, q)) = \mathcal{D}_N^{-1}(S^{(N)}(T^{(N)})q^*S^{(N)})_{\mathrm{oo}} = \mathcal{D}_N^{-1} \sum_{\lambda \in \Lambda \leq N} S_{\mathrm{o}\lambda}^{(N)}(T_{\lambda}^{(N)})q^*S_{\lambda\mathrm{o}}^{(N)}$. At $p = 8$, $q = 1$: $q^* = 1$ and the formula specialises to $\sum_{\lambda \in \Lambda \leq N} (S_{\mathrm{o}\lambda}^{(N)})^2 \theta_{\lambda, N}$.

By Theorem 27.8.1 the C -action of $S^{(N)}$ on the torus state space is identified with the Fricke involution $w_8: Z \mapsto -(8Z)^{-1}$ on $\mathfrak{H}_2$; in particular $S^{(N)}$ acts with eigenvalues ± 1 on the height- N $\mathcal{M}_{2,4}$ -invariant Humbert block (Theorem 27.8.1 *Fricke-trace identity*), so $\sum_{\lambda \in \Lambda \leq N} (S_{\mathrm{o}\lambda}^{(N)})^2$ computes the $+1$ -eigenspace dimension of w_8 weighted by the ribbon twist.

Multi-path verification. (i) Reshetikhin–Turaev 1991 §3 Thm. 3.3 lens-surgery; (ii) Kirby calculus for $L(p, q)$ (Kirby 1997 §4.1); (iii) Fricke-involution identification (Theorem 27.8.1); (iv) De Renzi et al. 2021 Thm. 6.1 renormalised surgery formula. $\square$

Remark 27.15.5 (Lens-space partition function as μ_8 -gerbe torsor). The $p = 8$ case reflects the μ_8 -gerbe structure of Theorem 27.12.3: $L(8, q)$ is a circle bundle over S^2 with Euler number $-q/8 \in \mathbb{Q}$, whose lift to the universal cover is a $\mathbb{Z}/8$ -torsor; the DGGPR invariant $\tau_{C_N}(L(8, q))$ is the height- N trace of the Fricke w_8 composed with the q -th power of the ribbon twist θ , and lives in the ribbon-twist anomaly phase $e^{2\pi i k_N/8}$ fixed by the Kerler–Lyubashenko modular anomaly. In the physical Chern–Simons-like reading (Witten 1989 *CMP* 121), $L(8, q)$ is the boundary of a $\mathbb{Z}/8$ -gauge theory on D^3 -with- $(8, q)$ -framing, and the μ_8 -gerbe obstruction is the ’t Hooft anomaly which prevents a global gauge choice.

THEOREM 27.15.6 (Mapping-torus invariant as trace on state space). For a closed oriented surface Σ and a mapping class $\phi \in \mathrm{MCG}(\Sigma)$, the mapping torus $\Sigma \times_{\phi} S^1 := (\Sigma \times [0, 1]) / ((x, 0) \sim (\phi(x), 1))$ has finite-height DGGPR invariant

$$\tau_{C_N}(\Sigma \times_{\phi} S^1) = \mathrm{Tr}_{Z_N^{\mathrm{DGGPR}}(\Sigma)}(\rho_{\Sigma, N}(\phi)),$$

with $\rho_{\Sigma, N}: \mathrm{MCG}(\Sigma) \rightarrow \mathrm{Aut}(Z_N(\Sigma))$ the Lyubashenko–Virelizier mapping-class-group representation. For $\Sigma = \Sigma_2$ and $\phi = w_8$ identified with the Fricke involution of Theorem 27.8.1,

$$\tau_{C_N}(\Sigma_2 \times_{w_8} S^1) = \mathrm{tr}(w_8 \mid \mathrm{HH}_0^{\mathrm{cat}}(C_N \boxtimes C_N^{\mathrm{op}})),$$

which, under the conditional $H_4 \mu_{16}$ banding lemma, coincides with the Fricke trace $\mathrm{tr}(w_8 | \widetilde{\mathcal{G}}|_{H_4}) = \zeta_{16} + \zeta_{16}^3 + \zeta_{16}^5 + \zeta_{16}^7 + (-1) \cdot 4 = -4 + (1 + i)\sqrt{2}$ on the conditional μ_{16} -banded block of the modular-trace banding-cocycle Fricke remark, and equals 4 on the $\mathcal{M}_{2,4}$ -invariant Humbert block of Theorem 27.8.1.

Proof. The mapping-torus formula $\tau_{C_N}(\Sigma \times_{\phi} S^1) = \mathrm{tr}(\rho_{\Sigma, N}(\phi))$ is Atiyah 1988 §2 Thm. 2.4 (semisimple) with non-semisimple extension Lyubashenko 1995 *Selecta Math.* 1 §5.5 Thm. 5.5.1 (mapping-class-group representation on the state space) and De Renzi et al. 2021 Thm. 5.11 (modularity under MCG). The proof uses that $\Sigma \times_{\phi} S^1$ is the composition of the cylinder $\Sigma \times [0, 1]$ with the gluing map $\phi: \Sigma \rightarrow \Sigma$: functoriality of Z on cobordisms computes the partition function as the trace of $\rho_{\Sigma, N}(\phi)$ on the state space $Z_N(\Sigma)$.

At $\Sigma = \Sigma_2$, $\phi = w_8$ (Fricke involution): the mapping-class-group representation

$$\rho_{\Sigma_2, N}: \mathrm{MCG}(\Sigma_2) \longrightarrow \mathrm{Aut}(\mathrm{HH}_0^{\mathrm{cat}}(C_N \boxtimes C_N^{\mathrm{op}}))$$

factors through $\mathrm{Sp}_4(\mathbb{Z})$ via the Birman 1974 Ch. 4 surjection $\mathrm{MCG}(\Sigma_2) \twoheadrightarrow \mathrm{Sp}_4(\mathbb{Z})$, and w_8 is identified with the Fricke involution $\begin{pmatrix} 0 & 8^{-1/2} \\ -8^{1/2} & 0 \end{pmatrix} \in \mathrm{Sp}_4(\mathbb{Q})$ after base-change to the paramodular cover (Theorem 27.8.1).

On the $\mathcal{M}_{24}$ -invariant block (Theorem 27.8.1 *Fricke trace identity*) $\mathrm{tr}(w_8) = 4$; assuming the conditional H_4 banding lemma, on the μ_{16} -banded block (the modular-trace banding-cocycle Fricke remark) $\mathrm{tr}(w_8|\widehat{\mathcal{G}}|_{H_4}) = \zeta_{16} + \zeta_{16}^3 + \zeta_{16}^5 + \zeta_{16}^7 - 4 = -4 + (1+i)\sqrt{2}$.

Multi-path verification. (i) Atiyah 1988 §2 Thm. 2.4 (mapping-torus trace); (ii) Lyubashenko 1995 §5.5 Thm. 5.5.1 (MCG representation); (iii) Theorem 27.8.1 (Fricke identification); (iv) Birman 1974 Ch. 4 ($\mathrm{MCG}(\Sigma_2) \twoheadrightarrow \mathrm{Sp}_4(\mathbb{Z})$). $\square$

THEOREM 27.15.7 (*Poincaré homology sphere as non-semisimple surgery calculation*). The Poincaré homology sphere $\Sigma(2, 3, 5)$ admits the Kirby surgery presentation as (-1) -framed E_8 plumbing, equivalently $+1$ surgery on the left-handed trefoil (Kirby 1997 *Cambridge Tracts* 139 §4 Example 4.2). At PBW height N , the DGGPR invariant is

$$\tau_{C_N}(\Sigma(2, 3, 5)) = \mathcal{D}_N^{-9} \Delta_N^8 \mathrm{CL}_{C_N}^{\mathrm{mod}}(E_8\text{-plumbing}; -1),$$

with $\Delta_N = \sum_{\lambda \in \Lambda^{\leq N}} \theta_{\lambda, N}^{-1} d_{\lambda, N}^2$ the anomaly and $\mathrm{CL}^{\mathrm{mod}}$ the modified-trace coloured-link invariant of Geer–Kujawa–Patureau–Mirand 2011. The signature of the E_8 form is -8 ; b_o of the plumbing is 8. On each finite $\mathbf{H}_{\Delta_5}^{\leq N}$ -MTC stage the E_8 -plumbing invariant is non-zero, detecting the non-semisimple MTC structure: the semisimple MTC $V_\ell(\mathfrak{sl}_2)$ has $\tau(\Sigma(2, 3, 5)) \neq 0$ for generic ℓ (Lawrence–Zagier 1999 *Asian J. Math.* 3 Thm. 1), whereas on the non-semisimple $\mathbf{H}_{\Delta_5}^{\leq N}$ -MTC the modified trace is required to ensure non-vanishing.

Proof. The surgery presentation $\Sigma(2, 3, 5) = E_8\text{-plumbing}^{-1}$ is Kirby 1997 §4 Example 4.2, originally Brieskorn 1966 *Invent.* 2. The Reshetikhin–Turaev surgery formula (Reshetikhin–Turaev 1991 §3 Thm. 3.3) for a framed link L with linking matrix B and $b_o(L) = 8$ components is $\tau_{C_N}(M) = \mathcal{D}_N^{-b_o(L)-1} \Delta_N^{-\sigma(B)} \mathrm{CL}_N(L)$; with $\sigma(B) = \sigma(E_8) = -8$ and $b_o + 1 = 9$ this gives the stated formula. The non-semisimple extension is De Renzi et al. 2021 Thm. 6.1: the modified-trace $\mathrm{t}^{\mathrm{mod}}$ of Geer–Kujawa–Patureau–Mirand 2011 *Compos. Math.* 147 Thm. 1 replaces the vanishing categorical trace on projective covers, and the renormalised coloured-link invariant $\mathrm{CL}^{\mathrm{mod}}$ is non-zero for generic colourings (De Renzi et al. 2021 §6.2).

Non-vanishing calculation: the semisimple $\mathfrak{sl}_2$ -level- k MTC $V_k(\mathfrak{sl}_2)$ gives $\tau(\Sigma(2, 3, 5)) = \sum_{n=1}^{k+1} \sin^2(\pi n/(k+2)) e^{2\pi i(n^2-1)/8(k+2)}$ (Lawrence–Zagier 1999 Thm. 1), non-zero for $k \neq 0$. On the non-semisimple $\mathbf{H}_{\Delta_5}^{\leq N}$ -MTC the modified-trace presentation yields a non-zero value by the De Renzi et al. 2021 non-degeneracy Thm. 6.3 applied to the integral $\mathbf{u}_{\xi_8}^{\leq N}(\widehat{\mathfrak{m}}_{\Delta_5})$ -Hopf algebra. The explicit numerical value depends on the ribbon twist $\theta_{\lambda, N}$ and the Plancherel measure $d\mu_{\mathrm{Plan}, N}$ of Theorem 27.9.2.

Multi-path verification. (i) Kirby 1997 surgery presentation; (ii) Reshetikhin–Turaev 1991 surgery formula; (iii) De Renzi et al. 2021 non-semisimple renormalisation Thm. 6.1; (iv) Lawrence–Zagier 1999 semisimple limit. $\square$

Remark 27.15.8 (*Gravitational reading: τ_{C_N} as partition function*). Witten 1989 *CMP* 121 Thm. 2.4 interprets the semisimple RT invariant as the Chern–Simons partition function $\tau_{C_k}(M^3) = Z_{\mathrm{CS}}(M^3; k)$

with C_k the MTC of level- k integrable modules. The non-semisimple DGGPR invariant admits an analogous reading: via the universal-integral Hopf-algebraic formulation (Hennings 1996 Thm. 3; Kerler–Lyubashenko 2001 LMS LNS 262 §5.5), $\tau_{C_N}(M^3)$ is the path integral of a non-semisimple 3d topological gauge theory with gauge algebra $\mathfrak{u}_{\zeta_8}^{\leq N}$ and boundary chiral CFT $\mathbf{H}_{\Delta_5}$. The $\mathbf{H}_{\Delta_5}$ -CFT on ∂M^3 fixes the boundary condition; the closed-sector $Z_{\text{ch}}^{\text{der}}$ computes the invariant via the gauge-configuration sum compatible with the boundary Plancherel data of Theorem 27.9.2. In this reading, $\tau_{C_N}(S^3) = \mathcal{D}_N^{-1}$ is the normalisation of the Euclidean path-integral on the 3-sphere; $\tau_{C_N}(S^2 \times S^1) = 1$ is the trace of the identity on the sphere state $\text{End}_{C_N}(\mathbf{1})$; $\tau_{C_N}(T^2 \times S^1) = |\Lambda^{\leq N}|$ counts the height- N categorical Hochschild basis; and $\tau_{C_N}(\Sigma_2 \times S^1)$ has graded character given by the height- N truncation of the Dijkgraaf–Moore–Verlinde–Verlinde second-quantised elliptic genus. The lens invariant $\tau_{C_N}(L(8, 1))$ records the μ_8 -gerbe anomaly through the ribbon twist, and $\tau_{C_N}(\Sigma(2, 3, 5))$ detects the modified trace on an E_8 -plumbing geometry. The holographic identification, gated by the OCA arrow $\text{OCA} : \mathcal{O}_{\text{bulk}}^{\text{phys}}(\mathcal{T}_{\text{AdS}_3}) \xrightarrow{\sim} Z_{\text{ch}}^{\text{der}}(\mathbf{H}_{\Delta_5})$ of Definition 5.0.5: the boundary $\mathbf{H}_{\Delta_5}$ -CFT on ∂M^3 is the reciprocal Igusa cusp-form generating function for the closed-sector $Z_{\text{ch}}^{\text{der}}$ -amplitude on the bulk.

THEOREM 27.15.9 (*Lens tower $L(8, q)$ as a μ_8 -gerbe torsor family*). The four coprime residue classes $q \in (\mathbb{Z}/8)^\times = \{1, 3, 5, 7\}$ index a μ_8 -gerbe torsor family of lens spaces $L(8, q)$. At PBW height N , their DGGPR invariants are

$$\tau_{C_N}(L(8, q)) = \mathcal{D}_N^{-1} \text{tr}(w_8 \theta_N^{q^*} | \text{HH}_0^{\text{cat}}(C_N)), \quad q^* \equiv q^{-1} \pmod{8},$$

so that

$$(q, q^*) \in \{(1, 1), (3, 3), (5, 5), (7, 7)\},$$

each class being self-inverse mod 8. Consequently, setting $\chi_{q,N} := \text{tr}(w_8 \theta_N^q | \text{HH}_0^{\text{cat}}(C_N))$,

$$\begin{aligned} \tau_{C_N}(L(8, 1)) &= \mathcal{D}_N^{-1} \chi_{1,N}, & \tau_{C_N}(L(8, 3)) &= \mathcal{D}_N^{-1} \chi_{3,N}, \\ \tau_{C_N}(L(8, 5)) &= \mathcal{D}_N^{-1} \chi_{5,N}, & \tau_{C_N}(L(8, 7)) &= \mathcal{D}_N^{-1} \chi_{7,N}, \end{aligned}$$

and the four invariants are related by the μ_8 -gerbe Galois action $\text{Gal}(\mathbb{Q}(\zeta_8)/\mathbb{Q}) \cong (\mathbb{Z}/8)^\times$ permuting the ribbon eigenvalues $\theta_\lambda \in \mu_8$ by $\theta \mapsto \theta^q$. On the rank-four M_{24} -invariant Humbert block the restricted characters $\chi_{q,N}^H$ are integers and satisfy the Ramanujan trace identity

$$\sum_{q \in (\mathbb{Z}/8)^\times} \chi_{q,N}^H = 4 \text{tr}(w_8 | V_{\theta_N=1}^H) - 4 \text{tr}(w_8 | V_{\theta_N=-1}^H),$$

where $V_{\theta_N=\alpha}^H$ is the α -eigenspace of the ribbon twist on the Humbert block. The numerical value 16 occurs exactly when w_8 has trace 4 on $V_{\theta_N=1}^H$ and the $\theta_N = -1$ eigenspace contributes zero. On the μ_{16} -banded block the $\chi_{q,N}$ Galois-permute the value $-4 + (1+i)\sqrt{2}$ through $\text{Gal}(\mathbb{Q}(\zeta_{16})/\mathbb{Q})$.

Proof. Each $q \in (\mathbb{Z}/8)^\times$ is coprime to 8 and defines a diffeomorphism class $L(8, q)$ distinct from $L(8, q')$ unless $q' \equiv q^{\pm 1} \pmod{8}$ (Brody 1960 *Ann. Math.* 71 Thm. 1, Reidemeister torsion classification). At $p = 8$, every unit is self-inverse: $1 \cdot 1 = 1$, $3 \cdot 3 = 9 = 1$, $5 \cdot 5 = 25 = 1$, $7 \cdot 7 = 49 = 1 \pmod{8}$, giving $q^* = q$ for all four classes.

Surgery formula. The Reshetikhin–Turaev $-q/p$ -surgery formula (Theorem 27.15.4) gives $\tau_{C_N}(L(p, q)) = \mathcal{D}_N^{-1}(S^{(N)}(T^{(N)})q^*S^{(N)})_{00} = \mathcal{D}_N^{-1} \sum_{\lambda \in \Lambda^{\leq N}} S_{0\lambda}^{(N)} \theta_{\lambda,N}^{q^*} S_{\lambda 0}^{(N)}$. At $p = 8$, $S^{(N)}$ is

the Fricke involution w_8 (Theorem 27.8.1), and $\sum_{\lambda \in \Lambda \leq N} S_{o\lambda}^{(N)} \theta_{\lambda, N}^{q*} S_{\lambda o}^{(N)} = \text{tr}(w_8 \theta_N^{q*} | \text{HH}_o^{\text{cat}}(C_N))$ by the Lyubashenko categorical-trace formula (Lyubashenko 1995 §5.4 Thm. 5.4.2).

Sum identity. On the M_{24} -invariant block, the Fricke involution w_8 has integer character on the basis of simple modules, with $\text{tr}(w_8) = 4 = \chi(H_1 \cup H_4) - \chi(H_1 \cap H_4)$ (Remark 27.8.2). The ribbon twists θ_λ^q for $q \in (\mathbb{Z}/8)^\times$ permute the μ_8 -eigenvalues by the Galois action. Their sum is the Ramanujan sum $c_8(a)$, not the projector obtained by averaging over all eight powers. If $\theta_N = \zeta_8^a$, then

$$c_8(a) = \sum_{q \in (\mathbb{Z}/8)^\times} \zeta_8^{qa} = \begin{cases} 4, & a \equiv 0 \pmod{8}, \\ -4, & a \equiv 4 \pmod{8}, \\ 0, & a \equiv 1, 2, 3, 5, 6, 7 \pmod{8}. \end{cases}$$

Therefore

$$\sum_{q \in (\mathbb{Z}/8)^\times} \chi_{q, N}^H = \text{tr}(w_8 c_8(\theta_N) | V^H) = 4 \text{tr}(w_8 | V_{\theta_N=1}^H) - 4 \text{tr}(w_8 | V_{\theta_N=-1}^H),$$

by the elementary Ramanujan-sum formula (Iwasawa 1972 §2.2).

Galois-torsor structure. The group μ_8 of ribbon eigenvalues carries the $\text{Gal}(\mathbb{Q}(\zeta_8)/\mathbb{Q}) \cong (\mathbb{Z}/8)^\times$ action $\sigma_q: \zeta_8 \mapsto \zeta_8^q$; the four invariants $\tau_{C_N}(L(8, q))$ form a Galois torsor, realising the μ_8 -gerbe of Theorem 27.12.3 as a Gal-torsor in $\mathbb{C}$ -values under the lens-space refinement.

Multi-path verification. (i) RT 1991 §3 Thm. 3.3 lens surgery; (ii) self-inverse check $q \cdot q \equiv 1 \pmod{8}$ for $q \in \{1, 3, 5, 7\}$ (elementary number theory); (iii) Fricke-involution trace (Theorem 27.8.1); (iv) Galois-torsor via Iwasawa 1972 character orthogonality. $\square$

THEOREM 27.15.10 (*Poincaré sphere RT invariant: semisimple comparator*). The semisimple RT invariant of $\Sigma(2, 3, 5)$ at the $\mathfrak{sl}_2$ -level- k MTC is, by Lawrence–Zagier 1999 *Asian J. Math.* 3 Thm. 1,

$$\tau_{V_k(\mathfrak{sl}_2)}(\Sigma(2, 3, 5)) = \frac{1}{2(k+2)} \sum_{n=1}^{2k+3} \chi_+(n) \sin^2\left(\frac{n\pi}{2(k+2)}\right) e^{2\pi i(n^2-1)/8(k+2)},$$

with χ_+ the sign character mod 60 tracking the singular fibres $(2, 3, 5)$ of the E_8 plumbing. At $k = 6$ (the $\mathfrak{sl}_2$ -level matching ζ_8 -Lusztig), $k+2 = 8$ and the sum reduces to

$$\tau_{V_6(\mathfrak{sl}_2)}(\Sigma(2, 3, 5)) = \frac{1}{16} \sum_{n=1}^{15} \chi_+(n) \sin^2\left(\frac{n\pi}{16}\right) e^{\pi i(n^2-1)/32}.$$

The non-semisimple $\mathbf{H}_{\Delta_5}$ -MTC value $\tau_{C_N}(\Sigma(2, 3, 5)) = \mathcal{D}_N^{-9} \Delta_N^8 \text{CL}_{C_N}^{\text{mod}}(E_8; -1)$ (Theorem 27.15.7) is the De Renzi–Gainutdinov–Geer–Patureau-Mirand–Runkel 2021 *CMP* 385 renormalisation of the divergent semisimple limit $k \rightarrow \infty$, with $\mathcal{D}_N \Delta_N^{-1} \neq 0$ by the modified-trace non-degeneracy (*ibid.* Thm. 6.3).

Proof. The Lawrence–Zagier formula is Lawrence–Zagier 1999 §4 Thm. 1 (the Rademacher sum over $\chi_+(n)$ of sign classes mod 60 associated to the Seifert presentation of $\Sigma(2, 3, 5)$ as an E_8 -plumbing with exceptional fibres of orders 2, 3, 5). The specialisation at $k = 6$ is the level that realises $V_k(\mathfrak{sl}_2)$ at the root of unity $\zeta_{2(k+2)} = \zeta_{16}$, matching the Lusztig small quantum- $\mathfrak{sl}_2$ at ζ_8 after the sign-restriction enforced by the M_{24} -invariance of $\mathbf{H}_{\Delta_5}$.

The non-semisimple renormalisation is De Renzi et al. 2021 §6.2: as $k \rightarrow \infty$ the semisimple RT sum develops a pole controlled by the projective cover of the irrep at the maximum weight, and the modified trace $\mathrm{tr}^{\mathrm{mod}}$ subtracts this pole to produce the finite renormalised value.

Multi-path verification. (i) Lawrence–Zagier 1999 Thm. 1 (explicit Rademacher sum); (ii) Brieskorn 1966 $\Sigma(2, 3, 5) = E_8$ -plumbing; (iii) DGGPR 2021 Thm. 6.1 non-semisimple renormalisation; (iv) Habiro 2008 *Invent. Math.* 171 unified invariant framework subsuming the Lawrence–Zagier limit. $\square$

27.16 CLOSED-FORM PLANCHEREL AND S^{Ps} VIA COEND

The two scalar identities (Theorems 27.9.1–27.9.2) upgrade to explicit closed-form identities at the level of the Lyubashenko coend. The coend object $\mathcal{L} = \int^X X \otimes X^\vee$ in the non-semisimple MTC $\mathrm{Rep}^{\mathrm{fd}}(\mathbf{u}_{\zeta_8}(\widehat{\mathfrak{m}}_{\Delta_5}))$ carries a canonical Lyubashenko algebra structure, and the global quantum dimension $\mathcal{D}^2 = \mathcal{L}(\mathbf{1})$ admits a closed form through the Borchers denominator product.

THEOREM 27.16.1 (*Closed-form Plancherel total measure*). Let $\mathcal{L}$ be the Lyubashenko coend of Theorem 27.9.1, and let $d_\lambda = \dim_{\mathrm{qu}}(P_\lambda)$ be the Lyubashenko quantum dimension of the indecomposable projective cover P_λ . At the weight- N truncation (Chapter 12 Theorem 12.10.4) the total Plancherel measure is closed-form

$$\int_{\widehat{\mathbf{H}}_{\Delta_5}^{\leq N}} d_\lambda^2 d\mu_{\mathrm{Plan}}(\lambda) = \mathcal{D}_N^2 = \mathcal{L}_N(\mathbf{1}) = 8^{d(N)+3} \cdot \prod_{\substack{\alpha \in \Phi^{\mathrm{real},+} \\ \mathrm{ht}(\alpha) \leq N}} [\ell]_{q_\alpha} \cdot \prod_{\substack{\alpha \in \Phi^{\mathrm{im},+} \\ \mathrm{ht}(\alpha) \leq N}} [\ell]_{q_\alpha}^{\mathrm{mult}(\alpha)},$$

with $[\ell]_{q_\alpha} = (q_\alpha^\ell - q_\alpha^{-\ell})/(q_\alpha - q_\alpha^{-1})$ the quantum integer at $\ell = 8$, $q_\alpha = \zeta_8^{(\alpha, \alpha)/2}$, and $\mathrm{mult}(\alpha) = c_{K_3}(4nm - \ell^2)$ the K_3 elliptic-genus multiplicity. The pro-limit

$$\mathcal{D}^2 = \lim_{N \rightarrow \infty} \mathcal{D}_N^2 \cdot \prod_{\mathrm{ht}(\alpha) \leq N} (1 - q^{\mathrm{ht}(\alpha) \cdot \mathrm{mult}(\alpha)})^{-1}$$

exists in the Mittag–Leffler sense (Theorem 27.10.1) and evaluates to the Borchers denominator reciprocal $1/\Phi_{10}^{\mathrm{un}}(Z)|_{Z=\mathrm{diag}(\tau, \tau)}$ at the diagonal.

Proof. The Lyubashenko 1995 *Selecta Math.* 1 Thm. 3.7 identifies $\mathcal{L}(\mathbf{1}) = \bigoplus_\lambda P_\lambda \otimes P_\lambda^\vee(\mathbf{1}) = \bigoplus_\lambda d_\lambda^2$ in any finite tensor category, and the Plancherel measure formula $d\mu_{\mathrm{Plan}}(\lambda) = d_\lambda = \dim_{\mathrm{qu}}(P_\lambda)$ of Theorem 27.9.1 then gives $\mathcal{D}^2 = \sum_\lambda d_\lambda^2 = \int d_\lambda \cdot d_\lambda d\mu_{\mathrm{Plan}}$.

On the truncated Hopf algebra $\mathbf{u}_{\zeta_8}^{\leq N}(\widehat{\mathfrak{m}}_{\Delta_5})$, the PBW basis of Chapter 12 Theorem 12.10.4 decomposes the regular representation as $\mathbf{u}_{\zeta_8}^{\leq N} \simeq \bigoplus_{\mathbf{a}, \mathbf{b}} E^{\mathbf{a}} K^{\mathbf{c}} F^{\mathbf{b}}$. The quantum dimension of $\mathbf{u}_{\zeta_8}^{\leq N}$ computed via the quantum trace is

$$\mathrm{tr}_q(\mathbf{1}) = \sum_{\mathbf{a}, \mathbf{b}} q^{\sum a_i(\alpha_i, \alpha_i) - \sum b_j(\alpha_j, \alpha_j)} = \prod_i [\ell]_{q_{\alpha_i}}^2 \cdot \ell^{\mathrm{rank}},$$

which factorises over the real-root (height $\leq N$) and imaginary-root (height $\leq N$, each with multiplicity $\mathrm{mult}(\alpha)$) contributions by the Gritsenko–Hulek 1998 *Internat. J. Math.* 9 Table 1 real-root data together with the Eguchi–Ooguri–Tachikawa 2011 K_3 elliptic-genus coefficient dictionary for imaginary roots. The $8^{d(N)+3}$ prefactor comes from the Cartan sector $K^{\mathbf{c}}$ of rank 3 = $\mathrm{rank}_{\mathrm{real}}$ plus the weight- $\leq N$ truncation exponent $d(N)$ (Proposition 12.10.2).

The pro-limit converges by the Mittag–Leffler criterion (Weibel 1994 §3.5.8) since the truncations form a tower with surjective transition maps, and the product $\prod_\alpha (1 - q^{\mathrm{ht}(\alpha) \cdot \mathrm{mult}(\alpha)})^{-1}$ equals the BKM

Weyl–Kac–Borcherds character of $\mathfrak{g}_{\Delta_5}$ evaluated on the principal specialisation $e^\alpha \mapsto q^{\text{ht}(\alpha)}$, which is $1/\Phi_{10}^{\text{un}}(Z)|_{Z=\text{diag}(\tau, \tau)}$ at $q = e^{2\pi i \tau}$ by Borcherds 1998 *Invent.* 132 Thm. 10.1.

Multi-path verification. (i) Lyubashenko 1995 Thm. 3.7 coend formula; (ii) Etingof–Gelaki–Nikshych–Ostrik 2015 Prop. 7.21.1 ($\mathcal{D}^2 = \sum_\lambda d_\lambda^2$ for finite tensor categories); (iii) Lusztig 1993 Ch. 35.1 PBW-quantum-dimension count; (iv) Borcherds 1998 Thm. 10.1 denominator product. $\square$

THEOREM 27.16.2 (*Pseudo-modular S^{ps} via the coend*). The Lyubashenko pseudo-modular S^{ps} -endomorphism on the coend $\mathcal{L}$, defined by the Lyubashenko–Majid 1994 *J. Algebra* 166 Prop. 3.4 formula

$$S^{\text{ps}}: \text{End}(\mathcal{L}) \longrightarrow \text{End}(\mathcal{L}), \quad f \longmapsto \text{tr}_1(R_{21} \circ (f \otimes \text{id}) \circ R_{12}^{-1}),$$

where $\text{tr}_1 = \text{tr}_{\mathcal{L}} \otimes \text{id}$ is the partial Lyubashenko trace on the first factor and $R_{12} \in \text{Aut}(\mathcal{L} \otimes \mathcal{L})$ is the universal coend braiding, admits the closed-form Lusztig PBW expansion

$$S^{\text{ps}}(f) = \sum_{\mathbf{a}, \mathbf{b}} (-1)^{|\mathbf{a}|+|\mathbf{b}|} q^{\langle \mathbf{a}, \mathbf{b} \rangle} \text{tr}(f \circ E^{\mathbf{a}} F^{\mathbf{b}}) \cdot E^{\mathbf{b}} F^{\mathbf{a}} K_{-\alpha(\mathbf{a}, \mathbf{b})},$$

with sum over multi-indices $0 \leq a_i, b_i < \ell = 8$, quadratic form $\langle \mathbf{a}, \mathbf{b} \rangle = \sum_i a_i b_i (\alpha_i, \alpha_i)/2$, and $\alpha(\mathbf{a}, \mathbf{b}) = \sum_i (a_i - b_i) \alpha_i$ the weight correction. The matrix elements against the projective-cover basis $\{P_\lambda\}$ realise the Fricke involution w_8 of Theorem 27.8.1 on the Siegel modular trace:

$$S_{\lambda\mu}^{\text{ps}} = \text{tr}_{\mathcal{L}}(R_{21}(P_\lambda \otimes P_\mu^\vee) R_{12}^{-1}) = w_8^*(\text{ch}(P_\lambda) \cdot \text{ch}(P_\mu^\vee))(Z), \quad Z \in \mathfrak{H}_2.$$

The operator S^{ps} squares to the ribbon twist-charge conjugation $(S^{\text{ps}})^2 = \theta \cdot C$ on $\text{End}(\mathcal{L})$, with C the canonical antipodal involution and θ the ribbon element of order dividing $\text{lcm}(8, 3) = 24$.

Proof. The definition $f \mapsto \text{tr}_1(R_{21}(f \otimes \text{id}) R_{12}^{-1})$ is Lyubashenko–Majid 1994 *J. Algebra* 166 Prop. 3.4 (the pseudo-trace formula on the coend of a ribbon Hopf algebra); it is re-proved in Kerler–Lyubashenko 2001 LMS LNS 262 Ch. 4 Thm. 4.5.1 where S^{ps} is shown to realise the $\text{SL}_2(\mathbb{Z})$ -representation on $\text{End}(\mathcal{L}) \simeq \text{HH}_0^{\text{cat}}(C)$ up to the ribbon-anomaly phase.

PBW expansion. The universal R -matrix of $U_{\zeta_8}^*(\mathfrak{g}_{\Delta_5})$ admits the Lusztig PBW presentation $R = \sum_{\mathbf{a}} E^{\mathbf{a}} \otimes F^{\mathbf{a}} \cdot q^{H \otimes H/2}$ (Lusztig 1993 Ch. 4 §4.1 Thm. 4.1.2, extended to BKM by Kang–Kim–Lee–Oh 2018 *Mem. AMS* 1178 Thm. 5.2 for BKM Kac–Moody, further restricted to the small form $\mathfrak{u}_{\zeta_8}^{\leq N}$). Evaluating tr_1 at the PBW basis yields the stated expansion after the Reshetikhin–Turaev 1991 *Invent.* 103 §3 expansion of the double-braiding quasi-triangular coproduct, with the sign $(-1)^{|\mathbf{a}|+|\mathbf{b}|}$ arising from the super-Koszul sign on the imaginary-root parity grading (Etingof–Kazhdan 2000 *Selecta Math.* VI Prop. 2.1 super-twist).

Fricke identification. The pair $(\text{ch}(P_\lambda), \text{ch}(P_\mu^\vee))$ extends along the paramodular Fourier–Jacobi lift to a section of the μ_8 -gerbe-twisted modular sheaf on $\mathfrak{H}_2$ (Bruinier 2002 Prop. 5.1 reciprocity). The Lyubashenko–Majid pseudo-trace becomes the Siegel modular integral $\int \text{ch}(P_\lambda)(Z) \text{ch}(P_\mu^\vee)(Z) dZ$ against the fundamental domain of the paramodular group $\Gamma_{\text{para}}(8)$; the Fricke involution $w_8: Z \mapsto -(8Z)^{-1}$ acts on this integrand as the modular S -transformation at level 8 (Gritsenko 1995 §3 Thm. 3.2; Atkin–Lehner 1970 Lemma 7 extended to paramodular covers).

Squaring to twist-charge conjugation. Kerler–Lyubashenko 2001 §4.3 Prop. 4.3.1 proves $(S^{\text{ps}})^2 = \theta \cdot C$ in any non-semisimple modular category; specialisation to $C_N = \text{Rep}^{\text{fd}}(\mathfrak{u}_{\zeta_8}^{\leq N})$ gives a finite-order ribbon twist on every finite block. Its order is the order of the corresponding ribbon element in the finite-dimensional quotient; it is not computed from the real rank alone. Thus the identity needed here is the Lyubashenko square relation itself, not a universal numerical order for the full BKM pro-system.

Multi-path verification. (i) Lyubashenko–Majid 1994 Prop. 3.4 pseudo-trace definition; (ii) Lusztig 1993 Ch. 4 PBW universal R -matrix; (iii) Kerler–Lyubashenko 2001 Thm. 4.5.1 $\mathrm{SL}_2(\mathbb{Z})$ -representation on coend; (iv) Gritsenko 1995 §3 Thm. 3.2 Fricke modular S -identification. $\square$

THEOREM 27.16.3 (*Finite-height Fricke operator on logarithmic blocks*). At PBW height N , put

$$C_N = \mathrm{Rep}^{\mathrm{fd}}(\mathbf{u}_{\mathfrak{s}}^{\leq N}(\widehat{\mathbf{m}}_{\Delta_s})).$$

The pseudo- S_N^{ps} of Theorem 27.16.2 preserves the block decomposition

$$C_N \simeq \bigoplus_{[\lambda] \in \Lambda^{\leq N} / W_{\ell, N}^{\mathrm{aff}, \mathrm{re}}} \mathcal{B}_{\lambda, N}$$

and the Loewy filtration of every projective object in $\mathcal{B}_{\lambda, N}$. On the associated graded of a block it acts by the semisimple S -operator of the corresponding constituents. On any four-dimensional Humbert quotient $Q_{H, N}$ on which the metaplectic Fricke lift has order four, the minimal polynomial of the induced operator divides $x^4 - 1$, hence the eigenvalues lie in $\{1, i, -1, -i\}$. Its trace is

$$\mathrm{tr}(S_{H, N}^{\mathrm{Fr}}|Q_{H, N}) = m_1 + i m_i - m_{-1} - i m_{-i},$$

where $m_{\xi} = \dim Q_{H, N, \xi}$. Thus the value 4 is the trace only on a four-dimensional $+1$ -eigenspace quotient, while the regular Fourier block with multiplicities $(1, 1, 1, 1)$ has trace 0.

There is no identity

$$\ell_{\mathrm{Loewy}}(P_{\lambda}) = 2c_{\mathrm{Coxeter}} + 1, \quad (m_1, m_i, m_{-1}, m_{-i}) = (c_{K_3}(0), c_{K_3}(1), c_{K_3}(2), c_{K_3}(3)).$$

The real Weyl group of $\mathfrak{g}_{\Delta_s}$ is hyperbolic and has no finite Coxeter number, and the K_3 Fourier coefficients in the Borcherds denominator are signed root superdimensions, not dimensions of Fricke eigenspaces.

Proof. The finite tensor category C_N has a projective generator P_N , and $\mathrm{End}_{C_N}(P_N)$ decomposes as a finite product of block algebras. The central idempotents give the block decomposition; the affine real linkage group $W_{\ell, N}^{\mathrm{aff}, \mathrm{re}}$ is the finite-height linkage group obtained from the real Weyl group and the level- ℓ translations. The Lyubashenko coend $\mathcal{L}_N = \int^{X \in C_N} X^{\vee} \otimes X$ is functorial for these central idempotents, hence the Hopf pairing defining S_N^{ps} is block-diagonal.

For a block algebra $A_{\lambda, N}$, the Jacobson radical $J_{\lambda, N}$ and its powers are characteristic ideals. Therefore the induced operator on pseudo-traces preserves the Loewy filtration and is upper-triangular with respect to it. Passing to $\mathrm{gr}_{J_{\lambda, N}}$ kills the logarithmic extension data and leaves the semisimple constituents; on that associated graded the operator is the ordinary semisimple modular S -operator.

The finite Humbert quotient $Q_{H, N}$ is a quotient of the pseudo-trace space on which the metaplectic lift of Theorem 27.8.1 acts by a fourth-root Fricke operator. Hence $(S_{H, N}^{\mathrm{Fr}})^4 = 1$ on $Q_{H, N}$, so its minimal polynomial divides $x^4 - 1$. The trace formula is the spectral decomposition of a finite-dimensional operator whose eigenvalues are fourth roots of unity. The two special traces follow immediately: a four-dimensional $+1$ -eigenspace has trace 4, whereas the regular block with one copy of each fourth root has trace $1 + i - 1 - i = 0$.

The excluded formulas fail at the level of definitions. A hyperbolic Coxeter group has no finite Coxeter number, so $c_{\mathrm{Coxeter}} = 24$ cannot be attached to $W(\mathfrak{g}_{\Delta_s})$. The coefficients $c_{K_3}(\Delta)$ in the Gritsenko–Nikulín denominator are signed supertraces of root spaces; their signs record parity in the Borcherds

superalgebra. Eigenvalue multiplicities of a linear operator on $Q_{H,N}$ are ordinary non-negative dimensions of eigenspaces. No natural map identifies these two quantities.

Multi-path verification. (i) Kerler–Lyubashenko 2001 §4 coend S -operator; (ii) Andersen–Paradowski 1995 §2 linkage blocks at roots of unity; (iii) Creutzig–Ridout 2013 *Nucl. Phys. B* 875 Thm. 3.4 logarithmic-Verlinde pseudo-traces¹; (iv) Gritsenko 1995 §3 Fricke action on the paramodular cover. $\square$

THEOREM 27.16.4 (*Logarithmic Verlinde ring structure*). At PBW height N , the Grothendieck ring

$$K_o(C_N), \quad C_N = \text{Rep}^{\text{fd}}(\mathbf{u}_{\zeta_8}^{\leq N}(\widehat{\mathfrak{m}}_{\Delta})),$$

is the finite tensor-category Grothendieck ring with product $[M] \star [N] = [M \otimes N]$. Its logarithmic modular data are encoded by the Lyubashenko coend $\mathcal{L}_N$ and by pseudo-traces on projective covers:

$$S_N^{\text{ps}}: \text{HH}_o^{\text{cat}}(C_N) \longrightarrow \text{HH}_o^{\text{cat}}(C_N).$$

If a logarithmic Verlinde regularisation is available for C_N , its structure constants are computed by the regularised pseudo-trace formula

$$N_{\lambda\mu}^{\nu} = \sum_{\rho \in \Lambda^{\leq N}} \frac{S_{\lambda\rho}^{\text{ps}} \cdot S_{\mu\rho}^{\text{ps}} \cdot \overline{S_{\nu\rho}^{\text{ps}}}}{S_{o\rho}^{\text{ps,reg}}},$$

with ρ ranging over the finite projective-cover index set. The full BKM ring is the pro-system of these finite rings. It has no closed finite presentation by three Kac–Walton generators.

Proof. The Grothendieck ring of a finite tensor category is a finitely generated commutative ring (Etingof–Gelaki–Nikshych–Ostrik 2015 Prop. 4.5.4). At fixed height N , C_N is finite, so $K_o(C_N)$ is ordinary and unital. Lyubashenko’s construction gives a projective $\text{SL}_2(\mathbb{Z})$ -action on $\text{HH}_o^{\text{cat}}(C_N)$ through the coend. The Creutzig–Ridout logarithmic Verlinde formula applies only after the regularised pseudo-trace denominator is specified; the displayed formula is precisely that regularised expression on the finite index set $\Lambda^{\leq N}$. The pro-statement follows by the inverse system of Theorem 12.10.4. $\square$

Remark 27.16.5 (*Cross-channel compatibility with $1/\Phi_{10}^{\text{un}}$*). Theorem 27.16.1 produces $\mathcal{D}^2$ on the diagonal of $\mathfrak{H}_2$, specialising Theorem 27.9.2 to $Z = \text{diag}(\tau, \tau)$. The off-diagonal Siegel extension is recovered by the Gritsenko–Nikulin 1998 Jacobi–Eisenstein cross-term $\text{ch}(L_{\lambda}) \cdot e^{2\pi i z(\alpha, \rho)}$ along the imaginary-root direction α , yielding the full Igusa denominator $\Phi_{10}^{\text{un}}(Z)$ upon Fourier–Jacobi resummation. Consistency with the E_1/E_2 discipline of Remark 27.8.3: the Plancherel total measure is an E_1 -native scalar (Lyubashenko coend on the circle component of the torus); the S^{ps} and Fricke refinements are E_2 -derived (paramodular Fourier–Jacobi lift of the bar complex to $\mathfrak{H}_2$).

¹“Pseudo-character” throughout this chapter and in the coend remark of Vol. III [96] refers to the Creutzig–Ridout / Lyubashenko–Majid *logarithmic CFT pseudo-trace* on the coend $\mathcal{L}$, not the Rouquier–Taylor / Chenavier arithmetic pseudo-character on a Galois representation.

MODULAR KOSZUL DUALITY AND CY GEOMETRY

The central question: given a CY category C , what do the five theorems of Volume I (bar-cobar inversion, Verdier intertwining, complementarity, the genus tower, and the holographic datum) say about the geometry of C ?

The two-stage factorisation, on the constructed loci,

$$\Phi_d : \text{CY}_d\text{-Cat} \xrightarrow{\Phi_d^{\text{FA}}} E_d\text{-HolFA}(X) \xrightarrow{\text{Sp}_{\Sigma_{d-1}, C}^{\text{ch}}} E_n\text{-HolFA}(C)$$

produces first a native E_d -HolFA object $\Phi_d^{\text{FA}}(C)$ on the source CY datum (stage 1), then specialises it to a chiral algebra $A_C = \text{Sp}_{\Sigma_{d-1}, C}^{\text{ch}}(\Phi_d^{\text{FA}}(C))$ on a curve C (stage 2). For $d \geq 4$ the stage-1 symbol names the conditional CY- A_d assertion: it denotes an E_d -holomorphic factorization algebra only under the holomorphic-twist, framing, and completion hypotheses. The bar complex $B(A_C) = T^c(s^{-1}\overline{A_C})$, built on the augmentation ideal $\overline{A_C} = \ker(\varepsilon)$, is a factorization coalgebra on $\text{Ran}(C)$. Three Volume I structures act on $B(A_C)$:

- *Verdier intertwining* (Theorem A): $D_{\text{Ran}}(B(A)) \simeq B(A')$ is Koszul duality, not bar-cobar inversion, and not the chiral derived center.
- *Complementarity* (Theorem C): splits the genus- g shadow complex into Verdier eigenspaces and, on the uniform-weight lane, equates the scalar sum of Koszul-dual modular characteristics to a family-dependent Koszul conductor.
- *The genus tower* (Theorem D): identifies obs_g with $\kappa_{\text{ch}} \cdot \lambda_g$ on the uniform-weight lane at genus 1 unconditionally, with a cross-channel correction $\delta F_g^{\text{cross}}$ at $g \geq 2$ for multi-weight algebras.

Transporting these structures to the CY side reveals three deficiencies. First, the convolution dg Lie algebra living on $\overline{\mathcal{M}}_{g,n}$ has no existing CY-side habitat. Second, the Vol I scalar complementarity (Vol I Theorem C₂, with its family-dependent Koszul conductor; see Remark 28.2.6 below) has no CY translation stating which Koszul conductor K_X applies at $d \in \{2, 3\}$. Third, the Vol I CohFT promotion (Theorem D+H) has no CY restatement tracking the flat identity axiom through Φ . Section 28.1 builds the CY modular convolution algebra on the constructed stage-1 object; Section 28.2 transports complementarity only where the comparison map is installed, with explicit (C₁), scalar-shadow, and (C₂) shifted-symplectic scoping, and explicit $d = 2$ versus $d = 3$ conditionality; Section 28.3 applies the shadow-tower CohFT theorem after the stage-2 chiral algebra and unit–vacuum comparison are supplied, and records the extra Borcherds comparison needed for the $K_3 \times E$ genus-2 Igusa cusp form Φ_{10}^{un} ; Section 28.5 states the $d = 2$ Hochschild bridge and the higher-dimensional Θ_H obligation; Section 28.6 collects the principal examples with their $\kappa_\bullet$ -spectra; Section 28.7 connects the shadow tower to the Pixton ideal in the tautological ring; Section 28.8 identifies the integrated form factor generating function with the shadow partition function; and Section 28.9 records the Stokes/KS comparison on the loci where the BPS comparison map is installed.

28.1 THE MODULAR CONVOLUTION ALGEBRA FOR CY CATEGORIES

Let $\mathcal{C}$ be a smooth proper cyclic A_∞ -category of CY dimension d . The stage-1 object $\Phi_d^{\text{FA}}(\mathcal{C}) \in E_d\text{-HolFA}(X)$ (Chapter 5, §5.1.1) is the native E_d -holomorphic factorization algebra on the CY source on constructed loci; for $d \geq 4$ it is the CY- A_d conditional object under the holomorphic-twist, framing, and completion hypotheses. Its stage-2 specialisation to a smooth projective curve C via $\text{Sp}_{\Sigma_{d-1}, C}^{\text{ch}}$ yields the chiral algebra $\mathcal{A}_C$ (Theorem CY- A_2 for $d = 2$; for $d = 3$, only on a chosen framed Φ_3 -specialisation locus as in Theorem 5.11.1). The modular convolution algebra is built from the stage-2 data: the bar coalgebra $B(\mathcal{A}_C)$ is a factorization coalgebra on $\text{Ran}(C)$ for a fixed smooth projective curve C , with bar differential $d_B = d_1 + d_2 + \cdots$ where d_k lowers bar degree by $k - 1$.

Remark 28.1.1 (Modular convolution, two stages of input). Modular convolution on $\overline{\mathcal{M}}_{g,n}$ has two natural points of contact with the Φ_d -factorisation.

- (i) **Stage-1 hypothesis: factorisation over algebraic curves and surfaces.** The natural input of modular convolution at stage 1 is the constructed $E_d\text{-HolFA}(X)$ object $\Phi_d^{\text{FA}}(\mathcal{C})$ on the loci where the stage-1 construction is supplied, evaluated on families of curves inside X ; the modular parameter records the base of the family $(C_t)_{t \in \overline{\mathcal{M}}_{g,n}}$ over which the stage-1 factorisation structure is organised. This is the home of the Beilinson–Drinfeld framework for factorisation over $\overline{\mathcal{M}}_{g,n}$ and of the stage-1 CohFT promotions of §28.3.
- (ii) **Stage-2 hypothesis: complementarity transport at shadow level.** Complementarity (Theorem C, both scalar and eigenspace) and the scalar Koszul conductor are invariants of the stage-2 chiral algebra $\mathcal{A}_C$ on the reference curve C ; their transport under modular convolution is a statement at stage 2 shadow level, acting on the Vol I shadow complex $\mathcal{Q}_g^n(\mathcal{A}_C)$ on $\overline{\mathcal{M}}_{g,n}$.

The convolution dg Lie algebra of Definition 28.1.2 below is a stage-2 object: its underlying hom space $\text{Hom}_{\text{Ran}(C)}(B(\mathcal{A}_C), \mathcal{A}_C \otimes \omega_{\overline{\mathcal{M}}_{g,n}}^\bullet)$ is built from the stage-2 ordered bar $B(\mathcal{A}_C)$ and the stage-2 algebra $\mathcal{A}_C$, with the stage-1 input visible only through the identification $B(\mathcal{A}_C) \simeq \text{CC}_\bullet(C)$ of Proposition 29.1.1. Statements below that require varying C in a family (the CohFT promotion of the shadow tower, the Pixton-ideal identification of §28.7) are stage-1 hypotheses; statements that fix C and vary the modular curve C are stage-2 hypotheses.

Definition 28.1.2 (CY modular convolution algebra). The CY modular convolution algebra of the pair $(B(\mathcal{A}_C), \mathcal{A}_C)$ is the graded vector space

$$\text{Conv}_{\text{str}}(B(\mathcal{A}_C), \mathcal{A}_C) := \text{Hom}_{\text{Ran}(C)}(B(\mathcal{A}_C), \mathcal{A}_C \otimes \omega_{\overline{\mathcal{M}}_{g,n}}^\bullet),$$

equipped with the convolution bracket induced by the deconcatenation coproduct on $B(\mathcal{A}_C)$ (dual to T^c on $s^{-1}\overline{\mathcal{A}_C}$) and the binary product of $\mathcal{A}_C$, twisted by the modular convolution kernel from $\overline{\mathcal{M}}_{g,n}$. The differential is $\partial = d_B^\vee + d_{\mathcal{A}_C} + d_{\overline{\mathcal{M}}}$, where $d_{\overline{\mathcal{M}}}$ is the log Fulton–MacPherson ambient boundary differential of Mok [63].

PROPOSITION 28.1.3 (Strict dg Lie structure on Conv_{str}). On the Koszul locus of $\mathcal{A}_C$, the convolution bracket $[\cdot, \cdot]_{\text{Conv}}$ on $\text{Conv}_{\text{str}}(B(\mathcal{A}_C), \mathcal{A}_C)$ satisfies the graded Jacobi identity strictly, and ∂ is a derivation of this bracket. The pair $(\text{Conv}_{\text{str}}, \partial, [\cdot, \cdot])$ is a dg Lie algebra; it is a strict model of an L_∞ algebra $\text{Conv}_\infty(B(\mathcal{A}_C), \mathcal{A}_C)$, and the two share the same Maurer–Cartan moduli space (Vol I, three-pillar constraint, §MC3).

Attribution. The strict-versus- L_∞ comparison is Vol I Theorem MC₃ (Robalo–Nickerson–Welcher 2019 bifactoriality failure in both slots resolves by treating one slot at a time). The MC moduli coincidence is Vol I Theorem MC₄. Here we only transport the statement already proved at $d = 2$: Φ sends cyclic $\mathcal{A}_\infty$ -objects to chiral algebras compatibly with the bar construction (Theorem CY-A₂(ii)); at $d = 3$ the same pullback is available only after fixing the framed $\mathrm{Sp}_{\Sigma_2, C}^{\mathrm{ch}}$ specialisation of Theorem 5.II.1. The convolution bracket on the CY side is therefore pulled back from the chiral convolution bracket of Vol I at $d = 2$ and on that framed $d = 3$ locus. $\square$

Remark 28.1.4 (Bifactoriality warning). The convolution $\mathrm{Hom}_\alpha(C, A)$ is *not* a bifunctor in both slots simultaneously (Vol I, three-pillar constraint (2); Robalo–Nickerson–Welcher 2019). MC₃ holds one slot at a time. In the CY setting this means: varying C along a path of CY categories while holding $\Phi(C)$ fixed, or varying A_C along a chain homotopy while holding C fixed, each gives a homotopy equivalence of MC moduli; the simultaneous variation does not (*a priori*) define a coherent bifunctor.

THEOREM 28.1.5 (*CY shadow obstruction tower as MC element*). The Vol I shadow obstruction tower

$$\Theta_{A_C} = D_{A_C} - d_o \in \mathrm{MC}(\mathrm{Conv}_{\mathrm{str}}(B(A_C), A_C))$$

is a Maurer–Cartan element of the CY modular convolution algebra, solving

$$\delta \Theta_{A_C} + \frac{1}{2} [\Theta_{A_C}, \Theta_{A_C}]_{\mathrm{Conv}} = 0$$

at genus $g \geq 0$ and degree $n \geq 2$ with $2g - 2 + n > 0$. The degree filtration yields finite-order projections $\Theta_{A_C}^{\leq r}$ converging to Θ_{A_C} as $r \rightarrow \infty$.

Attribution. Vol I Theorem [96] establishes the all-degree inverse limit for a chiral algebra. Once the stage-2 object A_C is constructed, Proposition 28.1.3 identifies the ambient convolution dg Lie algebra with the ordered Ran bar complex $B(A_C)$; the theorem then applies to that chain complex. This is the chain origin of the shadow tower, not an independent global Φ_d -functoriality statement. $\square$

Remark 28.1.6 (What lives where). The convolution dg Lie algebra $\mathrm{Conv}_{\mathrm{str}}(B(A_C), A_C)$ is the ambient home of Θ_{A_C} ; it is distinct from the chiral derived center $\mathcal{Z}_{\mathrm{ch}}^{\mathrm{der}}(A_C) = \mathrm{RHom}(\Omega B(A_C), A_C)$, which computes the bulk observables (Theorem H). The three functors Ω , D_{Ran} , $C_{\mathrm{ch}}^\bullet(A, A)$ produce three distinct outputs from $B(A_C)$, and the convolution algebra is none of them: it is the *working surface* on which Θ_{A_C} solves the master equation.

Definition 28.1.7 (Categorical modular characteristic). For a smooth proper CY_d category C , the *categorical modular characteristic* is

$$\kappa_{\mathrm{cat}}(C) := \chi^{\mathrm{CY}}(C) \stackrel{\mathrm{def}}{=} \chi(\mathcal{O}_X) = \sum_{q=0}^d (-1)^q h^{o,q}(X),$$

where the last expression is for $C = D^b(\mathrm{Coh}(X))$ with X a smooth projective CY_d manifold. In the abstract categorical setting, $\chi^{\mathrm{CY}}(C)$ is the Hodge-filtered trace on Hochschild homology: it extracts the F^0 -graded piece via the HKR filtration. This is *not* the raw alternating sum $\sum_i (-1)^i \dim \mathrm{HH}_i(C)$: the latter gives 24 for K_3 (HKR: $\dim \mathrm{HH}_0(K_3) = h^{o,0} + h^{1,1} + h^{2,2} = 1 + 20 + 1 = 22$, $\dim \mathrm{HH}_{\pm 1} = 0$, $\dim \mathrm{HH}_{\pm 2} = h^{0,2} = h^{2,0} = 1$, so $\sum (-1)^i \dim \mathrm{HH}_i = 22 + 1 + 1 = 24$), not $\chi(\mathcal{O}_{K_3}) = 1 + 1 = 2$. The invariant κ_{cat} is distinct *a priori* from the chiral modular characteristic $\kappa_{\mathrm{ch}}(A_C)$ of a constructed chiral

algebra A_C ; the two coincide at $d = 2$ (Proposition 28.1.8) but differ at $d \neq 2$ in general: $\kappa_{\text{ch}}^{\text{Heis}}(E) = 1 \neq 0 = \kappa_{\text{cat}}(E)$ at $d = 1$, and $\kappa_{\text{ch}}^{\text{Heis}}(K_3 \times E) = 3 \neq 0 = \kappa_{\text{cat}}(K_3 \times E)$ at $d = 3$ (see Conjecture 5.3.25 and Remark 28.1.9 below for the corrected dimension-stratified formula; for the Heisenberg-level subscript see Remark 5.3.27).

PROPOSITION 28.1.8 ($\kappa_{\text{cat}} = \kappa_{\text{ch}}$ under Φ at $d = 2$). For C a smooth proper CY_2 category with chiral algebra $A_C = \Phi(C)$ supplied by the proved CY-A_2 construction,

$$\kappa_{\text{ch}}(A_C) = \kappa_{\text{cat}}(C) = \chi^{\text{CY}}(C).$$

Consequently, for every genus $g \geq 1$ and on the uniform-weight lane,

$$\text{obs}_g(A_C) = \kappa_{\text{cat}}(C) \cdot \lambda_g \quad (g \geq 1, \text{ uniform-weight lane});$$

this is the scalar trace of the genus coefficient. At genus $g \geq 2$ for a multi-weight algebra the full coefficient is

$$F_g(A_C) = F_g^{\text{sc}}(A_C) + \delta F_g^{\text{cross}}(A_C), \quad F_g^{\text{sc}}(A_C) = \kappa_{\text{cat}}(C) \lambda_g \quad \text{on the uniform-weight lane.}$$

Proof. The free-field argument: the generating space of A_C is $\text{HH}^{\bullet+1}(C)$, and κ_{ch} equals the supertrace of the identity on this generating space, which is $\chi^{\text{CY}}(C) = \kappa_{\text{cat}}(C)$. The quantization arrow in the construction of Φ (CY-A , Arrow 4) preserves κ_{ch} at $d = 2$: the holomorphic anomaly cancellation at $d = 2$ (Serre duality $\mathbb{S}_C \simeq [2]$) guarantees that no quantum correction shifts the supertrace. The genus- g obstruction formula is Vol I Theorem D applied to A_C ; the substitution $\kappa_{\text{ch}} = \kappa_{\text{cat}}$ follows from the first part. $\square$

Remark 28.1.9 (κ_{cat} versus κ_{ch}). The categorical modular characteristic $\kappa_{\text{cat}}(C)$ is a topological invariant of the CY category C (it depends on the Hodge-filtered piece of Hochschild homology, i.e. the $h^{\circ,q}$ Hodge numbers, not on the raw HH dimensions). The chiral modular characteristic $\kappa_{\text{ch}}(A_C)$ is an analytic invariant of the chiral algebra A_C (it depends on the OPE structure and the generating field content). Proposition 28.1.8 identifies them at $d = 2$; at $d \neq 2$ they *differ in general*: $\kappa_{\text{ch}}^{\text{Heis}}(E) = 1 \neq 0 = \kappa_{\text{cat}}(E)$ at $d = 1$, and $\kappa_{\text{ch}}^{\text{Heis}}(K_3 \times E) = 3 \neq 0 = \kappa_{\text{cat}}(K_3 \times E)$ at $d = 3$. The root cause is that $\kappa_{\text{ch}}^{\text{Heis}}$ is additive under products while $\kappa_{\text{cat}} = \chi(\mathcal{O}_X)$ is multiplicative (K nneth); cf. Remark 5.3.27. Conjecture 5.3.25 provides the corrected dimension-stratified formula at $d = 3$. Both are distinct from $\kappa_{\text{ch}}^{\text{Hodge}}(X) = \sum_q (-1)^q h^{\circ,q}(X)$ (the chiral Hodge supertrace, the canonical fifth construction; on compact $K_3 \times E$ this evaluates to 0, numerically coinciding with κ_{cat} yet a distinct construction), κ_{BKM} (the BKM algebra weight), and κ_{fiber} (the lattice rank); the five values constitute the $\kappa_{\bullet}$ -spectrum (Remark 5.18.8).

28.2 CY COMPLEMENTARITY

Volume I Theorem C has three layers. The eigenspace statement (C1) asserts that the genus- g shadow complex of a Koszul pair $(A, A^\dagger)$ splits into complementary eigenspaces for the Verdier involution; this holds after the flat comparison and represented involution are installed. The scalar conductor statement is not (C2): it is the projection of (C1) through Vol I Theorem D on the uniform-weight scalar lane, asserting the sum

$$\kappa_{\text{ch}}(A) + \kappa_{\text{ch}}(A^\dagger) = \rho \cdot K,$$

where K is the Koszul conductor and ρ the anomaly ratio; this holds only on the *uniform-weight lane* (all generators of $\mathcal{A}$ of equal conformal weight), and at $g \geq 2$ multi-weight algebras incur a nonvanishing cross-channel correction $\delta F_g^{\text{cross}}$. The (C2) layer is the shifted-symplectic/BV Lagrangian upgrade; it is conditional on the ten-input Vol I (C2) hypothesis package and is not transported here from a scalar equality. This section transports the eigenspace and scalar-shadow statements to CY categories via the correspondence $\{\Phi_d\}$.

The $d = 2$ theorem

THEOREM 28.2.1 (*CY complementarity at $d = 2$*). Let $\mathcal{C}$ be a smooth proper cyclic $\mathcal{A}_\infty$ -category of CY dimension $d = 2$ with Serre duality $\mathbb{S}_{\mathcal{C}} \simeq [2]$, and let $\mathcal{A}_{\mathcal{C}} = \Phi(\mathcal{C})$ be its quantum chiral algebra supplied by the CY- $\mathcal{A}_2$ construction. Let $\mathcal{C}^!$ denote the Koszul dual CY_2 category (for $\mathcal{C} = D^b(\text{Coh}(X))$ with X a K_3 surface, $\mathcal{C}^! \simeq \text{Fuk}(X)$ under homological mirror self-duality). Then:

(C1^{CY}) *Eigenspace complementarity*. For every genus $g \geq 1$ and every degree $n \geq 1$ with $2g - 2 + n > 0$, the genus- g shadow complex satisfies

$$Q_g^n(\mathcal{A}_{\mathcal{C}}) \oplus Q_g^n(\mathcal{A}_{\mathcal{C}^!}) \simeq H^\bullet(\overline{\mathcal{M}}_{g,n}, \mathcal{Z}_{\text{ch}}^{\text{der}}(\mathcal{A}_{\mathcal{C}})),$$

as a direct sum of ± 1 eigenspaces for the Verdier involution induced by Serre duality on $D^b(\text{Coh}(\mathcal{C}))$. This is unconditional in the CY_2 case.

(C^{CY}_{scal}) *Scalar complementarity (restricted scope)*. Under the CY uniform-weight hypothesis (all generating fields of $\mathcal{A}_{\mathcal{C}}$ at equal conformal weight) and in the free-field/lattice Koszul class (the KM/Heisenberg branch, where the Koszul conductor $K = c(\mathcal{A}_{\mathcal{C}}) + c(\mathcal{A}_{\mathcal{C}^!})$ vanishes),

$$\kappa_{\text{ch}}(\mathcal{A}_{\mathcal{C}}) + \kappa_{\text{ch}}(\mathcal{A}_{\mathcal{C}^!}) = 0 \quad (\text{free-field/KM class}).$$

Away from the free-field class, the sum equals the family-dependent Koszul conductor and is nonzero in general: for the Virasoro class the analogous sum is $\kappa_{\text{ch}} + \kappa'_{\text{ch}} = 13$ (not 0), and for $\mathcal{W}_N$ it equals $c \cdot (H_N - 1)$ where $H_N = \sum_{j=1}^N 1/j$. For $\mathcal{C} = D^b(\text{Coh}(K_3))$ specifically, $\kappa_{\text{ch}}^{\text{Hodge}}(\mathcal{A}_{K_3}) = \chi^{\text{CY}}(K_3) = 2$ (Theorem CY-D, §27.1); the relevant chiral algebra is the $\widehat{\mathfrak{sl}}_2$ subalgebra at level $k = 1$ of the $\mathcal{N} = 4$ superconformal algebra, which lies in the free-field/KM class with $K = 0$, so the Verdier involution induced by the Mukai pairing gives the dual scalar -2 and the scalar sum vanishes on the K_3 free-field/KM branch. This vanishing is not universal across CY_2 categories.

Proof. (C1^{CY}): the eigenspace decomposition is the Φ_d -image of Vol I Theorem C1. The correspondence Φ_d is compatible with the Verdier involution (Chapter 5, Proposition on Serre-functor intertwining), so the direct sum decomposition of Vol I pulls back to a decomposition of $Q_g^n(\mathcal{A}_{\mathcal{C}}) \oplus Q_g^n(\mathcal{A}_{\mathcal{C}^!})$ indexed by Serre eigenvalues.

(C^{CY}_{scal}): under uniform weight, Vol I (C1) together with Vol I Theorem D gives $\kappa_{\text{ch}} + \kappa'_{\text{ch}} = 0$ for the Heisenberg/free-field classes. For K_3 , $\mathcal{A}_{K_3}$ is the $\mathcal{N} = 4$ superconformal algebra with $c = 6$, and all generators sit at conformal weights $\{1/2, 1, 3/2, 2\}$; the uniform-weight lane of interest is the $\widehat{\mathfrak{sl}}_2$ subalgebra at level $k = 1$, where $\kappa_{\text{ch}}^{\text{Hodge}} = 2$ is attained. The Verdier involution under the K_3 Mukai lattice self-duality $\Lambda_{K_3} \simeq \Lambda_{K_3}^\vee$ acts by a sign on odd-degree Hochschild classes, giving the dual scalar -2 . The sum vanishes. This is the scalar-shadow lane, not the Vol I (C2) shifted-symplectic upgrade. $\square$

Remark 28.2.2 (CY-D comparison). Substituting $d = 2$ (K_3) into $\kappa_{\text{ch}}^{\text{Hodge}}(A_C) = \chi^{\text{CY}}(C)$ (Theorem 27.1.1) gives $\kappa_{\text{ch}}^{\text{Hodge}}(\mathcal{A}_{K_3}) = \chi^{\text{CY}}(K_3) = 2$. This agrees with the chiral de Rham computation of Proposition 26.22.2.

Remark 28.2.3 (Categorical complementarity). Proposition 28.1.8 allows the scalar complementarity $(C_{\text{scal}}^{\text{CY}})$ to be restated on the categorical side. The *CY Koszul conductor* is

$$K_{\text{cat}} := \kappa_{\text{cat}}(C) + \kappa_{\text{cat}}(C^!) = \chi^{\text{CY}}(C) + \chi^{\text{CY}}(C^!).$$

On the free-field/KM branch (which includes K_3 under the Mukai self-duality), $K_{\text{cat}} = 0$: the Koszul dual categorical characteristic is $\kappa_{\text{cat}}(C^!) = -\kappa_{\text{cat}}(C)$. For K_3 specifically, $\kappa_{\text{cat}}(D^b(\text{Coh}(K_3))) = 2$ and $\kappa_{\text{cat}}(\text{Fuk}(K_3)) = -2$ under the Mukai-HMS involution, yielding $K_{\text{cat}} = 0$. Away from the free-field class, K_{cat} is nonzero and family-dependent on the scalar lane. This statement is not the Vol I (C_2) shifted-symplectic upgrade.

The $d = 3$ comparison criterion

THEOREM 28.2.4 (CY complementarity at $d = 3$ through the comparison criterion). Let X be a compact Calabi–Yau threefold and $C = D^b(\text{Coh}(X))$ its bounded derived category, with cyclic A_{∞} structure from the Serre trace. Assume X lies on a framed Φ_3 -specialisation locus, so that $A_X = \text{Sp}_{\Sigma_2, C}^{\text{ch}}(\Phi_3^{\text{FA}}(C))$ is defined as an E_1 -chiral algebra (Theorem 5.11.1). Let $C^!$ be a chosen Koszul-dual CY_3 category; under homological mirror symmetry this is $\text{Fuk}(X^{\vee})$ for the mirror threefold $X^{\vee}$. Assume the comparison maps

$$\Theta_A^{(3)} : \text{CC}_{\bullet}(C) \longrightarrow B^{\text{ord}}(A_X), \quad \Theta_B^{(3)} : D_{\text{Ran}} B^{\text{ord}}(A_X) \longrightarrow B^{\text{ord}}(A_{X^{\vee}})$$

are quasi-isomorphisms in the completed ordered-bar ambient, and that

$$\Theta_C^{(3)} : Q_g^n(A_X) \oplus Q_g^n(A_{X^{\vee}}) \longrightarrow H^{\bullet}(\overline{\mathcal{M}}_{g,n}, \mathcal{Z}_{\text{ch}}^{\text{der}}(A_X)), \quad \Theta_D^{\text{unif}} : \mathbb{C} \cdot (\kappa_{\text{ch}}(A_X) + \kappa_{\text{ch}}(A_{X^{\vee}})) \longrightarrow \mathbb{C} \cdot K_X$$

are compatible with the Vol I Theorem C complementarity pairing and the Vol I Theorem D uniform-weight scalar projection. Then:

$(C_1^{\text{CY}_3})$ The genus- g shadow complexes satisfy the eigenspace complementarity

$$Q_g^n(A_X) \oplus Q_g^n(A_{X^{\vee}}) \simeq H^{\bullet}(\overline{\mathcal{M}}_{g,n}, \mathcal{Z}_{\text{ch}}^{\text{der}}(A_X)),$$

through $\Theta_C^{(3)}$.

$(C_{\text{scal}}^{\text{CY}_3})$ Under the CY uniform-weight hypothesis (which is *not* generically satisfied for compact CY_3 : the chiral de Rham complex has fields in weights $\{1/2, 1, 3/2, 2, \dots\}$), and scope (the Koszul conductor is family-dependent: free-field/KM gives $K = 0$; Virasoro at the self-dual point $c = c^! = 13$ gives $K = \kappa_{\text{ch}}(V_c) + \kappa_{\text{ch}}(V_{c^!}) = c/2 + c^!/2 = 13$; $\mathcal{W}_N$ gives $K = c \cdot (H_N - 1)$ with $H_N = \sum_{j=1}^N 1/j$),

$$\kappa_{\text{ch}}(A_X) + \kappa_{\text{ch}}(A_{X^{\vee}}) = \rho \cdot K_X \quad (\text{CY}_3, \text{family-dependent, nonzero in general}),$$

where $K_X = c(A_X) + c(A_{X^{\vee}})$ is the CY Koszul conductor and ρ is the CY anomaly ratio. For $X = X_{\text{quintic}}$ with $\chi_{\text{top}} = -200$, the BCOV reading $\kappa_{\text{ch}}^{\text{BCOV}}(\mathcal{A}_{X_{\text{quintic}}}) = \chi_{\text{top}}/24 = -25/3$ gives a scalar sum of $-50/3$ on the self-mirror diagonal (distinct from the Hodge supertrace $\kappa_{\text{ch}}^{\text{Hodge}}(X_{\text{quintic}}) = 0$ by Serre at odd $d = 3$); the comparison Θ_D^{unif} is the exact map that identifies the BCOV scalar with $\rho \cdot K_{\text{quintic}}$.

Proof. The maps $\Theta_A^{(3)}$ and $\Theta_B^{(3)}$ put the framed CY_3 output in the same completed Koszul-reflection ambient as Vol I Theorems A and B. Applying Vol I Theorem C after $\Theta_C^{(3)}$ gives the eigenspace complementarity in $(\text{Cr}^{\text{CY}_3})$. Applying Vol I Theorem D only after projecting to the uniform-weight scalar lane gives $(C_{\text{scal}}^{\text{CY}_3})$ through Θ_D^{unif} . The multi-weight components of a compact CY_3 remain in the cross-channel correction $\delta F_g^{\text{cross}}$, so they are not collapsed into the scalar conductor statement. $\square$

Remark 28.2.5 (The remaining $d = 3$ comparison maps). Theorem 28.2.4 becomes a proved comparison only after the maps $\Theta_C^{(3)}$ and Θ_D^{unif} are supplied. Two independent obstructions block removing those hypotheses globally: (a) the uniform-weight hypothesis fails for compact CY_3 (chiral de Rham is multi-weight, so gives $\delta F_g^{\text{cross}} \neq 0$ at $g \geq 2$); (b) the BKM automorphic correction at $d = 3$ generates infinitely many imaginary root generators (§28.3 below), so even stating the Koszul conductor K_X requires resolving the degree- r shadow identification of theory_automorphic_shadow. Obstruction (a) persists even after the framed output $\mathcal{A}_X$ is chosen: uniform-weight is a property of the generating content of $\mathcal{A}_X$, not of the mere existence of a framed stage-2 specialisation.

Remark 28.2.6 (Degeneracy at vanishing modular characteristic warning). When $\kappa_{\text{ch}}(\mathcal{A}_C)$ vanishes (banana manifold, Heisenberg at level $k = 0$, Virasoro at $c = 0$; see §29.9), the free-field/KM branch of the scalar complementarity forces the Koszul-dual characteristic κ'_{ch} to vanish likewise, but this does *not* imply $\Theta_{\mathcal{A}_C}$ vanishes. Higher-degree shadow components can remain nonzero, sourced in the banana case by genus-0 GV invariants. The leading scalar complementarity degenerates; the full tower complementarity continues to encode nontrivial Koszul duality data. The Virasoro algebra at $c = 0$ sits on the free-field boundary of the $c = 13$ self-dual Virasoro family, where the generic scalar sum is $\kappa_{\text{ch}} + \kappa'_{\text{ch}} = 13$; $c = 0$ is the exceptional point of that family.

28.3 THE CY SHADOW COHFT

Volume I Theorem D promotes the shadow obstruction tower to a cohomological field theory (CohFT) on $\overline{\mathcal{M}}_{g,n}$ under a flat identity axiom: the axiom requires the flat identity to lie in the generating space (the vacuum of V). Every cross-reference below carries this conditionality explicitly.

CohFT structure

THEOREM 28.3.1 (CY shadow CohFT). Let $\mathcal{C}$ be a smooth proper cyclic A_∞ -category of CY dimension d , and suppose a constructed stage-2 chiral algebra $\mathcal{A}_C = \text{Sp}_{\Sigma_{d-1}, \mathcal{C}}^{\text{ch}}(\Phi_d^{\text{FA}}(\mathcal{C}))$ is supplied. **Assume:** the cyclic unit of $\mathcal{C}$ is identified with the vacuum $\mathbf{1}_{\mathcal{A}_C}$, and this vacuum lies in the generating space of $\mathcal{A}_C$ (equivalently, $\mathbf{1}_{\mathcal{A}_C}$ is flat for the Dubrovin connection of the shadow tower). Then the degree- n shadow classes

$$\Omega_{g,n}(\mathcal{A}_C) := \pi_{g,n,*}(\Theta_{\mathcal{A}_C}^{(g,n)}) \in H^\bullet(\overline{\mathcal{M}}_{g,n})^{\otimes n}$$

assemble into a CohFT: the pullbacks along the boundary maps $\overline{\mathcal{M}}_{g_1, n_1+1} \times \overline{\mathcal{M}}_{g_2, n_2+1} \rightarrow \overline{\mathcal{M}}_{g_1+g_2, n_1+n_2}$ and the loop $\overline{\mathcal{M}}_{g-1, n+2} \rightarrow \overline{\mathcal{M}}_{g,n}$ factor through the Koszul pair $(\mathcal{A}_C, \mathcal{A}_C^\dagger)$, and the unit axiom holds by the flat identity assumption.

Proof. Vol I Theorem D+H constructs the CohFT structure on the shadow tower of a chiral algebra with flat identity. The hypotheses supply exactly the stage-2 chiral algebra and unit–vacuum comparison needed to apply that theorem to $\mathcal{A}_C$; hence the pulled-back shadow classes on $\overline{\mathcal{M}}_{g,n}$ satisfy the CohFT axioms. The level at which the statement holds (ambient versus convolution, §29.1): this is the ambient level, built via Mok’s log Fulton–MacPherson boundary differential. $\square$

Remark 28.3.2 (conditionality). The flat identity hypothesis is conditional and must be stated at every cross-reference. Three scenarios where it fails: (i) CY categories without a categorical unit (rare but possible for nonunital $\mathcal{A}_\infty$ models); (ii) vertex algebras where the vacuum does not lie in the generating space (e.g. coset constructions); (iii) $\mathcal{W}$ -algebras with nontrivial BRST cohomology at degree zero. Every theorem that invokes Theorem 28.3.1, including the Igusa cusp form recovery below, inherits this hypothesis.

The $K_3 \times E$ CohFT and the Igusa cusp form

Remark 28.3.3 (Igusa Φ_{10}^{un} lives on tier-(iii); two scopes for κ_{BKM}). The Borchers lift at $K_3 \times E$ is a tier-(iii) specialisation in the sense of Remark 31.0.3 of Chapter 31: the single stage-1 object $\Phi_3^{\text{FA}}(D^b \text{Coh}(K_3 \times E))$ admits a family of (Σ_2, C) -specialisations indexed by admissible automorphism classes. Two distinct atlases realise the universal Borchers-weight identity $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2$, recorded with Scope (A)/(B) discipline.

Scope (A); CHL-averaged paramodular ladder. On $N \in \{1, 2, 3, 4, 6\}$ (the Gritsenko–Nikulin 1995 Part II Theorem 2.1 ladder), $(c_N(o)) = (10, 8, 6, 4, 2)$ and $(\kappa_{\text{BKM}}(\Phi_N)) = (5, 4, 3, 2, 1)$. Each Φ_N lives on the paramodular group $\Gamma_{\text{para}}^{(N)} \subset \text{Sp}_4(\mathbb{Z})$.

Scope (B); Gritsenko–Cléry 8-form atlas. On the Gritsenko–Cléry 2013 §3 atlas rows

$$(t, N; k) = (1, 1; 5), (2, 1; 2), (1, 2; 3), (3, 1; 1), (1, 3; 2), (4, 1; 1/2), (1, 4; 3/2), (2, 2; 1),$$

one has $(c_{t,N}(o, o)) = (10, 4, 6, 2, 4, 1, 3, 2)$ and $(\kappa_{\text{BKM}}(\Phi_{t,N})) = (5, 2, 3, 1, 2, 1/2, 3/2, 1)$. Integral weights live on paramodular groups and their normal extensions; the two half-integral rows use multiplier systems of orders 8 and 4. No quarter-integral or weight-0 row occurs in this eight-form atlas.

Both scopes agree at $N = 1$ (both giving $\kappa_{\text{BKM}}(\Delta_5) = 5$ on Δ_5) and diverge elsewhere: Scope (A) is the doubly-twined reading ($Z_{K_3}^{(g)} = 2\phi_{o,i}^{(g)}$, EOT factor absorbed), Scope (B) is the singly-twined reading with the factor kept outside. Every invocation of κ_{BKM} must name which scope. Primary: Gritsenko–Nikulin 1995 Pt II Theorem 2.1; Eguchi–Hikami 2011 at $N = 2$; Govindarajan–Krishna 2010 at $N \in \{3, 4, 6\}$; Gritsenko–Cléry 2013 §3 for Scope (B); Borchers 1998 Theorem 13.3 for the singular-theta weight formula; [96] Theorem 32.8.1 for the canonical table and [96] Theorem 19.6.1 for the chapter statement. The K_3 -fibre rank $\kappa_{\text{fiber}} = 24$ is a stage-1 invariant – a Kodaira count on the elliptic K_3 underneath $\Phi_3^{\text{FA}}(C)$ – and does *not* move under (Σ_2, C) -specialisation; the Hodge supertrace $\kappa_{\text{ch}}^{\text{Hodge}}(K_3 \times E) = 0$ is a tier-(i) intrinsic. The modular Koszul bridge reads: the stage-1 factorisation CohFT of Theorem 28.3.1 pushes forward along the Borchers singular theta correspondence to the tier-(iii) unnormalised Igusa square Φ_{10}^{un} (or Φ_N more generally), whose weight $\text{wt}(\Phi_{10}^{\text{un}}) = 10 = 2\kappa_{\text{BKM}}(\Delta_5)$ is the doubling of the chiral-half BKM weight under the Saito–Kurokawa lift target $\Phi_{10}^{\text{un}} = \Delta_5^2$ (rescale factor 4, not 2).

THEOREM 28.3.4 ($K_3 \times E$ shadow CohFT and Φ_{10}^{un}). Let $X = K_3 \times E$, with chiral algebra $\mathcal{A}_{K_3} \otimes H_1$ (chiral de Rham complex of K_3 tensored with the Heisenberg algebra of E), $\kappa_{\text{ch}}^{\text{Heis}}(K_3 \times E) = 3$ by rank-additivity (Proposition 27.2.3; K_3 -1 of §19.14). Assume the flat identity hypothesis. Then:

- (i) The shadow CohFT $\Omega_{g,n}(\mathcal{A}_{K_3} \otimes H_1)$ exists at all $g \geq 1$ and $n \geq 1$ with $2g - 2 + n > 0$ (Theorem 28.3.1).
- (ii) The Borchers multiplicative lift transports the genus-1 datum to genus-2 Siegel modular forms: the primitive input $\phi_{o,i}$ gives Δ_5 , while the full K_3 elliptic genus $2\phi_{o,i}$ gives the square

$$\Phi_{10}^{\text{un}}(\Omega) = \text{Borch}(2\phi_{o,i})(\Omega) = \Delta_5(\Omega)^2, \quad \text{wt}(\Phi_{10}^{\text{un}}) = 10,$$

this is the Igusa cusp form, §19.9 and chapters/examples/toroidal_elliptic.tex equation (5.1).

- (iii) The primitive BPS modular characteristic $\kappa_{\text{BKM}}(\Delta_5) = 5 = \text{wt}(\Delta_5)$ is distinct from the chiral characteristic $\kappa_{\text{ch}}^{\text{Heis}} = 3$ (the $\kappa_{\bullet}$ -spectrum polysemy, Remark 5.18.8; neither value is universal).
- (iv) The shadow obstruction tower of $\mathcal{A}_{K_3} \otimes H_1$ does *not* by itself reproduce Φ_{10}^{un} : four obstructions (K_{3-4} of §19.14) separate the shadow tower output from Φ_{10}^{un} . Namely, (O1) a categorical obstruction, (O2) the $\kappa_{\text{ch}}/\kappa_{\text{BKM}}$ mismatch $3 \neq 5$, (O3) second quantization (the Hilbert–Chow exceptional divisor), and (O4) the Schottky obstruction at $g \geq 4$ of codimension $(g-2)(g-3)/2$. The Borchers lift supplies precisely the combinatorial data needed to bridge these four obstructions.

Attribution. Parts (i), (iii), (iv) are Vol I/II results (§19.14, items K_{3-1} through K_{3-13} , proved in the K_3 modular-tower chapter of Vol I and in the holography part of Vol II). Part (ii) is the Borchers lift of Borchers (1998); its use as a modular characteristic is the observation of, not a theorem of Vol III. The conditionality propagates from Theorem 28.3.1. $\square$

PROPOSITION 28.3.5 (*Igusa, AdS, and Gritsenko–Clery layers of the modular Koszul bridge*). At the $K_3 \times E$ point the modular Koszul bridge separates three automorphic layers.

- (i) *Primitive BKM layer.* The Gritsenko–Nikulin denominator form Δ_5 satisfies

$$\kappa_{\text{BKM}}(\Delta_5) = c_1(o)/2 = 10/2 = 5 = \text{wt}(\Delta_5).$$

- (ii) *Dyonic AdS layer.* With the monic Borchers product normalisation for Δ_5 and theta-leading coefficient 64,

$$D_5 = 64^{-1} \Delta_5, \quad \Phi_{10}^{\text{un}} = \Delta_5^2, \quad \Phi_{10}^{\text{OP}} = D_5^2 = 4096^{-1} \Delta_5^2.$$

The Oberdieck–Pandharipande DT normalisation is therefore

$$Z_{\text{OP/DT}} = -(\Phi_{10}^{\text{OP}})^{-1} = -4096 \Delta_5^{-2}.$$

The genus-two universal dyonic partition form is

$$\Phi_{10}^{\text{un}} = \Delta_5^2, \quad \text{wt}(\Phi_{10}^{\text{un}}) = 10.$$

Consequently the AdS_3/CHL partition function reads the square of the primitive BKM denominator, not a second copy of κ_{BKM} .

- (iii) *Gritsenko–Clery throat atlas.* On the eight lattice-polarised throat cells

$$(t, N) = (1, 1), (2, 1), (1, 2), (3, 1), (1, 3), (4, 1), (1, 4), (2, 2),$$

the Borchers weights are

$$(\kappa_{\text{BKM}}(\Phi_{t,N})) = (5, 2, 3, 1, 2, 1/2, 3/2, 1),$$

with the half-integral multiplier-system rows kept separate from the CHL physical index set $\{1, 2, 3, 4, 6\}$.

The compatibility datum still absent from the pure CY-to-chiral statement is the product-level functor sending the BPS Hall convolution behind the AdS/CHL trace to the boundary chiral OPE. The automorphic identities above are proved as Borchers-weight and Gritsenko–Clery product computations with the displayed monic and Oberdieck–Pandharipande normalisations, without that functor; their interpretation as identities in the E_1 -chiral boundary requires it.

Proof. Part (i) is the Borchers singular-theta weight formula applied to the Gritsenko–Nikulin lift of the K_3 elliptic genus: the zero Fourier coefficient is $c_1(o) = 10$, hence the Borchers weight is $c_1(o)/2 = 5$. Part (ii) is the displayed product normalisation: the monic primitive product is Δ_5 , the theta-leading coefficient is 64, hence $D_5 = 64^{-1}\Delta_5$; $\Phi_{10}^{\text{un}} = \Delta_5^2$ and $\Phi_{10}^{\text{OP}} = D_5^2 = 4096^{-1}\Delta_5^2$. Therefore $Z_{\text{OP/DT}} = -(\Phi_{10}^{\text{OP}})^{-1} = -4096\Delta_5^{-2}$, and the weights double from 5 to 10. Part (iii) is precisely Scope (B) of Remark 28.3.3: the eight weights are the half-zero-coefficients of the Gritsenko–Cléry atlas. The integer-weight entries live on paramodular subgroups $\Gamma_t(N) \subset \text{Sp}_4(\mathbb{Q})$; the half-integer entries $\Delta_{1/2}, \nabla_{3/2}$ use the multiplier systems $v_\eta^3 \times v_H$ over Γ_4 and $\Gamma_0^{(2)}(4)$, not genuine metaplectic covers. The final sentence is the criterion of Theorem 31.2.11. $\square$

Remark 28.3.6 ($\kappa_\bullet$ -spectrum for $K_3 \times E$). Substituting $d = 2$ for K_3 into the CY-D formula $\kappa_{\text{ch}}^{\text{Hodge}}(A_C) = \chi^{\text{CY}}(C)$ gives $\kappa_{\text{ch}}^{\text{Hodge}}(\mathcal{A}_{K_3}) = 2$. Tensor-product additivity for the Heisenberg specialisation gives the Stage-2 rank $\kappa_{\text{ch}}^{\text{Heis}}(K_3 \times E) = 3$: the K_3 contribution 2 and the elliptic contribution 1 combine in the Heisenberg–Cartan construction. This is not the compact total-space Hodge supertrace and not the Koszul-dual scalar sum of Theorem 28.2.1. The Borchers value $\kappa_{\text{BKM}}(\Delta_5) = 5$ is the primitive denominator weight $c_1(o)/2 = 10/2$, equivalently half the weight of $\Phi_{10}^{\text{un}} = \Delta_5^2$. The five construction values

$$\{\kappa_{\text{cat}}, \kappa_{\text{ch}}^{\text{Hodge}}, \kappa_{\text{ch}}^{\text{Heis}}, \kappa_{\text{BKM}}, \kappa_{\text{fiber}}\}(K_3 \times E) = \{0, 0, 3, 5, 24\}$$

come from five distinct mathematical sources: $\kappa_{\text{cat}}(K_3 \times E) = \chi(\mathcal{O}_{K_3 \times E}) = \chi(\mathcal{O}_{K_3})\chi(\mathcal{O}_E) = 2 \cdot 0 = 0$; $\kappa_{\text{ch}}^{\text{Hodge}}(K_3 \times E) = 0$ by Serre at odd $d = 3$; $\kappa_{\text{ch}}^{\text{Heis}} = 3$ from the Heisenberg–Mukai specialisation; $\kappa_{\text{BKM}}(\Delta_5) = c_1(o)/2 = 5$ from the Borchers denominator at $N = 1$; and $\kappa_{\text{fiber}} = 24$ from the Mukai lattice rank. The compact total-space Hodge value $\kappa_{\text{ch}}^{\text{Hodge}}(K_3 \times E) = 0$ agrees with the total-space Euler reading, while the K_3 -fibre value $\chi(\mathcal{O}_{K_3}) = 2$ remains a per-fibre datum.

Toric CY_3 and the DT CohFT

Conjecture 28.3.7 (Toric CY_3 shadow CohFT). Let X_Σ be a smooth toric CY_3 with fan Σ . Conditional on a framed Φ_3 -specialisation for X_Σ , the shadow CohFT $\Omega_{g,n}(\mathcal{A}_{X_\Sigma})$ exists and satisfies:

- (i) The genus-0 generating function of $\Omega_{0,n}$ equals the topological vertex of Aganagic–Klemm–Mariño–Vafa;
- (ii) The full genus expansion equals the DT partition function $Z^{\text{DT}}(X_\Sigma)$, which is the MacMahon prefactor for $X_\Sigma = \mathbb{C}^3$ and the refined MacMahon for the resolved conifold (§29.2).

Remark 28.3.8 (Scope). Conjecture 28.3.7 is double-conditional: on the framed Φ_3 output and on the flat identity hypothesis (Remark 28.3.2). The resolved conifold case is the least obstructed: $\kappa_{\text{ch}} = 1$ is known (§27.1), and the vertex-algebra envelope has a flat vacuum. For $X_\Sigma = \mathbb{C}^3$, the CoHA is the positive half $Y^+(\widehat{\mathfrak{gl}}_1)$. The $\mathcal{W}_{1+\infty}$ vertex algebra enters only after passing through the Drinfeld double/centre and evaluating on the vacuum module. The MacMahon identification of the bar Euler product is Theorem 29.2.1; the upgrade to a full CohFT on $\overline{\mathcal{M}}_{g,n}$ requires the $d = 3$ degree-to-depth correspondence (theory_automorphic_shadow, §28.3).

28.4 GETZLER–KAPRANOV MODULAR OPERAD AND THE CHAIN-LEVEL BORCHERS-WEIGHT BRIDGE

The CohFT of Theorem 28.3.1 sits on the modular operad MMG whose (g, n) -component is $\overline{\mathcal{M}}_{g,n}$ (Getzler–Kapranov 1998 *Compositio Math.* 110). The modular-operadic structure; boundary-gluing

$\overline{\mathcal{M}}_{g_1, n_1+1} \times \overline{\mathcal{M}}_{g_2, n_2+1} \rightarrow \overline{\mathcal{M}}_{g_1+g_2, n_1+n_2}$ and self-gluing $\overline{\mathcal{M}}_{g, n+2} \rightarrow \overline{\mathcal{M}}_{g+1, n}$; is the geometric substrate on which the chain-level E_3 -Koszul duality of Stage-1 couples to the Borchers singular-theta correspondence. This section records the bridge: the Koszul dual of $\Phi_3^{\text{FA}}(C) \in E_d\text{-HolFA}(X)$ pairs, via the Getzler–Kapranov fundamental class on $\overline{\mathcal{M}}_{g, n}$, against the Borchers lift of the K_3 elliptic genus. The scalar read from the Borchers side is the denominator weight $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2$.

Chain-level fundamental class of $\overline{\mathcal{M}}_{g, n}$

Definition 28.4.1 (*Chain-level fundamental class*). The *chain-level fundamental class* of $\overline{\mathcal{M}}_{g, n}$ is the distinguished element

$$[\overline{\mathcal{M}}_{g, n}] \in C_{\bullet}^{\text{FM-log}}(\overline{\mathcal{M}}_{g, n}; \mathbb{Q})$$

of the Fulton–MacPherson logarithmic chain complex (Kim–Nishinou – Thomas 2019 *Adv. Math.* 335; Mok 2025). It represents the Poincaré dual of the top cohomology class after the log-FM compactification, and carries four properties: modular-operadic compatibility with gluing and self-gluing, cyclic-operadic compatibility at genus 0 (Kapranov 1999 *Compositio Math.* 115 Theorem 1.1), Torelli compatibility (pushforward to $\overline{\mathcal{A}}_g$ is well-defined for $g \leq 3$), and tautological compatibility (its pushforward along forgetful maps preserves the tautological structure).

PROPOSITION 28.4.2 (*Kapranov cyclic-operadic correspondence at genus 0*). The rational homology of the moduli space $\overline{\mathcal{M}}_{0, n+1}$ is isomorphic to the cyclic Gerstenhaber operad of degree -2 ,

$$H_{\bullet}(\overline{\mathcal{M}}_{0, n+1}; \mathbb{Q}) \simeq \text{Ger}_3^{\text{cyc}}(n),$$

as cyclic Σ_{n+1} -representations; this is the genus-0 stratum of the Getzler–Kapranov modular operad. The cyclic pairing on the E_3 Koszul dual of a smooth proper cyclic A_{∞} -category is pulled back from the cyclic-operadic pairing on $\text{Ger}_3^{\text{cyc}}$.

Attribution. Kapranov 1999 *Compositio Math.* 115 Theorem 1.1; the cyclic-operadic lift is §4 of the same paper. The connection with E_3 Koszul duality is classical (Kontsevich 2003 on formal deformation quantisation). $\square$

Modular-operadic Koszul pairing

Definition 28.4.3 (*Modular-Koszul pairing*). Let $C \in \text{CY}_d\text{-Cat}^{\text{dg}}$ and $\Phi_d^{\text{FA}}(C) \in E_d\text{-HolFA}(X)$ its Stage-1 object. The *modular-Koszul pairing* at (g, n) is

$$\langle -, - \rangle_{g, n}^{\text{mod}} : B^{E_d}(\Phi_d^{\text{FA}}(C))^{\otimes n} \otimes H_{\bullet}(\overline{\mathcal{M}}_{g, n}; \mathbb{Q}) \rightarrow k, \quad (28.1)$$

defined by composing the n -ary E_d -coalgebra coproduct on $B^{E_d}(\Phi_d^{\text{FA}}(C))$ with integration against $[\overline{\mathcal{M}}_{g, n}]$ via the Torelli factorisation $\tau : \overline{\mathcal{M}}_{g, n} \rightarrow \overline{\mathcal{A}}_{g, n}$ (well-defined for $g \leq 3$). At $d = 3$, the pairing requires a framed Stage-2 specialisation (Σ_2, C) (Theorem 5.11.1); at $d = 2$, no framing is needed.

Remark 28.4.4 (*Four voices on the pairing*). The modular-Koszul pairing (28.1) carries four equivalent readings, each surfacing a different structural aspect.

Beilinson. $B^{E_d}(\Phi_d^{\text{FA}}(C))$ specialises at Stage-2 to the chiral bar $B(\mathcal{A}_C)$ on $\text{Ran}(C)$; the pairing is the Beilinson–Drinfeld integration of $B(\mathcal{A}_C)$ against the class of the universal curve ([10] §3.4.11).

Kapranov. The genus-0 stratum of the pairing is the cyclic operadic action of $\text{Ger}_3^{\text{cyc}}$ on $B^{E_3}(\Phi_3^{\text{FA}}(C))$ (Proposition 28.4.2); higher-genus extension is the Getzler–Kapranov modular closure.

Costello. The pairing is the factorisation-envelope integral of $\Phi_d^{\text{FA}}(C)$ along $X \times \overline{\mathcal{M}}_{g,n}$, in the sense of Costello–Gwilliam [286] §10.2; the E_d -algebra structure on the CY source tensors with the modular-operadic structure on the moduli base.

Gaiotto. The pairing is the partition function of topological Chern–Simons theory on $X \times \overline{\mathcal{M}}_{g,n}$, identifying CFG 2026’s E_3 -observables with the chain-level Getzler–Kapranov pairing.

The four readings agree at the level of rational cohomology after localisation at $[\overline{\mathcal{M}}_{g,n}]$; the chain-level intertwining is governed by Kontsevich–Tamarkin E_3 -formality at $d = 3$.

Torelli–spin factorisation of the Borchers lift

The bridge from the modular-Koszul pairing on $\overline{\mathcal{M}}_{g,n}$ to the Borchers automorphic form on an orthogonal Shimura variety passes through the Torelli morphism and, at genus 2, the accidental spin identification $\text{Sp}_4 \simeq \text{Spin}(2, 3)$.

Definition 28.4.5 (Torelli and the genus-2 spin identification). The *Torelli morphism* $\tau: \overline{\mathcal{M}}_g \rightarrow \overline{\mathcal{A}}_g$ (van Geemen 1984) sends a stable curve to its Jacobian, a principally polarised abelian g -fold. It is birational on an open dense subset for $g \leq 3$, injective-immersive away from the hyperelliptic locus at $g = 3$, and obstructed at $g \geq 4$ by the Schottky locus of codimension $(g - 2)(g - 3)/2$.

At $g = 2$, the standard representation of Sp_4 gives $\text{PGSp}_4 \simeq \text{SO}(2, 3)$. Hence $\mathcal{A}_2$ may be read as the orthogonal Shimura variety $\text{Sh}_{\text{O}(2,3)}$ on which the paramodular Borchers forms live. This is not the Kuga–Satake construction and gives no map $\mathcal{A}_g \rightarrow \text{Sh}_{\text{O}(2,2g-1)}$ for general g .

The composite used below is

$$\iota_{\text{spin}} \circ \tau: \overline{\mathcal{M}}_2 \dashrightarrow \text{Sh}_{\text{O}(2,3)},$$

where ι_{spin} denotes the genus-2 spin identification.

PROPOSITION 28.4.6 (Borchers pullback under Torelli–spin). For C a smooth proper CY_d -category with framed Stage-2 data (Σ_2, C) at $d = 3$, and at $g = 2$, the modular-Koszul pairing (28.1) factors through the Torelli–spin composite:

$$\langle -, - \rangle_{2,0}^{\text{mod}} = \int_{\overline{\mathcal{M}}_2} \tau^* \iota_{\text{spin}}^* \Phi_N \cdot \text{ch}_d(\text{HH}^\bullet(C)), \quad (28.2)$$

where $\Phi_N \in \mathcal{M}_{k(N)}^{\text{aut}}(\text{O}(2, 3))$ is the Borchers lift at CHL level N (Scope (A)) or paramodular index m (Scope (B)), and ch_d is the degree- d Chern character of the Hochschild cohomology sheaf.

Proof. At $g = 2$, the Torelli morphism τ is birational onto its image, and the spin isomorphism identifies $\mathcal{A}_2$ with $\text{Sh}_{\text{O}(2,3)}$. The Borchers lift Φ_N is a holomorphic section of the Hodge line bundle $\omega^{k(N)}$ on $\text{Sh}_{\text{O}(2,3)}$; its pullback along $\iota_{\text{spin}} \circ \tau$ lives in $H^0(\overline{\mathcal{M}}_2, \omega_2^{k(N)})$, where ω_2 is the determinant of the Hodge bundle on $\overline{\mathcal{M}}_2$. Integration against $\text{ch}_d(\text{HH}^\bullet(C))$ gives (28.2). Detailed proof: Borchers 1998 *Invent. Math.* 132 Theorem 13.3 (singular-theta weight formula) specialised to $\text{O}(2, 3)$ combined with the $g = 2$ Torelli birationality. $\square$

The two-scope Borchers weight as chain-level supertrace

THEOREM 28.4.7 (Chain-level modular-Koszul bridge at $d = 3$, two scopes). Let $C = D^b\text{Coh}(K_3 \times E)$ with Stage-1 object $\Phi_3^{\text{FA}}(C) \in E_d\text{-HolFA}(K_3 \times E)$, and let $\mathcal{A}_C = \text{Sp}_{\Sigma_2, C}^{\text{ch}}(\Phi_3^{\text{FA}}(C))$

be the Stage-2 chiral algebra on a framed specialisation locus. At $(g, n) = (2, 0)$, the supertrace of the modular-Koszul pairing (28.1) recovers the Borchers weight:

$$s\mathrm{Tr} \langle B^{E_3}(\Phi_3^{\mathrm{FA}}(C)), [\overline{\mathcal{M}}_2] \rangle_{2,0}^{\mathrm{mod}} = c_N(0)/2 = \kappa_{\mathrm{BKM}}(\Phi_N),$$

universally at two scopes:

Scope (A); CHL-averaged paramodular ladder. On $N \in \{1, 2, 3, 4, 6\}$ (Gritsenko–Nikulin 1995 Pt. II Theorem 2.1; Eguchi–Hikami 2011 at $N = 2$; Govindarajan–Krishna 2010 at $N \in \{3, 4, 6\}$), the pairing uses the doubly-twined K_3 elliptic genus $Z_{K_3}^{(g)} = 2\phi_{0,1}^{(g)}$ (EOT factor absorbed), producing

$$(c_N(0), \kappa_{\mathrm{BKM}}(\Phi_N))_{N \in \{1,2,3,4,6\}} = ((10, 5), (8, 4), (6, 3), (4, 2), (2, 1)).$$

Each Φ_N lives on the paramodular group $\Gamma_{\mathrm{para}}^{(N)} \subset \mathrm{Sp}_4(\mathbb{Z})$.

Scope (B); Gritsenko–Cléry 8-form atlas. On atlas rows

$$(t, N; k) = (1, 1; 5), (2, 1; 2), (1, 2; 3), (3, 1; 1), (1, 3; 2), (4, 1; 1/2), (1, 4; 3/2), (2, 2; 1)$$

(Gritsenko–Cléry 2013 arXiv:1305.4884 §3), the pairing uses the singly-twined K_3 elliptic genus (EOT factor kept outside), producing

$$(c_{t,N}(0, 0), \kappa_{\mathrm{BKM}}(\Phi_{t,N})) = ((10, 5), (4, 2), (6, 3), (2, 1), (4, 2), (1, 1/2), (3, 3/2), (2, 1)).$$

The automorphy stratification is paramodular at integer weights and uses multiplier systems at the two half-integer rows.

The two scopes coincide at $N = 1$ (Igusa Δ_5), both giving $\kappa_{\mathrm{BKM}}(\Delta_5) = 5$, and diverge elsewhere by the doubly-twined/singly-twined averaging convention.

Proof. Combining Proposition 28.4.6 with the Borchers weight formula (Borchers 1998 *Invent. Math.* 132 Theorem 13.3): the singular-theta weight of the output equals half the zero Fourier coefficient of the input Jacobi form. The two scopes correspond to two averaging conventions: Scope (A) is the doubly-twined reading with EOT factor absorbed (Eguchi–Ooguri–Tachikawa 2011), Scope (B) is the singly-twined reading with EOT factor kept external (Gritsenko–Cléry 2013). Each is a well-defined specialisation of the modular-Koszul pairing at $(g, n) = (2, 0)$.

The primary literature ladder at Scope (A): Gritsenko–Nikulin 1995 [107] Pt. II Theorem 2.1 for $N = 1$ with $\Phi_1 = \Delta_5$ weight 5 and $c_1(0) = 10$; Eguchi–Hikami 2011 [214] for $N = 2$ with $c_2(0) = 8$ and weight 4; Govindarajan–Krishna 2010 [215] for $N \in \{3, 4, 6\}$ with $(c_N(0), \kappa_{\mathrm{BKM}}) = ((6, 3), (4, 2), (2, 1))$. The Scope (B) ladder follows from Gritsenko–Cléry 2013 [213] §3’s 8-form classification, with half-integral automorphy carried by the displayed multiplier systems.

The coincidence at $N = 1$ is forced by the Δ_5 diagonal: Gritsenko’s additive lift $\Delta_5 = \mathrm{Lift}_G(\eta^9 \mathfrak{S}_1)$ is canonical, independent of averaging convention.

The chain-level side: at the $K_3 \times E$ base point, the Hochschild cohomology has total dimension $48 = 24 \cdot 2$ (Künneth of $\mathrm{HH}^\bullet(K_3) = 24\text{-dim}$ and $\mathrm{HH}^\bullet(E) = 2\text{-dim}$). The supertrace of the modular-Koszul pairing on $[\overline{\mathcal{M}}_2]$ computes, via (28.2), as $10 \cdot \chi_{\mathrm{dR}}(K_3)/24 = 10$, halving by Borchers’ weight formula to $\kappa_{\mathrm{BKM}}(\Delta_5) = 5$. The twined readings at $N \geq 2$ (Scope (A)) and $m \geq 2$ (Scope (B)) use the twined Hochschild cohomology $\mathrm{HH}_{(g_N)}^\bullet(K_3 \times E)$, with twisted Euler characteristic $\chi_{\mathrm{dR}}^{(g_N)}(K_3)$ matching the twined Fourier coefficient $c_N(0)$. $\square$

Remark 28.4.8 (The $\kappa_\bullet$ -spectrum at $K_3 \times E$). The chain-level modular-Koszul bridge recovers only κ_{BKM} among the five construction values in the $K_3 \times E$ spectrum $\{\kappa_{\text{cat}}, \kappa_{\text{ch}}^{\text{Hodge}}, \kappa_{\text{ch}}^{\text{Heis}}, \kappa_{\text{BKM}}, \kappa_{\text{fiber}}\} = \{0, 0, 3, 5, 24\}$: $\kappa_{\text{cat}}(K_3 \times E) = 0$ is the Künneth-multiplicative Euler characteristic $\chi(O_{K_3})\chi(O_E) = 2 \cdot 0$; $\kappa_{\text{ch}}^{\text{Hodge}}(K_3 \times E) = \sum_q (-1)^q h^{0,q}(K_3 \times E) = 0$ is the compact chiral Hodge supertrace (the canonical fifth construction, numerically coinciding with κ_{cat} on the compact CY_3 yet a distinct construction); $\kappa_{\text{ch}}^{\text{Heis}}(K_3 \times E) = 3$ is the Heisenberg–Cartan rank $2 + 1$; $\kappa_{\text{BKM}}(\Delta_5) = 5$ is the Borchers weight derived here; $\kappa_{\text{fiber}}(K_3) = 24$ is the Mukai-lattice rank. The chain-level bridge computes the BKM weight directly from the Borchers input and does not decompose it into a chiral term plus a fibre Euler term. Such a decomposition fails on the CHL ladder; the universal identity is $\kappa_{\text{BKM}}(\Phi_N) = c_N(0)/2$ (Theorem 32.8.1). The same identity at $N = 1$ is the load-bearing input to the B-row Mukai-Heisenberg complementarity of Vol I [96] (Theorem C: $K^{\kappa_{\text{ch}}} = 8$ via Bruinier Heegner Chern-class reciprocity); the level-4 scalar shadow disclaimer of [99] bounds the operator-level promotion route.

Local-to-global assembly on the modular operad

Conjecture 28.4.9 (Genus-summed generating function). For $C = D^b\text{Coh}(K_3 \times E)$ on the framed Φ_3 -specialisation locus, the genus-summed generating function

$$Z_C^{\text{GK}}(q, z) := \sum_{g \geq 0, n \geq 0} \frac{q^g z^n}{n!} \text{sTr} \langle B^{E_3}(\Phi_3^{\text{FA}}(C)), [\overline{\mathcal{M}}_{g,n}] \rangle_{g,n}^{\text{mod}}$$

equals the Oberdieck–Pandharipande reduced Donaldson–Thomas scalar

$$Z_{K_3 \times E}^{\text{GK}}(q, z) = -(\Phi_{10}^{\text{OP}}(q, z, \tau))^{-1},$$

with $D_5 = 64^{-1}\Delta_5$ and $\Phi_{10}^{\text{OP}} = D_5^2 = 4096^{-1}\Delta_5^2$, by the four-arrow composite: (i) at fixed (g, n) , the pairing is an integral over $\overline{\mathcal{M}}_{g,n}$ of a Siegel-modular class of total weight $10 = 2 \kappa_{\text{BKM}}(\Delta_5)$, the weight of the Igusa-square denominator Φ_{10}^{OP} ; (ii) the genus-summed generating function is $\log Z^{\text{GK}}$, the BPS/GW generating function; (iii) Maulik–Nekrasov–Okounkov–Pandharipande 2006 identifies GW with DT on CY_3 ; (iv) Oberdieck 2018 *JEMS* 20 identifies $Z_{K_3 \times E}^{\text{DT}}$ with $-(\Phi_{10}^{\text{OP}})^{-1}$.

Remark 28.4.10 (The modular operad assembles local data globally). The modular operad MMG assembles the genus-0 E_3 -Koszul pairing into higher genera via:

- Boundary-gluing $\overline{\mathcal{M}}_{g_1, n_1+1} \times \overline{\mathcal{M}}_{g_2, n_2+1} \rightarrow \overline{\mathcal{M}}_{g_1+g_2, n_1+n_2}$, corresponding to the tensor product of E_3 -modules.
- Self-gluing $\overline{\mathcal{M}}_{g, n+2} \rightarrow \overline{\mathcal{M}}_{g+1, n}$, corresponding to the Hochschild trace on the E_3 -bimodule.

Iterating the self-gluing g times raises genus 0 to genus g ; the pairing at genus g reconstructs from genus-0 pieces via $\langle -, - \rangle_{g,n}^{\text{mod}} = \text{Tr}_{\text{Hoch}}^g(\langle -, - \rangle_{0, n+2g}^{\text{mod}})$. This is the genus-raising formula on the modular-operadic side.

Obstructions and scope

Remark 28.4.11 (Four obstructions limiting the bridge). Four obstructions limit the chain-level modular-Koszul bridge:

- (O1) *Schottky at $g \geq 4$.* The Torelli morphism $\tau: \overline{\mathcal{M}}_g \rightarrow \overline{\mathcal{A}}_g$ is not birational for $g \geq 4$ (Schottky locus of codimension $(g-2)(g-3)/2$). The bridge is clean at $g \leq 3$; at $g \geq 4$, a Schottky lift is required. For the Igusa Φ_{10}^{un} at $g = 2$, this is not an obstruction.

- (O₂) *Multiplier systems at Scope (B) weights 1/2, 3/2.* The half-integral rows require the multiplier systems $v_\eta^3 \times v_H$ on the corresponding paramodular groups. The bridge must carry those multipliers through the Torelli pullback.
- (O₃) *Hodge filtration off pure weight.* The pairing factors through the Hodge filtration; the Borcherds weight is the supertrace of the pure-weight sector. Off the pure-weight sector, a correction $\delta \kappa_{\text{BKM}}^{\text{mix}}$ appears.
- (O₄) *Framed Stage-2 conditionality.* The bridge requires $A_C = \text{Sp}_{\Sigma, C}^{\text{ch}}(\Phi_3^{\text{FA}}(C))$ on a framed specialisation locus (Theorem 5.11.1). Compact CY_3 without a framed specialisation does not support the bridge.

Remark 28.4.12 (Lorgat 2020 Conjecture 1 as two-scope sharpening). Lorgat 2020 arXiv:2004.09030 §4 conjectures (Conjecture 1) that the 8 Gritsenko–Cléry forms correspond to 8 distinct DT zeta-function specialisations of reduced $K_3 \times E$ -type partition functions, twined by 8 distinct Mathieu M_{24} traces. The chain-level modular-Koszul bridge of Theorem 28.4.7 provides the Scope (B) side of this conjecture: each paramodular index $(t, N) \in \{(1, 1), (2, 1), (1, 2), (3, 1), (1, 3), (4, 1), (1, 4), (2, 2)\}$ corresponds to a distinct framing $(\Sigma_2^{(t, N)}, C^{(t, N)})$ of the Stage-2 specialisation locus; the modular-Koszul pairing at each framing recovers the Borcherds weight $\kappa_{\text{BKM}}(\Phi_{t, N}) = c_{t, N}(\mathbf{o}, \mathbf{o})/2$. The chain-level identification of each framing with an M_{24} twist is the content of Lorgat’s Conjecture.

CFG 2026 identification of the physical side

Remark 28.4.13 (Costello–Francis–Gwilliam 2026 bridge). The chain-level modular-Koszul bridge pairs $B^{E_3}(\Phi_3^{\text{FA}}(C))$ against $[\overline{M}_{g, n}]$ via a cyclic-Koszul operation; CFG 2026 provides the physical face: local observables of topological Chern–Simons theory on $X \times \overline{M}_{g, n}$ form an E_3 -algebra over $\mathbb{Q}$ (CFG 2026 Theorem A), and the BPS partition function (CFG 2026 Theorem B) equals the supertrace of the modular-operadic pairing. The Kontsevich–Tamarkin E_3 -formality [294, 303] pins $\Phi_3^{\text{FA}}(C)$ up to $\text{GRT}_1(\mathbb{Q})$ -torsor action, which preserves the modular pairing (Kapranov 1999 *Compositio Math.* 115 Theorem 3.2: Grothendieck–Teichmüller action on the cyclic Gerstenhaber operad preserves the cyclic pairing); consequently, the Borcherds weight $\kappa_{\text{BKM}}(\Phi_N) = c_N(\mathbf{o})/2$ is $\text{GRT}_1(\mathbb{Q})$ -invariant, and the two-scope theorem holds universally across the torsor.

28.5 THE HOCHSCHILD BRIDGE

A persistent source of confusion in the CY correspondence is the multiplicity of “Hochschild” objects: the categorical Hochschild homology of C , the chiral Hochschild cohomology of A_C , and the derived center of A_C are three distinct mathematical objects that agree only in special cases and compute different invariants. The categorical Hochschild controls deformation theory; the chiral Hochschild controls the shadow tower; the derived center is the bulk algebra. A constructed comparison Θ_H is what relates these theories; without it they are not automatically identified by the notation Φ_d . Three Hochschild theories act on a CY category C with constructed stage-2 chiral algebra A_C , and distinguishing them is essential for the bridge to Volume I.

Definition 28.5.1 (Three Hochschild theories). Let C be a smooth proper CY_d category with a constructed stage-2 chiral algebra A_C .

- (i) *Categorical Hochschild.* The cyclic bar complex $\text{CC}_\bullet(C)$ with Hochschild differential b and Connes operator B . This is the topological invariant of C as a dg category: it carries the Gerstenhaber bracket and the $(2 - d)$ -shifted Poisson structure from the Serre pairing (Chapter 4).

- (ii) *Chiral Hochschild*. The chiral Hochschild cohomology $\text{ChirHoch}^*(A_C)$ of Volume I (Theorem H; stated on the curve-ambient, i.e. $d = 1$ ambient on the Ran space): amplitude $[0, 2]$ with Hilbert polynomial in t on the curve-ambient reading. When the Θ_H comparison is installed for Φ_d with $d \geq 2$, the CY_d -enlarged ambient contributes the additional degree- d cohomological lane; chain-level is infinite for class-M inputs at $d \geq 3$. This is the obstruction-theoretic invariant governing the shadow tower of A_C .
- (iii) *Derived center*. The chiral derived center $\mathcal{Z}_{\text{ch}}^{\text{der}}(A_C) = \text{RHom}(\Omega B(A_C), A_C)$: the algebraic closed-sector vertex, computed by chiral Hochschild *cochains* (not cohomology). It becomes a physical bulk target only after the Vol II HT open/closed comparison datum is installed.

These are distinct invariants. The categorical Hochschild lives on C (no curve geometry); the chiral Hochschild lives on A_C (curve geometry through the OPE); the derived center is the endomorphism algebra of the identity functor in the factorization category (curve geometry through $\text{Ran}(X)$).

At $d = 2$ the bridge theorem identifies how Φ intertwines the categorical and chiral sides.

THEOREM 28.5.2 (*Hochschild bridge*). Let C be a smooth proper CY_2 category and $A_C = \Phi(C)$ be supplied by the CY-A_2 construction. Then Φ induces:

- (i) A quasi-isomorphism of factorization coalgebras $\text{CC}_\bullet(C) \xrightarrow{\sim} B(A_C)$ on $\text{Ran}(X)$ (this is CY-A(ii) , Proposition 29.1.1).
- (ii) A map on cohomology $\text{HH}^\bullet(C) \rightarrow \text{ChirHoch}^*(A_C)$ that sends the Gerstenhaber bracket on $\text{HH}^\bullet(C)$ to the convolution bracket on $\text{ChirHoch}^*(A_C)$, and sends the Connes B -operator to the modular differential.
- (iii) A map $\text{HH}^\bullet(C, C) \rightarrow \mathcal{Z}_{\text{ch}}^{\text{der}}(A_C)$ from the categorical Hochschild cochains (the endomorphism algebra of the identity bimodule) to the chiral derived center, compatible with the Gerstenhaber product on the source and the chiral bracket on the target.

Proof. Part (i) is Proposition 29.1.1. For (ii): the Gerstenhaber bracket on $\text{HH}^\bullet(C)$ is a Lie bracket of degree -1 . Under Φ , this bracket becomes the convolution bracket of Vol I by functoriality of the bar construction: the deconcatenation coproduct on $B(A_C)$ and the binary product of A_C assemble into a bracket on $\text{Hom}_{\text{Ran}}(B(A_C), A_C)$, which restricts to $\text{ChirHoch}^*(A_C)$ on the cohomology. The Connes operator B on $\text{CC}_\bullet(C)$ corresponds, under the bar dictionary, to the degree-preserving component of the bar differential (Proposition 29.1.1(ii)), which is the modular differential on the chiral side. For (iii): the categorical Hochschild cochains $\text{CC}^\bullet(C, C)$ map to $\text{RHom}(\Omega B(A_C), A_C)$ by applying Φ to each hom-space and using the bar-cobar counit $\Omega B(A_C) \simeq A_C$ (the inversion face of Vol I Theorem A on the Koszul locus; the completed coderived strengthening is Vol I Theorem B). $\square$

Remark 28.5.3 (*Which Hochschild controls which invariant*). The categorical Hochschild $\text{HH}_\bullet(C)$ controls the deformation theory of C as a CY category: $\text{HH}^2(C)$ parametrizes first-order deformations, $\text{HH}^1(C)$ the infinitesimal automorphisms. The chiral Hochschild $\text{ChirHoch}^*(A_C)$ controls the shadow tower of A_C : the obstruction classes obs_g live in $\text{ChirHoch}^2(A_C) \otimes H^\bullet(\overline{\mathcal{M}}_{g,n})$. The derived center $\mathcal{Z}_{\text{ch}}^{\text{der}}(A_C)$ is the bulk algebra of the holographic datum: its elements are the operators that commute with all boundary insertions. Theorem 28.5.2 gives the $d = 2$ transmission; for $d \geq 3$ the corresponding statement is the Θ_H comparison obligation of Theorem 28.10.1.

THEOREM 28.5.4 (*Hochschild bridge at $d = 3$ through Θ_H*). For C a smooth proper CY_3 category with framed output $A_C = \text{Sp}_{\Sigma_3, C}^{\text{ch}}(\Phi_3^{\text{FA}}(C))$ (Theorem 5.11.1), assume there are chain maps

$$\Theta_H^{(3)} : \text{HC}_{\bullet}^-(C) \longrightarrow \text{ChirHoch}^*(A_C), \quad \Theta_A^{(3)} : \text{CC}_{\bullet}(C) \longrightarrow B^{\text{ord}}(A_C),$$

and

$$\Theta_Z^{(3)} : \text{CC}^{\bullet}(C, C) \longrightarrow \text{RHom}\left(\Omega B^{\text{ord}}(A_C), A_C\right)$$

compatible with the Connes operator versus the modular differential, with the Pantev–Toën–Vaquié–Vezzosi (-1) -shifted Poisson bracket versus the genus-0 convolution bracket, and with the Vol I Theorem B bar-cobar counit in the weight-completed / coderived ambient. Then the maps (i)–(iii) of Theorem 28.5.2 extend to $d = 3$. The (-1) -shifted Poisson structure on $\text{HH}^{\bullet}(C)$ maps to the genus-0 contribution of the convolution bracket on $\text{ChirHoch}^*(A_C)$; the genus- $g \geq 1$ components of the convolution bracket have no direct categorical-Hochschild source and arise from the curve geometry of $\text{Ran}(X)$ through Φ .

Proof. The comparison $\Theta_A^{(3)}$ gives the factorization-coalgebra part of Theorem 28.5.2(i). The map $\Theta_H^{(3)}$ carries the mixed complex $(\text{CC}_{\bullet}(C), b, B)$ to the chiral Hochschild complex and identifies B with the modular differential, so it gives (ii) after cohomology. The map $\Theta_Z^{(3)}$, together with the Vol I Theorem B counit $\Omega B^{\text{ord}}(A_C) \rightarrow A_C$ in the completed ambient, gives the derived-centre map in (iii). The remaining obstruction to an unconditional statement is therefore the construction of these three compatible chain maps, not a change in the Vol I Hochschild theorem. $\square$

28.6 PRINCIPAL EXAMPLES

The modular Koszul bridge produces concrete numerical data for each CY category: the $\kappa_{\bullet}$ -spectrum, the shadow class, and the genus- g obstruction tower. This section collects the principal examples.

$K_3 \times E$

The product $K_3 \times E$ (K_3 surface times an elliptic curve) is CY_3 with independently computable chiral algebra $\mathcal{A}_{K_3} \otimes H_1$. The four total-space $\kappa_{\bullet}$ -invariants arise from four distinct constructions; the K_3 -fibre per-fibre datum $\chi(\mathcal{O}_{K_3}) = 2$ appears separately as a per-fibre annotation, not a fifth total-space entry:

Subscript	Source	Value	Derivation
κ_{cat}	$\chi(\mathcal{O}_{K_3 \times E})$ (total space)	0	Künneth: $\chi(\mathcal{O}_{K_3}) \cdot \chi(\mathcal{O}_E) = 2 \cdot 0 = 0$
$\kappa_{\text{ch}}^{\text{Heis}}$	$\text{rank}_{\text{Cartan}}(\mathcal{A}_{K_3} \otimes H_1)$	3	Beauville: $\kappa_{\text{ch}}^{\text{Heis}}(K_3) + \kappa_{\text{ch}}^{\text{Heis}}(E) = 2 + 1$
κ_{BKM}	$\text{wt}(\Delta_5)$	5	Primitive BKM superalgebra weight; $\text{wt}(\Phi_{10}^{\text{un}}) = 10$
κ_{fiber}	$\text{rank}(\Lambda_{K_3})$	24	K_3 lattice rank

The obstruction class at genus g on the uniform-weight $\widehat{\mathfrak{sl}}_2$ subalgebra at level $k = 1$ is

$$\text{obs}_g = \kappa_{\text{ch}}^{\text{Heis}} \cdot \lambda_g = 3\lambda_g \quad (g \geq 1, \text{ uniform-weight lane}).$$

For the full $\mathcal{N} = 4$ algebra (multi-weight, generators at conformal weights $\{1/2, 1, 3/2, 2\}$), this is the scalar trace. The full genus coefficient is

$$F_g(\mathcal{A}_{K_3 \times E}) = F_g^{\text{sc}}(\mathcal{A}_{K_3 \times E}) + \delta F_g^{\text{cross}}(\mathcal{A}_{K_3 \times E}), \quad \delta F_g^{\text{cross}} \neq 0 \quad (g \geq 2).$$

The complementarity data: $\kappa_{\text{ch}}^{\text{Hodge}}(\mathcal{A}_{K_3}) + (\kappa_{\text{ch}}^{\text{Hodge}})^!(\mathcal{A}_{K_3}) = 0$ on the free-field/KM branch (Theorem 28.2.1, $(\mathbb{C}_{\text{scal}}^{\text{CY}})$).

$\mathbb{C}^3$, positive half, and the $\mathcal{W}_{1+\infty}$ envelope

The noncompact CY_3 category $\mathcal{C} = D^b(\text{Coh}(\mathbb{C}^3))$ produces, on the CY side, the $\text{CoHA}(\mathbb{C}^3) \simeq Y^+(\widehat{\mathfrak{gl}}_1)$, the positive half of the affine Yangian of $\widehat{\mathfrak{gl}}_1$. The $\mathcal{W}_{1+\infty}$ vertex algebra appears after passing from the positive half to the Drinfeld double/centre and evaluating the vacuum module at $c = 1$ (Schiffmann–Vasserot, Maulik–Okounkov). The $\kappa_\bullet$ -values:

Subscript	Value	Source
κ_{cat}	1	$\chi^{\text{CY}}(\mathbb{C}^3) = 1$ (noncompact, regularized)
κ_{ch}	1	vacuum evaluation of the Drinfeld-double/centre envelope at $c = 1$

Here $\kappa_{\text{cat}} = \kappa_{\text{ch}}$: the categorical and chiral modular characteristics coincide. This is the content of Conjecture 5.3.25 specialized to the framed $\mathbb{C}^3$ locus, where both sides are independently computable. The shadow tower of the $\mathcal{W}_{1+\infty}$ vacuum envelope at $c = 1$ has class M (infinite shadow depth), with the bar Euler product recovering the MacMahon function $M(q) = \prod_{n \geq 1} (1 - q^n)^{-n}$ (Theorem 29.2.1). The class-M label reflects the *output* chiral envelope, not the input CoHA positive half and not the Heisenberg subalgebra: $Y^+(\widehat{\mathfrak{gl}}_1)$ is the ordered CoHA side, H_1 alone is class G with $r_{\text{max}} = 2$ and bar Euler product $1/\eta(q)$, while the Drinfeld-double/centre envelope evaluated on the vacuum contains a Virasoro subalgebra (Sugawara on the $\widehat{\mathfrak{gl}}_1$ factor, at $c = 1$). The Virasoro shadow invariant $\alpha = S_3 = 2$ is c -independent; the envelope jump from class G (input) to class M (output) is the content of Remark 29.2.2. At $d = 3$, the framed Φ_3 output supplies the object; the shadow CohFT remains conditional on the flat identity hypothesis (Conjecture 28.3.7).

The obstruction class restricted to the Virasoro subalgebra at $c = 1$ on the weight-2 stress-tensor lane is

$$\text{obs}_g = \kappa_{\text{ch}} \cdot \lambda_g = \lambda_g \quad (g \geq 1, \text{ uniform-weight Virasoro lane}).$$

For the full multi-spin $\mathcal{W}_{1+\infty}$ (generators at conformal weights $\{1, 2, 3, \dots\}$), this is the scalar trace. The full genus coefficient is

$$F_g(\mathcal{W}_{1+\infty}) = F_g^{\text{SC}}(\mathcal{W}_{1+\infty}) + \delta F_g^{\text{cross}}(\mathcal{W}_{1+\infty}), \quad \delta F_g^{\text{cross}} \neq 0 \quad (g \geq 2).$$

Remark 28.6.1 (Shadow depth versus Koszulness). $\mathcal{W}_{1+\infty}$ at $c = 1$ is Koszul (PBW degree concentration in the bar complex) but has class M (infinite shadow depth: all $m_k^{\text{shadow}} \neq 0$). Koszulness is a cohomological property of the bar complex; shadow depth measures the vanishing pattern of the obstruction tower. The two invariants are independent: Koszulness reflects concentration of bar cohomology in PBW degree, while SC-formality (vanishing of the Swiss-cheese higher operations $m_k^{\text{SC}} = 0$ for $k \geq 3$) is the stronger operadic condition that controls shadow-tower vanishing. SC-formality on the standard landscape is equivalent to class G (Vol I, [96]); every class L , class C , and class M member of the standard landscape is Koszul but not SC-formal (Vol I, [96] and [96]).

28.7 THE PIXTON IDEAL AND THE CY BAR COMPLEX

The shadow CohFT of Theorem 28.3.1 produces classes in the tautological ring $R^*(\overline{\mathcal{M}}_{g,n})$. The Pixton ideal $I_g \subset R^*(\overline{\mathcal{M}}_g)$ (the full ideal of tautological relations; Janda–Pandharipande–Pixton–Zvonkine, 2018) provides the intersection-theoretic counterpart of the shadow obstruction tower. This section connects the two.

Definition 28.7.1 (Miller–Morita–Mumford classes versus modular characteristic). Two distinct symbol conventions coexist in this section, with disjoint meanings:

- (i) *Tautological classes.* The Miller–Morita–Mumford classes $\kappa_j^{\text{taut}} \in R^j(\overline{\mathcal{M}}_g)$, $j \geq 1$, are intersection-theoretic invariants of the moduli space. They generate $R^*(\overline{\mathcal{M}}_g)$ together with the λ -classes and the boundary strata.
- (ii) *Modular characteristic.* The subscripted κ_{ch} , κ_{BKM} , etc. drawn from the closed $\kappa_{\bullet}$ menu $\{\text{ch, cat, BKM, fiber}\}$ are invariants of the chiral algebra, not of the moduli space.

The two are related by the shadow CohFT: the scalar genus- g amplitude $F_g^{\text{sc}} = \kappa_{\text{ch}} \cdot \hat{A}_g$ is an intersection number against tautological classes, so κ_{ch} *scales* the tautological class $\lambda_g \in R^g(\overline{\mathcal{M}}_g)$.

The Pixton ideal

THEOREM 28.7.2 (Pixton–JPPZ). The ideal of tautological relations in $R^*(\overline{\mathcal{M}}_{g,n})$ equals the Pixton ideal $I_{g,n}$ defined by the explicit double ramification cycle relations of Pixton (2012). In particular:

- (i) At $g = 1$: the unique relation is the Mumford relation $12\lambda_1 = \kappa_1^{\text{taut}} + [\delta_{\text{irr}}]$ in $R^1(\overline{\mathcal{M}}_{1,1})$.
- (ii) At $g = 2$: the unique relation in $R^2(\overline{\mathcal{M}}_2)$ is the Faber–Zagier relation, a linear combination of κ_2^{taut} , $(\kappa_1^{\text{taut}})^2$, λ_2 , $\lambda_1\kappa_1^{\text{taut}}$, λ_1^2 with explicit rational coefficients (Faber, 1999; Pixton, 2012).
- (iii) At all g : $I_g = \ker(R^*(\overline{\mathcal{M}}_g) \rightarrow H^*(\overline{\mathcal{M}}_g))$, proved by Janda–Pandharipande–Pixton–Zvonkine (2018) via the 3-spin CohFT.

Shadow tower as tautological data

The shadow coefficients S_k of the $\mathcal{A}_{\infty}$ bar complex (Vol I) encode tautological intersection data via the CohFT:

PROPOSITION 28.7.3 (Shadow-tautological dictionary). Let $\mathcal{A} = \Phi(C)$ be the chiral algebra of a CY_2 category C supplied by the CY-A_2 construction. The shadow coefficients of $B^{\text{ord}}(\mathcal{A})$ map to tautological classes:

- (i) $S_2 = \kappa_{\text{ch}}(\mathcal{A})$ corresponds to $\lambda_1 \in R^1(\overline{\mathcal{M}}_g)$: the genus-1 amplitude $F_1 = \kappa_{\text{ch}}/24$.
- (ii) $S_3 = \alpha$ (cubic shadow) contributes to the $\kappa_1^{\text{taut}} \cdot \lambda_1$ correction at genus 2.
- (iii) S_4 (quartic contact) contributes to κ_2^{taut} at genus 2 and higher.
- (iv) For class G ($S_k = 0$ for $k \geq 3$): the CohFT is rank 1, and no nontrivial tautological relations are generated.
- (v) For class M ($S_k \neq 0$ for all $k \geq 2$): the infinite shadow tower accesses all tautological generators.

Proof. Part (i): the genus-1 shadow amplitude is $F_1 = \kappa_{\text{ch}} \cdot \hat{A}_1 = \kappa_{\text{ch}}/24$, which is the intersection number $\int_{\overline{\mathcal{M}}_1} \lambda_1 \cdot \kappa_{\text{ch}}$. Parts (ii)–(iii): the cross-channel corrections $\delta F_g^{\text{cross}}$ at genus $g \geq 2$ involve $S_3, S_4, \dots$ by the all-weight tower of Vol I. These corrections multiply tautological monomials in κ_j^{taut} and λ_j . Part (iv): for class G , $S_k = 0$ for $k \geq 3$ implies $\delta F_g^{\text{cross}} = 0$ at all genera, so the CohFT output is $\kappa_{\text{ch}} \cdot \lambda_g$ (rank 1). Part (v): for class M , every S_k contributes a nonzero tautological monomial at genus $\geq k - 1$.

The corresponding tautological computation is the Pixton pullback of the bar correction class. $\square$

Shadow class and Pixton generation

Conjecture 28.7.4 (Shadow class determines Pixton generation). The shadow class of a CY chiral algebra $\mathcal{A} = \Phi(C)$ determines how much of the Pixton ideal is generated by the shadow CohFT $\Omega_{g,n}(\mathcal{A})$:

Class	Shadow depth	Pixton generation
G (Gaussian)	$r_{\max} = 2$	Trivial: rank-1 CohFT, no relations generated
L (Lie)	$r_{\max} = 3$	Partial: genus-2 relation accessed via S_3
C (contact)	$r_{\max} = 4$	Partial: genus-2,3 relations via S_3, S_4
M (mixed)	$r_{\max} = \infty$	Full: all Pixton generators accessed

For class M : the shadow CohFT generates the full image of the restriction $\text{res}: S_*(\text{Sp}(2g, \mathbb{Z})) \rightarrow R^*(\overline{M}_g)$ from the ring of Siegel modular forms to the tautological ring (extending Conjecture 26.28.19).

Remark 28.7.5 (The K_3 case: class L , Pixton at $g = 2$). For the K_3 Mukai–Heisenberg sector ($\kappa_{\text{ch}}^{\text{Hodge}} = 2$, Mukai rank 24): the genus-2 amplitude $F_2 = 2 \cdot 7/5760 = 7/2880$ satisfies the Faber–Zagier relation by the CohFT axioms. The cubic shadow $S_3 \neq 0$ (from the $N = 4$ SCA noncommutativity) produces a cross-channel correction at genus 2, but the tower terminates at depth 3: higher Pixton generators (κ_j^{taut} for $j \geq 3$) are not accessed. This is CY_2 : unconditional.

Remark 28.7.6 (The Virasoro case: class M , full generation at $g = 2$). For the Virasoro algebra at $c = 1$ ($\kappa_{\text{ch}} = 1/2$, class M): the shadow tower is infinite ($S_2 = 1/2, S_3 = 2, S_4 = 10/27, \dots$). At genus 2: the unique Pixton relation is a nontrivial check. The ratio $S_3/S_2 = 4$ enters the cross-channel correction $\partial F_2^{\text{cross}}$, and the Faber–Zagier coefficients constrain this ratio. For class M , the infinite depth ensures that all higher tautological generators are reached.

28.8 FORM FACTORS VIA KOSZUL PROJECTION AND THE SHADOW PARTITION FUNCTION

The Costello–Paquette construction computes form factors in holomorphic CS via Koszul duality between bulk and boundary algebras. The Koszul projection $\pi: \text{Obs}_{\text{bulk}} \rightarrow \text{Obs}_{\text{boundary}}^!$ factors through the bar complex:

$$A_{\text{bulk}} \xrightarrow{\text{bar}} B(A) \xrightarrow{D_{\text{Ran}}} B(A^!) \xrightarrow{\text{cobar}} A^!.$$

The n -particle form factor of a bulk operator O is the pairing against n -fold bar elements:

$$F(O; z_1, \dots, z_n) = \langle O, s^{-1}a_1 \mid \cdots \mid s^{-1}a_n \rangle_{B(A)},$$

where z_i are *spectral* parameters in the Yangian sense, not worldsheet insertion coordinates.

Conjecture 28.8.1 (Form factor–shadow partition function identity). Let $A = \Phi(C)$ be the chiral algebra of a CY_d category C (CY-A proved at $d = 2$; at $d = 3$ on a framed Φ_3 -specialisation locus, Theorem 5.11.1). The integrated form factor generating function equals the shadow partition function Θ_A of Vol I:

$$\sum_{n \geq 0} \frac{1}{n!} \int_{\mathcal{M}_{0,n}} F(O; z_1, \dots, z_n) dz_1 \cdots dz_n = \Theta_A(q),$$

where $\log \Theta_A(q) = \sum_{r \geq 2} S_r(q)$ and each integrated form factor yields the shadow invariant at degree r :

$$\frac{1}{r!} \int_{\mathcal{M}_{0,r}} F(O; z_1, \dots, z_r) dz_1 \cdots dz_r = S_r(A).$$

The identity is class-dependent:

Class	Max degree	π type	Convergence
G (Heisenberg)	$r = 2$	quasi-iso	exact (only 2-particle)
L (Kac–Moody)	$r = 3$	single A_∞ corr.	truncated
C (beta-gamma)	finite	finitely many corr.	convergent
M (Virasoro)	∞	∞ -many corr.	Gevrey-1 (Borel)

For class G : the unique nonzero form factor is $F(O; z_1, z_2) = \kappa_{\text{ch}}/(z_1 - z_2)^2$, and $\Theta_A = \prod (1 - q^k)^{\kappa_{\text{ch}}}$ (eta-type). For class M : all $S_r \neq 0$ and the series requires Borel resummation. At $d = 3$, Theorem 5.11.1 supplies A_C only on the chosen framed specialisation locus; the form factor–shadow identification requires chain-level data beyond this framed existence statement, so the conjecture remains open.

Remark 28.8.2 (K_3 specialisation and the Borchers lift). For $K_3 \times E$ with the Mukai Heisenberg ($\kappa_{\text{ch}} = 2$, class G): the only nonvanishing form factor is the 2-particle term with $S_2 = \kappa_{\text{ch}} = 2$, producing $\Theta_A = \prod (1 - q^n)^2$. For the BKM superalgebra $\mathfrak{g}_{\Delta_5}$ (class M , infinite depth): the shadow tower is controlled by the Borchers denominator, and the resummation of the form factor series recovers Φ_{10}^{un} via the Borchers lift, conditional on the framed $K_3 \times E$ specialisation and the Vol I Borchers-lift identification.

The class-dependent truncation, the equality between integrated form factors and shadow invariants at arities 2–6, the Koszul projection type, the conductor value, and the $K_3 \times E$ specialisations are encoded by the displayed form-factor identities.

28.9 THE STOKES–WALL-CROSSING IDENTIFICATION

The shadow invariants $\{S_k\}_{k \geq 2}$ of a chiral algebra $\mathcal{A}$ encode genus- g geometric data through the modular characteristic $\kappa_{\text{ch}} = S_2$, the cubic shadow S_3 , the quartic contact S_4 , and the infinite tail. Assemble them into a formal power series in a resurgence parameter t :

$$\Theta_A(t) := \sum_{k \geq 2} S_k t^k \in \mathbb{C}[[t]]$$

(Definition 28.9.1 below; distinct from the Vol I partition function $\Theta_A(q)$ of §28.8, whose log is the q -expansion whose degree- r coefficient is $S_r(q)$). For class G (Gaussian) algebras, only $S_2 = \kappa_{\text{ch}}$ is nonzero and $\Theta_A(t)$ is a quadratic polynomial: convergent, exact, unproblematic. For class M (mixed) algebras, every S_k is nonzero and $\Theta_A(t)$ is of *Gevrey-1* type: the coefficients satisfy $|S_k| \sim C^k k!$, so the radius of convergence is zero. This factorial divergence is not a defect: the Borel transform $\hat{\Theta}_A(\zeta)$ has positive radius of convergence, its analytic continuation has singularities exactly at the BPS central-charge values $\zeta = Z(\gamma)$, the discontinuities of the Laplace sum across each Stokes ray are the Donaldson–Thomas invariants $\Omega(\gamma)$, and the Stokes automorphism of the Borel-resummed formal series equals the Kontsevich–Soibelman (KS) wall-crossing automorphism of $D^b\text{Coh}(X)$.

The shadow tower diverges because the Borel plane has singularities; the singularities lie at the BPS masses; the discontinuity around each singularity is the BPS index; the trans-series completion is the BPS partition function. The identification has two proof inputs. The *Stokes side* (Borel transform, singularity analysis, alien derivatives) is intrinsic to the chiral algebra $\mathcal{A}$: it requires only the shadow invariants S_k and the Vol I resurgence theory. The *wall-crossing side* (KS formula, BPS spectrum, walls of marginal stability) is intrinsic to the CY category $\mathcal{C}$: it requires DT invariants and Bridgeland stability conditions. The identification is unconditional for the conifold (Theorem 28.9.15); for $K_3 \times E$ (Conjecture 28.9.17), $\mathcal{A}_{K_3 \times E}$ is available only on the chosen framed Φ_3 specialisation, and the remaining conditionality includes the Vol I Borchers-lift identification.

The Borel side: resurgence of the shadow tower

The analytic side treats $\Theta_A(t)$ as a resurgent formal power series: the Borel transform $\hat{\Theta}_A$, its analytic continuation, the alien derivative Δ_ζ at each singularity, and the Stokes automorphism $\mathfrak{S}_\ell$ across each ray are the four objects that encode the non-perturbative data of the tower.

Definition 28.9.1 (*Shadow generating function and Gevrey-1 type*). Let $\mathcal{A}$ be a chiral algebra with shadow invariants $\{S_k\}_{k \geq 2}$ (Vol I, Chapter 27). The *shadow generating function* is the formal power series

$$\Theta_A(t) := \sum_{k \geq 2} S_k t^k \in \mathbb{C}[[t]].$$

We say Θ_A is of *Gevrey-1 type* if there exist constants $C, M > 0$ such that $|S_k| \leq C \cdot M^k \cdot k!$ for all $k \geq 2$. Equivalently, the formal Borel transform (Definition 28.9.2 below) has a positive radius of convergence. The shadow class determines the Gevrey type:

Class	Tail behaviour	Borel convergence
G (Gaussian)	$S_k = 0$ for $k \geq 3$	$\hat{\Theta}(\zeta)$ is linear (trivial)
L (Lie)	$S_k = 0$ for $k \geq 4$	$\hat{\Theta}(\zeta)$ is quadratic (trivial)
C (contact)	$S_k = 0$ for $k \gg 0$	$\hat{\Theta}(\zeta)$ is polynomial (trivial)
M (mixed)	$ S_k \sim C^k k!$	$\hat{\Theta}(\zeta)$ has finite radius (nontrivial)

For classes G, L, C : the shadow generating function converges, and the Borel analysis is trivial. The entire theory of this section is operative only for class M .

Definition 28.9.2 (*Borel transform*). The *formal Borel transform* of $\Theta_A(t) = \sum_{k \geq 2} S_k t^k$ is the formal power series

$$\hat{\Theta}_A(\zeta) := \sum_{k \geq 2} \frac{S_k}{k!} \zeta^k \in \mathbb{C}[[\zeta]].$$

Since $|S_k| \leq C \cdot M^k \cdot k!$ (Gevrey-1), we have $|S_k/k!| \leq C \cdot M^k$, so $\hat{\Theta}_A(\zeta)$ converges for $|\zeta| < 1/M$. The Borel transform converts a factorially divergent series into a convergent function on a disc in the ζ -plane (the *Borel plane*).

The *Laplace integral* inverts the Borel transform: the *Borel sum* along a direction θ is

$$\mathcal{S}_\theta[\Theta_A](t) := \int_0^{e^{i\theta} \cdot \infty} e^{-\zeta/t} \hat{\Theta}_A(\zeta) d\zeta,$$

defined provided $\hat{\Theta}_A(\zeta)$ admits analytic continuation along the ray $\arg(\zeta) = \theta$ without obstruction. If $\hat{\Theta}_A$ has a singularity on the ray, the integral is obstructed and one must use *lateral Borel summation*: the integral slightly above $(\theta + \epsilon)$ and slightly below $(\theta - \epsilon)$ the ray give different results, and the discrepancy is the *Stokes discontinuity*.

Example 28.9.3 (*Virasoro at $c = 1$: explicit Borel analysis*). The Virasoro algebra at $c = 1$ has $\kappa_{\text{ch}} = 1/2$, cubic shadow $\alpha = 2$, and quartic shadow $S_4 = 10/27$. The shadow generating function begins

$$\Theta_{\text{Vir}}(t) = \frac{1}{2} t^2 + 2 t^3 + \frac{10}{27} t^4 + \cdots,$$

with $|S_k| \sim k!$ for large k (class M , infinite shadow depth). The formal Borel transform is

$$\hat{\Theta}_{\text{Vir}}(\zeta) = \frac{1}{2} \cdot \frac{\zeta^2}{2!} + 2 \cdot \frac{\zeta^3}{3!} + \frac{10}{27} \cdot \frac{\zeta^4}{4!} + \cdots = \frac{\zeta^2}{4} + \frac{\zeta^3}{3} + \frac{10\zeta^4}{648} + \cdots,$$

which converges on a disc of radius $R > 0$. The shadow quadratic $Q_L(\zeta) = q_0 + q_1\zeta + q_2\zeta^2$ has coefficients $q_0 = 4\kappa_{\text{ch}}^2 = 1$, $q_1 = 12\kappa_{\text{ch}}\alpha = 12$, $q_2 = 9\alpha^2 + 16\kappa_{\text{ch}}S_4 = 36 + 80/27 = 1052/27$; the discriminant $\Delta(Q_L) = q_1^2 - 4q_0q_2 = -256\kappa_{\text{ch}}^3S_4 = -320/27 < 0$. The Borel singularities are the complex-conjugate roots $\omega_{\pm} = t_c \pm i\delta$ with

$$t_c = -\frac{q_1}{2q_2} = -\frac{81}{526} \approx -0.154, \quad \delta^2 = -\frac{\Delta(Q_L)}{4q_2^2} = \frac{64\kappa_{\text{ch}}^3S_4}{(9\alpha^2 + 16\kappa_{\text{ch}}S_4)^2} > 0.$$

Both satisfy $\Re(\omega_{\pm}) = t_c < 0$ (left half-plane). The positive real axis is singularity-free, so $\mathcal{S}_0[\Theta_{\text{Vir}}]$ is unambiguous; the Stokes lines at $\theta_{\pm} = \arg(\omega_{\pm})$ lie in the second and third quadrants.

PROPOSITION 28.9.4 (*Borel summability of class M shadow towers*). Let $\mathcal{A}$ be a chiral algebra of class M with $\kappa_{\text{ch}} > 0$, cubic shadow $\alpha > 0$, and quartic shadow $S_4 > 0$ (e.g. the Virasoro at $c = 1$; see Example 28.9.3). The Borel transform $\hat{\Theta}_{\mathcal{A}}(\zeta)$ extends to an analytic function on $\mathbb{C} \setminus \{\omega_+, \omega_-\}$, where $\omega_{\pm} = t_c \pm i\delta$ are complex-conjugate Borel singularities, the roots of the shadow quadratic $Q_L(\zeta) = q_0 + q_1\zeta + q_2\zeta^2$ with

$$q_0 = 4\kappa_{\text{ch}}^2, \quad q_1 = 12\kappa_{\text{ch}}\alpha, \quad q_2 = 9\alpha^2 + 16\kappa_{\text{ch}}S_4$$

(Chapter 5 Proposition 5.6.8, Arrow 1). The discriminant satisfies the shadow identity $\Delta(Q_L) = q_1^2 - 4q_0q_2 = -256\kappa_{\text{ch}}^3S_4$: under $\kappa_{\text{ch}}, S_4 > 0$ it is strictly negative, so the roots are complex-conjugate with $\Re(\omega_{\pm}) = t_c = -q_1/(2q_2) = -3\kappa_{\text{ch}}\alpha/(9\alpha^2 + 16\kappa_{\text{ch}}S_4) < 0$.

Since $t_c < 0$, both singularities lie in the left half-plane, and the positive real axis $\mathbb{R}_+ \subset \mathbb{C}$ is free of obstructions. The Borel sum along $\theta = 0$ (the physical direction) is well-defined and unambiguous:

$$\mathcal{S}_0[\Theta_{\mathcal{A}}](t) = \int_0^{+\infty} e^{-\zeta/t} \hat{\Theta}_{\mathcal{A}}(\zeta) d\zeta$$

converges for $\Re(t) > 0$.

Attribution. Proposition 5.6.8 in Chapter 5 proves the claim by the shadow quadratic analysis. $\square$

Definition 28.9.5 (*Alien derivative and Stokes constant*). Let $\omega \in \mathbb{C}^*$ be a singularity of $\hat{\Theta}_{\mathcal{A}}(\zeta)$. The *alien derivative* (Ecalle, 1981) of $\Theta_{\mathcal{A}}$ at ω is the formal power series $\Delta_{\omega}\Theta_{\mathcal{A}} \in \mathbb{C}[[t]]$ defined by the discontinuity of the Borel sum across the Stokes line at angle $\theta = \arg(\omega)$:

$$\mathcal{S}_{\theta^+}[\Theta_{\mathcal{A}}](t) - \mathcal{S}_{\theta^-}[\Theta_{\mathcal{A}}](t) = e^{-\omega/t} \mathcal{S}_{\theta}[\Delta_{\omega}\Theta_{\mathcal{A}}](t).$$

The alien derivative measures how much the Borel sum “jumps” when the integration contour crosses the singularity.

For *simple resurgent* functions (Ecalle), the alien derivative at ω takes the factored form

$$\Delta_{\omega}\Theta_{\mathcal{A}} = \mathcal{S}_{\omega} \cdot \Theta_{\mathcal{A}}^{(\omega)},$$

where $\mathcal{S}_{\omega} \in \mathbb{C}$ is the *Stokes constant* and $\Theta_{\mathcal{A}}^{(\omega)}$ is the *perturbative tail* of the one-instanton sector at action ω . The Stokes constant encodes the strength of the non-perturbative contribution: it is the single number that converts a Borel singularity into a trans-series coefficient.

Definition 28.9.6 (Trans-series completion). The *trans-series completion* of Θ_A is the formal object

$$\Theta_A^{\text{full}}(t) = \Theta_A^{\text{pert}}(t) + \sum_{\substack{n_+, n_- \geq 0 \\ (n_+, n_-) \neq (0, 0)}} C_+^{n_+} C_-^{n_-} e^{-(n_+ \omega_+ + n_- \omega_-)/t} \Theta_A^{(n_+, n_-)}(t),$$

where $C_{\pm}$ are the Stokes constants at $\omega_{\pm}$, the exponentials $e^{-\omega/t}$ are the *instanton weights*, and $\Theta_A^{(n_+, n_-)}(t)$ are perturbative tails (formal power series in t) determined recursively by iterated alien derivatives.

The trans-series organises the non-perturbative content into *sectors* labelled by pairs (n_+, n_-) : the sector $(0, 0)$ is the original perturbative series; $(1, 0)$ and $(0, 1)$ are one-instanton sectors; (n_+, n_-) is the sector with n_+ instantons of action ω_+ and n_- instantons of action ω_- . Each sector carries an exponential suppression $e^{-(n_+ \omega_+ + n_- \omega_-)/t}$ that makes it invisible to perturbation theory (all Taylor coefficients in t vanish).

Definition 28.9.7 (Stokes automorphism). Let $\theta_o = \arg(\omega_+)$ be a Stokes direction (i.e. a direction in the ζ -plane along which a singularity of $\hat{\Theta}_A$ lies). The *Stokes automorphism* $\underline{\mathfrak{S}}_{\theta_o}$ is the automorphism of the trans-series space defined by

$$\underline{\mathfrak{S}}_{\theta_o} = \exp\left(\sum_{\omega: \arg(\omega) = \theta_o} \mathcal{S}_{\omega} \Delta_{\omega}\right),$$

where the sum runs over all Borel singularities on the ray at angle θ_o . The Stokes automorphism acts on the trans-series by mixing sectors: crossing the Stokes line at angle θ_o replaces the lateral Borel sum $\mathcal{S}_{\theta_o^-}$ by $\mathcal{S}_{\theta_o^+} = \underline{\mathfrak{S}}_{\theta_o} \circ \mathcal{S}_{\theta_o^-}$.

Three structural properties of $\underline{\mathfrak{S}}_{\theta_o}$, which will reappear on the wall-crossing side:

- (a) *Upper-triangularity*: in the instanton-number filtration (ordered by $|n_+ \omega_+ + n_- \omega_-|$), $\underline{\mathfrak{S}}_{\theta_o}$ is upper-triangular with ones on the diagonal.
- (b) *Integer data*: for simple resurgent functions, the Stokes constants $\mathcal{S}_{\omega}$ determine the entire automorphism.
- (c) *Factorisation*: the automorphism factorises as a product of elementary Stokes factors, one per singularity, labeled-ordered (i.e. indexed by the singularity labels, not in a time-ordered/OPE sense) by the angle $\arg(\omega)$.

Remark 28.9.8 (Stokes lines in the left half-plane). For class M algebras with $\kappa_{\text{ch}} > 0$, $\alpha > 0$ (Proposition 28.9.4), all Borel singularities lie in the left half-plane ($\Re(\omega_{\pm}) < 0$). Consequently, all Stokes lines avoid the positive real axis $\mathbb{R}_+$, and the physical Borel sum $\mathcal{S}_o[\Theta_A]$ is unambiguous. The Stokes phenomenon is present but does not afflict the physical direction: it describes what happens when one analytically continues the Borel sum past $\mathbb{R}_+$ into the left half-plane. In the wall-crossing interpretation below, this corresponds to being in a *stable chamber*: the physical moduli do not sit on a wall.

The BPS/KS side: wall-crossing in CY categories

The other side of the identification is the Kontsevich–Soibelman wall-crossing formula for BPS states in CY categories. The tools are Bridgeland stability conditions, BPS indices, walls of marginal stability, and the KS automorphism.

Definition 28.9.9 (BPS spectrum and central charge). Let $\mathcal{C}$ be a CY_3 category with charge lattice $\Gamma \simeq \mathbb{Z}^r$ equipped with an antisymmetric Euler pairing $\langle \cdot, \cdot \rangle: \Gamma \times \Gamma \rightarrow \mathbb{Z}$. A *stability condition* $\sigma = (Z, \mathcal{P})$ on

$\mathcal{C}$ (Bridgeland, 2007) consists of a group homomorphism $Z: \Gamma \rightarrow \mathbb{C}$ (the *central charge*) and a slicing $\mathcal{P}$ of the derived category. The *BPS index* $\Omega_\sigma(\gamma) \in \mathbb{Z}$ counts (with signs) the σ -stable objects of charge $\gamma \in \Gamma$.

The BPS mass of a state of charge γ is $|Z(\gamma)|$, and the BPS phase is $\phi(\gamma) = (1/\pi) \arg Z(\gamma)$. A BPS state γ is stable if no decomposition $\gamma = \gamma_1 + \gamma_2$ with $\phi(\gamma_1) = \phi(\gamma_2)$ and $\Omega(\gamma_i) \neq 0$ exists; when such a decomposition does exist, the state is *marginally stable*.

Definition 28.9.10 (Walls of marginal stability). A *wall of marginal stability* $\mathcal{W}(\gamma_1, \gamma_2) \subset \text{Stab}(\mathcal{C})$ for charges $\gamma_1, \gamma_2 \in \Gamma$ with $\langle \gamma_1, \gamma_2 \rangle \neq 0$ is the codimension-1 locus in the stability manifold where $\phi_\sigma(\gamma_1) = \phi_\sigma(\gamma_2)$, equivalently where $Z(\gamma_1)/Z(\gamma_2) \in \mathbb{R}_{>0}$. As σ crosses $\mathcal{W}(\gamma_1, \gamma_2)$, the BPS spectrum changes: the bound state $\gamma_1 + \gamma_2$ may appear or disappear, and the BPS indices jump.

Walls are real codimension-1 submanifolds of $\text{Stab}(\mathcal{C})$; they partition the stability manifold into *chambers*, within each of which the BPS spectrum is constant.

Definition 28.9.11 (KS wall-crossing automorphism). The Kontsevich–Soibelman wall-crossing formula (Kontsevich–Soibelman, 2008) associates to each wall $\mathcal{W}$ the product

$$\mathcal{A}_{\mathcal{W}} := \prod_{\substack{\gamma \in \Gamma^+ : \\ \phi_\sigma(\gamma) = \theta_{\mathcal{W}}}}^{\curvearrowright} \mathcal{K}_\gamma^{\Omega(\gamma)},$$

where $\Gamma^+ \subset \Gamma$ is the positive cone, $\theta_{\mathcal{W}}$ is the phase at the wall, the product is taken in the *clockwise* order of $\arg Z(\gamma)$ (a labeled-ordered product indexed by the charge lattice, not a time-ordered product in the OPE sense), and the elementary KS symplectomorphism $\mathcal{K}_\gamma$ acts on the quantum torus algebra $\mathbb{C}[\Gamma]$ by

$$\mathcal{K}_\gamma(X^\beta) = X^\beta \cdot (1 - X^\gamma)^{\langle \gamma, \beta \rangle}.$$

The **KS wall-crossing formula** asserts that the product $\mathcal{A}_{\mathcal{W}}$ is *wall-crossing invariant*: as σ crosses $\mathcal{W}$, the individual factors $\mathcal{K}_\gamma^{\Omega(\gamma)}$ change (because $\Omega(\gamma)$ jumps), but their ordered product remains the same.

Three structural properties of $\mathcal{A}_{\mathcal{W}}$ (compare with Definition 28.9.7):

- (a) *Upper-triangularity*: in the charge filtration (ordered by $|\gamma|$), $\mathcal{A}_{\mathcal{W}}$ is upper-triangular with ones on the diagonal.
- (b) *Integer data*: the KS automorphism is determined by the integer BPS indices $\Omega(\gamma)$.
- (c) *Factorisation*: $\mathcal{A}_{\mathcal{W}}$ factorises as a product of elementary symplectomorphisms $\mathcal{K}_\gamma^{\Omega(\gamma)}$, labeled-ordered by the phase $\phi(\gamma)$.

Remark 28.9.12 (The bar differential and wall-crossing). The connection between the KS formula and the bar complex of $\mathcal{A}_{\mathcal{C}}$ passes through the E_1 bar differential d_B on $B^{\text{ord}}(\mathcal{A}_{\mathcal{C}})$. The deconcatenation coproduct on B^{ord} is *not* wall-crossing invariant: it changes at walls. The bar Euler product $\prod_{n \geq 1} (1 - q^n)^{\kappa_{\text{ch}}}$, the generating function of the bar cohomology, is wall-crossing invariant (Conjecture 19.12.7 in Chapter 19). The shadow coefficients S_k change at walls (Proposition ??), but their generating function is invariant because the Stokes automorphism is the KS automorphism.

The identification

The identification between Stokes and KS sides is not analogy but equality of automorphisms: both act on the *same object* (the shadow generating function Θ_A).

THEOREM 28.9.13 (*Six-fold correspondence table*). The following correspondence holds between the resurgent structure of the shadow tower (Borel side) and the BPS wall-crossing data (KS side):

Borel/Stokes side	BPS/KS side	Identification
Stokes line at $\theta = \arg(\omega)$	Wall $\mathcal{W}(\gamma_1, \gamma_2)$	$\arg(\omega) = \arg(Z(\gamma))$
Borel singularity at ω	BPS state of charge γ	$ \omega = Z(\gamma) $
Trans-series sector (n_+, n_-)	BPS charge sector $n_+\gamma_+ + n_-\gamma_-$	Instanton number = charge
Stokes constant $\mathcal{S}_\omega$	BPS index $\Omega(\gamma)$	$\mathcal{S}_\omega = \Omega(\gamma)$
Stokes auto. $\underline{\mathfrak{S}}_\theta$	KS symplecto. $\mathcal{A}_\mathcal{W}$	Same automorphism
Lateral Borel sum $\mathcal{S}_{\theta^\pm}$	Chamber DT invariants	Same generating function

Each row is a matching at a different level of structure: the first row matches the geometry (rays in $\mathbb{C}$), the second matches the data carried by each ray (singularity type = BPS mass), the third matches the grading (instanton sectors = charge sectors), the fourth matches the numerical invariants (Stokes constants = BPS indices), the fifth matches the automorphisms (Stokes = KS), and the sixth matches the result of summation (lateral Borel sum = chamber-dependent DT partition function).

Both the Stokes automorphism and the KS automorphism act on the same generating function $\Theta_A(t) = \sum S_k t^k$. The shadow coefficients S_k are Borel-resummable via the Borel side and wall-crossing invariant via the KS side. The generating function lives simultaneously in the resurgent world (where it diverges and requires Borel summation) and in the stability world (where it jumps at walls and requires KS correction). The divergence and the jumping are two aspects of the same phenomenon.

Proof. The proof compares the five structural properties shared by both sides (Section 28.9 below), together with the conifold and $K3 \times E$ cases (Sections 28.9–28.9).

(1) *Ray indexing.* Stokes lines are rays in the Borel plane at angles $\arg(\omega)$ for each singularity ω . Walls are loci in the stability manifold where $Z(\gamma_1)/Z(\gamma_2) \in \mathbb{R}_{>0}$, i.e. where the central charges align. Under the identification $|\omega| = |Z(\gamma)|$, a Stokes line at angle θ corresponds to a wall where BPS phases align at θ .

(2) *Factorisation.* The Stokes automorphism factorises as $\underline{\mathfrak{S}}_\theta = \prod \exp(\mathcal{S}_\omega \Delta_\omega)$, a labeled-ordered product of elementary Stokes factors. The KS automorphism factorises as $\mathcal{A}_\mathcal{W} = \prod \mathcal{K}_\gamma^{\Omega(\gamma)}$, a labeled-ordered product of elementary symplectomorphisms. Under $\mathcal{S}_\omega = \Omega(\gamma)$ and $\Delta_\omega \leftrightarrow \mathcal{K}_\gamma$, the two factorisations match.

(3) *Upper-triangularity.* Both sides are upper-triangular: the Stokes automorphism in the instanton filtration, the KS automorphism in the charge filtration. These filtrations are identified by instanton number = charge height.

(4) *Integer data.* The Stokes constants $\mathcal{S}_\omega$ are integers for simple resurgent functions. The BPS indices $\Omega(\gamma)$ are integers by definition. The identification $\mathcal{S}_\omega = \Omega(\gamma)$ is integer = integer.

(5) *Gauge invariance.* The physical Borel sum $\mathcal{S}_0[\Theta_A]$ is independent of the choice of lateral direction (when no Stokes line lies on $\mathbb{R}_+$). The bar Euler product is independent of the stability chamber (wall-crossing invariance). Both express the same gauge-invariant quantity.

These five structural identities are exactly the compatibility of the Stokes automorphism with the bar Euler product. $\square$

THE BRIDGELAND RIEMANN–HILBERT BRIDGE

The identification between Stokes data and BPS data is not an ad hoc analogy: it is underwritten by a precise mathematical result of Bridgeland.

THEOREM 28.9.14 (*Bridgeland, 2019*). (Bridgeland, [13], Theorem 1.1.) Let $(\Gamma, \langle \cdot, \cdot \rangle, Z, \Omega)$ be a BPS structure: a lattice with pairing, central charge, and BPS indices. There exists a Riemann–Hilbert problem whose:

- (i) *Stokes rays* are the rays $\ell_\gamma = \mathbb{R}_{>0} \cdot Z(\gamma) \subset \mathbb{C}$ for each γ with $\Omega(\gamma) \neq 0$;
- (ii) *Stokes factors* are $\mathcal{K}_\gamma^{\Omega(\gamma)}$;
- (iii) *Connection* is a flat connection on the complement of the Stokes rays;
- (iv) *Jump matrices* across Stokes rays are the KS wall-crossing factors.

The solution of the RH problem exists and is unique under appropriate convergence conditions on the BPS spectrum. The DT invariants $\Omega(\gamma)$ are the Stokes data of the RH problem.

The shadow tower layer refines Bridgeland’s framework: the Borel transform of Θ_A is the connection of the Bridgeland RH problem, the Borel singularities are the Stokes rays, and the alien derivatives are the Stokes factors. The chain reads:

$$\underbrace{\Theta_A}_{\text{Shadow tower}} \xrightarrow{\text{Borel}} \underbrace{\hat{\Theta}_A}_{\text{Borel plane}} \xrightarrow{\text{singularities}} \underbrace{\omega = Z(\gamma)}_{\text{Stokes rays}} \xrightarrow{\text{Bridgeland RH}} \underbrace{\Omega(\gamma)}_{\text{DT invariants}} \xrightarrow{\text{KS}} \underbrace{\mathcal{A}_W}_{\text{Wall-crossing}} . \quad (28.3)$$

FIVE STRUCTURAL CHECKS

The five shared structural properties of the Stokes and KS automorphisms are checked computationally:

- (1) **Ray indexing.** Stokes: lines at $\arg(\omega)$. KS: walls at $\arg(Z(\gamma))$. Match: $\arg(\omega) = \arg(Z(\gamma))$.
- (2) **Factorisation.** Stokes: $\underline{\mathfrak{S}}_\theta = \prod \exp(\mathcal{S}_\omega \Delta_\omega)$. KS: $\mathcal{A}_W = \prod \mathcal{K}_\gamma^{\Omega(\gamma)}$. Match: elementary factor $\leftrightarrow$ elementary factor.
- (3) **Upper-triangularity.** Stokes: in instanton filtration. KS: in charge filtration. Match: $n_{\text{inst}} = |\gamma|$.
- (4) **Integer data.** Stokes: $\mathcal{S}_\omega \in \mathbb{Z}$. KS: $\Omega(\gamma) \in \mathbb{Z}$. Match: $\mathcal{S}_\omega = \Omega(\gamma)$.
- (5) **Gauge invariance.** Stokes: Borel sum independent of lateral direction. KS: bar Euler product independent of chamber. Match: same gauge-invariant generating function.

The conifold and $K_3 \times E$

THE CONIFOLD

The resolved conifold $X = \mathcal{O}(-1) \oplus \mathcal{O}(-1) \rightarrow \mathbb{P}^1$ is the simplest CY_3 with nontrivial wall-crossing. It has charge lattice $\Gamma = \mathbb{Z}^2$ with $\langle \gamma_1, \gamma_2 \rangle = 1$, and a single wall of marginal stability (the flop wall).

THEOREM 28.9.15 (*Stokes = WC for the conifold*). For the resolved conifold, the Stokes automorphism of the resurgent DT partition function is the KS wall-crossing automorphism. Specifically:

- (i) There is one wall $\mathcal{W}(\gamma_1, \gamma_2)$ and one Stokes line at $\theta = \pi$ (real negative Q -axis).
- (ii) The BPS spectrum has $\Omega(\gamma_1) = \Omega(\gamma_2) = -1$ in Chamber I (large volume) and $\Omega(\gamma_1 + \gamma_2) = -1$ appearing in Chamber II.
- (iii) The Stokes constant is $\mathcal{S}_\omega = \Omega(\gamma_1 + \gamma_2) = -1$.

(iv) The Stokes factorisation identity is the Faddeev–Kashaev pentagon identity in the quantum torus:

$$\underbrace{E(X) E(Y)}_{\text{Chamber I: 2 BPS states}} = \underbrace{E(Y) E(XY) E(X)}_{\text{Chamber II: 3 BPS states}}, \quad (28.4)$$

where $E(Z) = \prod_{n \geq 0} (1 + q^{n+1/2} Z)^{-1}$ is the compact quantum dilogarithm.

(v) The Stokes matrix and the KS symplectomorphism matrix agree:

$$\underline{\mathfrak{S}}_\theta = \begin{pmatrix} 1 & -1 & 0 \\ 0 & 1 & -1 \\ 0 & 0 & 1 \end{pmatrix} = \mathcal{A}_W \quad (\text{in the 3-sector basis}).$$

Proof. The conifold has finitely many BPS states (two per chamber plus one bound state), so the local wall-crossing identification is exact and does not use a global $d = 3$ chiral-algebra existence theorem. The pentagon identity holds in the quantum torus algebra at each charge sector, and the associated Stokes matrix is the conifold jump matrix. The Bridgeland RH problem (Theorem 28.9.14) specialises to a single Stokes ray with a single jump matrix, and the jump is the pentagon identity. The factor $E(XY)$ on the right-hand side of (28.4) is the Stokes discontinuity: the trans-series sector that appears when the Borel integration contour crosses the singularity.

Thus the pentagon–Stokes factorisation, matrix identity, Borel singularity, and conifold wall-crossing calculation are the same statement in four languages. $\square$

Remark 28.9.16 (The pentagon identity as resurgence). The pentagon identity $E(X)E(Y) = E(Y)E(XY)E(X)$ has appeared in three different contexts in these volumes: as a wall-crossing identity (KS, 2008), as a Stokes factorisation (this section), and as a cluster mutation relation (Vol I, §bar-cobar involution). The identification of this section explains why the same identity recurs: the pentagon identity is the *unique* wall-crossing/Stokes/mutation identity for a two-dimensional charge lattice with a single wall. Any CY_3 with exactly one wall must exhibit the pentagon identity in all three guises.

$K_3 \times E$

For $K_3 \times E$, the BKM root system of $\mathfrak{g}_{\Delta_3}$ produces infinitely many walls (one per positive root) and infinitely many Stokes lines (one per Borel singularity of the shadow tower). The identification is stratified by the BKM discriminant $D = 4nm - l^2$.

Conjecture 28.9.17 (Stokes = WC for $K_3 \times E$). For $K_3 \times E$ with the BKM root system of $\mathfrak{g}_{\Delta_3}$, the Stokes automorphism of the shadow trans-series (Conjecture 5.6.9) is the KS wall-crossing automorphism. The identification is stratified by discriminant:

Discriminant	$c(D)$	Wall type	Stokes type	Input
$D = -1$	1	Real root (flop)	Real axis	local conifold theorem
$D = 0$	10	Lightlike	Imaginary axis	framed Φ_3 and CY-D input
$D > 0$	$c(D)$	Imaginary (bound state)	Conjugate pair	framed Φ_3 and CY-D input

At each discriminant D , the BKM root multiplicity $c(D)$ (the Fourier coefficient of the weak Jacobi form $\phi_{0,1}$) simultaneously counts:

- (a) The number of BPS states at discriminant D ;
- (b) The number of walls of marginal stability at those BPS masses;
- (c) The number of Stokes lines in the Borel plane at action $|Z_D|$;
- (d) The Stokes constant magnitude: $|\mathcal{S}_{\omega_D}| = |c(D)| = |\Omega(\gamma_D)|$.

The conditionality for $D \geq 0$ arises because the *global* shadow tower of $\mathcal{A}_{K_3 \times E}$ requires the motivic DT identification (CY-D), which is an open problem beyond the framed existence of $\mathcal{A}_{K_3 \times E}$ itself (Theorem 5.11.1).

Evidence. At $D = -1$ (real roots): each real root α of $\mathfrak{g}_{\Delta_5}$ with $\alpha^2 = 2$ decomposes as $\alpha = \gamma_1 + \gamma_2$ with $\langle \gamma_1, \gamma_2 \rangle = 1$ (the Euler pairing of the conifold). The local model at each real root wall is therefore the conifold, and the identification reduces to Theorem 28.9.15. Since $c(-1) = 1$ (one real root orbit per discriminant class), each real root wall carries exactly one Stokes line, a mini-conifold. The $K_3 \times E$ identification is thus a “stitching” of infinitely many conifold-type identifications (one per positive real root), together with the bound-state identifications at $D \geq 0$. At $D > 0$ (imaginary roots): the BKM multiplicities $c(D)$ grow exponentially ($|c(D)| \sim e^{4\pi\sqrt{D}}$; Rademacher), producing infinitely many walls and Stokes lines. These imaginary-root walls are the *source* of shadow class $\mathcal{M}$: infinitely many Borel singularities produce infinite shadow depth ($S_k \neq 0$ for all k). The shadow contribution from discriminant D at degree k is $\Delta S_k = c(D) \cdot D^{k-2}/k!$ (Proposition ??).

The global stitching of these infinitely many local identifications requires the full shadow tower of $\mathcal{A}_{K_3 \times E}$. The framed $K_3 \times E$ specialisation of Theorem 5.11.1 supplies the stage-2 output $\mathcal{A}_{K_3 \times E}$; the remaining conditionality includes the Vol I Borchers-lift identification of the bar Euler product with Φ_{10}^{un} .

The discriminant identification, Stokes-wall count, real-root conifold model, and imaginary-root Stokes structure give the same wall-crossing class. $\square$

Example 28.9.18 (Explicit discriminant table for $K_3 \times E$). The Fourier coefficient $f(n, l)$ of the weak Jacobi form $\phi_{0,1}$ of weight 0, index 1 depends only on $D = 4n - l^2$, and the valid discriminants are $D \in \{-1\} \cup \{D \geq 0 : D \equiv 0 \text{ or } 3 \pmod{4}\}$. Writing $c(D) = f(n, l)$ for any (n, l) with $4n - l^2 = D$ (per-discriminant convention), the first several values follow from the theta-ratio identity $\phi_{0,1} = 4 \sum_{i=2,3,4} (\theta_i(\tau, z)/\theta_i(\tau, 0))^2$:

D	$c(D)$	Wall type	# Stokes lines	$ \mathcal{S}_{\omega_D} $	Shadow degree
-1	1	Real root (flop)	1	1	2 only
0	10	Lightlike	10	10	2 only
3	-64	Imaginary (bound)	64	64	≥ 3
4	108	Imaginary (bound)	108	108	≥ 3
7	-513	Imaginary (bound)	513	513	≥ 3
8	808	Imaginary (bound)	808	808	≥ 3

The column “# Stokes lines” counts $|c(D)|$ Borel singularities at the BPS mass scale $|Z_D|$; the sign of $c(D)$ tracks the fermion number of the BPS multiplet. The absence of $D = 1, 2, 5, 6$ reflects the index-1 parity constraint $D \equiv 0, 3 \pmod{4}$ (for $D \geq 0$). The exponential growth $|c(D)| \sim e^{4\pi\sqrt{D}}/D^{3/4}$ (Rademacher) ensures that the shadow tower has infinite depth (class $\mathcal{M}$), and the accumulation of

Stokes lines in the Borel plane mirrors the accumulation of walls in the stability manifold. The shadow contribution from discriminant $D > 0$ at degree k is $\Delta S_k = c(D) \cdot D^{k-2}/k!$; summing over all admissible D reconstructs the full shadow tower.

Remark 28.9.19 (Finite conifold walls and infinite $K_3 \times E$ walls). The conifold has *finitely many* BPS states, and the pentagon identity is an exact algebraic identity in the quantum torus. The $K_3 \times E$ BKM root system is infinite. For the conifold, the identification requires no unconstructed objects: the DT partition function and its resurgent structure are explicit. For $K_3 \times E$, the chiral algebra $\mathcal{A}_{K_3 \times E}$ is available on the framed Φ_3 specialisation locus of Theorem 5.11.1; the remaining obstacle is the identification of the bar Euler product with the Borcherds denominator, together with the infinite stitching of local conifold-type identifications across the full BKM root system.

Remark 28.9.20 (The instanton gap is computable). For a class $\mathcal{M}$ chiral algebra $\mathcal{A}$, let F_g^{sh} denote the genus- g free energy computed from the perturbative shadow tower $\Theta_{\mathcal{A}}(t)$ and let F_g^{top} denote the exact topological string free energy (the Borel-resummed value). The difference $F_g^{\text{top}} - F_g^{\text{sh}}$ (the *instanton gap*) is a computable quantity. The shadow tower is Gevrey-1 divergent and Borel summable (Proposition 28.9.4), so the physical Borel sum $\mathcal{S}_0[\Theta_{\mathcal{A}}]$ exists and is unambiguous along $\mathbb{R}_+$. The instanton gap is encoded in the Stokes automorphism: the lateral Borel sums $\mathcal{S}_{\omega^\pm}$ differ by $\exp(\mathcal{S}_\omega \cdot \Delta_\omega)$, and the identification $\mathcal{S}_\omega = \Omega(\gamma)$ (Theorem 28.9.13) converts the Stokes discontinuity into BPS data. Since the Stokes automorphism is the KS wall-crossing automorphism, crossing a Stokes line shifts F_g by a sum over BPS charges weighted by $\Omega(\gamma)$, and the resulting trans-series gives F_g^{top} exactly. The instanton gap is therefore a derived quantity, determined by the perturbative shadow coefficients $\{S_k\}$ through the Borel–KS construction of (28.3).

The seven sections transport the Vol I modular Koszul machine into the CY geometric realm: the convolution algebra of §28.1 is the working surface, the complementarity of §28.2 is the duality statement, the CohFT of §28.3 is the genus tower, the Hochschild bridge of §28.5 identifies which Hochschild theory controls which invariant, the examples of §28.6 compute the $\kappa_\bullet$ -spectrum, the Pixton ideal of §28.7 connects the shadow tower to tautological classes, and the Stokes–wall-crossing identification of §28.9 reveals the non-perturbative content of the Gevrey-1 divergence. The $d = 2$ case uses the CY- A_2 construction (Theorem 28.2.1); the $d = 3$ case requires the comparison maps named in Theorem 28.2.4, Conjecture 28.3.7, Theorem 28.5.4, and Conjecture 28.9.17. The $\kappa_\bullet$ -values agree with the $K_3 \times E$ five-construction spectrum $\{\kappa_{\text{cat}}, \kappa_{\text{ch}}^{\text{Hodge}}, \kappa_{\text{ch}}^{\text{Heis}}, \kappa_{\text{BKM}}, \kappa_{\text{fiber}}\} = \{0, 0, 3, 5, 24\}$, with $\kappa_{\text{cat}}(K_3 \times E) = \chi(\mathcal{O}_{K_3}) \cdot \chi(\mathcal{O}_E) = 2 \cdot 0 = 0$ (Künneth-multiplicative categorical Euler) and $\kappa_{\text{ch}}^{\text{Hodge}}(K_3 \times E) = \sum_q (-1)^q h^{0,q}(K_3 \times E) = 0$ (compact chiral Hodge supertrace, the canonical fifth construction, numerically coincident with κ_{cat} yet a distinct construction).

28.10 CROSS-VOLUME ANCHORS

This chapter sits at five named bridges to Vols I–II. We list the explicit arrows; each arrow is a Φ -comparison only at the level where the corresponding stage-2 comparison map has been constructed.

THEOREM 28.10.1 (*Cross-volume comparison criterion*). Let

$$A_C^{(\Sigma, C)} = \text{Sp}_{\Sigma_{d-1}, C}^{\text{ch}}(\Phi_d^{\text{FA}}(C))$$

be a constructed stage-2 shadow. A Vol I or Vol II theorem pushes forward to Vol III as a theorem precisely on the part of the following comparison diagram that has been supplied by an explicit chain-level map:

- (a) *A. Bar-cobar*. The required map is

$$\Theta_A: B^{\text{ord}}(A_C^{(\Sigma, C)}) \longrightarrow \left(\int_{\Sigma_{d-1}} B_{E_d}(\Phi_d^{\text{FA}}(C)) \right) |_C.$$

At $d = 2$ this is the CY- A_2 bar dictionary. At $d = 3$ it is available only on the constructed framed locus of Theorem 5.11.1. At $d \geq 4$ the map is additional structure, not a consequence of the notation Φ_d^{FA} .

- (b) *B. Koszul/Verdier duality*. The required map is the completed Verdier comparison

$$\Theta_B: D_{\text{Ran}} B^{\text{ord}}(A_C^{(\Sigma, C)}) \longrightarrow B^{\text{ord}}(D_{\text{Ran}} A_C^{(\Sigma, C)}),$$

with finite graded pieces before taking products in the completed bar construction. This is proved on the CY₂ shadows and on the framed CY₃ Verdier spectral pages used in this chapter; for $d \geq 4$ the finite-piece and completion hypotheses must be checked anew.

- (c) *C. Quantum group realisation*. The required map is a braided comparison

$$\Theta_C: \text{Rep}(G(X)) \longrightarrow \mathcal{Z}\left(\text{Rep}^{E_1}(A_C^{(\Sigma, C)})\right).$$

For $K_3 \times E$ the proved core is the generator-level rank stratification and the pentagon colimit of the named intertwiners. The universal object $G(X)$ and the braided equivalence above are not constructed in general; the positive-half Hall algebra $Y^+(X)$ and its Drinfeld double are the required input data.

- (d) *D. Modular characteristic*. The Hodge branch is the supertrace

$$\Theta_D^{\text{Hodge}}: \kappa_{\text{ch}}^{\text{Hodge}}(X) = \sum_q (-1)^q h^{\circ, q}(X).$$

The Heisenberg–Mukai and Borchers branches require separate maps

$$\Theta_D^{\text{Heis}}: H_{\text{Muk}} \boxtimes H_E \rightarrow A_C^{(K_3, E)}, \quad \Theta_D^{\text{Borch}}: \text{Bor}(\phi) \rightarrow \mathfrak{g}_{\Delta_3}.$$

Thus $\kappa_{\text{ch}}^{\text{Heis}} = 3$ and $\kappa_{\text{BKM}}(\Delta_3) = 5$ on $K_3 \times E$ are construction-dependent values, not alternative evaluations of the Hodge supertrace.

- (e) *H. Hochschild comparison*. The required map is

$$\Theta_H: HC_{\bullet}^-(C) \longrightarrow \text{ChirHoch}(A_C^{(\Sigma, C)}).$$

On the chirally Koszul generic locus it identifies the $\tau_{\leq 2}$ piece with Vol I Theorem H. At $d \geq 3$ the residual CY degrees are carried by the derived centre, Drinfeld centre, and Verdier spectral pages; they are not killed by the Vol I curve theorem.

- (f) *Vol II K_3 mock pushforward*. The K_3 mock modular theorem is a $d = 2$ theorem for $\Phi_2(D^b \text{Coh}(K_3))$. Its pushforward to $K_3 \times E$ requires the extra comparison

$$\Theta_{\text{mock} \rightarrow K_3 \times E}: \Theta_{\Phi_2(K_3)} \boxtimes H_E \longrightarrow \Theta_{\Phi_3^{(K_3, E)}(K_3 \times E)}$$

compatible with the elliptic fibre, the DMVV second quantisation, and the Borchers lift. Without this map, the $d = 2$ mock theorem supplies evidence for the K_3 fibre, not a theorem for the full CY₃ target.

(g) *ZTE correction.* The exact rational matrix T solves the Yangian deformation-complex problem

$$\ell_1(T) + \ell_3(r, r, r) = 0$$

for the Yang R -matrix at the parameter $\hbar_Y$. Its Φ -interpretation requires a map

$$\Theta_{\text{ZTE} \rightarrow \Phi}: R_{\text{Yang}}(z) \longrightarrow \sigma_{V_u}(V_v) \in \mathcal{Z}\left(\text{Rep}^{E_i}(A_C^{(\Sigma, C)})\right)$$

and an identification of the ternary correction with the E_3 operations coming from $\Phi_3^{\text{FA}}(C)$. The computation is a chain-level calculation of the obstruction; it is not by itself a global CY-A or CY-C theorem.

(h) *Shadow tower origin.* The shadow tower is born in the ordered bar complex of the stage-2 chiral algebra:

$$\Theta_{A_C^{(\Sigma, C)}} = D_{A_C^{(\Sigma, C)}} - d_o \in \text{Hom}_{\text{Ran}}\left(B^{\text{ord}}(A_C^{(\Sigma, C)}), A_C^{(\Sigma, C)}\right).$$

Borcherds products, DT series, and BPS wall-crossing are comparison targets. The missing all-degree map is the motivic integration

$$\Theta_{\text{sh} \rightarrow \text{DT}}: H^\bullet\left(B^{\text{ord}}(A_C^{(\Sigma, C)})\right) \longrightarrow H_{\text{van}}^\bullet(\mathfrak{M}_{\text{DT}}(X))$$

compatible with Behrend signs and Hall multiplication.

Proof. The statement is a type check of the three ambient categories. Vol I Theorems A–D and H are theorems of chiral algebras on a curve and their ordered Ran bar complexes. Vol II supplies holographic or Swiss-cheese structures on boundary–bulk pairs. Vol III begins with a CY category and reaches a curve only after the two-stage construction $\text{Sp}_{\Sigma_d, C}^{\text{ch}} \circ \Phi_d^{\text{FA}}$. Hence every cross-volume transport factors through an explicit map from the CY or physical source to the stage-2 ordered bar, Hochschild, centre, or representation category. Items (a)–(h) list exactly those target objects. Where the named map is installed by CY-A₂, the framed CY-A₃ theorem, the Verdier spectral functor, or direct exact computation, the pushforward is proved. Where the map is not installed, the formula is a conditional identity. No additional cross-volume theorem can bypass this condition, because it would have to identify objects in different categories without a functor between them. $\square$

Remark 28.10.2 (Bridge to Vol I Koszul Reflection). Vol I [96] (Theorem A) establishes that the bar-cobar adjunction $(\Omega_X, \bar{B}_X)$ on $\text{Kosz}(X)$ defines an involutive Koszul reflection $\mathfrak{R}_A: A \mapsto A^!$ with $\mathfrak{R}^2 \simeq \text{id}$. Under the CY-to-chiral correspondence Φ_d (CY-A₂ proved at $d = 2$; at $d = 3$ restricted to a framed Φ_3 locus, Theorem 5.11.1), the Koszul reflection lifts to a categorical involution on the source CY category:

$$\mathfrak{R}_{A_C} = \Phi_*(\mathfrak{R}_C^{\text{cat}}),$$

where $\mathfrak{R}_C^{\text{cat}}$ is the Mukai/HMS involution on C ($\mathfrak{R}_C^{\text{cat}}$ is a manifold-level involution, while $\mathfrak{R}_{A_C}$ is the chiral algebra-level reflection; the two coincide under Φ at $d = 2$ and at $d = 3$ after the maps $\Theta_A^{(3)}$ and $\Theta_B^{(3)}$ are installed). At the level of complementarity (§28.2), this is exactly Theorem 28.2.1 (CI^{CY}): the eigenspace decomposition of the genus- g shadow complex under Verdier duality. The $d = 3$ analogue is Theorem 28.2.4 (CI^{CY₃}), conditional on the same comparison maps.

Remark 28.10.3 (Bridge to Vol I climax ($\tilde{\partial} = \text{KZ}^(\nabla_{\text{Arnold}})$, $\kappa_{\text{ch}} = -c_{\text{ghost}}(\text{BRST})$)).* Vol I [96] establishes the climax identity

$$\tilde{\partial}_X = \text{KZ}^*(\nabla_{\text{Arnold}}), \quad \kappa_{\text{ch}}(A) = -c_{\text{ghost}}(\text{BRST}(A)),$$

identifying the bar differential on $B(A)$ with the pullback of the operator-valued KZ–Arnold connection on $C_n(C)$; the Arnold forms are its configuration-space coefficients, while the KZ map supplies the operator labels. The same comparison identifies the chiral modular characteristic with the negative ghost central charge of the BRST resolution. Under Φ at $d = 2$ (CY- A_2 , proved), this gives the CY climax identity

$$\tilde{\partial}_{A_C} = \text{KZ}^*(\nabla_{\text{Arnold}}^{(\text{CY})}), \quad \kappa_{\text{ch}}(A_C) = -c_{\text{ghost}}(\text{BRST}(A_C)) = \chi^{\text{CY}}(C),$$

the second equality being Proposition 28.1.8. At $d = 3$ the chiral algebra is available only on a framed Φ_3 locus (Theorem 5.11.1); the climax identity then refines to the dimension-stratified statement that $\kappa_{\text{ch}}(A_X)$ records the $-c_{\text{ghost}}(\text{BRST}(A_X))$ after the dimension-dependent Hodge supertrace correction (§28.6; cf. Conjecture 5.3.25).

Remark 28.10.4 (Bridge to Vol I universal conductor). Vol I [96] establishes the universal κ_{ch} -conductor formula $K(A) = \kappa_{\text{ch}}(A) + \kappa_{\text{ch}}(A^\dagger) = -c_{\text{ghost}}(\text{BRST}(A))$ as a single scalar invariant of the Koszul-dual pair. The $d = 2$ CY image of this is Theorem 28.2.1 ($C_{\text{scal}}^{\text{CY}}$): on the free-field/KM branch (including the K3 Mukai–Heisenberg sector via Mukai self-duality), $K(A_C) = 0$; on the Virasoro branch at the self-dual point $c = c^\dagger = 13$, $K = c/2 + c^\dagger/2 = 13$; on the $\mathcal{W}_N$ branch, $K = c \cdot (H_N - 1)$. The $d = 3$ analogue is the family-dependent CY Koszul conductor $\rho \cdot K_X$ of Theorem 28.2.4 ($C_{\text{scal}}^{\text{CY}_3}$), conditional on Θ_D^{unif} . The Universal Trace Identity (Conjecture 29.15.1, cross-volume, in the bar-cobar bridge chapter) predicts a comparison between $K(A)$ and $\kappa_{\text{BKM}}(\Phi_\Lambda) = c_\Lambda(0)/2$ (Vol III 17.6.7); the putative comparison identity is, in precise terms, a comparison morphism from the Koszul reflection to the Borchers centre action. It becomes a theorem only after that comparison map is supplied.

Remark 28.10.5 (Bridge to Vol I shadow quadrichotomy). Vol I [96] establishes the G/L/C/M shadow class classification for chiral algebras and the spectral-curve Picard–Fuchs hierarchy controlling each class. For a constructed stage-2 shadow A_C , its CY shadow class is determined by:

- the cohomological dimension d of C (via $\kappa_{\text{ch}} = \chi^{\text{CY}}$ at $d = 2$, dimension-stratified at $d = 3$);
- the Hodge weight content of the chiral de Rham complex (controlling whether the shadow tower terminates);
- the BPS spectrum (for compact CY_3 , the BCOV holomorphic anomaly equation drives the tower to class M; the resolved conifold collapses to class G).

The Stokes–wall-crossing identification (Theorem 28.9.13, §28.9) then recovers the spectral-curve Picard–Fuchs hierarchy on the CY side: Borel singularities $\omega_\pm$ of $\tilde{\Theta}_A$ are the singular points of the spectral curve, and the Stokes constants are the Picard–Fuchs monodromy data.

Remark 28.10.6 (Bridge to Vol II universal holography master). Vol II [97] establishes universal celestial holography: the $\text{SC}^{\text{ch}, \text{top}}$ -structure on the bulk-boundary pair sits over chiral factorisation homology, with the $\text{SC}^{\text{ch}, \text{top}} \rightarrow E_3^{\text{top}}$ lift conditional on the topologisation $T = [Q, G]$ together with the T1–T5 infrastructure (finite propagation, anomaly cancellation, non-degeneracy, normal form, parity); the shadow-tower coefficients match the soft-factor hierarchy. Under Φ at $d = 2$ (CY- A_2 , proved), one obtains the K3-fibre input: the bar Euler product $\eta(q)^{24}$ is the chiral factorization homology of the

K_3 lattice VOA. Its extension to the full $K_3 \times E$ holographic datum requires the mock-to- $K_3 \times E$ comparison map of Theorem 28.10.1; only after that map and the Borchers lift are installed do the shadow coefficients assemble into the genus-2 Igusa cusp form Φ_{10}^{un} (Theorem 28.3.4). At $d = 3$, the Universal Trace Identity (§29.15 of the bar-cobar bridge chapter) predicts that the Vol II universal holography master extends to K_3 -fibered CY_3 with $K(\mathcal{A}_X)$ as the supertrace of the Vol II $\text{SC}^{\text{ch}, \text{top}}$ -structure on $(C_{\text{ch}}^\bullet(\mathcal{A}_X, \mathcal{A}_X), \mathcal{A}_X)$, restricted to a marked point on the curve.

The five bridges above are the load-bearing cross-volume anchors of this chapter. Each is a candidate Φ -comparison of a Vol I/II structure, proved only where the comparison maps of Theorem 28.10.1 are installed; each carries the distinction between manifold-level and construction-level invariants; and each carries the caveat that, on the $K_3 \times E$ branch, the bar Euler product identification with the Borchers denominator requires both the framed Φ_3 specialisation and the Vol I anchor.

28.11 HUMBERT MONODROMY AND THE ROOT-OF-UNITY COMPARISON

The $\mathcal{B}$ -family of §28.2 has the Mukai integer $2c_+(\text{Mukai}(K_3)) = 8$ on the K_3 input. The same integer occurs as a candidate order of local monodromy along the Humbert divisor $H_1 \subset \overline{\mathcal{A}}_2$ and as the order of a possible Lusztig root-of-unity specialisation. These are three structures with a common integer; Bruinier’s Heegner-divisor Chern-class formula controls the automorphic Chern class and does not by itself identify the formal deformation parameter with a numerical square.

The Humbert divisors and their Heegner structure

Definition 28.11.1 (Humbert divisors in $\overline{\mathcal{A}}_2$). The Humbert surfaces $H_D \subset \overline{\mathcal{A}}_2$, indexed by positive discriminants $D > 0$, are the Heegner loci parametrising principally polarised abelian surfaces admitting a primitive symmetric endomorphism of discriminant D (Humbert, *Sur les surfaces algébriques dans l’espace de Hilbert*, J. Math. Pures Appl. 9, 1899; modern treatment: van der Geer, *Hilbert modular surfaces*, Springer 1988, Ch. IX). For nonsquare D this is real multiplication by the quadratic order of discriminant D . The square-discriminant cases are split Heegner loci: H_1 is the decomposable locus and H_4 is the discriminant-4 component, equivalently the two-isogeny locus from products of elliptic curves. Both divisors are load-bearing for Δ_5 .

Remark 28.11.2 (Vanishing orders of Δ_5 on Humbert divisors). By Gritsenko–Nikulin, *Automorphic forms and Lorentzian Kac–Moody algebras II*, Int. J. Math. 9, 1998, Theorem 2.1: the Borchers form $\Delta_5 = \text{Grit}(\gamma^9 \mathfrak{d}_1)$ vanishes on H_1 to order 1 and on H_4 to order 2. Its square $\Delta_{10} = \Delta_5^2$ therefore vanishes to orders 2 and 4 respectively, and $\Phi_{10}^{\text{un}} = \Delta_{10}|_{\text{Sp}_4(\mathbb{Z})}$ (Igusa’s genus-two cusp form) to the same orders.

The monodromy identities

PROPOSITION 28.11.3 (Humbert monodromy comparison datum). Assume that the regular-singular $\mathcal{D}$ -module attached to Δ_5 has local exponents with denominators 8 and 16 on the chosen branches of H_1 and H_4 . Then the semisimple parts of the local monodromies have orders dividing

$$\text{ord}(\text{monodromy } \mathcal{L}^{\Delta_5}|_{H_1}) \mid 8, \quad \text{ord}(\text{monodromy } \mathcal{L}^{\Delta_5}|_{H_4}) \mid 16.$$

On the K_3 branch the integer 8 also equals the Mukai integer

$$2c_+(\text{Mukai}(K_3)) = 8,$$

since the Mukai lattice has signature $(4, 20)$. The equality of the monodromy order with this Mukai integer is a comparison datum on the fixed K_3 branch, not a consequence of Bruinier’s formula alone.

Proof via Bruinier. The key input is Bruinier, *Borcherds products on $O(2, l)$ and Chern classes of Heegner divisors*, Springer LNM 1780, 2002, Proposition 5.1. Specialised to the orthogonal group $O(\Lambda^{2,3})$ that acts on the genus-two orthogonal model, Bruinier’s proposition computes the rational Chern class

$$c_1(\mathcal{L}^{\Delta_5}|_{H_D}) \in \mathrm{CH}^1(H_D)$$

in terms of the Heegner divisor data of the Borcherds product. A regular-singular rank-one connection with exponent a/N has semisimple monodromy of order dividing N ; equality requires that the exponent be primitive and that no stack stabiliser or multiplier-system quotient reduces the order. Thus the displayed orders are branch-normalised comparison data. The Mukai equality is the separate lattice calculation $2c_+ = 8$ for $\Pi_{4,20}$. $\square$

PROPOSITION 28.II.4 (*Lusztig specialisation $\ell = 8$ and the deformation parameter*). The Lusztig specialisation at order $\ell = 8$ of the Hall–Drinfeld double

$$\mathcal{D}_{\hbar}(\mathcal{Y}_{\hbar}^{\mathrm{Hall}}(\mathrm{CoHA}_{K_3 \times E}))$$

is a specialisation of the exponentiated parameter q at a primitive eighth root of unity $\zeta = e^{2\pi i/8}$ (Lusztig, *Quantum groups at roots of unity*, Geom. Ded. 35, 1990). If one writes $q = \exp(\hbar)$ and chooses the principal branch, then $\hbar = 2\pi i/8$ modulo $2\pi i\mathbb{Z}$. There is no invariant statement $\hbar^2 = -1/8$. The expression $\hbar^2 K^{\kappa_{\mathrm{ch}}} = -1$ is therefore a gauge normalisation, not a theorem about the Hall–Drinfeld double.

Proof. The root-of-unity construction is a statement about q or ζ , not about a canonical complex number $\hbar$. Passing from q to $\hbar$ requires a logarithm and a choice of normalisation of the deformation parameter. The square of that logarithm changes under these choices. Hence the numerical equality $\hbar^2 = -1/8$ cannot be extracted from Lusztig’s specialisation or from Drinfeld’s formal parameter alone.

Felder–Wieczerkowski elliptic dynamical R -matrices produce an elliptic (not Siegel) dynamical R , geometric-genus-one in character; the Siegel-genus-two coupling captured by the Humbert stratification is not visible at that genus. The Siegel-dynamical R -matrix $R_{\mathrm{Sieg}, \mathrm{dyn}}$ is constructed in Chapter 20, Section 20.16. $\square$

One identity, three faces

Remark 28.II.5 (*Three occurrences of the number 8*). The integer 8 appears simultaneously in three a-priori unrelated mathematical settings.

- (*Face 1, Mukai.*) $8 = 2c_+(\mathrm{Mukai}(K_3))$ is the doubled positive-signature rank of the Mukai lattice of K_3 .
- (*Face 2, Bruinier.*) 8 is the primitive denominator expected for the H_1 local exponent in the chosen normalisation of the Δ_5 automorphic line.
- (*Face 3, Lusztig.*) $8 = \ell$ is the order of the root of unity at which the Hall–Drinfeld double is specialised, if that specialisation is constructed.

The manuscript may use their agreement as a comparison requirement. It must not use it as a proof that a formal parameter satisfies a canonical quadratic equation.

Remark 28.II.6 (*Scope of the comparison*). The comparison is confined to the fixed K_3 branch where the Mukai integer, the chosen automorphic exponent denominator, and the chosen root-of-unity order are all equal to 8. For other lattice inputs the three integers need not move in parallel. The Borcherds-weight identity $\kappa_{\mathrm{BKM}}(\Phi_N) = c_N(o)/2$ is the universal scalar theorem; the quadratic formula in $\hbar$ is not.

Remark 28.11.7 (Cross-reference to bi-based architecture). The monodromy datum lives on the parameter base (γ) of Definition 29.17.1. The Mukai datum lives on the chiral base (α) . The averaging datum (δ) is the fixed-branch correspondence $\text{av} = \pi_{\text{Sp}_4} \circ \mathcal{P}_{K_3}$, together with the marked Kodaira discriminant on E_{24}^{nod} . It gives a place where the two order-eight data may be compared.

28.12 VOL I $\leftrightarrow$ VOL III MODULAR KOSZUL BRIDGE AT THE K_3 BASE

Remark 28.12.1 (Vol I $\leftrightarrow$ Vol III modular Koszul bridge at the K_3 base). The modular Koszul bridge between Vol. I (modular Koszul duality on curves and $\tilde{\mathcal{M}}_{g,n}$) and Vol. III (CY-to-chiral functor Φ on CY_n landscapes) crystallises at the K_3 base point in the following way: the higher-genus modular Koszul pair $(B_{\text{ch}}^{(2)}(A), \Omega_X^{(2)})$ on $\tilde{\mathcal{A}}_2$ (Vol. I, §[96] (Vol I)) is matched with the CY-2 Koszul pair $(\text{Per}^b \text{Coh}(K_3), D^b \text{Coh}(K_3)^!)$ via the Gritsenko-additive lift Δ_5 of the Vol. I Jacobi cusp form. The commutativity of

$$\begin{array}{ccc} B_{\text{ch}}^{(2)}(A) & \xrightarrow{\Phi^{-1}} & \text{Per}^b \text{Coh}(K_3) \\ \downarrow \Omega_X^{(2)} & & \downarrow \text{Serre} \\ A & \xrightarrow{\Phi^{-1}} & D^b \text{Coh}(K_3)^! \end{array}$$

is the content of the comparison problem: the modular Koszul duality on $\tilde{\mathcal{A}}_2$ is compared with the CY-2 Koszul duality on $D^b \text{Coh}(K_3)$ through the fixed K_3 -period branch and its reduced spin projection. Primary-lit: Gritsenko 1995, Bruinier 2002 (arXiv:math/0108079), Mukai 1987, Bridgeland-Maciocia 2001. Cross-ref Chapter 20.

THE BAR-COBAR BRIDGE

The shadow obstruction tower Θ_A applies after a Calabi–Yau category has been specialised to a chiral algebra. The bridge has two parts: the stage-1 comparison between $\mathrm{CC}_\bullet(C)$ and the factorisation bar of $\Phi_d^{\mathrm{FA}}(C)$, and the stage-2 comparison from that factorisation bar to the ordered chiral bar $B(A_C)$ on the reference curve. The affine case $\mathbb{C}^3$ supplies the explicit model: the positive CoHA side, the passage to the centre/double where $\mathcal{W}_{1+\infty}$ appears, and the open-string-field-theory realisation of Koszul duality.

The bar construction in this chapter operates at two distinct stages of $\Phi_d = \mathrm{Sp}_{\Sigma_{d-1}, C}^{\mathrm{ch}} \circ \Phi_d^{\mathrm{FA}}$, and every statement below labels which stage its hypothesis lives on.

- (i) **Stage 1, factorisation bar** $\overline{B}_{E_d}^{\mathrm{fact}}$. On the canonical E_d -HolFA(X) object $\Phi_d^{\mathrm{FA}}(C)$, the bar is the E_d -hFA factorisation bar: a homotopy E_d -coalgebra on X computed via the factorisation-algebra cobar resolution. The identification $\mathrm{CC}_\bullet(C) \simeq \overline{B}_{E_d}^{\mathrm{fact}}(\Phi_d^{\mathrm{FA}}(C))$ is a statement about the stage-1 object before any curve-specialisation; $\mathrm{HH}^\bullet(C)$ is the input surface, and the Hodge filtration on Hochschild homology is the stage-1 degree filtration.
- (ii) **Stage 2, chiral ordered bar** $\overline{B}_{E_1}$. After $\mathrm{Sp}_{\Sigma_{d-1}, C}^{\mathrm{ch}}$ descends to a chiral algebra A_C on the reference curve, the relevant bar is the E_1 -chiral ordered tensor-coalgebra $\overline{B}(A_C) = T^c(s^{-1}\overline{A_C})$ with deconcatenation coproduct, on $\mathrm{Ran}(C)$. For $d \geq 3$ this specialised output is E_1 ; the E_2 -structure belongs to the derived or Drinfeld centre under the hypotheses stated below. This is the home of Θ_A , the Koszul reflection, and the stage-2 shadow tower.

The shadow obstruction tower Θ_A operates at stage 2; the categorical CY trace and the Hochschild bridge operate at stage 1; the universal trace identity of §29.15 lives on the $\mathrm{HH}^\bullet(C)$ input surface (stage 1) with numerical specialisations read off at stage 2.

29.1 CY BAR COMPLEX VS CHIRAL BAR COMPLEX

Let C be a smooth proper CY_3 category with Serre functor $\mathbb{S}_C \simeq [3]$. Assume that the stage-1 object $\Phi_3^{\mathrm{FA}}(C)$ and a framed specialisation datum (Σ_2, C) have been constructed. The two-stage factorisation

$$\Phi_3^{(\Sigma_2, C)} : \mathrm{CY}_3\text{-Cat} \xrightarrow{\Phi_3^{\mathrm{FA}}} E_3\mathrm{HolFA}(X) \xrightarrow{\mathrm{Sp}_{\Sigma_2, C}^{\mathrm{ch}}} E_1\mathrm{HolFA}(C)$$

produces first the E_3 factorisation algebra $\Phi_3^{\mathrm{FA}}(C)$ on the CY source, then the E_1 chiral algebra

$$A_C = \mathrm{Sp}_{\Sigma_2, C}^{\mathrm{ch}}(\Phi_3^{\mathrm{FA}}(C))$$

on C . The canonical bar comparison at stage 1 is

$$\mathrm{CC}_\bullet(C) \simeq \overline{B}_{E_3}^{\mathrm{fact}}(\Phi_3^{\mathrm{FA}}(C)).$$

The comparison with the ordered chiral bar on C is the additional stage-2 map

$$\Theta_A^{(3)} : \mathrm{CC}_\bullet(C) \longrightarrow B^{\mathrm{ord}}(A_C),$$

defined only after the framed specialisation and the relevant completion datum are fixed. For compact non-formal CY_3 inputs this map is a theorem only after the corrected TCFT comparison identifies the raw termwise operator $B_{\mathrm{term}}^{(2)}$ with Costello's $B_{\mathrm{TCFT}}^{(2)}$, or after a complete separated strongly convergent filtered $\mathrm{HH}_{E_i}^{-2}$ theorem replaces that comparison.

The precise dictionary is as follows.

PROPOSITION 29.1.1 (*Bar complex dictionary*). Assume that $\Theta_A^{(3)}$ is a quasi-isomorphism in the weight-completed pro-nilpotent factorisation-coalgebra category. Then the following identifications hold after transport along $\Theta_A^{(3)}$:

- (i) The Hochschild differential b on $\mathrm{CC}_\bullet(C)$ corresponds to the collision-contraction part of the ordered bar differential on $B^{\mathrm{ord}}(A_C)$.
- (ii) The Connes operator $B : \mathrm{HH}_n(C) \rightarrow \mathrm{HH}_{n+1}(C)$ corresponds to the cyclic S^1/BV operator on the transported bar object: a separate cyclic-rotation operator on $B^{\mathrm{ord}}(A_C)$, distinct from its internal collision-contraction differential.
- (iii) The cyclic rotation action on $\mathrm{CC}_\bullet(C)$ corresponds to the factorisation-coalgebra cocomposition maps on $B^{\mathrm{ord}}(A_C)$, indexed by collision trees or stable graphs after passage to the modular envelope.
- (iv) The Hodge filtration on $\mathrm{HH}_*(C)$ corresponds to the completed bar-length filtration: the degree- r truncation records tensor length $\leq r$ after the chosen specialisation and completion.

Proof. The stage-1 statement is the cyclic trace comparison for $\Phi_3^{\mathrm{FA}}(C)$. Applying the framed specialisation produces A_C and the map $\Theta_A^{(3)}$. Once this map is a quasi-isomorphism in the completed ambient, each operator on $\mathrm{CC}_\bullet(C)$ is transported to the ordered bar complex. The differential b is generated by multiplication/collision contractions, hence becomes the collision part of d_B . The operator B is generated by cyclic rotation in the mixed complex, hence becomes the cyclic/BV operator on the bar side. The filtration statement follows from tensor-length completion and the Hodge filtration compatibility in the stage-1 trace comparison. $\square$

Remark 29.1.2 (*Five objects*). The chiral algebra and its Koszul constructions are five different objects:

- (1) A , the stage-2 E_i chiral algebra for $d \geq 3$.
- (2) $B(A) = T^c(s^{-1}\tilde{A})$, the ordered bar coalgebra.
- (3) $A^i = H^\bullet(B(A))$, the bar-cohomology coalgebra.
- (4) $A^! = D_{\mathrm{Ran}}(A^i)$, the Koszul dual algebra; equivalently $D_{\mathrm{Ran}}(B(A)) \simeq B(A^!)$ on the Verdier comparison surface.
- (5) $\mathcal{Z}_{\mathrm{ch}}^{\mathrm{der}}(A) = C_{\mathrm{ch}}^\bullet(A, A) \simeq \mathrm{RHom}(\Omega(B(A)), A)$, the chiral derived centre (the universal closed-sector internal object; identification with a physical bulk requires the OCA arrow $\mathrm{OCA} : \mathcal{O}_{\mathrm{bulk}}^{\mathrm{phys}}(\mathcal{T}) \xrightarrow{\sim} \mathcal{Z}_{\mathrm{ch}}^{\mathrm{der}}(A)$ of Definition 5.0.5).

The cobar recovery $\Omega(B(A)) \simeq A$ is inversion back to the original algebra. The remaining three objects A^i , $A^!$, and the derived centre $\mathcal{Z}_{\mathrm{ch}}^{\mathrm{der}}(A)$ sit on their own constructions: A^i as the bar cohomology coalgebra, $A^!$ as the Verdier–Koszul dual, and the derived centre as the chiral Hochschild cochain algebra.

The CY cyclic bar complex corresponds to the bar coalgebra under the comparison above; the derived centre sits at the next level of the universal arrow.

29.2 THE SHADOW TOWER OF $\mathbb{C}^3$: MACMAHON MEETS KOSZUL

The affine threefold $\mathbb{C}^3$ is the simplest case where both sides of the CY-to-chiral correspondence are explicit. Its CoHA side is the positive half $\text{CoHA}(\mathbb{C}^3) \simeq Y^+(\widehat{\mathfrak{gl}}_1)$; the $\mathcal{W}_{1+\infty}$ vertex algebra appears only after the Drinfeld double/centre and vacuum evaluation of the envelope.

THEOREM 29.2.1 (*Shadow tower of $\mathbb{C}^3$*). The toric $\mathbb{C}^3$ shadow has the following two characters and one scalar genus-one invariant.

- (i) The Hall character is the MacMahon function and the Koszul bar Euler product is its inverse:

$$\text{ch } Y^+(\widehat{\mathfrak{gl}}_1) = M(q), \quad \chi_{\text{bar}}(q) = M(q)^{-1}, \quad M(q) = \prod_{n \geq 1} (1 - q^n)^{-n}.$$

Equivalently, if $V_{\text{BPS}} = \bigoplus_{n \geq 1} V_n$ and $\dim V_n = n$, then

$$\text{ch Sym}(V_{\text{BPS}}) = M(q), \quad H^\bullet(B \text{Sym}(V_{\text{BPS}})) \cong \Lambda(V_{\text{BPS}}[1]).$$

- (ii) The scalar modular characteristic of the evaluated Heisenberg vacuum sector is

$$\kappa_{\text{ch}}^{\text{Heis}}(\mathbb{C}^3) = 1.$$

The equality follows from the level-one OPE $J(z)J(w) \sim (z-w)^{-2}$. It is not the Virasoro value $c/2$.

- (iii) The finite $\mathcal{W}_N$ conductor $c(H_N - 1)$ is a family invariant of principal $\mathcal{W}_N$ -algebras. Its $N \rightarrow \infty$ divergence is not a scalar modular characteristic of the $\mathbb{C}^3$ Hall output.

Remark 29.2.2 (Envelope creates infinite depth from abelian input). The Heisenberg algebra H_1 (a single free boson) has shadow depth class G with $r_{\text{max}} = 2$: the tower terminates at degree 2, and $\kappa_{\text{ch}} = 1$ is the only nonvanishing shadow invariant.

The vertex algebra $\mathcal{W}_{1+\infty}$ at $c = 1$, the factorization envelope of the Lie conformal algebra of polyvector fields on $\mathbb{C}^3$, has shadow depth class M with $r_{\text{max}} = \infty$. The spin-2 channel (Virasoro at $c = 1$) already has infinite shadow depth, with $\kappa_2 = 1/2$, $\alpha_2 = 2$, $S_4 = 10/27$.

This discrepancy between input (class G, depth 2) and output (class M, depth ∞) reflects the non-conservativity of the factorization envelope on shadow invariants. Normal ordering, Wick contractions, and OPE singular terms generate higher-degree shadows invisible at the E_1 -level. Each stage of the operad filtration $E_1 \rightarrow E_2 \rightarrow E_\infty$ introduces genuinely new invariants.

29.3 OPEN STRING FIELD THEORY: KOSZUL DUALITY AT CHAIN LEVEL

For $\mathbb{C}^3$, the cyclic $\mathcal{A}_\infty$ -algebra is the exterior algebra $\mathcal{A} = \wedge^*(V)$ with $V = \mathbb{C}^3$, equipped with the CY₃ trace $\langle a, b \rangle = \text{Tr}(a \wedge b)$ (projection to top degree).

THEOREM 29.3.1 (*Chain-level Koszul duality for $\mathbb{C}^3$*). The Koszul duality pair for $\mathcal{A} = \wedge^*(\mathbb{C}^3)$ satisfies:

- (i) $\mathcal{A}^! = \text{Sym}^*(\mathbb{C}^{3*})$, the symmetric algebra on the dual vector space. This is the $\text{Com}^! = \text{Lie}$ incarnation at the chain level: the exterior algebra (free Com-algebra on V) is Koszul dual to the symmetric algebra (free Lie-algebra envelope on V^*).

(ii) The bar complex $B(\bigwedge^* V)$ has cohomology concentrated in bar degree 1:

$$H^*(B(\bigwedge^* V)) \simeq \text{Sym}^*(V^*[-1]),$$

confirming that $\mathcal{A}$ is Koszul (chirally and classically).

(iii) The bar-cobar round-trip recovers $\mathcal{A}$ itself:

$$\Omega(B(\bigwedge^* V)) \xrightarrow{\sim} \bigwedge^* V.$$

29.4 OPERADIC E_3 KOSZUL SELF-DUALITY AND THE STAGE-1 SELF-PAIRING

The $\mathbb{C}^3$ -specific chain-level Koszul duality of Theorem 29.3.1 lifts to an operadic-level statement holding for every CY_3 category: the E_3 -operad is Koszul self-dual up to shift, and this operadic self-duality supplies the Stage-1 object $\Phi_3^{\text{FA}}(C)$ with a canonical self-pairing of degree 3 that descends under $\text{Sp}_{\Sigma_2, C}^{\text{ch}}$ to the bar-cobar construction chiral Koszul duality on C .

THEOREM 29.4.1 (*Fresse–Ayala–Francis: E_n Koszul self-duality up to shift*). Over $\mathbb{Q}$, there is a quasi-isomorphism of dg-operads

$$E_n^! \simeq E_n\{n\}$$

in the $(\infty, 1)$ -category of dg-operads. Equivalently at the cohomology level, $\text{Ger}_n^! \simeq \text{Ger}_n\{n\}$, with Ger_n the Gerstenhaber operad of shift $1 - n$ (commutative product in degree 0, graded Lie bracket of degree $1 - n$, Leibniz coupling). For $n = 3$: the E_3 -operad is Koszul self-dual up to a shift by 3, matching the CY_3 Serre shift on Hochschild cohomology.

Proof. Two independent routes, both reducing to classical Ginzburg–Kapranov computations. Route A (algebraic): the quadratic presentation of Ger_n has generators μ (degree 0, commutative product) and $\{-, -\}$ (degree $1 - n$, graded Lie bracket) with associativity, Jacobi, and Leibniz relations. The Koszul dual operad has dual generators $\mu^\vee$ and $\{-, -\}^\vee$ with dual relations; Fresse 2011 *Selecta Math.* 17 Theorem 1 verifies that the Koszul dual equals $\text{Ger}_n\{n\}$ by direct computation of $R^\perp$. Route B (topological): the Fulton–MacPherson compactification $\overline{F}(k, \mathbb{R}^n)^{\text{FM}}$ is an oriented compact $n(k - 1)$ -manifold with corners; Ayala–Francis 2014 arXiv:1409.2478 Theorem 2.1 (*Poincaré/Koszul duality*) establishes that the Poincaré pairing on this compactification realises the operadic Koszul self-duality $C_\bullet(D_n)^! \simeq C_\bullet(D_n)\{n\}$ at the Fulton–MacPherson chain level. The two routes agree modulo the Grothendieck–Teichmüller torsor $\text{GRT}_1(\mathbb{Q})$ parametrising E_n -formality zig-zags (Calaque–Willwacher 2011 arXiv:1111.0810). $\square$

COROLLARY 29.4.2 (*E_3 Koszul shift and bar-cobar inversion*). For an augmented E_3 -algebra $\mathcal{A}$ with pro-nilpotent augmentation ideal $\overline{\mathcal{A}}$, the bar-cobar round-trip is the inversion map

$$\Omega^{E_3}(B^{E_3}(\mathcal{A})) \xrightarrow{\sim} \mathcal{A}$$

on the pro-nilpotent Koszul locus. The shift in Theorem 29.4.1 belongs to the E_3 Koszul dual cooperad and to the induced duality pairing: the Koszul duality datum is shifted by $\{3\}$, while inversion recovers the original algebra. For $\mathcal{A} = \text{HH}^\bullet(C)$ on a CY_3 category, this shifted duality datum matches the categorical Serre shift $\mathbb{S}_C \simeq [3]$.

Proof. By Theorem 29.4.1, the Koszul dual E_3 -operad satisfies $E_3^! \simeq E_3\{3\}$. This fixes the shift in the duality pairing and in the bar construction. The adjunction $\Omega^{E_3} \dashv B^{E_3}$ still has counit $\Omega^{E_3} B^{E_3}(\mathcal{A}) \rightarrow$

$\mathcal{A}$, and this counit is a quasi-isomorphism on the pro-nilpotent Koszul locus (Fresse 2011 Theorem 3.2; Francis 2013 *Compos. Math.* 149 Corollary 5.3). Pro-nilpotence gives convergence of the bar spectral sequence. The CY_3 Serre shift is therefore recorded by the self-duality pairing, not by replacing the target of the inversion map. $\square$

THEOREM 29.4.3 (*Stage-1 operadic Poincaré self-pairing*). Let C be a CY_3 category with cyclic A_∞ -structure of parity $+3$, CY trace $\langle -, - \rangle_{\text{CY}} : \text{HH}^\bullet(C)^{\otimes 2} \rightarrow \mathbb{Q}[3]$, and constructed cyclic stage-1 assembly $\Phi_3^{\text{FA}}(C)$. The Stage-1 object $\Phi_3^{\text{FA}}(C) \in E_d\text{-HolFA}(X)$ carries a canonical cyclic self-pairing

$$\langle -, - \rangle_{\Phi_3^{\text{FA}}} : \Phi_3^{\text{FA}}(C) \otimes \Phi_3^{\text{FA}}(C) \longrightarrow \omega_X[3]$$

of cohomological degree 3, equivalently a Koszul self-duality datum on Stage-1 in the sense of Theorem 29.4.1. This Stage-1 self-pairing is:

- (i) E_3 -cyclic: compatible with the E_3 -algebra structure, satisfying $\langle \mu_{E_3}(a, b), c \rangle = (-1)^{|a|(|b|+|c|)} \langle b, \mu_{E_3}(c, a) \rangle$ at arity 2, with the configuration-space-labelled-tree generalisation at higher arity;
- (ii) Fulton–MacPherson realised: on each stratum of $\overline{F}(k, X)^{\text{FM}}$, the local pairing is the Ayala–Francis Poincaré pairing pulled back via the CG Locality Axiom;
- (iii) Compatible with B^{E_3} : under the E_3 -bar of $\text{HH}^\bullet(C)$, the Stage-1 pairing satisfies $\langle a, b \rangle_{\Phi_3^{\text{FA}}} = \langle B^{E_3}(a), B^{E_3}(b) \rangle_{B^{E_3}}$ with the right-hand side valued in degree -3 , summing to total degree 0 on the bar;
- (iv) Cyclicity-preserving under $\text{Sp}_{\Sigma_2, C}^{\text{ch}}$: the Stage-2 output $\text{Sp}_{\Sigma_2, C}^{\text{ch}}(\Phi_3^{\text{FA}}(C))$ carries a cyclic pairing of degree 1 on C , the chiral Koszul pairing, obtained by integrating the Stage-1 degree-3 pairing over Σ_2 via factorisation homology.

Proof. Existence of the pairing. The cyclic A_∞ -pairing on C produces an E_3 -cyclic structure on $\text{HH}^\bullet(C)$ via Kontsevich–Soibelman 2009 Theorem 10.2.1 (cyclic $A_\infty \rightarrow$ cyclic E_d Gerstenhaber shift) combined with the PTVV shift law. The CG Locality Axiom (Costello–Gwilliam 2017 §2.6, Theorem 3.2.3) lifts cyclic structure on the E_d -algebra input to cyclic structure on the factorisation-algebra output $\Phi_3^{\text{FA}}(C)$.

(i) *E_3 -cyclicity.* At arity 2, the pairing identity is the cyclic A_∞ -pairing identity of C transported through the assembly; at arity 3 and higher, the identity follows from the Fulton–MacPherson-labelled tree compatibility of the CG assembly.

(ii) *Fulton–MacPherson realisation.* Each stratum of $\overline{F}(k, X)^{\text{FM}}$ is locally modelled on $\overline{F}(k_i, \mathbb{R}^3)^{\text{FM}}$; by Theorem 29.4.1 Route B, the Poincaré pairing on this local model realises the operadic Koszul self-duality. CG Locality supplies the pullback to the global factorisation algebra.

(iii) *Bar compatibility.* The E_3 -bar $B^{E_3}(\text{HH}^\bullet(C))$ is dualised via the Koszul pairing of Theorem 29.4.1; the degree on the bar complex is -3 by the shift in the E_3 -bar definition (Fresse 2011 §3), matching the Stage-1 pairing's degree $+3$ under the total-degree-0 constraint.

(iv) *Specialisation to chiral Koszul.* Factorisation homology $\int_{\Sigma_2}$ on a closed oriented 2-cycle integrates a degree-3 pairing to a degree-1 pairing on the residual E_1 -chiral algebra (Ayala–Francis 2014 factorisation-homology degree formula). The Stage-2 output $\text{Sp}_{\Sigma_2, C}^{\text{ch}}(\Phi_3^{\text{FA}}(C))$ then carries the chiral Koszul pairing of degree 1, matching the Francis–Gaitsgory chiral Koszul duality $\text{Lie}^{\text{ch}} \leftrightarrow \text{Com}^{\text{ch, fact}}$. $\square$

Remark 29.4.4 ($\mathbb{C}^3$: Theorem 29.3.1 recovered). Theorem 29.3.1 (iii) at $\mathcal{A} = \wedge^*(\mathbb{C}^3)$ with $\Omega(B(\wedge^* V)) \simeq \wedge^* V$ is the E_1 -level shadow of Corollary 29.4.2 at $\mathcal{A} = \text{HH}^\bullet(\text{Perf}(\mathbb{C}^3)) = \text{PV}^\bullet(\mathbb{C}^3) = \mathbb{Q}[x_1, x_2, x_3] \otimes \wedge^\bullet[\partial_1, \partial_2, \partial_3]$. At the E_3 -level, the Koszul self-duality pairing carries the Serre shift on polyvector fields;

the bar-cobar round-trip itself recovers the original E_3 algebra. After $\mathrm{Sp}^{\mathrm{ch}}$, the E_1 round-trip produces $\wedge^* V$ as stated. The Stage-1 self-pairing of Theorem 29.4.3 at $\mathbb{C}^3$ coincides with the Ayala–Francis Poincaré pairing on $\overline{F}(k, \mathbb{R}^3)^{\mathrm{FM}}$ pulled back through the polyvector-field factorisation algebra.

Remark 29.4.5 (Compatibility diagram with chiral Koszul duality). The compatibility of the Stage-1 E_3 bar-cobar with the Stage-2 chiral Koszul duality fits into a commutative square:

$$\begin{array}{ccc} \Phi_3^{\mathrm{FA}}(C) & \xrightarrow{B^{E_3}} & B^{E_3}(\Phi_3^{\mathrm{FA}}(C)) \\ \mathrm{Sp}_{\Sigma_2, C}^{\mathrm{ch}} \downarrow & & \downarrow \mathrm{Sp}_{\Sigma_2, C}^{\mathrm{ch}} \\ \mathrm{Sp}_{\Sigma_2, C}^{\mathrm{ch}}(\Phi_3^{\mathrm{FA}}(C)) & \xrightarrow{B^{\mathrm{ch}}} & B^{\mathrm{ch}}(\mathrm{Sp}_{\Sigma_2, C}^{\mathrm{ch}}(\Phi_3^{\mathrm{FA}}(C))) \end{array}$$

quasi-commuting in the $(\infty, 1)$ -category of factorisation algebras. Dunn-additivity $E_3 = E_2 \otimes^{\mathrm{Dunn}} E_1$ factorises the E_3 -bar as $B^{E_2} \circ B^{E_1}$; integrating over Σ_2 via $\int_{\Sigma_2}$ collapses the E_2 -factor (Ayala–Francis Poincaré–Koszul on the 2-cycle), leaving the residual B^{E_1} which is the chiral bar-cobar. The shift $\{3\}$ on the Stage-1 side becomes $\{3 - 2\} = \{1\}$ after $\int_{\Sigma_2}$, matching the E_1 -cohomological convention (Francis–Gaitsgory 2012 Theorem 6.4.2).

Remark 29.4.6 (Chain-level vs $(\infty, 1)$ -categorical readings). The operadic Koszul self-duality of Theorem 29.4.1 is a statement in $\mathrm{Op}(\mathrm{Ch}(\mathbb{Q}))$ (dg-operads); it holds independently of any E_3 -algebra choice and applies to both chain-level objects and $(\infty, 1)$ -categorical functors. The chain-level bar-cobar of Corollary 29.4.2 is the object-level theorem on a specific E_3 -algebra; the Stage-1 self-pairing of Theorem 29.4.3 is the functorial upgrade to the Stage-1 output. The $(\infty, 1)$ -categorical Φ_3^{FA} -functor inherits the operadic self-duality as a target-category symmetry on the subcategory of pro-nilpotent E_3 -algebras with cyclic structure of parity $+3$. The functor Φ_3^{FA} carries this self-duality to the Stage-1 output; its source $\mathrm{CY}_3\text{-}\mathbf{Cat}^{\mathrm{dg}}$ is a category of cyclic A_∞ -categories, and the Koszul self-duality lives on the target operadic side after the Stage-1 assembly. Both readings are preserved under the Stage-1 assembly.

The chain-level content is instantiated at $\mathbb{C}^3$ in Theorem 29.3.1 and at CY_3 categories via Theorem 29.4.3. The $n = 2$ arity-by-arity pairing and the $n = 3$ arity-2 Poincaré pairing on $\overline{F}(2, \mathbb{R}^3)^{\mathrm{FM}} \simeq S^2$ are direct configuration-space computation.

29.5 FROM SHUFFLE PRODUCT TO λ -BRACKET: THE SEVEN-ARROW CHAIN

The Schiffmann–Vasserot shuffle presentation of $Y^+(\widehat{\mathfrak{gl}}_1)$ does *not* directly produce the λ -bracket of $R_{\mathbb{C}^3}$. Seven comparison arrows are required.

Construction 29.5.1 (The seven-arrow chain). The chain connecting the shuffle algebra to the chiral algebra:

- (i) **Shuffle algebra** $\mathrm{Sh}(h_1, h_2, h_3)$: the associative algebra with generators $e(z)$ at each spectral parameter z and multiplication by the rational shuffle kernel $\zeta(z_i - z_j) = \prod_a (z_i - z_j + h_a)/(z_i - z_j - h_a)$.
- (ii) **Positive affine Yangian** $Y^+(\widehat{\mathfrak{gl}}_1)$: the positive RTT half with generators e_j, ψ_j ; Schiffmann–Vasserot prove $\mathrm{Sh}^+ \simeq Y^+(\widehat{\mathfrak{gl}}_1) \simeq \mathrm{CoHA}(\mathbb{C}^3)$.
- (iii) **Drinfeld double/centre and $\mathcal{W}_{1+\infty}$ modes**: adjoining the negative half and passing to the centre/vacuum evaluation gives the Feigin–Frenkel realization of $\mathcal{W}_{1+\infty}$ as the limit $\lim_{N \rightarrow \infty} \mathcal{W}_N$, with explicit mode algebra generators $\mathcal{W}_n^s$ for spin s and mode n .

- (iv) **OPE modes:** the vertex algebra OPE $W^s(z)W^{s'}(w) \sim \sum_n C_n^{ss'}(W)(z-w)^{-n-1}$, extracting the singular coefficients $C_n^{ss'}$.
- (v) **λ -bracket:** $\{W_\lambda^s W^{s'}\} = \sum_n \lambda^{(n)} C_n^{ss'}(W)$, where $\lambda^{(n)} = \lambda^n/n!$ is the divided power.
- (vi) **Lie conformal algebra $R_{\mathbb{C}^3}$:** the $\mathrm{GL}(3)$ -invariant subalgebra of the Schouten–Nijenhuis Lie conformal algebra on polyvector fields $\mathrm{PV}^*(\mathbb{C}^3)$.
- (vii) **Factorization envelope $U^{\mathrm{ch}}(R_{\mathbb{C}^3})$:** the enveloping vertex algebra, which by the Nishinaka–Vicedo construction recovers $W_{1+\infty}$.

Arrows $1 \rightarrow 2$ is Schiffmann–Vasserot. Arrows $2 \rightarrow 3$ pass through the Drinfeld double/centre and the Prochazka–Rapcak vacuum evaluation; this is where $W_{1+\infty}$ enters, not at the CoHA-positive-half stage. Arrows $3 \rightarrow 4$ is the standard mode-to-OPE dictionary. Arrow $4 \rightarrow 5$ requires the divided-power convention. Arrows $5 \rightarrow 6$ is the Kontsevich–Soibelman identification of $R_{\mathbb{C}^3}$ as the $\mathrm{GL}(3)$ -invariant part of $\mathrm{PV}^*(\mathbb{C}^3)$ with the Schouten–Nijenhuis bracket. Arrow $6 \rightarrow 7$ is the factorization envelope.

The composition $1 \rightarrow 7$ is the framed toric Φ_3 output for $\mathbb{C}^3$; the identity at step 2 is $\mathrm{CoHA}(\mathbb{C}^3) = Y^+(\widehat{\mathfrak{gl}}_1)$, while the $W_{1+\infty}$ vertex algebra is reached only after the Drinfeld double/centre and vacuum evaluation.

Remark 29.5.2 (Shuffle product $\neq \lambda$ -bracket). The shuffle product on $\mathrm{Sh}(h_1, h_2, h_3)$ is an associative product on symmetric functions of the spectral parameters, while the λ -bracket is a Lie conformal bracket on fields. The two are related by the seven-arrow chain above, not by a direct identification. In particular, the shuffle kernel $\zeta(z)$ is *not* the OPE kernel: the OPE has poles at $z = 0$ (collision singularities), while the shuffle kernel has poles at $z = \pm h_a$ (Yangian structure function poles). These coincide only after the identification of the parameters h_a with the deformation parameters of $W_{1+\infty}$ and the passage from additive to multiplicative spectral parameters.

29.6 KOSZUL DUALITY: CY VS CHIRAL

The chiral Koszul duality of the bar-cobar construction (Theorems A and B) descends to CY Koszul duality exactly along the stage-2 comparison maps.

THEOREM 29.6.1 (*CY Koszul duality dictionary through the comparison maps*). Let $\mathcal{C}$ be a CY_3 category with framed stage-2 chiral algebra $A_{\mathcal{C}} = \mathrm{Sp}_{\Sigma_2, \mathcal{C}}^{\mathrm{ch}}(\Phi_3^{\mathrm{FA}}(\mathcal{C}))$. Assume the comparison maps

$$\Theta_A^{(3)} : \mathrm{CC}_\bullet(\mathcal{C}) \longrightarrow B^{\mathrm{ord}}(A_{\mathcal{C}}), \quad \Theta_B^{(3)} : D_{\mathrm{Ran}} B^{\mathrm{ord}}(A_{\mathcal{C}}) \longrightarrow B^{\mathrm{ord}}(A_{\mathcal{C}^!})$$

are quasi-isomorphisms in the weight-completed / pro-conilpotent ambient, and assume the genus and scalar comparisons

$$\Theta_C^{\mathrm{der}} : Q_g(A_{\mathcal{C}}) \oplus Q_g(A_{\mathcal{C}^!}) \longrightarrow H^*(\overline{\mathcal{M}}_g, \mathcal{Z}_{\mathrm{ch}}^{\mathrm{der}}(A_{\mathcal{C}})), \quad \Theta_D^{\mathrm{unif}} : \mathbb{C} \cdot (\kappa_{\mathrm{ch}}(A_{\mathcal{C}}) + \kappa_{\mathrm{ch}}(A_{\mathcal{C}^!})) \longrightarrow \mathbb{C} \cdot K_{\mathcal{C}}$$

are compatible with the bar-cobar construction Theorem C pairing and the bar-cobar construction Theorem D uniform-weight scalar projection. Then:

- (i) The chiral Koszul dual $A^!$ corresponds to the *mirror* CY category:

$$A_{\mathcal{C}}^! \simeq A_{\mathcal{C}^!}$$

where $\mathcal{C}^!$ is the Koszul dual CY category (for $\mathcal{C} = D^b(\mathrm{Coh}(X))$ of a CY manifold X , this is $\mathcal{C}^! \simeq \mathrm{Fuk}(X^\vee)$ under homological mirror symmetry).

(ii) The complementarity theorem (Theorem C) gives:

$$Q_g(A_C) + Q_g(A_{C^!}) = H^*(\overline{M}_g, \mathcal{Z}(A_C))$$

where $\mathcal{Z}(A_C) = \mathcal{Z}_{\text{ch}}^{\text{der}}(A_C)$ is the chiral derived center.

(iii) The modular characteristics satisfy a family-dependent Koszul conductor relation:

$$\kappa_{\text{ch}}(A_C) + \kappa_{\text{ch}}(A_{C^!}) = \rho \cdot K$$

where K is the Koszul conductor. For the free-field and affine Kac–Moody classes the examples lie in the classical G/L zero-sum lane: $\kappa_{\text{ch}}(A) + \kappa_{\text{ch}}(A^!) = 0$. The Mukai self-dual K3 branch sits on the B-row of the conductor table, with

$$K^{\kappa_{\text{ch}}^{\text{Mukai}}} = 2c_+(\Pi_{4,20}) = 8,$$

the CY-to-chiral construction Mukai-enhanced Heisenberg point supplied by Bruinier Heegner Chern-class reciprocity. For the Virasoro class, $K = 13$ (the self-dual point $c = 13$). The conductor depends on the family, with each family computing its own value.

Proof. The map $\Theta_A^{(3)}$ transports the categorical cyclic bar complex to the ordered chiral bar complex of the framed output, so the bar-cobar construction Theorem A applies to A_C in the same completed ambient. The map $\Theta_B^{(3)}$ identifies Verdier duality of the chiral bar with the bar of the Koszul-dual framed output; hence the bar-cobar construction Koszul reflection sends A_C to $A_{C^!}$. The comparison Θ_C^{der} then carries the bar-cobar construction derived-centre complementarity theorem to the displayed genus- g decomposition, and Θ_D^{unif} carries the bar-cobar construction genus obstruction scalar to the CY conductor line. The the bar-cobar construction theorem statements transport through these maps; the obstruction lives in the construction and compatibility of the four named comparison maps themselves. $\square$

29.7 THE FIVE THEOREMS IN THE CY SETTING

THEOREM (*The five theorems for CY chiral algebras*). Let $A = A_C$ be the framed stage-2 chiral algebra of a CY_3 category C . Then:

Theorem A (adjunction; the bar-cobar construction Tia narrowed). The bar-cobar adjunction $\Omega^{\text{ch}} \dashv B^{\text{ch}}$ (cobar left, bar right) restricts to CY chiral algebras: $B(A_C)$ is a factorization coalgebra on the stage-2 reference $\text{Ran}(C)$ in the Francis–Gaitsgory ambient, taken in its *weight-completed* / *pro-conilpotent* form $\text{pro-CoAlg}_{\text{conil}}(\text{Fact}(C))$ whenever A_C has unbounded conformal-weight grading (class M and, more generally, any CY chiral algebra whose bar filtration has unbounded conformal weight); the raw bounded direct-sum ambient $\text{Ch}(\text{Vect})$ suffices for class G/class L CY loci only. In the stated ambient, $D_{\text{Ran}}(B(A_C)) \simeq B(A_{C^!})$ (the bar-cobar construction Tib Verdier intertwining, unconditional on the chiral side). At $d = 2$ CY-A(ii) gives $\text{CC}_{\bullet}(C) \simeq B(A_C)$; at $d = 3$ the same identification is exactly the comparison map $\Theta_A^{(3)}$ of Theorem 29.6.1. See the bar-cobar construction Remark 18.1.7 (class-M pro-conilpotent discipline; [97]).

Theorem B (inversion). Bar-cobar inversion $\Omega(B(A_C)) \xrightarrow{\sim} A_C$ holds on the Koszul locus (the bar-cobar construction Tic Koszul-conditional inversion). For CY categories this requires both the stage-2 bar comparison and the formality/Koszul condition on the transported cyclic bar coalgebra; it is not a formal consequence of $\text{CC}_{\bullet}(C)$ alone. For CY chiral algebras whose pre-image under Φ is in class M,

the chain-level inversion holds at the strict ML weight-completed / pro / coderived level (the bar-cobar construction [96], [96]), not at the raw direct-sum ambient.

Theorem C (complementarity). Through Θ_C^{der} , the CY Euler characteristic $\chi(C)$ splits into complementary halves: $Q_g(C) + Q_g(C^\dagger)$ recovers the full Hochschild cohomology. Perfectness of the pairing (the bar-cobar construction [96]) is unconditional for the CY chiral algebras lying over the Heisenberg family and over affine Kac–Moody at positive-integer or boundary-admissible level; for affine Kac–Moody at generic non-critical k outside these loci the boundary-stratum finiteness is conjectural (the bar-cobar construction [96]), and for the class-M boundary stratum it is conjectural (the bar-cobar construction [96]). The classical G/L examples satisfy $\kappa_{\text{ch}}(A) + \kappa_{\text{ch}}(A^\dagger) = 0$; the Mukai self-dual $K3$ branch is the separate B-row ceiling $K^{\kappa_{\text{ch}}^{\text{Mukai}}} = 2c_+(\Pi_{4,20}) = 8$, not a zero-sum G/L example.

Theorem D (modular characteristic). Through Θ_D^{unif} , the genus- g obstruction class is $\text{obs}_g(A_C) = \kappa_{\text{ch}}(A_C) \cdot \lambda_g$ on the uniform-weight lane, with $\lambda_g = c_g(\mathbb{E})$ the top Chern class of the Hodge bundle $\mathbb{E} \rightarrow \overline{\mathcal{M}}_g$ (the bar-cobar construction Theorem D) and $\kappa_{\text{ch}}(A_C)$ the specific modular characteristic of A_C itself (not a generic constant). The numerical scalar free energy is obtained only after Faber–Pandharipande integration, $F_g(A_C) = \kappa_{\text{ch}}(A_C) \lambda_g^{\text{FP}}$. The derived-centre complementarity datum $\kappa_\Sigma := \kappa_{\text{ch}}(A) + \kappa_{\text{ch}}(A^\dagger)$ is family-indexed to $\{0, 8, 13, 250/3, 98/3\}$ per the bar-cobar construction Theorem C, with the 8 entry reserved for the B-row. The critical-level iff is restricted to the Kac–Moody-internal regime (the bar-cobar construction). At $d = 2$ with $h^{1,0} = 0$, Proposition 5.3.13 gives $\kappa_{\text{ch}}(A_C) = \chi(\mathcal{O}_X)$; at $d = 3$, the formula is dimension-stratified: $\kappa_{\text{ch}}^{\text{BCOV}} = \chi_{\text{top}}/24$ is the BCOV scalar (conjectural as a chiral comparison; note $\chi_{\text{top}}/24 \neq \chi(\mathcal{O}_X)$ in general since $\chi(\mathcal{O}_X) = 0$ for all CY_3 by Serre duality), $\kappa_{\text{ch}}^{\text{Heis}} = \kappa_{\text{ch}}(A_S) + \kappa_{\text{ch}}(A_E)$ for the Heisenberg product lane, and $\kappa_{\text{ch}} \neq \chi(\mathcal{O}_X)$ in general (Conjecture 5.3.25; Theorem 5.14.1).

Theorem H (Hochschild; ordered-bar model). Theorem H is the bar-cobar construction concentration theorem for $\text{ChirHoch}^*(A_C)$: on the Koszul locus it has amplitude $[0, 2]$ and Hilbert polynomial in t . The ordered coderivation complex is a model for this theorem, not the theorem itself. Under the PBW/Koszul and unitary ordered-to-symmetric descent hypotheses of Proposition 29.7.1, $H^*(\text{CoDer}(B^{\text{ord}}(A_C))) \cong \text{ChirHoch}^*(A_C)$, and the bar-cobar construction Theorem H then gives the degree concentration. The HKR decomposition, Connes operator, and categorical Hodge structure of C map to $\text{ChirHoch}^*(A_C)$ only after the stage-2 model comparison. Symmetric-bar concentration on classes G/L at generic parameter follows by the averaging corollary; the E_1 -only regime and class-M non-generic points inherit the bar-cobar construction conjectural boundary condition.

PROPOSITION 29.7.1 (Ordered-bar model for chiral Hochschild). Let A be a strongly admissible stage-2 E_1 -chiral algebra on a smooth curve. Assume:

- (i) A carries a PBW filtration whose associated graded is chirally Koszul;
- (ii) the ordered bar coalgebra $B^{\text{ord}}(A)$ carries an R -matrix descent datum satisfying the Yang–Baxter equation and strong unitarity $R_{12}(z)R_{21}(-z) = \text{id}$;
- (iii) the finite-weight truncations are compatible with the ordered-to-symmetric descent.

Then the ordered coderivation complex computes chiral Hochschild cohomology:

$$H^*(\text{CoDer}(B^{\text{ord}}(A))) \cong \text{ChirHoch}^*(A).$$

Consequently, if A lies in the bar-cobar construction Theorem H Koszul locus, this cohomology is concentrated in degrees $\{0, 1, 2\}$.

Proof. At tensor degree n , the ordered configuration space $\text{Conf}_n^{\text{ord}}(C)$ is a finite étale Σ_n -cover of $\text{Conf}_n(C)$. The ordered bar is the cofree tensor coalgebra on this cover, with differential given by ordered collision residues. The Yang–Baxter equation makes the monodromy representation of the pure braid group compatible with triple collisions; strong unitarity makes the adjacent-transposition operators square to the identity, so the braid action descends to an R -twisted Σ_n -action. Finite étale descent is exact in the Francis–Gaitsgory factorisation ambient, hence the symmetric chiral bar is recovered as

$$B^{\text{ch}}(A)_n \simeq (B^{\text{ord}}(A)_n)^{R\text{-}\Sigma_n}.$$

Coderivations of a cofree conilpotent coalgebra are determined by their projection to cogenerators. Since projection to cogenerators and finite étale descent commute, the coderivation complex of the descended coalgebra is the descended coderivation complex:

$$\text{CoDer}(B^{\text{ch}}(A)) \simeq \text{CoDer}(B^{\text{ord}}(A))^{R\text{-}\Sigma^\bullet}.$$

The PBW filtration is finite on each weight truncation and the associated graded is the pole-free Koszul model, where ordered and symmetric bars differ only by the ordinary Koszul sign coinvariants. The comparison spectral sequence is therefore an isomorphism at E_1 , and convergence follows from the finite-weight hypothesis. Thus the ordered coderivation cohomology agrees with the symmetric bar coderivation cohomology. By the standard chiral Hochschild bar model, the latter is $\text{ChirHoch}^*(A)$. Applying the bar-cobar construction Theorem H gives the stated concentration on the Koszul locus. $\square$

29.8 CURVED BAR-COBAR AND THE MUMFORD BOUNDARY DATUM

The genus- g bar complex $\overline{B}^{(g)}(A_C)$ of a CY chiral algebra carries two Hodge classes. The determinant-line curving is the local Chern–Weil representative

$$m_{\text{o,det}}^{(g,n)} = \kappa_{\text{ch}}(A_C) \cdot \lambda_1(\mathbb{E}_g), \quad \lambda_1(\mathbb{E}_g) = c_1(\mathbb{E}_g),$$

on $\overline{\mathcal{M}}_{g,n}$. The Theorem D obstruction class is instead

$$\text{obs}_g(A_C) = \kappa_{\text{ch}}(A_C) \cdot \lambda_g, \quad \lambda_g = c_g(\mathbb{E}_g).$$

Booth–Lazarev [282] prove the associative curved bar–cobar Quillen equivalence $\Omega \dashv B$ on curved A_∞ -coalgebras; the chiral instantiation on factorisation coalgebras over $\text{Ran}(X) \times \overline{\mathcal{M}}_{g,n}$ is an upgrade with three structural obstructions, of which the determinant-line descent is identically closed.

PROPOSITION 29.8.1 (κ_{ch} *determinant curving is the Mumford boundary datum*). Let A_C be a CY chiral algebra with $\kappa_{\text{ch}}(A_C) \in \mathbb{Q}$. The genus-indexed determinant curving $m_{\text{o,det}}^{(g,n)} = \kappa_{\text{ch}}(A_C) \cdot \lambda_1(\mathbb{E}_g)$ satisfies

$$\partial^* m_{\text{o,det}}^{(g,n)} = \pi_1^* m_{\text{o,det}}^{(g_1, n_1+1)} + \pi_2^* m_{\text{o,det}}^{(g_2, n_2+1)} \quad (g = g_1 + g_2 \text{ separating clutching}),$$

and $\partial'^* m_{\text{o,det}}^{(g,n)} = m_{\text{o,det}}^{(g-1, n+2)}$ at non-separating clutching.

Proof. Linearity of pullback on Mumford’s boundary relation $\partial^* \lambda_1(\mathbb{E}_g) = \pi_1^* \lambda_1(\mathbb{E}_{g_1}) + \pi_2^* \lambda_1(\mathbb{E}_{g_2})$ ([283]; [284] for non-separating). $\square$

LEMMA 29.8.2 (*Mumford curving descent to the top Hodge obstruction*). The determinant-line curving $\kappa_{\text{ch}}(A_C)c_1(\mathbb{E}_g)$ is the Chern–Weil input for the Hodge bundle. Together with Mumford GRR, the same Hodge-bundle curvature canonically determines the Theorem D obstruction class $\kappa_{\text{ch}}(A_C)c_g(\mathbb{E}_g)$. Under clutching,

$$\partial^*c_g(\mathbb{E}_g) = \pi_1^*c_{g_1}(\mathbb{E}_{g_1})\pi_2^*c_{g_2}(\mathbb{E}_{g_2})$$

on separating boundary divisors, while $\partial'^*c_g(\mathbb{E}_g) = 0$ on the non-separating boundary $\overline{\mathcal{M}}_{g-1,n+2}$. After integration against the Faber–Pandharipande insertion ψ_1^{2g-2} on $\overline{\mathcal{M}}_{g,1}$, this class gives the scalar coefficient λ_g^{FP} .

Proof. Mumford’s GRR formula computes the Chern character of the Hodge bundle $\mathbb{E}_g = R^0\pi_*\omega_\pi$ in the tautological ring. Choosing the Chern connection on $\mathbb{E}_g$, the determinant curvature $\text{tr } \Omega_{\mathbb{E}_g}$ represents $c_1(\mathbb{E}_g)$, while the invariant polynomial $\det(1 + \Omega_{\mathbb{E}_g})$ represents the total Chern class; its degree- g component is $c_g(\mathbb{E}_g)$. This is the Chern–Weil transgression from the determinant-line representative to the top Hodge class. Multiplication by the scalar $\kappa_{\text{ch}}(A_C)$ preserves the construction.

On a separating boundary stratum, Mumford’s clutching identity gives $\partial^*\mathbb{E}_g \simeq \pi_1^*\mathbb{E}_{g_1} \oplus \pi_2^*\mathbb{E}_{g_2}$. Whitney multiplicativity of Chern classes therefore gives $\partial^*c_g(\mathbb{E}_g) = \pi_1^*c_{g_1}(\mathbb{E}_{g_1})\pi_2^*c_{g_2}(\mathbb{E}_{g_2})$ in top bidegree, i.e. the product displayed in the statement. On the non-separating boundary, $\partial'^*\mathbb{E}_g \simeq \mathbb{E}_{g-1} \oplus \mathcal{O}$; the rank is $g-1$ plus a trivial line, hence $c_g(\mathbb{E}_{g-1} \oplus \mathcal{O}) = 0$. The Faber–Pandharipande formula evaluates the resulting Hodge integral $\int_{\overline{\mathcal{M}}_{g,1}} \psi_1^{2g-2}c_g(\mathbb{E}_g)$, producing the numerical coefficient denoted λ_g^{FP} . $\square$

Ran-space contractibility ($\text{Ran}(C) \simeq \text{pt}$ for every connected C ; [10] Ch. 3.4.1) and the vanishing $\lambda_1(\mathbb{E}_0) \equiv 0$ on $\overline{\mathcal{M}}_{0,n}$ collapse the chiral curved bar–cobar problem at $g=0$ to the associative Lefèvre–Hasegawa Quillen equivalence, for every value of κ_{ch} . At $g \geq 1$, Prop. 29.8.1 reduces the fibred equivalence over $\overline{\mathcal{M}}_{g,n}$ to étale-local constancy (a single determinant-line curvature after trivialising $\lambda_1(\mathbb{E}_g)$), with boundary compatibility automatic from the Mumford relation; Lemma 29.8.2 transgresses this local curving to the top Hodge obstruction class $\lambda_g = c_g(\mathbb{E}_g)$ used in Theorem D. The residual obstruction at each genus is the descent-gluing theorem along an étale cover of $\overline{\mathcal{M}}_{g,n}$ for cofibrantly generated model structures in the curved setting, and the sewing-analytic comparison $D^{\text{co},g}(A_C) \hookrightarrow \text{IndHilb}^g(A_C^{\text{sew}})$, which holds as a dense realisation on class G/L loci and promotes to an isomorphism of nuclear Fréchet spaces on class M loci in the weight-completed ambient: $\widehat{D}^{\text{co},g}(\widehat{A}_C) \xrightarrow{\sim} \text{IndHilb}^g(\widehat{A}_C^{\text{sew}})$, each stage A_C/F^{N+1} being class G/L by finite-weight truncation, and the cofiltered limit along surjective transitions a nuclear Fréchet space by Grothendieck (the bar–cobar construction [96] + [96]).

The concrete non-null example is local $\mathbb{P}^2$, where $\kappa_{\text{ch}}^{\text{loc}} = 3/2$ generates a non-zero curved bar complex at every $g \geq 1$. The compact Hodge-supertrace lane of $K_3 \times E$ has $\kappa_{\text{ch}}^{\text{Hodge}}(K_3 \times E) = 0$, hence an uncurved bar at every genus on that lane; the Heisenberg and Borchers lanes are different scalar constructions.

29.9 COMPACT CY₃ EXAMPLES

The following compact CY₃ families illustrate the range of shadow tower behaviour. For *strict* compact CY₃ with $h^{3,0} = 1$ and simply-connected universal cover, the *conjectural* BCOV scalar is $\kappa_{\text{ch}}^{\text{BCOV}} = \chi_{\text{top}}/24$, which differs from $\chi(\mathcal{O}_X)$; the latter vanishes for all CY₃ by Serre duality. The BCOV scope excludes two families encountered below: (a) *generalised* CY₃ with torsion canonical ($h^{3,0} = 0$), such as Enriques $\times E$,

where the BKM weight κ_{BKM} of an associated Borchers lift is the relevant automorphic invariant; (b) K_3 -fibered products $K_3 \times E$, where $\chi_{\text{top}} = 0$ but the Heisenberg-additive $\kappa_{\text{ch}}^{\text{Heis}}(K_3 \times E) = \kappa_{\text{ch}}^{\text{Heis}}(\mathcal{A}_{K_3}) + \kappa_{\text{ch}}^{\text{Heis}}(\mathcal{A}_E) = 3$ (fibre-level) and $\kappa_{\text{BKM}}(\Delta_5) = 5$ (Borchers weight) govern the shadow tower. Shadow depth class, Hochschild data, and BKM structure vary across all three regimes.

The banana manifold: vanishing scalar lane with nontrivial tower

The banana manifold X_{ban} (Schoen's CY_3 , the fiber product of two rational elliptic surfaces over $\mathbb{P}^1$) has Hodge numbers $h^{1,1} = h^{2,1} = 19$ and Euler characteristic $\chi = 0$.

PROPOSITION 29.9.1 (*Shadow tower of the banana manifold*). The shadow obstruction tower of X_{ban} has:

- (i) $\kappa_{\text{ch}}^{\text{BCOV}} = \chi_{\text{top}}/24 = 0$. The degree-2 BCOV scalar shadow *vanishes*; identifying it with $\kappa_{\text{ch}}(\mathcal{A}_X)$ requires the framed shadow comparison.
- (ii) $S_4 = -44$ (quartic shadow from the genus-0 GV invariants $n_{d_1, d_2}^0 = -2$ of the banana curve classes).
- (iii) The shadow tower starts at degree 4, not degree 2, on the BCOV scalar lane.
- (iv) The critical discriminant $\Delta = 8\kappa_{\text{ch}}^{\text{BCOV}} S_4 = 0$ on that lane. The standard single-line classification (G/L/C/M) does not directly apply.
- (v) Shadow depth class: M (infinite tower) shifted to degree 4. The BKY partition function involves infinitely many banana-curve BPS states, generating an infinite shadow tower whose leading term is quartic.

Remark 29.9.2 ($\kappa_{\text{ch}} = 0$ does not imply $\Theta_A = 0$). The banana manifold is the prototypical example: $\kappa_{\text{ch}} = 0$ does not imply $\Theta_A = 0$. The vanishing of κ_{ch} means the bar complex is uncurved ($d^2 = 0$ at the leading scalar level), but the higher-degree components of Θ_A (the quartic shadow Q and beyond) are nonvanishing, sourced by the instanton contributions (genus-0 GV invariants of the banana curves).

Three CY_3 examples with $\kappa_{\text{ch}} = 0$ show qualitatively different behaviour:

- Heisenberg at $k = 0$: $\kappa_{\text{ch}} = 0$, trivially uncurved, class G.
- Virasoro at $c = 0$: $\kappa_{\text{ch}} = 0$, but higher shadows from contact terms (class M).
- Banana manifold: $\kappa_{\text{ch}} = 0$, but higher shadows from *instantons* (class M, shifted to degree 4).

Enriques $\times E$: the $\mathbb{Z}_2$ quotient of $K_3 \times E$

Let $S_{\text{Enr}} = K_3/\iota$ be an Enriques surface (ι a fixed-point-free involution), and E an elliptic curve. The product $S_{\text{Enr}} \times E$ is a generalized CY_3 (the canonical bundle $K_{S_{\text{Enr}} \times E}$ is 2-torsion, so $h^{3,0} = 0$). Nevertheless, the shadow tower machinery applies to the associated vertex algebra, and the Borchers lift on $O(2, 10)$ provides the automorphic structure.

THEOREM 29.9.3 (*Shadow tower of Enriques $\times E$*). The shadow data of $\text{Enriques} \times E$ is:

- (i) $\kappa_{\text{BKM}}(\tilde{\Delta}_5^{\text{Enr}}) = 5$, the weight of the full Enriques BKM denominator. The metaplectic square root Δ_5^{Enr} has weight $5/2$. Allcock's weight-4 form is a discriminant form on the Enriques moduli space, not the denominator of this BKM root system.
- (ii) Root multiplicities come from the Enriques elliptic genus $\phi_{\text{Enr}} = \phi_{\text{o}, \text{i}}^{\text{EZ}} = \frac{1}{2} Z_{K_3}$; the Fourier coefficients are the Eichler–Zagier coefficients $f_{\text{Enr}}(n, l) = f^{\text{EZ}}(n, l)$.
- (iii) The ratio $\kappa_{\text{BKM}}(\Delta_5)/\kappa_{\text{BKM}}(\tilde{\Delta}_5^{\text{Enr}}) = 1$. The quotient changes the lattice and the multiplier system; it does not divide the BKM weight.

(iv) Shadow depth class: M (infinite tower), driven by the infinite BKM root spectrum.

Remark 29.9.4 (The $\mathbb{Z}_2$ quotient on κ_{BKM}). The passage from $K_3 \times E$ to $\text{Enriques} \times E$ does not halve κ_{BKM} . In the BKM denominator normalization both rows use the Eichler–Zagier constant term $c(o) = 10$, hence both full denominators have Borcherds weight 5. The Enriques metaplectic form has weight $5/2$ because it is a square root. The Allcock weight-4 form belongs to the Enriques moduli discriminant and is a different automorphic scalar.

The quintic threefold: non-integer BCOV shadow scalar and BKM obstruction

The quintic hypersurface $Q \subset \mathbb{P}^4$ has $h^{1,1} = 1$, $h^{2,1} = 101$, $\chi = -200$.

PROPOSITION 29.9.5 (Quintic shadow tower). This proposition records the scalar BCOV/GW shadow lane. It does not construct a quintic Φ_3 output or a Hilbert $O(2, 2)$ target. The shadow data of the quintic is:

- (i) $\kappa_{\text{ch}}^{\text{BCOV}} = \chi/24 = -25/3$ (non-integer BCOV shadow scalar).
- (ii) The non-integrality of $\kappa_{\text{ch}}^{\text{BCOV}}$ obstructs a naive BKM superalgebra: BKM root multiplicities must be integers, and the standard denominator-identity machinery requires integral Borcherds lift weight. The quintic has no natural Borcherds–Kac–Moody structure.
- (iii) The shadow metric $Q_L(t) = 4(\kappa_{\text{ch}}^{\text{BCOV}})^2 + 12\kappa_{\text{ch}}^{\text{BCOV}}\alpha t + (9\alpha^2 + 16\kappa_{\text{ch}}^{\text{BCOV}}S_4)t^2$ is well-defined for fractional $\kappa_{\text{ch}}^{\text{BCOV}}$. With $\kappa_{\text{ch}}^{\text{BCOV}} = -25/3$: $Q_L(o) = 2500/9 > 0$.
- (iv) The GW invariants are known to high degree:

$$n_1^o = 2875, \quad n_2^o = 609250, \quad n_3^o = 317206375, \quad n_4^o = 242467530000.$$

These are BPS state counts via the Gopakumar–Vafa formula.

- (v) Shadow depth class: M (infinite tower). The quintic has an infinite BPS spectrum with curves of all degrees and genera; the shadow tower is controlled by the BCOV holomorphic anomaly equation.

Remark 29.9.6 ($\chi/24$ integrality survey). The quantity $\chi/24$ is an integer if and only if $12 \mid (h^{1,1} - h^{2,1})$. Among standard complete intersections:

- $\mathbb{P}^5[3, 3]$: $\chi = -144$, $\kappa_{\text{ch}}^{\text{BCOV}} = -6$ (integer).
- $\mathbb{P}^5[2, 4]$: $\chi = -176$, $\kappa_{\text{ch}}^{\text{BCOV}} = -22/3$ (non-integer).
- $\mathbb{P}^7[2, 2, 2, 2]$: $\chi = -128$, $\kappa_{\text{ch}}^{\text{BCOV}} = -16/3$ (non-integer).
- Quintic: $\chi = -200$, $\kappa_{\text{ch}}^{\text{BCOV}} = -25/3$ (non-integer).

Non-integrality of the BCOV shadow scalar is the generic situation for compact CY_3 manifolds. A BKM structure requires additional input beyond the BCOV prediction.

PROPOSITION 29.9.7 (Quintic shadow coefficients from Gromov–Witten data). Assume the framed large-complex-structure Φ_3 locus of Theorem 5.11.1. At the large complex structure limit (LCS degeneration type), the first shadow coefficients of the quintic chiral algebra are:

- (i) $S_2 = \kappa_{\text{ch}}^{\text{BCOV}} = -25/3$. The scalar shadow, from the genus-1 BCOV constant-map contribution $F_1 = \kappa_{\text{ch}}^{\text{BCOV}}/24 = -25/72$.
- (ii) $S_3 = \alpha = -3/5$ (classical). The cubic shadow, from the Yukawa coupling: $\alpha = C_{\text{III}}/\kappa_{\text{ch}}^{\text{BCOV}} = 5/(-25/3) = -3/5$, where $C_{\text{III}} = H^3 = 5$ is the triple intersection number. At the quantum level, α

receives instanton corrections of the form $\alpha(q) = -3/5 + \sum_{d \geq 1} \alpha_d q^d$, where $\alpha_1 = n_1^o / \kappa_{\text{ch}}^{\text{BCOV}} = 2875/(-25/3) = -345$.

- (iii) $S_4 = 0$ (classical). The quartic shadow vanishes classically because $\partial^4 F_0^{\text{cl}} / \partial t^4 = 0$ for the cubic prepotential. Instanton corrections are nonzero: the leading correction is proportional to $n_1^o \cdot t^4 / \kappa_{\text{ch}}^{\text{BCOV}} = -345$. The non-vanishing of S_4 after instanton corrections promotes the shadow class from **L** to **M**.

The classical shadow tower ($S_4 = 0$) is class **L** (depth 3): the shadow metric $Q_L(t) = (-50/3 - 9t/5)^2$ is a perfect square with discriminant $\Delta = 0$. Instanton corrections destroy the perfect-square structure, promoting to class **M** (infinite depth).

Proof. The scalar shadow $S_2 = \kappa_{\text{ch}}^{\text{BCOV}}$ follows from the definition of the BCOV shadow tower at degree 2. The cubic shadow $S_3 = \alpha$ is the normalised Yukawa coupling: the classical prepotential $F_0^{\text{cl}} = (5/6)t^3$ gives $C_{\text{III}} = \partial^3 F_0^{\text{cl}} / \partial t^3 = 5$. The recursive shadow tower with $\kappa_{\text{ch}}^{\text{BCOV}} = -25/3$, $\alpha = -3/5$, $S_4 = 0$ gives $a_0 = 2\kappa_{\text{ch}}^{\text{BCOV}} = -50/3$, $a_1 = 3\alpha = -9/5$, and $a_n = -(1/(2a_0)) \sum_{j=1}^{n-1} a_j a_{n-j} = 0$ for all $n \geq 2$, since $q_2 - a_1^2 = 81/25 - 81/25 = 0$ and all subsequent terms vanish by induction. The classical tower terminates at depth 3. For the instanton promotion: $C(q) = 5 + \sum_{d \geq 1} \sum_{d'|d} n_{d'}^o d'^3 q^d$ has nonzero coefficients at all positive degrees (since $n_1^o = 2875 \neq 0$), so the instanton-corrected $S_4 \neq 0$, giving $\Delta = 8\kappa_{\text{ch}}^{\text{BCOV}} S_4 \neq 0$ and class **M**. $\square$

Remark 29.9.8 (Comparison with $K_3 \times E$). The quintic and $K_3 \times E$ are both class **M** but differ structurally:

	Quintic	$K_3 \times E$
$h^{1,1}$ (lattice rank)	1	21
Active scalar lane	$\kappa_{\text{ch}}^{\text{BCOV}} = -25/3$ (fractional)	$\kappa_{\text{ch}}^{\text{Heis}} = 3$ (integer)
Borcherds scalar	absent without a Borcherds input	$\kappa_{\text{BKM}}(\Delta_5) = 5$
Automorphic target	rank-1 BCOV/MO substitute; Hilbert $O(2, 2)$ pairing open	$\mathbb{H}_2 / \text{Sp}_4(\mathbb{Z})$ (Siegel)
BKM structure	none constructed; rank-1 Heegner shadow only	$\mathfrak{g}_{\Delta_5}$
GV lattice	$\mathbb{Z}$ (one Kahler modulus)	Mukai lattice (rank 24)
Shadow class	M	M

The quintic tower is *rank-1*: it lives on a one-dimensional charge lattice $H_2(X, \mathbb{Z}) \cong \mathbb{Z}$. The $K_3 \times E$ tower is *rank-21*: it lives on the Picard lattice of the K_3 factor. Both have infinite depth, but the quintic is combinatorially simpler (a single GV sequence n_d^g) while $K_3 \times E$ is structurally richer (the BKM denominator formula organises the full lattice spectrum).

For Q there is no Jacobi input, hence no Borcherds denominator and no value of κ_{BKM} . The quintic is non- K_3 -fibred, with $h^{1,1} = 1$ and rigid Picard lattice. What is proved here is the rank-1 substitute: BCOV/GW/PT data live on the one-dimensional charge lattice and supply genus-by-genus coefficients. A genuine Hilbert $O(2, 2)$ automorphic target would require an explicit weight-two lattice, pairing, and normalisation map from the quintic chain complex to $\mathbb{H}_1 \times \mathbb{H}_1 / \Gamma$; that pairing is not constructed in this chapter. Hence the zeroth BKM coefficient is not recorded as the value of a degenerate Hilbert modular form. Zinger higher-genus GW, Klemm–Pandharipande BPS numbers, and Pandharipande–Thomas stable pairs populate the non-zero rank-1 coefficients for $d \geq 1$. In the current convention $\alpha_{\text{BCOV}}(Q) = 0$

as a class in $H^{\circ,1}(Q)$, while the scalar genus-one coefficient $\chi(Q)/24 = -25/3$ is nonzero. Paths 2 and 3 (BV, MO) provide BCOV/MO substitutes, not a constructed CY-B₃ Hilbert-pairing theorem.

PROPOSITION 29.9.9 (*Tier-III orthogonal target and quintic Booth–Lazarev obstruction datum*). This proposition records the obstruction datum; it does not construct an orthogonal or Hilbert pairing. Let X be a compact non-K₃-fibred CY₃ with $h^{1,1}(X) \geq 3$. A CY-B₃ tier-III upgrade to an orthogonal or Hilbert Shimura target requires, before any automorphic denominator or BKM weight is asserted, the following chain-level datum:

$$\langle -, - \rangle_X^{\text{orth}} : B^{E_1}(\Phi_3^{(\Sigma_2, C)}(\text{Perf } X)) \otimes C_\bullet(\mathcal{D}_X, \mathcal{L}_X^{w_X}) \longrightarrow \mathbb{C},$$

where $\mathcal{D}_X = \text{SO}(2, 2h^{1,1}(X))/\text{SO}(2)\text{SO}(2h^{1,1}(X))$ up to the arithmetic quotient by a specified Γ_X , $\mathcal{L}_X$ is the automorphic line, and the boundary rank-2 case is the Hilbert target $\mathbb{H}_1 \times \mathbb{H}_1/\Gamma$. This pairing must be a chain map, must identify the chosen integral lattice and its normalisation, and must commute with the E_1 -chiral differential, sewing, and Verdier/Koszul reflection. None of these data is supplied by the rank-1 BCOV/GW/PT coefficients of the quintic, nor by the K₃-fibred Siegel Δ_5 pairing.

For the quintic Q , the residual chiral Booth–Lazarev obstructions are therefore exactly the two chain complexes

$$O_1^{\text{BL}}(Q) \in H^1(\text{Ran}(C), \text{Aut}_\otimes(\text{Gen}_{\text{BL}})) \simeq \varprojlim_n I_n$$

and

$$O_3^{\text{BL}}(Q) \in \varprojlim_g A^{\text{sew}, g} \subset \varprojlim_g \text{Ext}_{\text{top}}^1(D^{\text{co}, \text{ch}, g}(\Phi_3^{\text{FA}}(\text{Perf } Q)), \text{IndHilb}^g(A^{\text{sew}})).$$

The first is killed only by a Čech o-cochain trivialising the Smith-recognition cocycle $j_{n,m}^* I_{n+m} - I_n \boxtimes I_m$. The second is killed only by a sewing homotopy proving nuclear convergence of the BCOV genus tower. At the LCS point the current computation gives the leading sign

$$\kappa_{\text{ch}}^{\text{BCOV}}(Q) = -25/3, \quad S_{4,1}^{\text{inst}}(Q) = 2875/(-25/3) = -345, \quad (\kappa_{\text{ch}}^{\text{BCOV}}(Q))^3 S_{4,1}^{\text{inst}}(Q) > 0,$$

which is a first coefficient in the expected Borel sector. It is not a vanishing theorem for $O_3^{\text{BL}}(Q)$. The missing lemma is the full BCOV Borel sign lemma: after fixing the sewing sector and normalisation, the Borel transform of the sewing defect must be analytic on the positive ray and the full instanton-corrected quadratic form must remain sign-definite so that $\|\sigma_{\text{sew}}^{(N)}\| \rightarrow 0$ in the nuclear IndHilb topology.

Proof. The orthogonal/Hilbert claim is a statement about a pairing between the E_1 chiral bar complex and chains on an arithmetic Shimura target. A Siegel modular form attached to a K₃ fibre lives on a different lattice and cannot supply the chain map above for a non-K₃-fibred X . The BCOV/GW/PT data of Q give scalar and rank-1 coefficient systems on $H_2(Q, \mathbb{Z}) \cong \mathbb{Z}$; they do not specify an even lattice of signature $(2, 2h^{1,1})$, an arithmetic group, a line-bundle normalisation, or a chain-level pairing compatible with B^{E_1} .

The two Booth–Lazarev complexes are the residual complexes after the Mumford collapse of the genus-curving obstruction: O_1^{BL} is the Ran-space Smith-recognition Mittag–Leffler defect in the configuration-count direction, and O_3^{BL} is the sewing Mittag–Leffler defect in the genus direction. A vanishing proof for either is exactly a nullhomotopy in its displayed complex. The quintic shadow calculation gives only the LCS leading coefficient $S_{4,1}^{\text{inst}} = 2875/(-25/3)$, hence the displayed sign check is arithmetic evidence for the first Borel coefficient. Nuclear convergence of the full sewing defect is a statement about the entire BCOV tower and its Stokes data; it is not implied by one coefficient. $\square$

Remark 29.9.10 (Mirror symmetry and the shadow tower). The mirror quintic $\tilde{Q}$ (Greene–Plesser orbifold) has $h^{1,1} = 101$, $h^{2,1} = 1$, $\chi = +200$, giving $\kappa_{\text{ch}}^{\text{BCOV}}(\tilde{Q}) = +25/3$ (conjectural). The BCOV-shadow complementarity $\kappa_{\text{ch}}^{\text{BCOV}}(Q) + \kappa_{\text{ch}}^{\text{BCOV}}(\tilde{Q}) = -25/3 + 25/3 = 0$ is consistent with the KM/free-field anti-symmetry class of the bar-cobar construction (both values conjectural). Mirror symmetry exchanges the rank-1 tower of the quintic with a rank-101 tower of the mirror, exchanging Kahler moduli with complex structure moduli.

Remark 29.9.11 (Conifold transition and shadow phase transition). At the conifold point ($\psi = 1$ in the Greene–Plesser family, degeneration type: conifold), a 3-cycle $C \subset Q$ vanishes, and the Yukawa coupling $C(z)$ acquires a double pole. The cubic shadow $\alpha = C/\kappa_{\text{ch}} \rightarrow \infty$, and the shadow tower degenerates. After the conifold transition to the resolved conifold $Y = \text{Tot}(\mathcal{O}(-1) \oplus \mathcal{O}(-1) \rightarrow \mathbb{P}^1)$: $\kappa_{\text{ch}}(Y) = 1$ and the shadow class is **G** (depth 2). This is a *phase transition* in the shadow classification: **M** $\rightarrow$ **G**.

The three degeneration types of the mirror quintic family produce distinct shadow tower behaviours:

- (a) *Large complex structure* ($z = 0$): class **M**, $\alpha = -3/5 + O(q)$ (fully populated tower).
- (b) *Conifold* ($z = 1/3125$): class degenerates ($\alpha \rightarrow \infty$); phase transition **M** $\rightarrow$ **G**.
- (c) *Gepner/orbifold* ($z = \infty$): class **M** (orbifold), $\mathbb{Z}_5$ -equivariant tower.

Hochschild homology of compact CY₃ examples

The Hochschild homology $\text{HH}_*(D^b(\text{Coh}(X)))$ is computed from the HKR decomposition $\text{HH}_p \simeq \bigoplus_q H^q(X, \Omega_X^{3-p})$ using the CY₃ isomorphism $\wedge^p T_X \simeq \Omega_X^{3-p}$.

PROPOSITION 29.9.12 (Hochschild data of compact CY₃ examples). (i) $X = K_3 \times E$: $\dim \text{HH}_* = 96$, with Hodge decomposition

$$(\dim \text{HH}_0, \dim \text{HH}_1, \dim \text{HH}_2, \dim \text{HH}_3) = (4, 44, 44, 4).$$

The palindromic symmetry $\dim \text{HH}_p = \dim \text{HH}_{3-p}$ reflects Serre duality.

(ii) $X = Q$ (quintic): $\dim \text{HH}_* = 208$, with

$$(\dim \text{HH}_0, \dim \text{HH}_1, \dim \text{HH}_2, \dim \text{HH}_3) = (2, 102, 102, 2).$$

The concentration in degrees 1 and 2 reflects $h^{1,1} = 1$ and $h^{2,1} = 101$: moduli dominate, and the CY structure contributes only the top and bottom forms.

29.10 INTEGRABLE SYSTEMS AND LATTICE MODELS

The shadow obstruction tower admits a dictionary with classical integrable systems, where the conserved quantities I_r correspond to shadow invariants at each degree.

The Calogero–Moser/Bethe dictionary

The Calogero–Moser system with N particles on a line and inverse-square interaction $V(x) = \sum_{i < j} g^2/(x_i - x_j)^2$ has N independent conserved quantities $I_1, I_2, \dots, I_N$ (the Sekiguchi operators), with $I_2 = H$ (the Hamiltonian) and I_k of degree k in the momenta.

Conjecture 29.10.1 (Shadow-integrable dictionary). There is a dictionary between the shadow obstruction tower invariants and the Calogero–Moser conserved quantities:

$$\begin{aligned} I_2 \text{ (quadratic Hamiltonian)} &\longleftrightarrow \kappa_{\text{ch}} \text{ (modular characteristic),} \\ I_3 \text{ (cubic integral)} &\longleftrightarrow C \text{ (cubic shadow),} \\ I_4 \text{ (quartic integral)} &\longleftrightarrow Q \text{ (quartic shadow / contact invariant).} \end{aligned}$$

The Bethe ansatz equations for the Calogero–Moser system correspond to the Maurer–Cartan equation $D\Theta + \frac{1}{2}[\Theta, \Theta] = 0$ of the modular convolution algebra, projected to each degree: the r -th conserved quantity I_r is the genus-0 degree- r projection of the MC element Θ_A .

Remark 29.10.2. The dictionary is *structural*, not a theorem. It captures the parallel between two filtration structures: the degree filtration on Θ_A (controlling the shadow depth classification G/L/C/M) and the degree filtration on the conserved quantities I_r (controlling the integrability class of the Calogero–Moser system). The coupling constant g^2 maps to κ_{ch} , the number of particles N maps to the number of strong generators, and the Bethe roots map to the shadow metric zeros.

Lattice finite-size corrections

For a critical lattice model (e.g., the XXX Heisenberg spin chain of length L), the finite-size corrections to the ground-state energy are controlled by the central charge c and conformal dimensions of the associated CFT:

$$E_0(L) = L\varepsilon_\infty - \frac{\pi c}{6L} + O(L^{-3}).$$

More generally, the full finite-size spectrum organizes into an asymptotic expansion

$$E_n(L) - L\varepsilon_\infty = \frac{2\pi}{L} \left(-\frac{c}{12} + h_n + \bar{h}_n \right) + \sum_{k \geq 2} \frac{a_k(n)}{L^{2k-1}}.$$

Conjecture 29.10.3 (Finite-size corrections as shadow tower). The finite-size correction coefficients $a_k(n)$ correspond to shadow tower data: the leading coefficient $a_1 = -c/12 = -\kappa_{\text{ch}}/6$ recovers κ_{ch} , and the higher coefficients a_k for $k \geq 2$ encode the degree- $(2k)$ shadow projections. The decay rate of the corrections is $q = e^{-2\pi/L}$, matching the shadow tower variable.

Crystal melting: combinatorial vs bar-algebraic degree

The MacMahon function $M(q)$ counts plane partitions (3D Young diagrams), and the crystal melting model of Okounkov–Reshetikhin–Vafa interprets the DT partition function of $\mathbb{C}^3$ as a statistical-mechanical partition function on the crystal lattice $\mathbb{Z}_{\geq 0}^3$.

Remark 29.10.4 (Combinatorial degree $\neq$ bar degree). The crystal melting “degree” (the number of boxes removed from the corner of the crystal) does *not* match the bar complex degree (the tensor length in $B^{(n)}(A)$).

The crystal partition function organizes by the number of boxes:

$$M(q) = \sum_{\pi \in \mathcal{PP}} q^{|\pi|}, \quad |\pi| = \text{number of boxes in plane partition } \pi.$$

The bar complex organizes by tensor length:

$$B(A) = \bigoplus_{n \geq 1} \tilde{A}^{\otimes n}[n], \quad \tilde{A} = \ker(\varepsilon), \quad \text{degree } n = \text{number of tensor factors.}$$

These two gradings are *not* compatible: a plane partition with k boxes does not correspond to a bar element of degree k . Rather, the crystal melting expansion is an exponential reorganization of the bar complex: $\log M(q) = \sum_k \sigma_2(k) q^k / k$ is the free energy, while the bar complex detects the individual OPE modes.

The fundamental mismatch: crystal melting is a *tensor-algebraic* construction (counting 3D diagrams in $\mathbb{Z}^3$), while the bar complex is a *factorization-algebraic* construction (organized by collision patterns on $\text{Ran}(X)$). The two agree in the graded *character* (both reproduce $M(q)$ or its inverse) but not in the *degree structure*.

29.II GRAND ATLAS OF CY_3 SHADOW INVARIANTS

Table 29.1 collects the shadow tower data for 18 CY_3 families spanning the full range of shadow behaviour.

TABLE 29.1: Grand atlas of CY_3 shadow invariants. Columns: CY_3 family, topological Euler characteristic χ , Hodge numbers $h^{1,1}$ and $h^{2,1}$, active scalar lane, shadow depth class, and data source. For non-compact toric CY_3 : the active scalar is $\kappa_{\text{ch}} = \chi(S)/2$ where S is the compact base (Proposition 34.15.1). For compact CICYs: the active scalar is the BCOV shadow scalar $\kappa_{\text{ch}}^{\text{BCOV}} = \chi_{\text{top}}/24$, not the Hodge-supertrace κ_{ch} . For Borchers-admissible K_3 -fibre rows: the column records κ_{BKM} (the automorphic weight), not κ_{ch} ; see Remark 29.9.4. Families above the first rule are non-compact toric; between the rules are K_3 -fibre Borchers rows; below are compact complete intersections and special families. BV = Borcea–Voisin.

CY_3	χ	$h^{1,1}$	$h^{2,1}$	active scalar	Class	Source
$\mathbb{C}^3$	;	;	;	1	G	MacMahon

Banana (Schoen)	0	19	19	0	$M^{\geq 4}$	BKY
BV(1, 1, 1)	-108	6	60	-9/2	M	Voisin–Borcea
BV(10, 0, 0)	0	35	35	0	?	Voisin–Borcea
BV(10, 8, 0)	0	19	19	0	?	Voisin–Borcea
BV(20, 2, 0)	120	61	1	5	M	Voisin–Borcea

† These entries record κ_{BKM} (Borchers automorphic weight), not κ_{ch} ; for $\text{K}_3 \times E$, the Heisenberg reading is $\kappa_{\text{ch}}^{\text{Heis}} = 3$ while the compact trace is 0.

Key patterns visible in the atlas:

- (i) **Toric depth bound:** for toric CY_3 with N vertices in the web diagram, the shadow depth satisfies $r_{\max} \leq N$. The cases $N = 1$ (trivial), 2 (Gaussian), 3 (Lie), 4 (contact) are realized; $N \geq 5$ gives class M.
- (ii) **Compact CY_3 are generically class M:** all compact CY_3 with $\chi \neq 0$ have infinite shadow depth, driven by the infinite BPS spectrum.
- (iii) **Active-scalar integrality:** among the atlas families, $\mathbb{P}^5[3, 3]$ ($\kappa_{\text{ch}}^{\text{BCOV}} = -6$), $K_3 \times E$ ($\kappa_{\text{BKM}}(\Delta_5) = 5$), Enriques $\times E$ ($\kappa_{\text{BKM}}(\tilde{\Delta}_5^{\text{Enr}}) = 5$), and $BV(20, 2, 0)$ ($\kappa_{\text{ch}}^{\text{BCOV}} = 5$) have integral active scalars. For compact CICYs, $\kappa_{\text{ch}}^{\text{BCOV}} = \chi/24$ is integral only when $24 \mid \chi$; on Borchers-admissible K_3 -fibre rows, κ_{BKM} is integral because it is an automorphic weight.
- (iv) **BKM structure requires integral automorphic weight:** the Borchers-admissible K_3 -fibre rows carry BKM superalgebras via Borchers lifts; compact CICYs with non-integral $\kappa_{\text{ch}}^{\text{BCOV}}$ do not.
- (v) $\kappa_{\text{ch}}^{\text{Hodge}} = 0$ **does not imply trivial tower:** the banana manifold and the balanced Borcea–Voisin families ($r = 10$) have vanishing Hodge supertrace but may have nontrivial higher-degree shadows sourced by instantons.
- (vi) **Borcea–Voisin as BCOV-scalar interpolation:** the BV family parametrized by (r, a, δ) gives $\kappa_{\text{ch}}^{\text{BCOV}} = \chi_{\text{top}}/24 = (r - 10)/2$, interpolating between $-9/2$ at $r = 1$ and 5 at $r = 20$. This last value is a BCOV scalar on a Borcea–Voisin row; it is not the compact total-space Hodge supertrace of $K_3 \times E$, which is 0.

Remark 29.11.1 (Enriques $\times E$ scalar distinction). The Enriques row has $\kappa_{\text{BKM}}(\tilde{\Delta}_5^{\text{Enr}}) = 5$ for the full BKM denominator and metaplectic square-root weight $5/2$ for Δ_5^{Enr} . The Allcock weight-4 Borchers product on $O(2, 10)$ is a moduli discriminant scalar. The naive BCOV-shadow scalar $\kappa_{\text{ch}}^{\text{BCOV}} = \chi/24$ does not apply because Enriques $\times E$ is a generalized CY_3 with $h^{3,0} = 0$ and torsion canonical class.

29.12 FORM FACTORS VIA KOSZUL DUALITY AND THE SHADOW PARTITION FUNCTION

The Costello–Paquette construction computes form factors in holomorphic Chern–Simons theory via Koszul duality between bulk and boundary algebras. The Koszul projection $\pi: \text{Obs}_{\text{bulk}} \rightarrow \text{Obs}_{\text{bdry}}^!$ factors through the bar complex $B(A)$, and the n -particle form factor

$$F(O; z_1, \dots, z_n) = \langle \text{vac} | O(o) | z_1, \dots, z_n \rangle$$

is computed by pairing the bulk operator O against n -fold bar elements:

$$F(O; z_1, \dots, z_n) = \langle O, s^{-1}a_1 | \cdots | s^{-1}a_n \rangle_{B(A)}.$$

Here z is the Yangian spectral parameter (not a worldsheet coordinate; the distinction is essential, cf. Remark 9.9.12 in the E_1 -chiral bialgebra chapter).

Conjecture 29.12.1 (Form factor–shadow PF identity). For a chiral algebra A arising from a CY category $\mathcal{C}$ via the functor Φ , the generating function of integrated form factors equals the shadow partition function:

$$\sum_{n \geq 2} \frac{1}{n!} \int_{\mathcal{M}_{0,n}} F(O; z_1, \dots, z_n) dz_1 \cdots dz_n = \log \Theta_A(q),$$

where $\Theta_A = \prod_{k \geq 1} (1 - q^k)^{a_k}$ is the bar Euler product of the bar-cobar construction. The integrated n -particle form factor equals the shadow invariant at degree n :

$$\frac{1}{n!} \int_{\mathcal{M}_{0,n}} F(\mathcal{O}; z_1, \dots, z_n) = S_n(A).$$

The identity is realised differently at each shadow depth class.

PROPOSITION 29.12.2 (*Form factor truncation by shadow class*). The n -particle form factor $F(\mathcal{O}; z_1, \dots, z_n)$ truncates according to the shadow class of A :

- (i) **Class G** (Heisenberg, depth 2): only the 2-particle form factor is nonzero. The Koszul projection π is a quasi-isomorphism, and $F(\mathcal{O}; z_1, z_2) = \kappa_{\text{ch}} / (z_1 - z_2)^2$ (Wick contraction). All higher form factors vanish: the bar complex is formal, and $B^{\text{der}}(A) = B(A)$.
- (ii) **Class L** (Kac–Moody, depth 3): the 3-particle form factor is the first loop correction, with integrated value $S_3 = \alpha$ (the cubic shadow). The Koszul projection carries a single A_∞ -correction from m_3 . All form factors with $n \geq 4$ vanish.
- (iii) **Class C** ($\beta\gamma$, finite depth): finitely many form factors are nonzero. The correction series converges, and π carries finitely many A_∞ -corrections.
- (iv) **Class M** (Virasoro, infinite depth): *all* form factors are nonzero. The Koszul projection π carries infinitely many A_∞ -corrections. The integrated form factor series $\sum S_n$ is Gevrey-1 divergent and Borel summable. For the spin-2 channel of $\mathcal{W}_{1+\infty}$ at $c = 1$: $S_2 = 1/2$, $S_3 = 2$, $S_4 = 10/27$ (matching the A_∞ -bar computation of §29.2).

Proof. The shadow class determines the depth of the A_∞ -tower on $B(A)$, hence the maximal degree of nonvanishing bar elements contributing to $\langle \mathcal{O}, s^{-1}a_1 | \cdots | s^{-1}a_n \rangle$. For class G, the bar complex is formal ($m_k = 0$ for $k \geq 3$), so only the binary pairing ($n = 2$) contributes. For class L, $m_3 \neq 0$ but $m_k = 0$ for $k \geq 4$, so only $n \leq 3$ contributes. For class M, all m_k are nonzero, giving contributions at every degree. The Gevrey-1 growth for class M follows from the Gevrey-1 growth of the shadow invariants (the bar-cobar construction, Theorem D). The integrated values S_n match the shadow invariants by the comparison of the moduli-space integral $\int_{\mathcal{M}_{0,n}}$ with the degree- n projection of the shadow tower (the Costello–Gwilliam factorisation-algebra integration). $\square$

Remark 29.12.3 (*Koszul conductor and form factor normalisation*). The Koszul conductor $K = \kappa_{\text{ch}}(A) + \kappa_{\text{ch}}(A^\dagger)$ controls the normalisation of form factors through the complementarity theorem (Theorem C, the bar-cobar construction). For the three standard non-B families:

- (a) Heisenberg: $K = 0$. The bulk and boundary form factors are *anti-symmetric*: $S_2(A) + S_2(A^\dagger) = 0$.
- (b) Kac–Moody: $K = 0$. Anti-symmetric, with Feigin–Frenkel involution $k \mapsto -k - 2h^\vee$.
- (c) Virasoro: $K = 13$. The conductor is nonzero: $c/2 + (26 - c)/2 = 13$ for all c . The form factor normalisation absorbs the conductor through the modular correction $\delta F_g^{\text{cross}}$.

PROPOSITION 29.12.4 (*K_3 bar Euler product from form factors*). The Mukai–Heisenberg shadow of $Y(\mathfrak{g}_{K_3})$ has rank 24 with 24 Heisenberg generators, each of class G with per-generator $\kappa_{\text{ch}}^{\text{Heis}} = 1$. The form factor computation gives:

- (i) Per-generator 2-particle form factor: $F(\mathcal{O}; z_1, z_2) = 1/(z_1 - z_2)^2$.
- (ii) Total 2-particle form factor: $\sum_{i=1}^{24} 1 = 24$, equals the bar Euler exponent.

- (iii) All higher form factors vanish (class G).
- (iv) Bar Euler product: $\prod_{n \geq 1} (1 - q^n)^{24} = \eta(q)^{24}/q = \Delta(q)/q$.
- (v) First coefficients: 1, -24, 252, -1472, 4830, -6048 (Ramanujan τ shifted).

The bar Euler exponent is $24 = \text{rank}(\Lambda_{\text{Mukai}})$, not $\kappa_{\text{ch}}^{\text{Hodge}}(K_3) = 2 = \chi(\mathcal{O}_{K_3})$. The Hodge scalar is read from the source surface, while the bar exponent counts the class-G generators of the Mukai Heisenberg shadow. This per-generator free-field computation is not the Mukai self-dual B-row conductor; the latter is $K^{\kappa_{\text{ch}}^{\text{Mukai}}} = 2c_+(\Pi_{4,20}) = 8$.

29.13 TOPOLOGICAL STRING AMPLITUDES FROM THE BAR COMPLEX

The topological string partition function $Z_{\text{top}}(X, g_s) = \exp(\sum_{g \geq 0} g_s^{2g-2} F_g(X))$ admits a genus-by-genus derivation from the shadow obstruction tower. The shadow–Feynman dictionary identifies the genus- g amplitude F_g with the integrated degree- $(g+1)$ shadow invariant, and the holomorphic anomaly equation of Bershadsky–Cecotti–Ooguri–Vafa with the Maurer–Cartan recursion on the bar complex.

Genus-1 seed: $F_1 = S_2/24$

PROPOSITION 29.13.1 (F_1 from the shadow tower). For a CY₃ category $\mathcal{C}$ with chiral algebra $\mathcal{A} = \Phi(\mathcal{C})$, the genus-1 free energy on a specified scalar lane is

$$F_1 = \kappa_{\text{scalar}}(\mathcal{A}) \cdot \lambda_1^{\text{FP}} = \frac{S_2}{24},$$

where $S_2 = \kappa_{\text{scalar}}$ is the active degree-2 shadow invariant on that lane and $\lambda_1^{\text{FP}} = 1/24$ is the Faber–Pandharipande intersection number on $\overline{\mathcal{M}}_{1,1}$. For the quintic this scalar is $\kappa_{\text{ch}}^{\text{BCOV}}$, not the Hodge-supertrace κ_{ch} .

Geometry	active scalar	$F_1 = \kappa_{\text{scalar}}/24$
$\mathbb{C}^3$	1	1/24
Conifold	1	1/24
Local $\mathbb{P}^2$	3/2	1/16
$K_3 \times E$	3	1/8
Quintic	-25/3	-25/72

Genus-2: BCOV recursion and S_3

PROPOSITION 29.13.2 (*Universal ratio F_2/F_1*). On the scalar lane, the ratio of consecutive genus amplitudes is universal:

$$\frac{F_2}{F_1} = \frac{\lambda_2^{\text{FP}}}{\lambda_1^{\text{FP}}} = \frac{7}{240},$$

independently of the chiral algebra $\mathcal{A}$ and the geometry X . The shadow invariant $S_3 = \alpha$ (the cubic shadow) controls the off-diagonal correction beyond the scalar lane: for multi-weight algebras, $F_2^{\text{full}} = F_2^{\text{scalar}} + C_2 \cdot S_3 \cdot (\text{off-diagonal correction})$.

Remark 29.13.3 (Shadow–Feynman rule). The naive identification “ L -loop = S_{L+1} ” from shadow–Feynman requires refinement. The shadow invariant S_{g+1} at degree $g+1$ controls the degree- $(g+1)$ piece of the Maurer–Cartan element Θ . The genus- g free energy F_g is the *integrated* version:

$$F_g = \int_{\overline{\mathcal{M}}_g} \Theta^{(g+1)}(A),$$

so on the scalar lane $F_g^{\text{sc}} = \kappa_{\text{ch}} \cdot \lambda_g^{\text{FP}}$ depends only on $S_2 = \kappa_{\text{ch}}$, not on the higher S_k .

Gopakumar–Vafa invariants from the bar complex

The genus- g free energy receives instanton corrections from BPS states at each curve class β . The GV multi-cover formula [248] expresses the free energy in terms of the integer BPS invariants n_g^β through the expansion of $(2 \sin(k\lambda/2))^{2g-2}$. For a genus-0 BPS state, the propagator $(2 \sin(u/2))^{-2}$ has the Laurent expansion

$$\frac{1}{(2 \sin(u/2))^2} = \frac{1}{u^2} + \frac{1}{12} + \frac{u^2}{240} + \frac{u^4}{6048} + \cdots,$$

computed by series inversion of $\sin^2(z)/z^2$ (all coefficients positive, since $\csc^2 > 0$).

PROPOSITION 29.13.4 (*GV integrality from bar integrality*). For toric CY_3 targets, if the E_1 page of the bar spectral sequence of $\mathcal{A}_X$ has integer entries, then all Gopakumar–Vafa invariants n_g^β are integers.

$K_3 \times E$: DMVV as bar complex generating function

Conjecture 29.13.5 (*DMVV formula from the bar complex*). Assume the bar-cobar construction Borchers-lift identification and the motivic DT comparison. The Dijkgraaf–Moore–Verlinde–Verlinde product formula [35]

$$Z_{\text{DMVV}}(p, y, q) = \prod_{(n,l,m) > 0} \frac{1}{(1 - p^n y^l q^m)^{c(4nm - l^2)}}$$

is recovered from the bar complex of $\mathcal{A}_{K_3 \times E}$ via the four-arrow bridge:

- (i) Framed CY-to-chiral specialisation $\text{Sp}_{\Sigma_2, C}^{\text{ch}}(\Phi_3^{\text{EA}}(D^b \text{Coh}(K_3 \times E))) = \mathcal{A}_{K_3 \times E}$ (Theorem 5.11.1, conditional on the chosen $K_3 \times E$ framed locus).
- (ii) Bar Euler product Θ_A (the bar-cobar construction).
- (iii) Borchers lift identification $\Theta \rightarrow \Delta_5$ with the primitive BKM denominator kept at Δ_5 and the monic product $D_5 = 64^{-1} \Delta_5$; this is mediated by the bar-cobar construction bridge.
- (iv) Reduced OP/DT scalar comparison (Oberdieck–Pandharipande, Oberdieck–Pixton, Oberdieck):

$$Z_{\text{DT}}^X = Z_{\text{OP}}^X = -(\Phi_{10}^{\text{OP}})^{-1} = -4096 \Delta_5^{-2}, \quad \Phi_{10}^{\text{OP}} = D_5^2 = 4096^{-1} \Delta_5^2.$$

At rank 1, the Gottsche formula $\sum_{n \geq 0} \chi(\text{Hilb}^n(K_3)) q^n = \prod_{k \geq 1} (1 - q^k)^{-24}$ is unconditionally recovered from constant bar exponents $a_k = 24 = \kappa_{\text{fiber}}$.

Holomorphic anomaly from shadow non-termination

PROPOSITION 29.13.6 (*Shadow class determines anomaly type*). The holomorphic anomaly equation $\bar{\partial}_i F_g = \frac{1}{2} \bar{C}_i^{jk} (D_j D_k F_{g-1} + \sum_{r=1}^{g-1} D_j F_r D_k F_{g-r})$ is the genus- g projection of the Maurer–Cartan equation $D\Theta + \frac{1}{2}[\Theta, \Theta] = 0$ in the bar dgLa (structural identification of Costello–Li). The shadow class determines the anomaly type:

Class	$\tilde{\partial}F_g = 0?$	Genus expansion	Mock modular?	Example
G	yes	polynomial	no	Heisenberg
L	for $g \gg 0$	polynomial	no	Yangian
C	no	convergent	no	$\beta\gamma$ system
M	no	Gevrey-1 divergent	yes	Virasoro, $K_3 \times E$

The holomorphic anomaly is the shadow tower's non-termination: class M algebras have infinite shadow depth, producing a Gevrey-1 divergent genus expansion whose Borel resummation requires non-holomorphic mock modular completions.

29.14 CATEGORICAL S-DUALITY FROM THE BAR COMPLEX

S-duality in physics ($\tau \mapsto -1/\tau$) exchanges strong and weak coupling. The bar-cobar adjunction of the bar-cobar construction provides a precise categorical incarnation: the swap of roles in the adjunction $\Omega^{\text{ch}} \dashv B^{\text{ch}}$ (cobar left, bar right) between factorisation algebras and factorisation coalgebras realises the categorical S-duality as the interchange of the unit and counit faces of the same adjunction under $g_s \mapsto 1/g_s$.

The bar-cobar adjunction as S-duality

PROPOSITION 29.14.1 (*Bar-cobar adjunction as a categorical S-duality model*). Let A be an E_1 -chiral algebra in the Koszul locus, or in the weight-completed Positselski locus where the bar-cobar construction completed inversion applies. Suppose a coupling parameter g_s rescales the bar differential $d_{\text{bar}} = g_s \cdot \mu$, where μ is the chiral bracket. The bar-cobar adjunction

$$B: E_1\text{-ChirAlg} \rightleftarrows E_1\text{-ChirCoalg}: \Omega$$

gives two equivalent descriptions of the same object:

- (i) $B_{g_s}(A)$ is the bar coalgebra with differential $d = g_s \cdot \mu$.
- (ii) $\Omega_{1/g_s}(B_{g_s}(A))$ is the cobar algebra with differential rescaled by the reciprocal coproduct term.
- (iii) The counit $\Omega(B(A)) \xrightarrow{\sim} A$ is bar-cobar inversion (the counit face of the bar-cobar construction Theorem A; the strict ML weight-completed coderived strengthening is the bar-cobar construction Theorem B on the Positselski locus for classes G/L/C/M). It identifies the cobar reconstruction with A ; it does not identify the bar coalgebra $B(A)$ with the algebra A .

Thus the exchange of bar and cobar descriptions models $g_s \leftrightarrow 1/g_s$. The involutivity is the triangle identity for the adjunction on the stated locus. The self-dual point $g_s = 1$ is the point where the two differential normalisations agree, not a literal equality between $B(A)$ and $\Omega(B(A))$.

Proof. Items (i) and (ii) are the definitions of the bar and cobar differentials with the chosen coupling normalisation. Item (iii) is the content of the bar-cobar construction bar-cobar counit on the stated locus: $\Omega \circ B \simeq \text{id}$. The involution property follows from the unit-counit identities of the adjunction. $\square$

The Koszul conductor as S-duality invariant

THEOREM 29.14.2 (*Conductor invariance under S-duality*). The Koszul conductor $K = \kappa_{\text{ch}}(A) + \kappa_{\text{ch}}(A^\dagger)$ is invariant under the S-duality exchange $A \leftrightarrow A^\dagger$:

$$K(A) = K(A^\dagger).$$

Proof. By definition, $K(A) = \kappa_{\text{ch}}(A) + \kappa_{\text{ch}}(A^!)$ and $K(A^!) = \kappa_{\text{ch}}(A^!) + \kappa_{\text{ch}}(A^{!!})$. On the Koszul locus, bar-cobar inversion gives $A^{!!} \simeq A$, so $\kappa_{\text{ch}}(A^{!!}) = \kappa_{\text{ch}}(A)$ and $K(A^!) = \kappa_{\text{ch}}(A^!) + \kappa_{\text{ch}}(A) = K(A)$. $\square$

Remark 29.14.3 (The conductor classifies S-duality strength). The three standard families illustrate a trichotomy:

Family	Class	Conductor K	S-duality involution	Type
Heisenberg H_k	G	o	$k \leftrightarrow -k$	trivial
Kac–Moody $V_k(\mathfrak{sl}_2)$	L	o	$k \leftrightarrow -k - 2h^\vee$	Langlands
Virasoro Vir_c	M	13	$c \leftrightarrow 26 - c$	non-perturbative

For class G, the bar differential vanishes and the coupling exchange is invisible: S-duality is *trivial* (perturbative = non-perturbative). For class L, the Feigin–Frenkel involution $k \mapsto -k - 2h^\vee$ is the Langlands duality map, with self-dual point at the critical level $k = -h^\vee$. For class M, the infinite $\mathcal{A}_\infty$ tower participates non-trivially in the exchange: S-duality requires Borel resummation of the Gevrey-1 divergent coupling series.

S-duality for the K_3 Yangian: the Fricke involution

For the K_3 Yangian $Y(\mathfrak{g}_{K_3})$ (conjectural), S-duality on the E modulus in $K_3 \times E$ is realised by the Fricke involution.

Conjecture 29.14.4 (Fricke = S-duality on K_3 Yangian moduli). The Fricke involution $W_N: \tau \mapsto -1/(N\tau)$ on the moduli space of K_3 Yangians acts by transporting the Koszul model across the family. On a Koszul chart this means there is an algebra equivalence

$$Y(\mathfrak{g}_{K_3})(W_N\tau) \simeq \Omega_{W_N\tau}(B_\tau(Y(\mathfrak{g}_{K_3})(\tau))),$$

where the right-hand side is the cobar reconstruction of the transported bar coalgebra. The bar coalgebra itself is not identified with the reconstructed algebra. At the self-dual point $\tau_* = i/\sqrt{N}$, the Yangian is preserved: the heterotic and type IIA descriptions coincide (strong–weak self-duality).

The Fricke involution acts on the *moduli space* of Yangians (mapping $Y(\mathfrak{g}_{K_3})(\sigma)$ to $Y(\mathfrak{g}_{K_3})(W_N(\sigma))$), not on a single Yangian algebra (cf. Chapter 18, Paragraph on the Fricke involution).

The key S-duality data for K_3 :

- (i) $\kappa_{\text{ch}}^{\text{Hodge}}(K_3) = 2$ is *preserved* under Fricke at all N (the value is moduli-independent).
- (ii) The Koszul conductor $K = \text{o}$ only on the free-field summand: S-duality is trivial on the free-field scalar there. The Mukai self-dual K_3 branch remains the separate B-row datum $K^{\kappa_{\text{ch}}^{\text{Mukai}}} = 2c_+(\Pi_{4,20}) = 8$.
- (iii) The bar Euler product $\eta(\tau)^{24}$ *transforms* under Fricke with weight 12:

$$\eta(-1/(N\tau))^{24} = (N\tau/i)^{12} \cdot \eta(N\tau)^{24},$$

exchanging the perturbative (additive Saito–Kurokawa) and non-perturbative (multiplicative Borchers) expansions.

- (iv) For $N = 1$, $W_1 = S$ is the standard S-duality with $\tau_* = i$ and $g_s^{\text{het}} = 1$.

S-duality for the Virasoro: $c \leftrightarrow 26 - c$

PROPOSITION 29.14.5 (*Virasoro S-duality*). The Virasoro Koszul involution $c \leftrightarrow 26 - c$ satisfies:

- (i) Conductor $K = c/2 + (26 - c)/2 = 13$, independent of c .
- (ii) Self-dual point $c = 13$, with $\kappa_{\text{ch}} = 13/2$.
- (iii) Physical interpretation: exchanges the matter sector (c) and the ghost sector ($26 - c$) in bosonic string theory. At $c = 26$: ghost cancellation. At $c = 0$: trivial matter with full ghost.

This is *genuinely non-perturbative*: the Virasoro is class M with infinite shadow depth, so the S-duality exchange activates the full A_∞ tower of higher operations.

Proof. The conductor computation is immediate: $K = c/2 + (26 - c)/2 = 26/2 = 13$. The self-dual point $c = 26 - c$ gives $c = 13$. The physical interpretation follows from the BRST cohomology of the bosonic string, where the total central charge $c_{\text{matter}} + c_{\text{ghost}} = c + (26 - c) = 26$ cancels the conformal anomaly. The class M statement follows from the computation of the shadow tower of Vir_c (the bar-cobar construction shadow-quadrichotomy, [96]). $\square$

29.15 THE UNIVERSAL TRACE IDENTITY

the bar-cobar construction attaches to a chiral algebra $\mathcal{A}$ the conductor $K(\mathcal{A}) = -c_{\text{ghost}}(\text{BRST}(\mathcal{A}))$ under the quasi-free BRST hypothesis. the CY-to-chiral construction attaches to a $K3$ -fibered Calabi–Yau threefold X with Borchers datum $\mathfrak{g}_\Lambda$ the BKM weight $\kappa_{\text{BKM}}(\Phi_\Lambda) = c_\Lambda(o)/2$. In the two-stage factorisation $\Phi_d = \text{Sp}^{\text{ch}} \circ \Phi_d^{\text{FA}}$, any common trace object must be built before scalar specialisation: the proposed centre is a stage-1 object whose stage-2 shadows carry the bar-cobar construction conductor and the CY-to-chiral construction Borchers weight. The universal Borchers weight identity is the row-by-row formula

$$\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2.$$

On the Gritsenko–Cléry eight-row catalogue the weights are

$$(5, 2, 3, 1, 2, 1/2, 3/2, 1), \quad c_N(o) \in \{10, 4, 6, 2, 4, 1, 3, 2\},$$

with no weight-0 form and no quarter-weight form (Theorem 32.8.1 in [96]). At the canonical Virasoro/ $K3 \times E$ point $K(\text{Vir}_{c=24}) = 12 + 1 = 13$ on the self-dual line $c + c^\dagger = 26$, while $\kappa_{\text{BKM}}(\Delta_5) = 5$ via Gritsenko’s paramodular form Δ_5 . The scalars do not coincide, and no rescaling $K = \lambda \cdot \kappa_{\text{BKM}}$ survives dimensional analysis. The unification cannot be scalar; it must be operator-level.

Conjecture 29.15.1 (*Universal Trace Identity*). There is a universal centre object $\mathfrak{Z}$ in the cross-volume Φ -bridged setting such that:

- (i) For any chiral algebra $\mathcal{A}$ with quasi-free BRST resolution, $K(\mathcal{A}) = \text{tr}_{\mathfrak{Z}(\mathcal{A})}(\mathfrak{R}_\mathcal{A})$ where $\mathfrak{R}_\mathcal{A}$ is the Koszul reflection acting on the centre $\mathfrak{Z}(\mathcal{A})$ of the trinity $\text{Trinity}(\mathcal{A})$ (the centre construction Chiral Hochschild Trinity Theorem).
- (ii) For a $K3$ -fibered CY_3 chart X with named Borchers input f_X , the scalar identity $\kappa_{\text{BKM}}(\Phi_{f_X}) = c_{f_X}(o)/2$ is automorphic. The centre trace $\kappa_{\text{BKM}}(\Phi_{f_X}) = \text{tr}_{\mathfrak{Z}(\Phi(X))}(\mathfrak{B}_X)$ is asserted only after the centre action $\mathfrak{B}_X$ and its Hall trace comparison have been constructed.

- (iii) The two reflections $\mathfrak{R}_A$ and $\mathfrak{B}_X$ are expected to be two presentations of one universal involution $\mathcal{I}$ on $\mathfrak{Z}$, related, when the comparison data exist, by a morphism

$$\Phi_{\#}(\mathfrak{R}_{A_X}) \dashrightarrow \mathfrak{B}_X.$$

The numerical values across the Virasoro/ $K_3 \times E$ and Bershadsky–Polyakov cases that motivated the conjecture ($K(\text{Vir}_{c=24}) = c/2 + c^{\dagger}/2 = 12 + 1 = 13$ on the Virasoro self-dual line $c + c^{\dagger} = 26$; $\kappa_{\text{BKM}}(\Delta_5) = c_1(\mathfrak{o})/2 = 5$ via Gritsenko’s Δ_5 ; $K(\text{BP}) = 196$ on the Bershadsky–Polyakov self-dual locus) are *not* required to coincide or to sit in any scalar ratio: they are traces of different operators after the corresponding centre actions have been constructed, and the conjectural content is the comparison of those operators, not a rescaling of their scalar shadows.

Remark 29.15.2 (Bridge obligations). Conjecture 29.15.1 is a structural unification hypothesis, not a constructed bridging diagram. The the bar-cobar construction conductor $K(A) = -c_{\text{ghost}}(\text{BRST}(A))$ depends on a quasi-free BRST resolution (ghost spectrum); the CY-to-chiral construction BKM weight $\kappa_{\text{BKM}}(\Phi_{\Lambda}) = c_{\Lambda}(\mathfrak{o})/2$ depends on the Borchers lift of a Jacobi form attached to the K_3 elliptic genus. The two invariants come from *different mathematical objects* via *different functors*.

The bridging diagram in (3), which would make the displayed comparison literal, requires three constructions:

- The universal centre object $\mathfrak{Z}$ in a cross-volume category. Candidates: the chiral Hochschild trinity centre (the centre construction Trinity Theorem), the categorified Koszul-self-dual subcategory, or the factorisation-homology centre on $S^1 \times \text{Ran}(X)$.
- The Borchers reflection $\mathfrak{B}_X$ as an explicit operator on $\mathfrak{Z}(\Phi(X))$, rather than only as a Borchers character polynomial.
- The comparison morphism (3). This requires the CY-to-chiral correspondence Φ_d to be lifted to the relevant centre actions and Koszul reflections, rather than only on objects.

These three constructions are the hypotheses of the Universal Trace Identity.

Remark 29.15.3 (Three load-bearing precedents). The conjecture has three load-bearing precedents:

- the bar-cobar construction Theorem A: the Koszul duality functor $A \mapsto A^{\dagger} = D_{\text{Ran}} H^{\bullet} B(A)$ is involutive on $\text{Kosz}(X)$, while the counit $\Omega_X \tilde{B}_X(A) \xrightarrow{\sim} A$ is the separate bar-cobar reconstruction map. These are related by the four animating morphisms $\eta, \varepsilon, K, \psi(\hbar)$.
- the centre construction Chiral Hochschild Trinity Theorem: the three Hochschild constructions on A in the logarithmic-finite-type class coincide via factorisation homology on S^1 , with the trinity centre $\mathfrak{Z}(\text{Trinity}(A))$ as the natural target of the Koszul reflection.
- the CY-to-chiral construction Borchers denominator datum: a named vector-valued modular or Jacobi input f determines a denominator form Φ_f by the Borchers singular theta lift, and $\kappa_{\text{BKM}}(\Phi_f) = c_f(\mathfrak{o})/2$. This is a scalar automorphic construction. It becomes an operator on a chiral centre only after a Hall source, a centre action, and a trace comparison have been constructed.

The conjecture asserts that these three reflections – Koszul K , Trinity $\mathfrak{Z}$, Borchers $\mathfrak{B}$ – are three presentations of one universal involution $\mathcal{I}$ on the cross-volume centre. The structural shape of the conjecture is robust; only the explicit identification across the three reflections remains open.

Remark 29.15.4 (Candidate universal centre: factorisation homology on $S^1 \times \text{Ran}(X)$). Among the three candidate constructions for the universal centre $\mathfrak{Z}$ named in Remark 29.15.2, the *factorisation homology*

on $S^1 \times \text{Ran}(X)$ is the most natural, combining the centre construction Trinity centre $\int_{S^1} \mathcal{A}$ with the bar-cobar construction chiral structure on $\text{Ran}(X)$ in a single object:

$$\mathfrak{Z}(\mathcal{A}) := \int_{S^1 \times \text{Ran}(X)} \mathcal{A} \in \text{Mod}_{\mathfrak{Z}_{\text{ch}}^{\text{der}}(\mathcal{A})}.$$

Three structural checks confirm the candidate:

(a) *Trinity restriction.* Collapsing the Ran-space to a chosen base-point recovers the centre construction Trinity centre $\mathfrak{Z}(\mathcal{A})|_{\text{pt} \in \text{Ran}(X)} = \int_{S^1} \mathcal{A}$.

(b) *Koszul reflection acts naturally.* The the bar-cobar construction Koszul reflection $\mathfrak{R}_{\mathcal{A}}$ on $\mathcal{A}$ lifts to $\mathfrak{Z}(\mathfrak{R}_{\mathcal{A}})$ on $\mathfrak{Z}(\mathcal{A})$ via the universal functoriality of factorisation homology in the input chiral algebra. Involutivity $\mathfrak{R}^2 \simeq \text{id}$ on $\text{Kosz}(X)$ extends to $\mathfrak{Z}(\mathfrak{R})^2 \simeq \text{id}$ on $\mathfrak{Z}(\text{Kosz}(X))$.

(c) *Borcherds scalar and centre action are separate.* For $\mathcal{A} = \Phi(X)$ with X K_3 -fibered, the K_3 elliptic genus $\phi_{0,1}^{K_3}$ gives the denominator form Φ_f and the scalar $\kappa_{\text{BKM}}(\Phi_f)$. An operator $\mathfrak{B}_X$ on $\mathfrak{Z}(\Phi(X))$ is an additional centre action to be constructed from Hall and trace data; it is not supplied by the singular theta lift alone.

Under this candidate, the bridging-diagram construction reduces to three tractable technical constructions: (i) $\mathfrak{Z}$ -functoriality on Koszul reflections (automatic from universal property of factorisation homology); (ii) construction of a centre action whose scalar trace is the Borcherds denominator weight of the named K_3 elliptic-genus input; (iii) supertrace formula $\text{tr}_{\mathfrak{Z}(\mathcal{A})}(\mathfrak{R}_{\mathcal{A}}) = K(\mathcal{A}) = -\epsilon_{\text{ghost}}(\text{BRST}(\mathcal{A}))$ (via collapse of the Ran-space to the centre construction Trinity-centre supertrace identity).

Each of the three remaining constructions is the natural extension of the corresponding precedent (the bar-cobar construction Koszul Reflection, the centre construction Trinity, the Borcherds denominator construction) from a single dimension/site to the cross-volume bridge.

PROPOSITION 29.15.5 ($\mathfrak{Z}$ -functoriality on Verdier reflection kernels). The candidate universal centre $\mathfrak{Z}(\mathcal{A}) := \int_{S^1 \times \text{Ran}(X)} \mathcal{A}$ is functorial with respect to Verdier reflection kernels: for every quasi-isomorphism $f: \mathcal{A} \rightarrow \mathcal{A}'$ of augmented complete chiral algebras and every coevaluation kernel $\mathfrak{R}_{\mathcal{A}} \in \mathcal{A}^! \hat{\otimes} \mathcal{A}$ induced by the universal twisting morphism $\bar{B}(\mathcal{A}) \rightarrow \mathcal{A}$, the induced diagram

$$\begin{array}{ccc} \mathfrak{Z}(\mathcal{A}) & \xrightarrow{\mathfrak{Z}(\mathfrak{R}_{\mathcal{A}})} & \mathfrak{Z}(\mathcal{A}^!) \\ \downarrow \mathfrak{Z}(f) & & \downarrow \mathfrak{Z}(f^!) \\ \mathfrak{Z}(\mathcal{A}') & \xrightarrow{\mathfrak{Z}(\mathfrak{R}_{\mathcal{A}'})} & \mathfrak{Z}(\mathcal{A}'^!) \end{array}$$

commutes up to canonical homotopy, where $f^!: \mathcal{A}^! \rightarrow \mathcal{A}'^!$ is the Koszul-dual quasi-isomorphism induced by Theorem A. The involutivity $\mathfrak{R}^2 \simeq \text{id}$ on $\text{Kosz}(X)$ extends to $\mathfrak{Z}(\mathfrak{R})^2 \simeq \text{id}$ on $\mathfrak{Z}(\text{Kosz}(X))$.

Proof. Functoriality of factorisation homology in the input chiral algebra is the universal property of the factorisation-homology functor $\int_M: \text{Alg}^{\text{fact}}(\text{IndCoh}(\text{Ran}(X))) \rightarrow \text{Mod}_{\text{Ran}(X)}$ established by Lurie HA §5.5 and Francis HA appendix. For any morphism of input chiral algebras $f: \mathcal{A} \rightarrow \mathcal{A}'$, the induced $\int_M(f): \int_M \mathcal{A} \rightarrow \int_M \mathcal{A}'$ is a chain-level map of factorisation-homology output, natural in M .

Specialising to $\mathcal{M} = S^1 \times \text{Ran}(X)$ (the E_1 -cyclic factorisation-homology site) and to the Koszul reflection $\mathfrak{R}_{\mathcal{A}}$ as a particular morphism in $\text{Alg}_X^{\text{fact, aug, comp}}$ via Theorem A, the diagram above is the naturality square of $\int_{S^1 \times \text{Ran}(X)}$ applied to the commutative square in $\text{Alg}_X^{\text{fact, aug, comp}}$:

$$\begin{array}{ccc} \mathcal{A} & \xrightarrow{\mathfrak{R}_{\mathcal{A}}} & \mathcal{A}^! \\ \downarrow f & & \downarrow f^! \\ \mathcal{A}' & \xrightarrow{\mathfrak{R}_{\mathcal{A}'}} & \mathcal{A}'^! \end{array}$$

which commutes by Theorem A: the Koszul reflection is functorial in quasi-isomorphisms by the universal property of the bar–cobar adjoint equivalence $(\Omega_X, \bar{B}_X)$. The naturality square commutes up to canonical homotopy because both compositions $\mathfrak{Z}(\mathfrak{R}_{\mathcal{A}'} \circ f) \circ \mathfrak{Z}(f^!)$ and $\mathfrak{Z}(f^!) \circ \mathfrak{Z}(\mathfrak{R}_{\mathcal{A}})$ realise the same universal map $\int_{S^1 \times \text{Ran}(X)} (\mathfrak{R}_{\mathcal{A}'} \circ f) = \int_{S^1 \times \text{Ran}(X)} (f^! \circ \mathfrak{R}_{\mathcal{A}})$ in the $(\infty, 1)$ -category of factorisation-homology outputs.

Involutivity at the centre level: $\mathfrak{Z}(\mathfrak{R})^2 = \mathfrak{Z}(\mathfrak{R} \circ \mathfrak{R})$ by functoriality, and $\mathfrak{R}^2 \simeq \text{id}$ on $\text{Kosz}(X)$ by Theorem A, so $\mathfrak{Z}(\mathfrak{R})^2 \simeq \mathfrak{Z}(\text{id}) = \text{id}_{\mathfrak{Z}(\mathcal{A})}$ on $\mathfrak{Z}(\text{Kosz}(X))$. $\square$

PROPOSITION 29.15.6 (*Supertrace identity via Trinity-centre collapse*). Assume the centre construction Chiral Hochschild Trinity Theorem supplies the κ_{ch} -conductor identification $\text{str}(\text{centre}(\text{Trinity}(\mathcal{A}))) = -c_{\text{ghost}}(\text{BRST}(\mathcal{A}))$ on the Trinity centre $\int_{S^1} \mathcal{A}$. For every chiral algebra $\mathcal{A}$ in the logarithmic-finite-type class admitting a quasi-free BRST resolution, the chain-level supertrace of the Koszul reflection $\mathfrak{R}_{\mathcal{A}}$ acting on the candidate centre $\mathfrak{Z}(\mathcal{A}) := \int_{S^1 \times \text{Ran}(X)} \mathcal{A}$ equals the bar-cobar construction κ_{ch} -conductor:

$$\text{tr}_{\mathfrak{Z}(\mathcal{A})}(\mathfrak{R}_{\mathcal{A}}) = K(\mathcal{A}) = -c_{\text{ghost}}(\text{BRST}(\mathcal{A})).$$

The identity follows from the collapse of the Ran-space factor (choosing a base-point $\text{pt} \hookrightarrow \text{Ran}(X)$ to recover the centre construction Trinity centre $\int_{S^1} \mathcal{A}$) together with the conditional κ_{ch} -conductor identification on the centre construction Chiral Hochschild Trinity centre.

Proof. By Proposition 29.15.5, $\mathfrak{Z}$ and $\mathfrak{R}$ commute up to canonical homotopy. Restrict $\mathfrak{Z}(\mathcal{A}) = \int_{S^1 \times \text{Ran}(X)} \mathcal{A}$ along the inclusion $\text{pt} \hookrightarrow \text{Ran}(X)$ given by a chosen marked point $x_0 \in X$, producing $\mathfrak{Z}(\mathcal{A})|_{x_0} = \int_{S^1 \times \text{pt}} \mathcal{A} = \int_{S^1} \mathcal{A}$, which is exactly the centre construction Trinity centre $\text{Trinity}(\mathcal{A}) = \int_{S^1} \mathcal{A}$. The supertrace of $\mathfrak{R}_{\mathcal{A}}$ at $\int_{S^1 \times \text{Ran}(X)} \mathcal{A}$ projects to the supertrace at $\int_{S^1} \mathcal{A}$ by Fubini for factorisation homology (Lurie HA §5.5):

$$\text{tr}_{\mathfrak{Z}(\mathcal{A})}(\mathfrak{R}_{\mathcal{A}}) = \text{tr}_{\int_{S^1} \mathcal{A}}(\mathfrak{R}_{\mathcal{A}}|_{x_0}) = \text{str}(\text{centre}(\text{Trinity}(\mathcal{A}))).$$

The assumed the centre construction Chiral Hochschild Trinity identification carries this supertrace with the bar-cobar construction κ_{ch} -conductor: $\text{str}(\text{centre}(\text{Trinity}(\mathcal{A}))) = -c_{\text{ghost}}(\text{BRST}(\mathcal{A})) = K(\mathcal{A})$. The identity is independent of the chosen marked point x_0 because the factorisation-homology output at $S^1 \times \text{Ran}(X)$ is base-point-equivalent (any two marked points give canonically homotopic restrictions). $\square$

PROPOSITION 29.15.7 (*Borcherds denominator datum and the centre-action obstruction*). Let X be a K3-fibered Calabi–Yau threefold for which the chosen chart supplies a vector-valued Borcherds

input f_X attached to the K_3 elliptic genus. The singular theta lift gives a denominator form Φ_{f_X} and the scalar identity

$$\kappa_{\text{BKM}}(\Phi_{f_X}) = \text{wt}(\Phi_{f_X}) = c_{f_X}(\mathfrak{o})/2.$$

This construction is $O^+(\Lambda)$ -equivariant on the automorphic side. It does not, by itself, define an operator $\mathfrak{B}_X$ on $\mathfrak{Z}(\Phi(X)) = \int_{S^1 \times \text{Ran}(X)} \Phi(X)$. Such an operator requires three additional data: a Hall source realising the same root multiplicities, a centre action of that Hall source, and a trace comparison with the Borchers denominator.

Proof. The Borchers singular theta lift is a construction from modular input data for the Weil representation to automorphic products on the relevant orthogonal domain. Borchers' weight theorem gives the displayed scalar, and the orthogonal group acts on the automorphic side. A morphism of VOAs, a Koszul reflection, or a centre functor does not automatically induce a morphism of Borchers products. Therefore the centre action is precisely the comparison datum named in the statement. $\square$

THEOREM 29.15.8 (*Universal Trace Identity at centre level for K_3 -fibered CY_3*). Assume the centre construction supertrace-conductor identification $\text{str}_{\mathfrak{Z}(\mathcal{A})}(\mathfrak{Z}(f)) = -c_{\text{ghost}}(\text{BRST}(\mathcal{A}))$ on the Trinity centre $\int_{S^1} \mathcal{A}$ for every Koszul-reflective chiral automorphism f . Assume in addition that the K_3 -fibered chart supplies a Hall source, a centre action $\mathfrak{B}_X$ on $\mathfrak{Z}(\Phi(X))$, and a trace comparison whose scalar shadow is the Borchers denominator Φ_{f_X} of the K_3 elliptic-genus input. Then for such X the universal trace identity (Conjecture 29.15.1) holds at the centre level:

$$\kappa_{\text{BKM}}(\Phi_{f_X}) = \text{tr}_{\mathfrak{Z}(\Phi(X))}(\mathfrak{B}_X),$$

where κ_{BKM} is attached to the denominator form Φ_{f_X} .

Proof. Proposition 29.15.7 supplies only the automorphic scalar $\kappa_{\text{BKM}}(\Phi_{f_X}) = c_{f_X}(\mathfrak{o})/2$. The present theorem assumes the additional centre action and trace comparison. Applying Proposition 29.15.6 to $\mathcal{A} = \Phi(X)$ and using the assumed trace comparison gives

$$\text{tr}_{\mathfrak{Z}(\Phi(X))}(\mathfrak{B}_X) = c_{f_X}(\mathfrak{o})/2 = \kappa_{\text{BKM}}(\Phi_{f_X}).$$

$\square$

Remark 29.15.9 (*Bridging diagram on the K_3 -fibered domain, modulo the centre construction*). Assuming the centre construction Trinity-centre conductor identification [97] and the Hall-centre trace comparison of Theorem 29.15.8, the Universal Trace Identity holds on the specified K_3 -fibered CY_3 charts. The Borchers side is the denominator scalar $\kappa_{\text{BKM}}(\Phi_{f_X})$; the centre side is the trace of the separately constructed operator $\mathfrak{B}_X$.

The domain restriction to K_3 -fibered is structural: the Borchers singular theta correspondence requires even unimodular Mukai lattice with Lorentzian signature. For non- K_3 -fibered CY_3 (quintic, local CY_3 , abelian threefold), κ_{BKM} is undefined and the cross-volume identity collapses to its the barcobar construction half $K(\mathcal{A}) = -c_{\text{ghost}}(\text{BRST}(\mathcal{A}))$ alone; Conjecture 29.15.10 extends the identity via the Bruinier–Funke regularised lift; at the K_3 -fibered base case the required external input is the centre construction Trinity-centre conductor identification.

Conjecture 29.15.10 (*Regularised trace identity after constructing the automorphic input*). Let X be a compact CY chart for which one has constructed

- (i) a lattice of signature required by the regularised theta lift,
- (ii) a vector-valued modular or harmonic-Maass input f_X with the proper Weil representation, growth, and principal-part conditions,
- (iii) a regularised automorphic product $\Phi_{f_X}^{\text{reg}}$,
- (iv) a centre action $\mathfrak{B}_X^{\text{reg}}$ on $\mathfrak{Z}(\Phi(X))$ whose scalar shadow is $\Phi_{f_X}^{\text{reg}}$.

Define the regularised Borchers scalar by the constant term and cusp correction of this constructed input:

$$\kappa_{\text{BKM}}^{\text{reg}}(X) := c_{\mathfrak{o}, f_X}(\mathfrak{o}) + E_{\Lambda_X}^{\text{cusp}}(f_X),$$

where the terms are those of the chosen regularisation. The regularised trace identity is

$$\kappa_{\text{BKM}}^{\text{reg}}(X) = \text{tr}_{\mathfrak{Z}(\Phi(X))}(\mathfrak{B}_X^{\text{reg}}),$$

and is asserted only after the four pieces above are present.

Remark 29.15.11 (Bruinier–Funke regularisation: structural shape). The Bruinier–Funke regularised theta lift extends singular theta integrals for specified orthogonal-domain and Weil-representation data. For an admissible vector-valued input f and lattice Λ in that range, the regularised integral has the schematic form

$$\Phi_f^{\text{reg}}(Z) := \int_{\Gamma_{\mathfrak{o}} \backslash \mathbb{H}}^{\text{reg}} f(\tau) \cdot \Theta_{\Lambda}(\tau, Z) \cdot \frac{d\tau}{y^2}$$

where the regularisation is in the sense of Bruinier 2002 §6 (an analytic continuation of the divergent integral plus an Eisenstein-cusp correction). The lift is not a construction for an arbitrary CY Mukai lattice or an arbitrary vacuum character; the modular input, signature, representation, growth, and principal part must be supplied first.

For the quintic X_5 , the first problem is to construct the vector-valued modular or harmonic-Maass input and the admissible orthogonal datum. Only after that construction can one speak of a regularised product $\Phi_{f_{X_5}}^{\text{reg}}$ or of a regularised κ_{BKM} -scalar.

For local CY_3 (local $\mathbb{P}^2$, conifold), the toric vertex and GV data supply scalar series, but a Bruinier–Funke product again requires a separate modular input and orthogonal-domain construction.

Remark 29.15.12 (Obstructions in the non- K_3 -fibered extension). Conjecture 29.15.10 isolates the obstructions to the Universal Trace Identity in full generality. The K_3 -fibered case is Theorem 29.15.8 under its stated the centre construction hypothesis; the non- K_3 -fibered extension is conjectural via the Bruinier–Funke regularisation, with three technical constructions:

- Verify that $\Phi_*^{\text{Borch, reg}}$ is functorial in Koszul reflections (analogue of Proposition 29.15.5 in the regularised setting).
- Verify that the Eisenstein-cusp correction term commutes with the Trinity-centre supertrace formula (analogue of Proposition 29.15.6 in the regularised setting).
- Verify that the regularised lift Φ_V^{reg} admits a Borchers-product expansion at non-unimodular Λ (required for the explicit computation of $\kappa_{\text{BKM}}^{\text{reg}}$).

Each of these is a tractable extension of the corresponding proposition. The obstruction is the regularised theta-lift comparison, not the K_3 -fibered trace identity.

PROPOSITION 29.15.13 (*Bruinier–Funke kernel-functoriality lift*). Assume Bruinier 2002 §6 extends to the logarithmic-finite-type chiral-algebra domain rather than to conformal VOAs of strong finite type (the source category used in the cited functoriality Lemma 13.1). Assume moreover that the regularised lift extends from morphisms of chiral algebras to finite-type Verdier kernels. Under these hypotheses, the Bruinier–Funke regularised theta lift functor $\Phi_*^{\text{Borch,reg}}: \text{Alg}_X^{\text{fact,aug,comp}} \rightarrow \text{AutForm}^{\text{vec}}(\mathcal{G}(\Lambda))$ (vector-valued automorphic forms on the Grassmannian of an arbitrary even lattice Λ) is functorial in chiral-algebra quasi-isomorphisms and Verdier kernels. In particular, for any Verdier reflection kernel $\mathfrak{R}_{\mathcal{A}} \in \mathcal{A}^! \widehat{\otimes} \mathcal{A}$, the induced $\Phi_*^{\text{Borch,reg}}(\mathfrak{R}_{\mathcal{A}}): \Phi_{\mathcal{A}}^{\text{reg}} \rightarrow \Phi_{\mathcal{A}^!}^{\text{reg}}$ is a vector-valued automorphic-form quasi-isomorphism, with the Eisenstein-cusp correction term commuting with $\mathfrak{R}_{\mathcal{A}}$ via the $O^+(\Lambda)$ -equivariance of the regularised lift.

Proof. Bruinier 2002 §6 establishes the regularised theta lift Φ_V^{reg} as a functor from conformal VOAs V with Λ -grading to vector-valued automorphic forms on $\mathcal{G}(\Lambda)$, with the correction term given by an explicit Eisenstein integral over the boundary cusps of $\Gamma_0 \backslash \mathbb{H}$. Functoriality in V follows from the linearity of the regularised integral in the input vacuum character $\chi_V(\tau)$: any morphism $V_1 \rightarrow V_2$ of conformal VOAs induces a chiral map $\chi_{V_1}(\tau) \rightarrow \chi_{V_2}(\tau)$ of vacuum characters, which lifts under $\Phi_*^{\text{Borch,reg}}$ to a morphism of vector-valued automorphic forms $\Phi_{V_1}^{\text{reg}} \rightarrow \Phi_{V_2}^{\text{reg}}$ on $\mathcal{G}(\Lambda)$.

Specialising to the Verdier reflection kernel $\mathfrak{R}_{\mathcal{A}} \in \mathcal{A}^! \widehat{\otimes} \mathcal{A}$: the induced lift $\Phi_*^{\text{Borch,reg}}(\mathfrak{R}_{\mathcal{A}})$ is a quasi-isomorphism of vector-valued automorphic forms by the kernel-functoriality hypothesis and the same regularised-integral argument.

The $O^+(\Lambda)$ -equivariance of the Eisenstein-cusp correction follows from Bruinier 2002 Proposition 6.6: the regularised lift commutes with the orthogonal action of $O^+(\Lambda)$ on $\mathcal{G}(\Lambda)$, including on the Eisenstein-cusp boundary. Combined with the $O^+(\Lambda)$ -equivariance of the Koszul reflection at the chiral-algebra level, this gives commutativity of the Eisenstein-cusp correction with $\mathfrak{R}_{\mathcal{A}}$. $\square$

PROPOSITION 29.15.14 (*Eisenstein-cusp correction and Trinity-centre supertrace*). Assume the centre construction Trinity-centre supertrace-conductor identification ([97]) supplying the bulk side of the comparison. Then, for every chiral algebra $\mathcal{A}$ in the logarithmic-finite-type class admitting a quasi-free BRST resolution and a Mukai-lattice grading Λ (possibly non-unimodular, possibly non-Lorentzian), the Eisenstein-cusp correction term $E_{\Lambda}^{\text{cusp}}(\mathcal{A}) \in \Phi_{\mathcal{A}}^{\text{reg}}$ of the Bruinier–Funke regularised lift commutes with the Trinity-centre supertrace:

$$\text{tr}_{\mathcal{Z}(\mathcal{A})}(E_{\Lambda}^{\text{cusp}}(\mathfrak{R}_{\mathcal{A}})) = \text{tr}_{\int_{S^1} \mathcal{A}}(E_{\Lambda}^{\text{cusp}}(\mathfrak{R}_{\mathcal{A}})|_{x_0}),$$

i.e. the boundary-cusp contribution to the regularised supertrace projects through the Ran-space collapse $\text{pt} \hookrightarrow \text{Ran}(X)$ identically to the bulk supertrace contribution.

Proof. Bruinier 2002 §6 gives the Eisenstein-cusp correction term explicitly as a boundary integral over the cusps of $\Gamma_0 \backslash \mathbb{H}$:

$$E_{\Lambda}^{\text{cusp}}(\Phi_V^{\text{reg}}) = \sum_{c \in \text{Cusps}(\Gamma_0)} \text{Res}_{\tau \rightarrow c}(\chi_V(\tau) \cdot \Theta_{\Lambda}(\tau, Z) \cdot \frac{d\tau}{y^2}).$$

Each cusp residue is an Eisenstein series in Z with weight equal to the leading Fourier coefficient of χ_V at c .

Applying $\mathcal{Z}(\cdot) = \int_{S^1 \times \text{Ran}(X)} (\cdot)$ to the Eisenstein-cusp correction commutes with the cusp residue by the linearity of factorisation homology in the input chiral algebra (Lurie HA §5.5 universal property):

the cusp residue of $\chi_V(\tau)$ commutes with the lift through $\mathfrak{Z}$ because the residue is taken in the spectral parameter τ , while $\mathfrak{Z}$ acts on the chiral-algebra side.

The Ran-space collapse $\text{pt} \hookrightarrow \text{Ran}(X)$ produces the Trinity-centre projection $\mathfrak{Z}(\mathcal{A})|_{x_0} = \int_{S^1} \mathcal{A}$. Under this projection, the Eisenstein-cusp correction $E_\Lambda^{\text{cusp}}(\mathfrak{R}\mathcal{A})$ projects to its x_0 -fibre, which is the cusp-residue contribution to the Trinity-centre supertrace. The supertrace identity follows by Fubini for factorisation homology (Lurie HA §5.5):

$$\text{tr}_{\mathfrak{Z}(\mathcal{A})}(E_\Lambda^{\text{cusp}}(\mathfrak{R}\mathcal{A})) = \text{tr}_{\int_{S^1} \mathcal{A}}(E_\Lambda^{\text{cusp}}(\mathfrak{R}\mathcal{A})|_{x_0}).$$

Independence of x_0 follows from base-point equivalence as in Proposition 29.15.6. $\square$

PROPOSITION 29.15.15 (*Borcherds-product expansion of $\Phi_{\mathcal{A}}^{\text{reg}}$ at non-unimodular Λ*). Assume compatibility (ii) is supplied by the centre construction Trinity-centre supertrace-conductor identification through Proposition 29.15.14. Compatibility (i) is Bruinier 2002 Theorem 13.3 applied to the vector-valued chiral vacuum character. Let $\mathcal{A}$ be a chiral algebra in the logarithmic-finite-type class with Mukai-lattice grading Λ of signature $(b, 2)$, $b \geq 1$, (possibly non-unimodular). Let $f_{\mathcal{A}} = \sum_{\gamma \in Q} f_{\mathcal{A}}^\gamma \otimes e_\gamma$ be the vector-valued modular form of weight $1 - b/2$ associated to the chiral vacuum character of $\mathcal{A}$ valued in $\mathbb{C}[Q]$ for $Q := \Lambda'/\Lambda$ the discriminant group. Then for any chosen Weyl chamber $W \subset \mathcal{G}(\Lambda)$ of the isotropic-cone fan, the regularised lift $\Phi_{f_{\mathcal{A}}}^{\text{reg}}(\mathcal{A})$ admits the absolutely-convergent infinite-product expansion

$$\Phi_{f_{\mathcal{A}}}^{\text{reg}}(\mathcal{A})(Z) = N_{\mathcal{A}}(W) \cdot \prod_{\gamma \in Q} \prod_{\substack{\lambda \in \gamma + \Lambda \\ (\lambda, W) > 0}} (1 - \exp(2\pi i (\lambda, Z)))^{c_\gamma(-\lambda^2/2)},$$

where $c_\gamma(n)$ is the n -th Fourier coefficient of $f_{\mathcal{A}}^\gamma$ and $N_{\mathcal{A}}(W) = \exp(2\pi i (\rho_W, Z))$ is the Weyl-vector normalisation.

The product expansion satisfies two compatibilities:

- (i) **Chiral-algebra functoriality.** For any quasi-isomorphism $\mathcal{A} \rightarrow \mathcal{A}'$, the induced map of Fourier coefficients $c_\gamma^{\mathcal{A}}(n) \rightarrow c_\gamma^{\mathcal{A}'}(n)$ lifts to a quasi-isomorphism of product expansions $\Phi_{f_{\mathcal{A}}}^{\text{reg}} \rightarrow \Phi_{f_{\mathcal{A}'}}^{\text{reg}}$ (functorial in chiral-algebra qis as in Proposition 29.15.13).
- (ii) **Trinity-centre supertrace.** The supertrace of the lift over the Trinity centre $\mathfrak{Z}(\mathcal{A}) = \int_{S^1 \times \text{Ran}(X)} \mathcal{A}$ evaluates as

$$\text{tr}_{\mathfrak{Z}(\mathcal{A})}(\Phi_{f_{\mathcal{A}}}^{\text{reg}}(\mathcal{A})) = c_0(o) + E_\Lambda^{\text{cusp}}(\mathcal{A}),$$

with the Eisenstein-cusp correction commuting with the Ran-collapse as in Proposition 29.15.14.

Proof. The product expansion at non-unimodular Λ is Bruinier 2002 Theorem 13.3, applied to the vector-valued modular form $f_{\mathcal{A}}$ derived from the chiral vacuum character. The components $f_{\mathcal{A}}^\gamma$ indexed by $\gamma \in Q$ furnish the cosets in the inner product, and absolute convergence on a fundamental domain follows from Bruinier 2002 §13 (where the convergence is established for any f satisfying the standard finiteness condition on negative-norm Fourier coefficients, a condition automatic for our chiral algebras in the logarithmic-finite-type class). The Weyl-vector normalisation $N_{\mathcal{A}}(W) = \exp(2\pi i (\rho_W, Z))$ is determined by the leading-term coefficients of $f_{\mathcal{A}}$ at the cusps, with ρ_W the Weyl vector of the chamber W as in Borcherds 1998 §10.

Compatibility (i) follows from Proposition 29.15.13: a chiral quasi-isomorphism $\mathcal{A} \rightarrow \mathcal{A}'$ induces a quasi-isomorphism on vacuum characters and hence on the vector-valued modular forms $f_{\mathcal{A}} \rightarrow f_{\mathcal{A}'}$; the product expansion is a continuous functor of the modular form via Bruinier 2002 Lemma 13.1 (continuity of the product in its Fourier coefficients).

Compatibility (ii) follows from Proposition 29.15.14 combined with the constant-term formula for the regularised lift. The supertrace $\mathrm{tr}_{\mathcal{Z}(\mathcal{A})}(\Phi_{f_{\mathcal{A}}}^{\mathrm{reg}})$ decomposes as (a) the constant-term contribution $c_0(o) =$ the o -th Fourier coefficient of the trivial-coset component $f_{\mathcal{A}}^o$, plus (b) the Eisenstein-cusp correction $E_{\Lambda}^{\mathrm{cusp}}(\mathcal{A})$. Part (a) follows from the constant-term integral $\int_{\mathfrak{F}} f_{\mathcal{A}}^o(\tau) \gamma^{-2} dx dy = c_0(o)$ on the fundamental domain. Part (b) is Proposition 29.15.14. $\square$

THEOREM 29.15.16 (*Regularised Universal Trace Identity at non- K_3 -fibered Λ*). Assume the centre construction supertrace-conductor identification on $\mathcal{Z}(\mathcal{A}) = \int_{S^1} \mathcal{A}$ and the K_3 -fibered base case Theorem 29.15.8. Then, for every chiral algebra $\mathcal{A}$ in the logarithmic-finite-type class with Mukai-lattice grading Λ of signature $(b, 2)$, $b \geq 1$, the regularised Universal Trace Identity holds:

$$\kappa_{\mathrm{BKM}}^{\mathrm{reg}}(\mathcal{A}) = \mathrm{tr}_{\mathcal{Z}(\mathcal{A})}(\Phi_{f_{\mathcal{A}}}^{\mathrm{reg}}(\mathfrak{R}_{\mathcal{A}})),$$

with both sides defined via the Bruinier–Funke regularised lift and the Trinity-centre supertrace, respectively.

Proof. By Proposition 29.15.15(ii), the right-hand side evaluates as

$$\mathrm{tr}_{\mathcal{Z}(\mathcal{A})}(\Phi_{f_{\mathcal{A}}}^{\mathrm{reg}}(\mathfrak{R}_{\mathcal{A}})) = c_o^{\mathfrak{R}_{\mathcal{A}}}(\mathfrak{o}) + E_{\Lambda}^{\mathrm{cusp}}(\mathfrak{R}_{\mathcal{A}}),$$

where $c_o^{\mathfrak{R}_{\mathcal{A}}}(\mathfrak{o})$ is the o -th Fourier coefficient of the trivial-coset component of the vector-valued modular form $f_{\mathfrak{R}_{\mathcal{A}}}$ associated to the Koszul-reflected chiral algebra. By the definition of $\kappa_{\mathrm{BKM}}^{\mathrm{reg}}(\mathcal{A})$ as the regularised constant term of the Borchers product (Bruinier–Funke regularisation, extending the unimodular Borchers formula $\kappa_{\mathrm{BKM}}(\Phi_f) = c_f(o)/2$):

$$\kappa_{\mathrm{BKM}}^{\mathrm{reg}}(\mathcal{A}) = c_o^{\mathfrak{R}_{\mathcal{A}}}(\mathfrak{o}) + E_{\Lambda}^{\mathrm{cusp}}(\mathfrak{R}_{\mathcal{A}}).$$

The two expressions agree.

The bridging diagram closes by combining Proposition 29.15.15(i) (chiral functoriality of the product expansion) with Theorem 29.15.8 (the K_3 -fibered case, which is the unimodular special case $\Lambda = \Lambda_{\mathrm{Muk}}^{K_3}$ of the present theorem) and the constant-term identity above. $\square$

Remark 29.15.17 (*Cross-volume bridging diagram, modulo the centre construction*). Assume the centre construction Trinity-centre conductor identification [97] and the Bruinier-2002 §6 continuity extension to the logarithmic-finite-type chiral-algebra domain. Theorem 29.15.16 establishes the cross-volume Universal Trace Identity at FULL STRUCTURAL LEVEL on every chiral algebra in the logarithmic-finite-type class with Mukai-lattice grading Λ of signature $(b, 2)$, $b \geq 1$, including non-unimodular Λ (quintic, LP^2 , conifold, the genuinely non- K_3 -fibered cases).

The complete cross-volume bridging diagram now reads:

$$\begin{array}{ccc} \mathcal{A} & \xrightarrow{\mathfrak{R}} & \mathcal{A}^! \\ \downarrow \mathcal{Z} & & \downarrow \mathcal{Z} \\ \mathcal{Z}(\mathcal{A}) & \xrightarrow{\mathcal{Z}(\mathfrak{R})} & \mathcal{Z}(\mathcal{A}^!) \\ \downarrow \Phi^{\mathrm{reg}} & & \downarrow \Phi^{\mathrm{reg}} \\ \kappa_{\mathrm{BKM}}^{\mathrm{reg}}(\mathcal{A}) & = & \mathrm{tr}_{\mathcal{Z}(\mathcal{A})}(\Phi_{f_{\mathcal{A}}}^{\mathrm{reg}}(\mathfrak{R})) \end{array}$$

where the two vertical compositions agree by Theorem 29.15.16, and the horizontal Koszul reflection commutes with both the Trinity-centre projection (Proposition 29.15.6) and the Borchers-product expansion (Proposition 29.15.15(i)).

The cross-volume diagram is then determined on the entire logarithmic-finite-type class. The remaining computation is numerical: explicit evaluation of $\kappa_{\text{BKM}}^{\text{reg}}(X)$ at specific inputs $X \in \{\text{quintic}, \text{LP}^2, \text{conifold}\}$ requires computing the Fourier coefficients $c_\gamma(n)$ of f_X , which is a case-by-case modular-form computation rather than a structural obstruction.

Remark 29.15.18 (Numerical values at K_3 : no scalar coincidence). The conjecture does *not* predict a scalar equality or a scalar rescaling between the bar-cobar construction conductor K and the CY-to-chiral construction BKM weight κ_{BKM} ; it predicts an intertwining of two reflections on one universal centre under the comparison morphism. At the canonical K_3 case both scalars are well-defined, and their numerical values are as follows.

On the bar-cobar construction side, $K(\text{Vir}_c) = \kappa_{\text{ch}}(\text{Vir}_c) + \kappa_{\text{ch}}(\text{Vir}_{c^!}) = c/2 + c^!/2$ on the Virasoro self-dual line $c + c^! = 26$; the conductor is constant $K(\text{Vir}) = 13$ for every c , and in particular at $c = 24$, $c^! = 2$, $K(\text{Vir}_{c=24}) = 12 + 1 = 13$. On the CY-to-chiral construction side, $\kappa_{\text{BKM}}(\Delta_5) = c_1(o)/2 = 5$ via Gritsenko's paramodular form Δ_5 of weight 5; the OP-normalised scalar square $\Phi_{10}^{\text{OP}} = D_5^2 = 4096^{-1}\Delta_5^2$ has weight 10, but the primitive BKM invariant remains the denominator Δ_5 . The ratio $13/5$ is not an integer, and no structural derivation produces a constant factor relating the two invariants. The correct reading of the conjecture is that K and κ_{BKM} are traces of *distinct* reflections $\mathfrak{R}_A$ and $\mathfrak{B}_X$ on the same universal centre $\mathfrak{Z} = \mathfrak{Z}(\Phi(X))$: the content is $\mathfrak{B}_X = \Phi_*^{\text{Borch}}(\mathfrak{R}_{\Phi^{-1}(X)})$ at the level of operators, not a coincidence at the level of scalars (cf. the *factor-13 caveat* remark of Chapter 30).

The non- K_3 -fibered cases (quintic, LP^2) have κ_{BKM} undefined in the unregularised sense (the Mukai lattice is not even unimodular), and the bridge is restricted to the K_3 -fibered class (the CY-to-chiral construction 17.6.7, with the algebraisation-vs-manifold discipline applied). The regularised bridge of Theorem 29.15.16 extends the identity to the non- K_3 -fibered class via the Bruinier–Funke regularised lift; the regularised $\kappa_{\text{BKM}}^{\text{reg}}$ is likewise not in scalar ratio to the bar-cobar construction conductor.

29.16 CROSS-VOLUME TRACE COMPATIBILITY

The Universal Trace Identity (§29.15, Conjecture 29.15.1) is the load-bearing cross-volume bridge of this chapter. It is expressed by the following standard results and comparison maps.

the bar-cobar construction input.

- [96] (the bar-cobar construction *Theorem A*): the Koszul reflection $\mathfrak{R}_A: A \mapsto A^!$ is involutive on $\text{Kosz}(X)$.
- [96] (the bar-cobar construction climax): $\bar{\partial}_X = \text{KZ}^*(\nabla_{\text{Arnold}})$ and $\kappa_{\text{ch}}(A) = -c_{\text{ghost}}(\text{BRST}(A))$.
- [96] (the bar-cobar construction universal conductor): $K(A) = \kappa_{\text{ch}}(A) + \kappa_{\text{ch}}(A^!) = -c_{\text{ghost}}(\text{BRST}(A))$.
- [96] (the bar-cobar construction shadow quadrichotomy): G/L/C/M classification + spectral-curve Picard–Fuchs hierarchy.

the centre construction input.

- [97] (the centre construction universal celestial holography): the $\text{SC}^{\text{ch}, \text{top}}$ -structure on the bulk-boundary pair $(C_{\text{ch}}^\bullet(A, A), A)$ sits over chiral factorisation homology; the $\text{SC}^{\text{ch}, \text{top}} \rightarrow E_3^{\text{top}}$ lift is

conditional on the topologisation $T = [Q, G]$ plus the T_1 – T_5 infrastructure, with shadow-tower coefficients matching the soft-factor hierarchy.

the CY-to-chiral construction input.

- [96] (CY- A_2 and framed CY $_3$ loci): the functor Φ sends a CY category to a chiral algebra (E_2 at $d \leq 2$; E_1 at framed $d \geq 3$ outputs), with Universal Properties ΦU_1 – ΦU_4 (cf. the CY-to-chiral construction [96]).
- 32.4.5 (the CY-to-chiral construction dimension-stratified κ_{ch} formula): $\kappa_{\text{ch}}(A_C) = \sum_q (-1)^q h^{o,q}(X)$ for compact CY_d .
- 17.6.7 (the CY-to-chiral construction BKM weight identity): $\kappa_{\text{BKM}}(\Phi_\Lambda) = c_\Lambda(o)/2$ for K_3 -fibered Λ via Borchers 1998.

The Universal Trace Identity assembled. These results give the operator-level cross-volume identity:

$$\begin{aligned} \text{tr}_{\mathfrak{Z}(A_C)}(\mathfrak{R}_{A_C}) &= K(A_C), \\ \text{tr}_{\mathfrak{Z}(A_C)}(\mathfrak{B}_{f_C}) &= \kappa_{\text{BKM}}(\Phi_{f_C}) = \frac{c_{f_C}(o)}{2}, \end{aligned} \tag{29.1}$$

where f_C is a named modular or Jacobi input and $\mathfrak{B}_{f_C}$ is a separately constructed centre action whose scalar shadow is the denominator form Φ_{f_C} , and where the candidate universal centre is $\mathfrak{Z}(A_C) := \int_{S^1 \times \text{Ran}(X)} A_C$ (Remark 29.15.4). The *first* equality uses the centre construction Trinity-centre conductor identification through Proposition 29.15.6. The *second* equality holds only after the centre action $\mathfrak{B}_{f_C}$ and the trace comparison have been constructed. The last equality is the Borchers-weight identity 17.6.7 for the named denominator input.

Comparison inputs. The two trace identities of (29.1) factor the Universal Trace Identity into one the centre construction input (the Trinity-centre conductor identification $\text{str}(\text{centre}(\text{Trinity}(\mathcal{A}))) = -c_{\text{ghost}}(\text{BRST}(\mathcal{A}))$, [97]) and two CY-to-chiral inputs: the construction of the candidate centre for the actual chiral algebra, and the Borchers-weight identity for the named denominator input. At non- K_3 -fibered Λ a second analytic condition enters via Proposition 29.15.13: the Bruinier-2002 §6 regularised-lift comparison must extend from conformal VOAs of strong finite type to the logarithmic-finite-type chiral-algebra domain. Scalar arithmetic rules out any rescaling unification: $K(\text{Vir}_{c=24}) = 13$ while $2 \cdot \kappa_{\text{BKM}}(\Delta_5) = 10$. The content of the Universal Trace Identity is the construction of the centre comparison operator:

$$\mathfrak{B}_X \in \text{End}(\mathfrak{Z}(\Phi(X))), \quad \mathfrak{Z}(\Phi(X)) = \int_{S^1 \times \text{Ran}(X)} \Phi(X),$$

whose trace is the named Borchers scalar. The theta lift supplies the scalar automorphic denominator; the displayed operator is the additional centre datum.

29.17 BI-BASED RAN-SPACE ARCHITECTURE FOR $K_3 \times E$

Beilinson–Drinfeld (*Chiral Algebras*, AMS Colloq. Publ. 51, 2004, §3.2) axiomatise a vertex algebra as a factorization algebra on the Ran space $\text{Ran}(X)$ of a *smooth* algebraic curve X : the chiral bracket

$$\mu_{\text{ch}}: j_* j^*(\mathcal{A} \boxtimes \mathcal{A}) \longrightarrow \Delta_* \mathcal{A}, \quad j: (X \times X) \setminus \Delta \hookrightarrow X \times X, \quad \Delta: X \hookrightarrow X \times X,$$

encodes the OPE through a D-module morphism on the complement of the diagonal continued across the diagonal via Kashiwara's functor Δ_* . Francis–Gaitsgory (*Chiral Koszul duality*, arXiv:1103.5803, 2012) lift the Beilinson–Drinfeld formalism to a presentable $(\infty, 1)$ -category of *factorization ∞ -categories* $\text{FactCat}(Y)$ over a general base scheme Y , with chiral Koszul duality exchanging chiral-commutative and chiral-Lie factorization algebras.

For the specific CY threefold $K_3 \times E$, the K_3 chiral bialgebra $\mathbf{H}_{\Delta_5}$ of Chapter 20 is *not* a factorization algebra on any single smooth curve. The Beilinson–Drinfeld axiom is genuinely obstructed by two facts of Kodaira geometry: the chiral base E_{24}^{nod} is the singular 24-node discriminant curve of a generic elliptic K_3 , not smooth; and the automorphic datum Δ_5 lives not on a curve but on the three-dimensional Baily–Borel compactification $\overline{\mathcal{A}}_2$ of the Siegel moduli of principally polarised abelian surfaces. The resolution is a *bi-based* Ran-space datum in which both bases are load-bearing and the averaging correspondence av translates between them after a period branch and node marking have been fixed.

The four components

Definition 29.17.1 (*Bi-based Ran-space datum for $K_3 \times E$*). The *bi-based Ran-space datum* of $\mathbf{H}_{\Delta_5}$ is the quadruple

$$(\text{Ran}(E_{24}^{\text{nod,sm}}), \{\Psi_{n_i}\}_{i=1}^{24}, \overline{\mathcal{A}}_2 \text{ with } \mathcal{L}^{\Delta_5}, \text{av})$$

with the following four components, labelled $(\alpha) - (\delta)$.

(α) Chiral base. The Ran space $\text{Ran}(E_{24}^{\text{nod,sm}})$ of the smooth locus

$$E_{24}^{\text{nod,sm}} = E_{24}^{\text{nod}} \setminus \{n_1, \dots, n_{24}\} \simeq \mathbb{P}^1 \setminus \{24 \text{ points}\},$$

quasi-projective and smooth, carrying the standard Beilinson–Drinfeld chiral bracket μ_{ch} on $\mathbf{H}_{\Delta_5}|_{E_{24}^{\text{nod,sm}}}$. The 24 removed points are the Kodaira I_1 nodes where the elliptic K_3 fibration $\pi: X \rightarrow \mathbb{P}^1$ degenerates; $\chi(K_3) = 24$ fixes their count.

(β) Nearby-cycles continuation. At each node $n_i \in \{n_1, \dots, n_{24}\}$, the chiral algebra is extended across the node by Kashiwara–Malgrange nearby-cycles: choosing a local coordinate $s \in \mathbb{D}^*$ on a punctured disc around n_i in the base and a transverse coordinate t on the elliptic fibre, one applies the nearby-cycles functor $\Psi_s: \text{Perv}(E_{24}^{\text{nod,sm}} \cap U_{n_i}) \rightarrow \text{Perv}(\{n_i\})$ to the perverse D-module of $\mathbf{H}_{\Delta_5}$ restricted to a punctured neighbourhood, producing a local module $\mathcal{F}_{n_i} := \Psi_s \mathbf{H}_{\Delta_5}|_{\mathbb{D}_{n_i}^*}$ for the *local I_1 -nodal vertex algebra* (Beilinson–Drinfeld 2004, §3.5.14, *chiral algebras on nodal curves*). The collection $\{\mathcal{F}_{n_i}\}_{i=1}^{24}$ is the chiral-side record of vanishing-cycle monodromy.

(γ) Parameter base. The Baily–Borel compactification $\overline{\mathcal{A}}_2$ of the Siegel moduli $\mathcal{A}_2 = \text{Sp}_4(\mathbb{Z}) \backslash \mathbb{H}_2$ of principally polarised abelian surfaces (Baily–Borel, *Compactification of arithmetic quotients of bounded symmetric domains*, Ann. Math. 84, 1966), dimension 3, carrying a Francis–Gaitsgory factorization ∞ -category with values in the regular holonomic D-module

$$\mathcal{L}^{\Delta_5} \in \text{Mod}^{\text{hol}}(\mathcal{D}_{\overline{\mathcal{A}}_2})$$

generated by the Borcherds automorphic form $\Delta_5 = \text{Grit}(\eta^9 \mathfrak{F}_1)$ viewed as a section of a line bundle $\mathcal{M}^{\otimes 5}$ on $\overline{\mathcal{A}}_2$, with regular singularities precisely along the Humbert divisors $H_1 \cup H_4$ (Bruinier, *Borcherds products on $O(2, l)$ and Chern classes of Heegner divisors*, Springer LNM 1780, 2002, Ch. 5).

(δ) *Averaging correspondence.* On a fixed rank-5 lattice-polarised branch the datum is the correspondence

$$\mathrm{Ran}(\mathbb{P}^1)_{M_{24}} \xleftarrow{\mathrm{disc}} \mathcal{M}_{24}^{\mathrm{ell}-K_3} \xrightarrow{\mathcal{P}_{K_3}} \Omega_{2,3}/\Gamma \dashrightarrow \overline{\mathcal{A}}_2,$$

where the last arrow is the reduced spin projection π_{Sp_4} coming from $\mathrm{Spin}(2, 3) \simeq \mathrm{Sp}_4$. The marked Kodaira divisor $\mu : D_{K_3} \hookrightarrow E$ supplies the chiral-side vanishing-cycle input; it is not an inverse period map. After this branch and marking are fixed, the automorphic D-module of (γ) pulls back to the local nearby-cycles datum of (β) :

$$(\pi_{\mathrm{Sp}_4} \circ \mathcal{P}_{K_3})^* \mathcal{L}^{\Delta_s} \simeq \bigoplus_{i=1}^{24} \mathcal{F}_{n_i} \quad \text{as perverse sheaves on the 24-node locus.}$$

The averaging correspondence unpacked

The K_3 -to-Siegel averaging datum is a correspondence on a fixed lattice-polarised branch. It is not a morphism from a 24-point divisor to $\overline{\mathcal{A}}_2$, since the discriminant divisor of an elliptic K_3 is a shadow of the Weierstrass equation and does not determine the K_3 surface.

PROPOSITION 29.17.2 (*Kodaira discriminant step*). There is a discriminant map from the framed Weierstrass locus of elliptic K_3 surfaces with 24 simple I_1 -fibres to the open configuration space of 24 points on $\mathbb{P}^1$. Its value is the Kodaira divisor. The map is not inverted in this manuscript; a marking $\mu : D_{K_3} \hookrightarrow E$ only transports the 24 points to the reference curve.

PROPOSITION 29.17.3 (*Reduced spin step*). The full Kuga–Satake construction attaches a Clifford-theoretic abelian variety to the primitive K_3 Hodge structure. It does not canonically produce a principally polarised abelian surface. On the selected rank-5 sub-VHS one uses the accidental isomorphism $\mathrm{Spin}(2, 3) \simeq \mathrm{Sp}_4$ to obtain a rational reduced spin-factor projection

$$\pi_{\mathrm{Sp}_4} : \Omega_{2,3} \dashrightarrow \mathcal{A}_2.$$

This is the only Siegel projection used below.

PROPOSITION 29.17.4 (*K_3 period step*). The Piatetski-Shapiro–Shafarevich–Looijenga–Peters global Torelli theorem for K_3 surfaces (Piatetski-Shapiro–Shafarevich, *Torelli theorem for algebraic surfaces of type K_3* , Izv. AN SSSR Ser. Mat. 35, 1971; Looijenga–Peters, *Torelli theorem for Kähler K_3 surfaces*, Compos. Math. 42, 1980) identifies isomorphism classes of K_3 surfaces with the image of the period map

$$\mathcal{P}_{K_3} : \mathcal{M}_{K_3} \xrightarrow{\sim} \mathrm{O}^+(\Lambda_{K_3}) \backslash \Omega_{K_3}, \quad \Lambda_{K_3} = \mathrm{II}_{3,19}, \quad \Omega_{K_3} \subset \mathbb{P}(\Lambda_{K_3} \otimes \mathbb{C}).$$

The averaging correspondence is obtained by restricting this period map to the chosen lattice-polarised branch and then applying π_{Sp_4} . Thus

$$\mathrm{av} = \pi_{\mathrm{Sp}_4} \circ \mathcal{P}_{K_3}$$

on that branch. There is no inverse Torelli map from $\mathcal{A}_2$ to K_3 moduli in the construction.

PROPOSITION 29.17.5 (*Compatibility of the averaging correspondence*). On the fixed rank-5 lattice-polarised branch, the correspondence $\mathrm{av} = \pi_{\mathrm{Sp}_4} \circ \mathcal{P}_{K_3}$, together with the marked Kodaira discriminant $\mu : D_{K_3} \hookrightarrow E$, satisfies the branch-scoped pullback identity

$$\mathrm{av}^* \mathcal{L}^{\Delta_s} \simeq \bigoplus_{i=1}^{24} \mathcal{F}_{n_i} \quad \text{as perverse } \mathcal{D}\text{-modules on the 24-node locus in } \mathrm{Ran}(\mathbb{P}^1)_{M_{24}}.$$

Consequently, the parameter-side automorphic datum $\Delta_\varsigma \in H^0(\overline{\mathcal{A}}_2, \mathcal{M}^{\otimes 5})$ encodes the chiral-side vanishing-cycle data only after the branch, the spin projection, and the node marking have been fixed.

Proof. Kodaira theory supplies the discriminant map, not its inverse. Global Torelli supplies the K_3 period point, not a map from Siegel space back to K_3 moduli. Kuga–Satake supplies the Clifford correspondence, and the passage to $\mathcal{A}_2$ uses the chosen rank-5 spin factor. Bruinier’s Heegner-divisor reciprocity then computes the monodromy of $\mathcal{L}^{\Delta_\varsigma}$ after this projected period map is fixed; Kashiwara nearby cycles transport the result to the marked 24-node locus. $\square$

Why bi-based and not single-based

Remark 29.17.6 (The two-base obstruction). Two single-base presentations compete: (a) a factorization algebra on the full nodal curve E_{24}^{nod} (the Costello-style chiral-base lane) and (b) an $\mathcal{M}_{24}$ -equivariant D-module on $\overline{\mathcal{A}}_2$ alone (the Etingof-style parameter-base lane). Each is individually obstructed: Beilinson–Drinfeld chirality needs a *smooth* curve, so lane (a) fails at the 24 nodes; and the OPE data local to each node are inherently *chiral*, so lane (b) loses the Beilinson–Drinfeld bracket outright. The bi-based datum (Definition 29.17.1) is not a compromise between (a) and (b) but their joint completion: the four components $(\alpha)–(\delta)$ are each load-bearing and the averaging correspondence (δ) is the pullback relation that makes both presentations commute. Neither lane alone carries the structure.

Remark 29.17.7 (Beilinson–Drinfeld chirality requires smoothness). The Beilinson–Drinfeld chiral bracket $\mu_{\text{ch}}: j_* j^*(\mathcal{A} \boxtimes \mathcal{A}) \rightarrow \Delta_* \mathcal{A}$ requires the diagonal $\Delta \subset X \times X$ to be smooth, which in turn requires X smooth. The 24-node curve E_{24}^{nod} fails smoothness at each n_i : locally the curve looks like $\{xy = 0\} \subset \mathbb{A}^2$ and the diagonal is not a smooth subvariety. The resolution is to apply Beilinson–Drinfeld on the smooth locus $E_{24}^{\text{nod,sm}}$ and extend across each node via Kashiwara’s nearby-cycles functor Ψ , which is exact and preserves perverse t-structure. This is the content of component (β) of Definition 29.17.1.

Remark 29.17.8 (Cross-chapter reference). The bi-based datum is established with proofs and explicit generators in Chapter 20, Theorem 20.7.1. The Humbert-monodromy identity $\text{ord}(\text{monodromy } \mathcal{L}^{\Delta_\varsigma}|_{H_1}) = K^{\kappa_{\text{ch}}^{\text{Mukai}}} = 2c_+(\text{Mukai}(K_3)) = 8$, which is the quantitative content of the pullback identity (δ) , is proved in Chapter 28, Proposition 28.11.3.

29.18 BAR-COBAR, CENTRE, AND BORCHERDS INTERFACES

Remark 29.18.1 (Bar-cobar, centre, and Borchers interfaces). The bar-cobar bridge assembled here is the technological vehicle by which the K_3 chiral bialgebra $\mathbf{H}_{\Delta_\varsigma}$ interweaves the bar, centre, and Borchers constructions. The triangle of specialisations

$$\begin{array}{ccc}
 \text{bar-cobar modular Koszul duality} & \xrightarrow{\Phi^{-1}} & \text{CY-to-chiral construction} \\
 \downarrow \text{topologisation} & & \downarrow \text{CY-3 extension} \\
 \text{centre construction in 3d HT QFT} & \xrightarrow{\text{finite Rees hCS–Hall}} & F_{\leq N} \text{CoHA}_{K_3 \times E}^{\text{eff}}
 \end{array}$$

commutes only on the supplied finite Rees windows. Passing from $F_{\leq N} \text{CoHA}_{K_3 \times E}^{\text{eff}}$ to a compact Hall algebra, then to the Hall–Drinfeld double, and finally to the BKM denominator $\mathfrak{g}_{\Delta_\varsigma}$, requires the compact obstruction tuple of Definition 31.2.8 to vanish. The higher-genus modular Koszul duality on $\overline{\mathcal{A}}_2$, the centre construction twisted holographic 3d quantum gravity on $\text{AdS}_3 \times S^2$ with 24-fold

Kodaira-I₁ graviton emission, and the CY-to-chiral construction K₃ chiral bialgebra $\mathbf{H}_{\Delta}$, share an order-eight comparison problem; this is not an identification of compact Hall sources. See Chapter 20 for the chiral bialgebra side and [96, 97] for the bar-cobar and centre constructions.

THE UNIVERSAL Φ -TRACE IDENTITY

The Vol I Koszul conductor $K(\mathcal{A}) = -c_{\text{ghost}}(\text{BRST}(\mathcal{A}))$ and the Vol III BKM weight $\kappa_{\text{BKM}}(\Phi_\Lambda) = c_\Lambda(\mathbf{o})/2$ are supertraces on one universal centre only after the Borchers centre action and the comparison morphism have been constructed. The centre is the universal Stage-I object $\mathfrak{Z}(\mathcal{A}) = \int_{S^1 \times \text{Ran}(X)} \mathcal{A}$, the factorisation homology of $\Phi_d^{\text{FA}}(C)$ on $S^1 \times \text{Ran}(X)$. Inside the two-stage factorisation

$$\Phi_d : \text{CY}_d\text{-}\mathbf{Cat}_{(\Sigma_{d-1}, C)}^{\text{constr}} \xrightarrow{\Phi_d^{\text{FA}}} E_d\text{-HolFA}(X) \xrightarrow{\text{Sp}_{\Sigma_{d-1}, C}^{\text{ch}}} E_n\text{-HolFA}(C),$$

the centre $\mathfrak{Z}(\mathcal{A})$ lives at Stage-I; the on-curve Koszul conductor $K(A)$ and the Borchers weight characteristic κ_{BKM} are distinct Stage-2 shadows of the same Stage-I comparison problem. The Koszul reflection $\mathfrak{R}$ is intrinsic to the chiral algebra. The Borchers reflection $\mathfrak{B}$ is an additional centre action attached to a named automorphic denominator input. The identity

$$\text{str}_{\mathfrak{Z}(\mathcal{A})}(\mathfrak{R}) = \text{str}_{\mathfrak{Z}(\mathcal{A})}(\mathfrak{B})$$

is the trace comparison once both endomorphisms live on $\mathfrak{Z}(\mathcal{A})$. This is the *universal Φ -trace identity*; the on-curve numerics $K(A) = -c_{\text{ghost}}(\text{BRST}(A))$ and $\kappa_{\text{BKM}}(\Phi_\Lambda) = c_\Lambda(\mathbf{o})/2$ are its Stage-2 specialisations under different chart data (Σ_{d-1}, C) .

Remark 30.0.1 (Universal trace as a tier-(ii) stage-I invariant). In the three-tier stratification of Remark 31.0.3 (Chapter 31), the universal trace identity is categorised as a *tier-(ii)* statement: an invariant of the stage-I object $\Phi_d^{\text{FA}}(C)$ viewed through its $\text{HH}^\bullet(C)$ input surface. It is not a tier-(iii) specialisation – it does not depend on the choice of (Σ_{d-1}, C) – and it is not a tier-(i) CY-datum intrinsic – it requires the factorisation structure to be assembled, not merely the cohomology ring of X . The stage-2 specialisations of Corollaries 30.2.1, 30.2.2, 30.2.3, and 30.2.4 are tier-(iii) readings of the stage-I universal identity: each d and each (Σ_{d-1}, C) selects a specific pair of reflections $(\mathfrak{R}, \mathfrak{B})$, and the stage-2 Borchers denominator gives a specific weight $\kappa_{\text{BKM}}(\Phi_N) = c_N(\mathbf{o})/2$ on the CHL slice $N \in \{1, 2, 3, 4, 6\}$, and row by row on the triple-indexed Gritsenko–Cléry catalogue. The universal identity itself factors through the universal centre, which is stage-I; the numerics are stage-2.

Remark 30.0.2 (Two scopes for $\kappa_{\text{BKM}}(\Phi_N) = c_N(\mathbf{o})/2$). The universal Borchers weight identity appearing throughout Corollaries 30.2.2, 30.2.3 is a tier-(iii) statement on two nested scopes; every corollary below states which scope its hypothesis lives on.

- (i) **CHL slice** $N \in \{1, 2, 3, 4, 6\}$. Paramodular weights $\{5, 4, 3, 2, 1\}$ via the five admissible Frame-shape classes of $\mathcal{M}_{2,4}$; this is the slice where the BKM superalgebra attached to the Borchers product carries a $\mathbb{Z}/N$ -twined Jacobi generator.
- (ii) **Gritsenko–Cléry 8-form scope**. The eight forms are indexed by $(t, N; k) \in \{(1, 1; 5), (2, 1; 2), (1, 2; 3), (3, 1; 1), (1, 3; 2), (4, 1; 1), (2, 2; 1), (3, 2; 1)\}$ with weights $(5, 2, 3, 1, 2, \frac{1}{2}, \frac{3}{2}, 1)$. This is not an $N = 1, \dots, 8$ CHL ladder. Its row-wise identity is $\kappa_{\text{BKM}}(F_{t,N}) = \text{wt}(F_{t,N})$.

The CHL slice $(5, 4, 3, 2, 1)$ tuple is the CHL-averaged paramodular weight sequence $\text{wt}(\Delta_1^{(N)}) = (5, 4, 3, 2, 1)$ of Gritsenko 1999 Thm. 1.2 at $N \in \{1, 2, 3, 4, 6\}$ with $c_N(o) = (10, 8, 6, 4, 2)$, produced as the additive lift of the weight- $k(N)$ index-1 Jacobi input. The Gritsenko–Cléry 8-form catalogue (Gritsenko–Cléry 2008 arXiv:0812.3962 Thm. 1.4, Theorem 32.8.2) is an independent family indexed by triples $(t, N; k) \in \{(1, 1; 5), (2, 1; 2), (1, 2; 3), (3, 1; 1), (1, 3; 2), (4, 1; \frac{1}{2}), (1, 4; \frac{3}{2}), (2, 2; 1)\}$ with weight tuple $(5, 2, 3, 1, 2, \frac{1}{2}, \frac{3}{2}, 1)$ and twice-weight tuple $(10, 4, 6, 2, 4, 1, 3, 2)$; no weight-0 row, no weight- $\frac{1}{4}$ row, no entry on the spin double cover $\widetilde{\text{Mp}}_4$, with half-integer entries using multiplier systems $v_\eta^3 \times v_H$ over Γ_4 and $\Gamma_0^{(2)}(4)$. The CHL ladder and the GC catalogue overlap only at $(t, N) = (1, 1)$ with $F_{1,1} = \Delta_5$. The universal Borchers-weight identity $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2$ holds on the CHL ladder; the row-wise GC identity is $\kappa_{\text{BKM}}(F_{t,N}) = \text{wt}(F_{t,N})$.

30.1 THE IDENTITY

Let $\mathcal{A}$ be a chiral algebra in the logarithmic-finite-type class admitting a quasi-free BRST resolution [96]. Let X be a smooth projective Calabi–Yau manifold of dimension d , with $\Phi_d(D^b(\text{Coh}(X))) = \mathcal{A}_X$ the image under the CY-to-chiral correspondence $\{\Phi_d\}$ of Chapter 5. Let $\mathcal{Z}(\mathcal{A}) := \int_{S^1 \times \text{Ran}(X)} \mathcal{A}$ denote the universal centre: the factorisation-homology output of $\mathcal{A}$ on the product of the cyclic circle S^1 and the Ran space of X (Vol II Chiral Hochschild Trinity Theorem; cf. the candidate-centre discussion in Chapter 29, [96]). Let $\mathfrak{R}_{\mathcal{A}} : \mathcal{A} \mapsto \mathcal{A}^!$ be the Vol I Koszul reflection (Theorem A, [96]). For X in the K_3 -fibered domain, let $\mathfrak{B}_X$ denote the centre endomorphism whose scalar shadow is the named Borchers denominator. Its construction and its comparison with $\mathfrak{R}_{\mathcal{A}_X}$ are part of the datum, not a formal consequence of the singular theta lift.

THEOREM 30.1.1 (*Universal Φ -trace comparison with centre action*). Let $\mathcal{A}$ be a chiral algebra in the logarithmic-finite-type class for which the Vol I quasi-free BRST resolution and the Vol II chiral Hochschild centre object $\mathcal{Z}(\mathcal{A})$ are constructed. Let X be a Calabi–Yau input with a named orthogonal Borchers datum (Λ, f_X) : an even lattice of orthogonal type, a Weil-representation modular input with integral principal part, and a denominator form Φ_{f_X} . Suppose further that a centre action $\mathfrak{B}_{f_X} \in \text{End}(\mathcal{Z}(\mathcal{A}_X))$ and a comparison morphism

$$\Phi_{\#}(\mathfrak{R}_{\mathcal{A}_X}) \dashrightarrow \mathfrak{B}_{f_X}$$

have been constructed. Then:

- (i) **Koszul side.** The Vol I Koszul conductor is the centre supertrace of the Koszul reflection:

$$K(\mathcal{A}) = -c_{\text{ghost}}(\text{BRST}(\mathcal{A})) = \text{tr}_{\mathcal{Z}(\mathcal{A})}(\mathfrak{R}_{\mathcal{A}}).$$

- (ii) **Borchers side.** The Borchers scalar is the weight of the named denominator form, and the centre trace is the trace of the separately constructed centre action:

$$\kappa_{\text{BKM}}(\Phi_{f_X}) = c_{f_X}(o)/2 = \text{tr}_{\mathcal{Z}(\mathcal{A}_X)}(\mathfrak{B}_{f_X}).$$

- (iii) **Comparison bridge.** The two reflections are compared by the chosen morphism:

$$\Phi_{\#}(\mathfrak{R}_{\mathcal{A}_X}) \dashrightarrow \mathfrak{B}_{f_X}.$$

(iv) **Unified diagram.** The two supertraces live on the common centre object once the comparison bridge is supplied:

$$\begin{array}{ccc}
 \mathcal{A} & \xrightarrow{\mathfrak{R}} & \mathcal{A}^\dagger \\
 \downarrow \mathfrak{Z} & & \downarrow \mathfrak{Z} \\
 \mathfrak{Z}(\mathcal{A}) & \xrightarrow{\mathfrak{Z}(\mathfrak{R})} & \mathfrak{Z}(\mathcal{A}^\dagger) \\
 \downarrow \Phi_\# & & \downarrow \Phi_\# \\
 \mathfrak{Z}(\mathcal{A}_X) & \xrightarrow{\mathfrak{B}_{f_X}} & \mathfrak{Z}(\mathcal{A}_X).
 \end{array}$$

Proof. Clause (i) is the supertrace-trinity centre-collapse identity of [96] combined with the Chiral Hochschild Trinity Theorem of [97]. The equality $\kappa_{\text{BKM}}(\Phi_{f_X}) = c_{f_X}(\mathfrak{o})/2$ in clause (ii) is the Borchers-weight identity for the named orthogonal input. The second equality in clause (ii) is precisely the trace comparison hypothesis for $\mathfrak{B}_{f_X}$. Clause (iii) is the chosen comparison morphism. Clause (iv) is the resulting common-centre diagram. $\square$

Remark 30.1.2 (The object traced). The trace in clauses (i)–(ii) is a supertrace of an *involutive endofunctor* on a *factorisation-homology module* $\mathfrak{Z}(\mathcal{A}) \in \text{Mod}_{\mathfrak{Z}^{\text{der}}(\mathcal{A})}$: a cyclic-cohomology class in the sense of Connes–Karoubi, realised explicitly via Costello–Gwilliam factorisation homology on $S^1 \times \text{Ran}(X)$. The Fourier–Mukai-kernel trace on $D^b(\text{Coh}(X))$ sits one functorial layer upstream of Φ ; the centre supertrace here lives on the factorisation-homology module of the chiral output.

30.2 DIMENSION-STRATIFIED SPECIALISATIONS

The universal identity specialises at each CY dimension d to a named evaluation. The four specialisations below are four *reductions* of Theorem 30.1.1 at the standard inputs: one theorem, four named evaluations along the dimension axis.

COROLLARY 30.2.1 ($d = 1$: *the Vol I half alone*). For $X = E$ an elliptic curve with $\mathcal{A}_E = \Phi_1(D^b(\text{Coh}(E))) = \text{Heis}_{\Lambda_E}$ the elliptic Heisenberg vertex algebra with Narain momentum lattice of signature $(1, 1)$; the Borchers singular theta correspondence outputs a modular function of weight $\mathfrak{o}$. Theorem 30.1.1 reduces to its Vol I half: $K(\mathcal{A}_E) = \text{tr}_{\mathfrak{Z}(\mathcal{A}_E)}(\mathfrak{R})$. The Koszul reflection carries the entire identity at $d = 1$; the Borchers reflection collapses to the trivial scalar on the weight-zero output.

Proof. At rank-1 Lorentzian lattice $\text{II}_{1,1}$, the Borchers lift of the trivial VOA is $J(\tau) - 744$ (Borchers 1992), a modular function of weight $\mathfrak{o}$; the weight formula $c_\Lambda(\mathfrak{o})/2 = \mathfrak{o}$ gives vanishing κ_{BKM} on the lattice side. The Koszul side $K(\text{Heis}_{\Lambda_E}) = \mathfrak{o}$ also vanishes on the free-field branch (Mukai self-duality at rank 1; see [96] in the modular-Koszul bridge). Both sides collapse to the trivial identity $\mathfrak{o} = \mathfrak{o}$; the comparison bridge is vacuous at $d = 1$. $\square$

COROLLARY 30.2.2 ($d = 2$: *K₃ CHL slices*). For the CHL/Nikulin K₃ slice X_N with $N \in \{1, 2, 3, 4, 6\}$, Theorem 30.1.1 (ii) specialises to the Borchers weight formula

$$\kappa_{\text{BKM}}(\Phi_N) = c_N(\mathfrak{o})/2 \in \{5, 4, 3, 2, 1\},$$

via [96] applied to the orbifold-averaged Jacobi form ϕ_N . At $N = 1$, the comparison bridge (iii) uses the K₃ topological vertex algebra $\mathcal{V}_{K_3}^{\text{top}}$ and the weight lattice $\Lambda^{3,2}$; the scalar automorphic shadow is Gritsenko’s paramodular cusp form Δ_5 .

COROLLARY 30.2.3 ($d = 3$: $K_3 \times E$ via Δ_5 and its unnormalised Φ_{10}^{un} square). For $X = K_3 \times E$ with Mukai lattice Λ even unimodular of signature $(3, 2)$, Theorem 30.1.1 (ii) specialises to

$$\kappa_{\text{BKM}}(\Delta_5) = c_1(o)/2 = 10/2 = 5,$$

the Borchers weight of the primitive Gritsenko–Nikulin form Δ_5 . The monic denominator product is $D_5 = 64^{-1}\Delta_5$. The unnormalised Igusa square is $\Phi_{10}^{\text{un}} = \Delta_5^2$, while the reduced DT/OP character uses the OP-normalised form $\Phi_{10}^{\text{OP}} = D_5^2 = 4096^{-1}\Delta_5^2$:

$$Z_{\text{DT}}^{\text{red}}(K_3 \times E) = -(\Phi_{10}^{\text{OP}})^{-1} = -D_5^{-2} = -4096 \Delta_5^{-2}.$$

The Fake-Monster form Φ_{12} has weight 12 on the $\text{II}_{25,1}$ row and is a different BKM object. The Koszul conductor on the CY side is $K(\mathcal{A}_{K_3 \times E}) = o$ (free-field branch via Mukai self-duality + Künneth with $K(\text{Heis}_E) = o$), so the two supertraces are *not the same normalised numerical invariant*; they trace *two different reflections* on the same centre $\mathfrak{Z}(\mathcal{A}_{K_3 \times E})$, and the bridge (iii) $\mathfrak{B}_{K_3 \times E} = \Phi_*^{\text{Borch}}(\mathfrak{R})$ is the structural identity.

COROLLARY 30.2.4 ($d \geq 4$: E_1 -stabilisation, Vol I half alone). For $d \geq 4$, Φ_d is E_1 -stabilised via the $\pi_d(BU)$ obstruction (Theorem 11.5.1); no native braiding is promoted to a Borchers singular theta lift. Theorem 30.1.1 (i) applies directly; the Borchers half is conjecturally defined via higher-rank regularisations that lie beyond the current correspondence. The Vol I conductor identity remains unconditional.

30.3 NUMERICAL EVIDENCE AND THE FACTOR-13 CAVEAT

A numerical table illustrates that Theorem 30.1.1 is *not* an assertion of numerical equality $K = \kappa_{\text{BKM}}(\Phi)$; it is an assertion of a centre comparison morphism. At the canonical inputs:

d	Input	$K(\mathcal{A})$	κ_{BKM}	Relation
1	Heis_{Λ_E}	o	undefined (lattice not $(b^+, 2)$ with $b^+ \geq 2$)	Borchers half vacuous
2	K_3	o	5	two reflections on $\mathfrak{Z}(\Phi_2(K_3))$
2	$K_3/\mathbb{Z}_2$	o	4	orbifold averaging reduces $c_N(o)$
3	$K_3 \times E$	o	5	Δ_5 weight; $D_5 = 64^{-1}\Delta_5$ and $\Phi_{10}^{\text{OP}} = D_5^2$

The zero values on the K -column correspond to the free-field branch with Mukai-symmetric Koszul pairing. At Virasoro with central charge $c = 13$ (the Vol I point where $\text{Vir}_c^! = \text{Vir}_{26-c}$ coincides with Vir_c), the universal conductor evaluates as $K = c + c^! = 13 + 13 = 26$; on the $\mathcal{W}_N$ branch $K = c(H_N - 1)$. The numerical invariants K and κ_{BKM} do not coincide; they trace distinct reflections, and the structural unification lies in clause (iii) of Theorem 30.1.1.

Remark 30.3.1 (Against a constant ratio K/κ_{BKM}). The Vol I conductor is $K(\text{Vir}_c) = \kappa_{\text{ch}}(\text{Vir}_c) + \kappa_{\text{ch}}(\text{Vir}_c^!) = c/2 + c^!/2$ on the Virasoro dual-pair line $c + c^! = 26$, so $K(\text{Vir}) = 13$ at every admissible c (in particular at the self-dual point $c = c^! = 13$, $K = 13/2 + 13/2 = 13$). The Vol III $K_3 \times E$ Gritsenko weight is $\kappa_{\text{BKM}}(\Phi_1) = c_1(o)/2 = 5$. The ratio $13/5$ is not an integer, and no heuristic derivation produces a constant factor relating the two invariants: K is the Vol I conductor trace, while κ_{BKM} is the Gritsenko–Nikulin/Borchers weight $c_1(o)/2$. They are related by the comparison morphism of clause (iii), not by a scalar rescaling.

30.4 BEYOND THE LOGARITHMIC-FINITE-TYPE CLASS

Theorem 30.1.1 is proved on two domains: the K_3 -fibered CY_3 domain of the K_3 -fibered identity of [96] and the non- K_3 -fibered Mukai- $(b^+, 2)$ -graded domain of [96]. Three independent directions remain:

- (a) **Non-quasi-free BRST resolutions.** All standard chiral families are chirally Koszul, but not all admit a quasi-free BRST resolution in the sense required by Vol I's universal conductor. Outside the quasi-free BRST class, both sides are defined only after passing through the Trinity double cover (Vol II [97] (i)–(ii)). The obstruction is the absence of a quasi-free BRST replacement compatible with the Trinity double cover.
- (b) **Lattices outside the orthogonal Borchers range.** The Borchers product used here requires a specified even lattice of orthogonal type, a Weil-representation input, an integral principal part, and a Weyl chamber. Lattices outside that package do not inherit a denominator form by formal extension. The open problem is to supply the corresponding automorphic input and then compare it with the Koszul-reflection trace.
- (c) **Class M chain-level.** The centre construction of Vol I [96] uses the inf-categorical ∞ -functor $\int_{S^1 \times \text{Ran}(X)}$; a chain-level $\mathfrak{R}$ -equivariant model for class M inputs (Vol I Virasoro, $\mathcal{W}_N$) requires the weight-completed ambient of Vol II [97]. The obstruction is the absence of a raw bar-complex model carrying the same $\mathfrak{R}$ -equivariance as the weight-completed ambient.

The three directions are orthogonal: (a) removes the BRST quasi-freeness hypothesis, (b) removes the signature restriction, (c) moves from ∞ -categorical to chain-level. A closed Φ_3 theorem on compact CY_3 inputs combines these three with the S^3 -framing input: either a corrected TCFT comparison or a complete E_7 -Hochschild filtration theorem of the kind spelled out in Chapter 7. Theorem 30.1.1 holds structurally on its natural domain and on the constructed compact branches; closure on compact CY_3 proceeds through the joint construction of the framing datum and the three independent directions.

30.5 THE IDENTITY IN ONE LINE

The identity has the compressed form

$$K(\mathcal{A}) = \text{tr}_{\mathcal{Z}(\mathcal{A})}(\mathfrak{R}_{\mathcal{A}}), \quad \kappa_{\text{BKM}}(\Phi_{\Lambda}) = \text{tr}_{\mathcal{Z}(\Phi(X))}(\mathfrak{B}_X), \quad \mathfrak{B}_X = \Phi_*^{\text{Borch}}(\mathfrak{R}_{\Phi(X)}).$$

Two reflections, one centre, one functor. The ghost charge $-c_{\text{ghost}}$ and the Borchers weight $c_{\Lambda}(o)/2$ are two supertrace readings of the same universal involution, projected through two specialisations of Φ .

Φ -output shift at K_3 input: [2], not [3]

The homological shift of Φ_d at $CY-d$ input is *Hochschild-dimension-forced*. The functor Φ_d sends a smooth proper cyclic A_{∞} -category of CY dimension d to a factorisation algebra $\mathcal{A}$ whose Verdier–Koszul dual $\mathcal{A}^!$ is obtained via $D_{\text{Ran}} \circ B$ on $\text{Ran}(C)$ and carries a $[d]$ -shift. The Verdier–Koszul operation, ordinary bar–cobar inversion, and the chiral derived centre $Z_{\text{ch}}^{\text{der}}(\mathcal{A})$ each operate on $\mathcal{A}$ through distinct functorial constructions: bar–cobar inversion returns $\mathcal{A}$ on the comparison locus, $D_{\text{Ran}} \circ B$ produces the Verdier–Koszul dual with $[d]$ -shift, and $Z_{\text{ch}}^{\text{der}}(\mathcal{A})$ produces the universal closed-sector internal object at the centre-sector level (identification with a physical bulk requires the OCA arrow $\text{OCA} : \mathcal{O}_{\text{bulk}}^{\text{phys}}(\mathcal{T}) \xrightarrow{\sim} Z_{\text{ch}}^{\text{der}}(\mathcal{A})$ of Definition 5.0.5). The shift appears because the Serre functor $\mathbb{S}_C \simeq [d]$ on the input category induces the cyclic-trace of degree $-d$ on the output coalgebra. This is the operadic Koszul degree of the bar construction in the sense of Lurie, *Higher Algebra*, §6.3.1.5 (Koszul self-duality with $CY-d$ shift),

and Francis–Gaitsgory, *Chiral Koszul duality*, arXiv:1103.5803, 2012. The shift is intrinsic to the CY dimension of the input category, independent of which ambient space hosts the factorization.

THEOREM 30.5.1 (*Φ -output shift at K_3 input is $[2]$*). For the K_3 input category $\mathcal{C} = D^b\mathrm{Coh}(K_3)$, the Φ -output homological shift is $[2]$, consistent with CY_2 . Concretely,

$$(\Phi_2(D^b\mathrm{Coh}(K_3)))^! \simeq \Phi_2(D^b\mathrm{Coh}(K_3))^{\mathrm{coalg}}[2],$$

with the Mukai–Heisenberg identification $\Phi_2(D^b\mathrm{Coh}(K_3)) \simeq \mathcal{H}_{\mathrm{Muk}}$ at the E_2 -chiral target of Φ_2 .

Proof. K_3 is Calabi–Yau of complex dimension 2; its derived category $D^b\mathrm{Coh}(K_3)$ is smooth and proper with Serre functor $\mathbb{S}_{\mathcal{C}} \simeq [2]$ (Bondal–Orlov, *Reconstruction of a variety from the derived category and groups of autoequivalences*, Compos. Math. 125, 2001). The Hochschild cohomology is bi-graded

$$\mathrm{HH}^\bullet(D^b\mathrm{Coh}(K_3)) = \bigoplus_{p+q=\bullet} H^p(K_3, \Lambda^q T_{K_3}),$$

concentrated in degrees 0 through 4, with Poincaré-like duality $\mathrm{HH}^k \simeq \mathrm{HH}^{4-k}$ induced by the CY_2 Mukai pairing. Lurie’s HA 6.3.1.5 Koszul self-duality with CY_d shift specialised to $d = 2$ gives the $[2]$ -shift on the Verdier–Koszul dual $A^!$ (distinct from bar–cobar inversion $\Omega(B(A)) = A$, which is unshifted). The Mukai–Heisenberg identification is the Φ_2 -computation of the Φ_2 Mukai–Heisenberg section of Chapter 5. $\square$

Remark 30.5.2 (*The ambient-vs-input distinction*). The Koszul shift is determined by the CY dimension of the *input category*, not by the ambient factorization base. For a CY_3 input whose constructed framed Φ_3 output has been chosen, the shift is $[3]$; for Φ_2 input with K_3 , the shift is $[2]$. For the quintic $X \subset \mathbb{P}^4$, such a choice is part of the compact CY_3 strictification problem, not an automatic consequence of the dimension count. The source of the conflation: K_3 (CY_2) is the input category, while the auxiliary CY_3 spaces

$$K_3 \times \mathbb{C}, \quad K_3 \times \mathbb{C}^3, \quad K_3 \times E$$

appear only as *ambient factorization bases* hosting the output algebra. These two roles are distinct:

- *Input category.* The K_3 derived category $D^b\mathrm{Coh}(K_3)$ is the object fed to Φ_2 ; it is CY_2 ; the Koszul shift is $[2]$.
- *Ambient base.* The auxiliary CY_3 space $K_3 \times E$ is where the K_3 chiral output is hosted as a factorization algebra; after the finite Hall–Borcherds recognition conditions its comparison target is $\mathbf{H}_{\Delta_s}$ (bi-based: chiral base $E_{24}^{\mathrm{nod}, \mathrm{sm}}$, parameter base $\overline{\mathcal{A}}_2$; see Chapter 20, Theorem 20.7.1, and Chapter 29, Section 29.17).

The $[3]$ -shift on a framed Φ_3 -output for a true CY_3 input is a separate, simultaneously-true statement (the Φ_3 CY_3 -output section of Chapter 5); it does not displace the $[2]$ -shift for Φ_2 at K_3 .

Remark 30.5.3 (*Bi-based Ran-space comparison*). The $[2]$ -shift on $(\mathbf{H}_{\Delta_s})^!$ is visible on both sides of the bi-based Ran-space datum of Chapter 29, Definition 29.17.1:

- *Chiral base side* (α, β). The Beilinson–Drinfeld chiral algebra on $\mathrm{Ran}(E_{24}^{\mathrm{nod}, \mathrm{sm}})$ has bar complex in bar degrees 0, 1, 2, $\dots$; the $[2]$ -shift means its Koszul dual coalgebra sits in cohomological degree +2 relative to the primitive generators. At each of the 24 Kodaira nodes, the nearby-cycles $\mathcal{D}$ -module $\mathcal{F}_{n_i} = \Psi_{s_i}(\mathbf{H}_{\Delta_s}|_{\mathbb{D}_{n_i}^*})$ carries the same $[2]$ -shift in its perverse t-structure (Beilinson–Drinfeld 2004, §3.5.14).

- *Parameter base side* (γ). On $\overline{\mathcal{A}}_2$, the holonomic $\mathcal{D}$ -module $\mathcal{L}^{\Delta_5}$ has cohomological degree equal to the complex dimension of its singular support divided by two: Humbert divisors H_1, H_4 are codimension-1 in the 3-dimensional parameter base, contributing degree +2 to the perverse t-structure shift via $\dim \overline{\mathcal{A}}_2 - \text{codim}(H_D) = 2$. This agrees with the $[2]$ -shift on the chiral side through the averaging-morphism pullback $\text{av}^* \mathcal{L}^{\Delta_5} \simeq \bigoplus_{i=1}^{24} \mathcal{F}_{n_i}$ of Corollary 20.7.5.

The $[2]$ -vs- $[3]$ confusion is resolved by distinguishing the Φ_d -input (CY dimension of the source category, which determines the shift) from the *ambient factorization base* (geometric space hosting the output algebra, which does not). See Chapter 20, Theorem 20.8.1, for the full chain-level and $(\infty, 1)$ -categorical statement.

30.6 THE Φ UNIVERSAL TRACE AT THE K_3 BASE

Remark 30.6.1 (Φ universal trace at the K_3 base). The universal trace identity

$$\text{Tr}_{\Phi_d(C)}^{\text{ch}}(\Phi_d(a)) = \text{Tr}_C^{\text{CY}}(a) \quad (a \in \text{HH}^\bullet(C)),$$

through the CY-to-chiral functor Φ_d , is a statement at the *stage-1* level: both sides are traces on $\text{HH}^\bullet(C)$, the categorical Hochschild cohomology of the input CY category C , before any curve-specialisation via Sp^{ch} . The stage-2 shadow recovers the on-curve Koszul conductor $K(A_C)$ and the Borchers weight characteristic $\kappa_{\text{BKM}}(\Phi_\Lambda)$ as distinct numerical specialisations of the stage-1 supertrace. The K_3 realisation is conditional on the Heegner comparison and the finite Hall–Borchers recognition conditions: for $C = D^b \text{Coh}(K_3)$ and the comparison output $\Phi(C) \simeq \mathbf{H}_{\Delta_5}\text{-mod}^{\text{ch}}$, the two trace maps coincide via the Gritsenko–Nikulin 1997–98 denominator identity

$$\Phi_{10}^{\text{OP}}(Z) = D_5(Z)^2 = \prod_{(n,l,m) > 0} (1 - q^n \zeta^l p^m)^{c(nm,l)},$$

with $c(nm, l)$ the K_3 elliptic-genus Fourier coefficient spectrum. The left-hand-side chiral trace and the right-hand-side CY trace are compared through the fixed-branch projected period correspondence $\pi_{\text{Sp}_4} \circ \mathcal{P}_{K_3}$, which provides the compactification compatibility for the trace identity. At the K_3 base point the primitive BKM trace is the weight-5 form Δ_5 , the monic denominator product is $D_5 = 64^{-1} \Delta_5$, and the reduced DT/OP theorem uses the OP-normalised square $\Phi_{10}^{\text{OP}} = D_5^2 = 4096^{-1} \Delta_5^2$. The Fake-Monster Φ_{12} is absent: it lives on the $\Pi_{25,1}$ lattice row. The comparison with the K_3 chiral bialgebra is made in Chapter 20; the source inputs are Gritsenko–Nikulin 1996–98, Eguchi–Ooguri–Tachikawa 2011, and Borchers 1995.

30.7 $\{\Phi_d\}$ OUTPUT IS d -DEPENDENT; ONE Φ PER CATEGORY TYPE

Remark 30.7.1 (Scope of $\{\Phi_d^{(\Sigma_{d-1}, C)}\}_{d, (\Sigma, C)}$: a two-parameter correspondence). At fixed d , Stage-1 is a functor $\Phi_d^{\text{FA}}: \text{CY}_d\text{-Cat} \rightarrow E_d\text{-HolFA}(X)$ (canonical up to $\text{GRT}_1(\mathbb{Q})$ -torsor); the chart-specialised level-2 output

$$\Phi_d^{(\Sigma_{d-1}, C)} = \text{Sp}_{\Sigma_{d-1}, C}^{\text{ch}} \circ \Phi_d^{\text{FA}}: \text{CY}_d\text{-Cat} \longrightarrow E_{n(d)}\text{-ChirAlg}(C), \quad n(d) = \begin{cases} \infty, & d = 1, \\ 2, & d = 2, \\ 1, & d \geq 3, \end{cases}$$

is $\text{per-}(d, \Sigma_{d-1}, C)$. The full collection $\{\Phi_d^{(\Sigma_{d-1}, C)}\}_{d \geq 1, (\Sigma, C)}$ is a two-parameter correspondence, not a single functor across d : the target $E_{n(d)}\text{-ChirAlg}(\mathcal{M}_d)$ depends on d through the operadic level

forced by the PTVV shift law and Dunn–Lurie additivity, and depends on (Σ_{d-1}, C) through the level-2 chart specialisation (Chapter 5, Remark $\{\Phi_d\}$ -is-not-a-unified-functor; Francis–Gaitsgory 2012, arXiv:1103.5803). The three data points at $d \in \{1, 2, 3\}$:

$d = 1$ (**elliptic curve** E). $\Phi_1(D^b(\text{Coh}(E))) = \text{Heis}_{\Lambda_E}$, a lattice Heisenberg VOA; output is E_∞ -chiral (fully E_∞ -commutative at rank 1 Lorentzian signature). Borchers side is vacuous (Corollary 30.2.1).

$d = 2$ (**K3**). $\Phi_2(D^b(\text{Coh}(K_3))) = \mathcal{H}_{\text{Muk}}$, the Mukai–Heisenberg chiral bialgebra; output is E_2 -chiral with non-trivial braiding (Theorem 30.5.1). The Borchers lift of the normalized K3 Jacobi input $\phi_{0,1}$ produces the paramodular form Δ_5 (Corollary 30.2.2), with $\kappa_{\text{BKM}}(\Delta_5) = 5$; the doubled elliptic genus $2\phi_{0,1}$ gives the Igusa-square lane.

$d = 3$ (**K3 $\times$ E**). On the chosen constructed $K_3 \times E$ framed locus, $\text{Sp}_{\Sigma_2, C}^{\text{ch}}(\Phi_3^{\text{FA}}(D^b(\text{Coh}(K_3 \times E))))$ has $\mathbf{H}_{\Delta_5}$ as conditional Hall–Borchers recognition target; output is E_1 -chiral. The Dunn–Lurie additivity statement records the operadic level drop after Stage-2 specialisation along Σ_2 ; it is not a proof of a compact Φ_3 output, a contractible lifting space, or a global Hall/CoHA comparison.

The change of target operadic level across d is structural: it is not a choice of presentation, it is the content of the $(\infty, 2)$ -categorical CY-to-chiral theorem. The universal trace identity Theorem 30.1.1 is *per- d* (Corollaries 30.2.1, 30.2.2, 30.2.3, 30.2.4); its statement at any single d does not imply the statement at another d without a dedicated argument.

Remark 30.7.2 (One Φ per category type: six routes $\neq$ six Φ 's). The universal trace identity at a fixed d uses *one* Φ_d with *one* source category and *one* output. The six routes to $G(K_3 \times E)$ of Chapter 23 are not six applications of Φ_3 ; only route R_1 uses the framed $K_3 \times E$ Φ_3 specialisation. The remaining five routes (Borchers lift, Mukai–Heisenberg vertex algebra, threefold Kummer, holomorphic half-twist, BLLPR/6d Schur) are *independent* constructions whose outputs are compared with $\text{Sp}_{\Sigma_2, C}^{\text{ch}}(\Phi_3^{\text{FA}}(D^b(\text{Coh}(K_3 \times E))))$ via named intertwiners α_{ij} – see Chapter 23, Remark 23.14.1, for the per-route taxonomy with distinct generator ranks $\rho^{R_i} \in \{3, 12, 24\}$. Writing “six Φ_3 ’s, one per route” is a functor-per-route conflation, closely related to the requirement that the denominator = bar Euler identity needs both the framed $K_3 \times E$ Φ_3 specialisation and the Vol I anchors simultaneously (see Section 26.31, Remark 26.32.1). The universal trace identity of Theorem 30.1.1 relates *two* trace computations across *one* Φ_d at a fixed d ; it does not split into several parallel Φ ’s, and it does not collapse across different d .

Remark 30.7.3 ($\kappa_{\text{cat}}(K_3 \times E) = 0$: per-route-independent CY-side invariant). On the CY side of the framed Φ_3 locus at $X = K_3 \times E$, the categorical invariant is

$$\kappa_{\text{cat}}(K_3 \times E) = \chi(\mathcal{O}_{K_3 \times E}) = \chi(\mathcal{O}_{K_3}) \cdot \chi(\mathcal{O}_E) = 2 \cdot 0 = 0,$$

by Serre duality for CY_3 ($\chi(\mathcal{O}) = 0$ for every compact CY_3) and Künneth for coherent cohomology. This is the total-space value. The fibre-K3 value $\kappa_{\text{cat}}(K_3) = \chi(\mathcal{O}_{K_3}) = 2$ is a separate K3 categorical invariant; it is not the $K_3 \times E$ fibre-rank invariant, which is $\kappa_{\text{fiber}}(K_3 \times E) = \text{rk } \bar{H}(K_3, \mathbb{Z}) = 24$. The universal trace identity (30.1.1) at $d = 3$ uses the total-space value: in the dimension-stratified specialisation $d = 3$ (Corollary 30.2.3), the Koszul conductor $K(\mathcal{A}_{K_3 \times E}) = 0$ holds on the free-field Heisenberg branch, consistent with $\kappa_{\text{cat}}(K_3 \times E) = 0$ and with the comparison statements of Chapter 19, Remark 26.32.2, and Chapter 23, Remark 23.14.3.

Remark 30.7.4 (Trace identity on the framed K3 branch). The $d = 3$ specialisation of the universal trace identity, restricted to the framed K3 chiral bialgebra branch $\mathbf{H}_{\Delta_5}$, has eight numerical faces: (A)

the order-eight comparison among Mukai doubling, the Humbert H_1 local-exponent datum, and the Lusztig order $\ell = 8$; (B) the central-charge pair $(c_{4d}, c_{2d}) = (107/6, -214)$ from Chacaltana–Distler and Beem–Rastelli; (C) BKM Cartan rank 3 (Gritsenko–Nikulin $\det = -32$) against Mukai rank 24; (D) $\kappa_{\text{BKM}}(\Delta_5) = 5$ from the Siegel weight; (E) five duality frames converging on the Narain lattice $\Pi_{3,19}$ at weight 5; (F) the Heegner pattern $c_n \propto [H_n]$ at $n = 1, 2, 3$; (G) the Arthur packet of the squared Igusa form, $\psi_{\Delta_{10}} = \phi_{\Delta_{E_6}} \boxplus \text{Sym}^1$, with $\Delta_{E_6} = E_6 \Delta \in S_{18}(\text{SL}_2(\mathbb{Z}))$ and $|a_p(\Delta_{E_6})| \leq 2p^{17/2}$ for $p \leq 11$; (H) the Schur-index plethystic expansion. These identities are compatibility data on the framed Φ_3 branch; the CY-C isomorphism claim (Conjecture 23.2.1) remains the missing comparison theorem.

30.8 KONTSEVICH FORMALITY BRIDGE: FRAMED Φ_3 IMAGE AS SUPER-KONTSEVICH DEFORMATION QUANTISATION

The $d = 3$ Φ -universal trace identity compares, on the constructed framed $K_3 \times E$ locus after the finite Hall–Borcherds recognition conditions and Heegner comparison, the image denoted $\mathbf{H}_{\Delta_5} := \text{Sp}_{\Sigma_2, C}^{\text{ch}}(\Phi_3^{\text{FA}}(D^b(\text{Coh}(K_3 \times E))))$ with the Etingof–Kazhdan super-quantisation of the Gritsenko–Nikulin classical chiral Lie bialgebra $(\mathfrak{g}_{\Delta_5}, \delta_{\text{GN}})$ after the framing and comparison data have fixed the order-eight root-of-unity branch (Kazhdan classical-limit theorem, [96]). The Kontsevich admissible-graph expansion produces the same formal deformation class on this branch and makes the motivic origin of its transcendental coefficients transparent.

THEOREM 30.8.1 (*Conditional super-Kontsevich comparison on the framed $K_3 \times E$ branch*). Assume the constructed $K_3 \times E$ Φ_3 branch: a fixed formality/associator point, a chain-level S^3 -framing homotopy, the Costello correction or the complete HH^{-2} filtration theorem, the Stage-2 specialisation datum $(\Sigma_2, C) = (K_3, E)$, the Borcherds–Gritsenko comparison map, the finite Hall–Borcherds recognition conditions, and the Heegner comparison. Under these hypotheses, the comparison datum identifies the chiral bialgebra

$$\mathbf{H}_{\Delta_5} = \text{Sp}_{\Sigma_2, C}^{\text{ch}}(\Phi_3^{\text{FA}}(D^b(\text{Coh}(K_3 \times E))))$$

with the completed super-Kontsevich deformation quantisation of $(\mathfrak{g}_{\Delta_5}, \delta_{\text{GN}})$ at the chosen order-eight root-of-unity branch, in the conditional comparison gauge characteristic selected by the line $H^2(\mathfrak{g}_{\Delta_5})^{\mathbb{Z}/2, K(1)} \cong \mathbb{C} \cdot \Delta_5$. The identification is:

- (i) **Classical end.** The $\hbar \rightarrow 0$ limit of $\mathbf{H}_{\Delta_5}$ is the Gritsenko–Nikulin super-chiral Lie bialgebra with r -matrix $r(u, Z) = \Omega_{\text{Mukai}}/u + \partial_Z \log \Phi_{10}^{\text{un}} \cdot \Omega_{K_3} + O(u^{-2})$.
- (ii) **Super-Kontsevich formality.** The L_∞ -quasi-isomorphism $\mathcal{U}^{\text{super}} : \text{Hoch}^\bullet(\mathfrak{g}_{\Delta_5}^{\text{super}}) \simeq_{L_\infty} \text{PVec}^\bullet(\mathfrak{g}_{\Delta_5}^{\text{super}})$ transports the Poisson bivector $r(u, Z)$ to an associative star product on the completed enveloping algebra.
- (iii) **Order-eight specialisation.** The completed formal star product is specialised through the chosen dyadic completion and compared with $\mathbf{H}_{\Delta_5}$ in the selected gauge class.

The theorem is branchwise. It does not construct Φ_3 for arbitrary compact CY_3 categories and does not supply Hall/CoHA, PBW, or no-extra-relations data. Primary: Kontsevich 2003 *Lett. Math. Phys.* 66; Shoikhet 2003 *Adv. Math.* 179; Etingof–Kazhdan 1996–2000 *Selecta Math.* 2, 4, 6; Tamarkin 1998 (arXiv:math/9803025); Cattaneo–Felder 2001 *Comm. Math. Phys.* 228.

Proof. The combined super-Kontsevich formality, completed order-eight star-product specialisation, and gauge-class comparison of [96], Theorem *defq-unified-kontsevich-theorem*, give the asserted comparison. The scope of the present theorem is the conditional restatement of that result inside the constructed

framed Φ_3 image branch of the Φ -universal trace identity: after the comparison datum is fixed, the chosen $d = 3$ specialisation is compared with the super-Kontsevich quantisation. $\square$

Remark 30.8.2 (Motivic-Galois reading of the Φ_3 trace coefficients). Under Theorem 30.8.1, the transcendental coefficients entering the trace computations in $\mathrm{tr}_3(\mathcal{A}_{K_3 \times E})(\mathfrak{B}_X)$ on the Borchers side and $\mathrm{tr}_3(\mathcal{A}_{K_3 \times E})(\mathfrak{R}_{\mathcal{A}_{K_3 \times E}})$ on the Koszul side are Kontsevich admissible-graph weights, equivalently MZVs $\zeta(s_1, \dots, s_r)$ in the Furusho–Brown $\mathbb{Q}$ -span, equivalently Drinfeld associator pentagon coefficients $\phi^{(n)}$ (Vol I [96] Theorem *defq-unified-motivic-origin*). The trace identity is therefore $\mathrm{GRT}_1(\mathbb{Q})$ -equivariant: the motivic Galois action on the MZV $\mathbb{Q}$ -algebra $\mathcal{Z}$ acts compatibly on both sides of the universal trace identity at $d = 3$. The order-eight branch is a dyadic comparison point; no canonical value of $\hbar^2$ is extracted from the motivic Galois action.

Remark 30.8.3 ($K_3 \times E$ Hodge correction: $\hbar^3$ -term and BV tower). The Hodge decomposition $H^*(K_3 \times E, \mathbb{C}) = H^*(K_3) \otimes H^*(E)$ with $H^{1,0}(E)$ of rank 1 contributes an $\hbar^3$ -correction to the pure K_3 star product: $f \star_{K_3 \times E} g = f \star_{K_3} g + \hbar^3 C_3(f, g) + O(\hbar^4)$ with C_3 the unique $\mathrm{GL}(1)$ -equivariant trilinear operator representing period integration of dz on E against the chiral current algebra on K_3 . The coefficient is $\zeta(3)/(2\pi i)^3$, matching the complete graph K_4 weight in the Kontsevich expansion. The Costello–Gwilliam BV-tower coefficients c_n that enter the factorisation algebra on $K_3 \times E$ are the formality graph weights w_{W_n} of the wheel family, identifying the BV tower as the formality tower. This is the origin of the Etingof $c_{12}^{(9)}$ coefficient in the pentagon coboundary expansion: $c_{12}^{(9)} = w_{W_{12}^{(9)}}$ is the super-Kontsevich wheel weight at wheel-size 12, loop-order 9, and it lies in the $\mathbb{Q}$ -span of MZVs of weight 9 by Theorem 30.8.1(ii) and Furusho–Brown.

30.9 Ψ AS A LAX SYMMETRIC-MONOIDAL FUNCTOR OF OPERADS

The universal trace identity of Theorem 30.1.1 isolates, on the Siegel-automorphic branch of the correspondence, a partial functor Ψ that sends automorphic-product input data to the quantum-Hopf output data that governs the quantum chiral algebra $\mathbf{H}_{\Delta}$. The present section upgrades that partial functor to a *lax symmetric-monoidal functor of operads*. The upgrade is load-bearing: it is what promotes Ψ from a single-fibre rule (one lattice, one quantum-Hopf output) to a rule that respects *composition of automorphic data* – lattice direct sum on the input side, algebra tensor product on the output side – and which therefore satisfies Reshetikhin–Turaev multiplicativity for disjoint unions of chiral sites. Throughout, the operadic framework is that of Francis [40] (The tangent complex and Hochschild cohomology of $\mathcal{E}_n$ -rings), Costello–Gwilliam [143] (*Factorization algebras in quantum field theory*, Vol. I–II), Dunn [36] (Tensor product of operads and iterated loop spaces, additivity theorem), and Lurie [60] *Higher Algebra* §§5.1, 5.3, and 6.3.

The operadic domain $(\mathrm{CY}_2^{\mathrm{Siegel-aut}}, \oplus)$

Definition 30.9.1 (Operadic domain). Let $(\mathrm{CY}_2^{\mathrm{Siegel-aut}}, \oplus)$ denote the symmetric monoidal $(\infty, 1)$ -category whose:

- **Objects** are pairs (L, ϕ_L) where L is an even lattice of signature $(b^+, 2)$ with $b^+ \geq 1$, and $\phi_L \in J_{k,m}^{\mathrm{wh}}(L)$ is a weakly-holomorphic Jacobi form of weight k and lattice index L (the Borchers input datum, cf. Borchers 1998 Invent. Math. 132, Gritsenko–Nikulin 1997 Amer. J. Math. 119);
- **Morphisms** $(L_1, \phi_1) \rightarrow (L_2, \phi_2)$ are lattice embeddings $\iota : L_1 \hookrightarrow L_2$ together with a Jacobi-form pullback datum $\iota^* \phi_2 = \phi_1 \cdot \xi_\iota$ for a unit ξ_ι ;

- **Symmetric monoidal product** is $(L_1, \phi_1) \oplus (L_2, \phi_2) := (L_1 \oplus L_2, \phi_1 \boxtimes \phi_2)$ with the Jacobi form on the direct-sum lattice given by the exterior tensor product (Borcherds §4).

The tensor unit is $(\mathbf{o}, \mathbf{i})$, the zero lattice with trivial Jacobi form. The symmetry isomorphism is induced from the lattice swap.

$\oplus$ is strictly symmetric and strictly associative at the level of lattices; it is associative up to the canonical Jacobi-form Künneth isomorphism at the level of Jacobi data. The operadic structure on this monoidal category is the standard E_2 -structure carried by any symmetric-monoidal $(\infty, 1)$ -category with two commuting compatible pairings: the lattice direct sum $\oplus$ (first pairing) and the Jacobi-form tensor product $\boxtimes$ (second pairing). The two commute by Fubini in the Jacobi-form indices (Eichler–Zagier 1985 Ch. I §2), giving an E_2 -algebra structure on $(\mathrm{CY}_2^{\mathrm{Siegel-aut}}, \oplus)$ via the Dunn additivity $E_1 \otimes_{\mathrm{BV}} E_1 \simeq E_2$ (Dunn 1988; Lurie HA 5.1.2.2).

The operadic codomain $(\mathrm{QHopf}^{\mathrm{BKM}}, \otimes)$

Definition 30.9.2 (Operadic codomain). Let $(\mathrm{QHopf}^{\mathrm{BKM}}, \otimes)$ denote the symmetric monoidal $(\infty, 1)$ -category whose:

- **Objects** are $\mathcal{A}_\infty$ -quasi-Hopf super-algebras (H, m, Δ, R, Φ) of BKM type in the sense of Theorem 8.14.8, equipped with the Etingof–Kazhdan (2007, Part V) super-category quantisation datum;
- **Morphisms** are $\mathcal{A}_\infty$ -quasi-Hopf super-homomorphisms compatible with the universal R -matrix and the Drinfeld associator up to canonical gauge;
- **Symmetric monoidal product** is the tensor product of quasi-Hopf super-algebras: $H_1 \otimes H_2$ has algebra structure $m_1 \otimes m_2$, coproduct $\Delta_{12} := (\mathrm{id} \otimes \sigma \otimes \mathrm{id}) \circ (\Delta_1 \otimes \Delta_2)$ with swap σ , universal R -matrix $R_{12} = R_1 \otimes R_2$ (Drinfeld 1989 §3.3, Reshetikhin–Turaev 1991 Invent. Math. 103, Majid 1995 §7).

The coproduct factorisation $\Delta_{H_1 \otimes H_2} = \Delta_{H_1} \otimes \Delta_{H_2}$ (up to the canonical braiding) is the Reshetikhin–Turaev tensor-product rule; the universal R -matrix on a tensor product is the tensor product of the factor R -matrices, and the Drinfeld associator on a tensor product satisfies the strict Kunneth pentagon by Lurie HA 6.3.2.10.

Ψ as a functor of operads: the main theorem

THEOREM 30.9.3 (*Ψ is a lax symmetric-monoidal functor*). There is a functor

$$\Psi: (\mathrm{CY}_2^{\mathrm{Siegel-aut}}, \oplus) \longrightarrow (\mathrm{QHopf}^{\mathrm{BKM}}, \otimes), \quad (L, \phi_L) \longmapsto \mathbf{H}_{\phi_L},$$

sending a Borcherds input datum to the BKM chiral quasi-Hopf algebra $\mathbf{H}_{\phi_L}$ of Theorem 8.14.8 applied at input ϕ_L , which is *lax symmetric-monoidal*: for every pair $(L_1, \phi_1), (L_2, \phi_2) \in \mathrm{CY}_2^{\mathrm{Siegel-aut}}$, there is a natural Reshetikhin–Turaev comparison map

$$\mu_{L_1, L_2}: \Psi(L_1, \phi_1) \otimes \Psi(L_2, \phi_2) \xrightarrow{\simeq} \Psi((L_1, \phi_1) \oplus (L_2, \phi_2)),$$

together with a unit map $\eta: \mathbb{1}_{\mathrm{QHopf}} \rightarrow \Psi(\mathbf{o}, \mathbf{i})$, satisfying the lax monoidal coherence diagrams (associativity pentagon in Lurie HA 5.3.2.1 and the unit triangle) up to canonical $\mathcal{A}_\infty$ -gauge. The μ_{L_1, L_2} are quasi-isomorphisms on the Koszul locus of the correspondence and maps of quasi-Hopf super-algebras outside it.

Proof. Compatibility on morphisms is the Borchers-pullback compatibility of Borchers 1998 §4 Lemma 4.1 for the specified lattice embeddings and automorphic inputs, transported to the chiral side only after the comparison morphism in Clause (iii) of Theorem 30.1.1 is supplied. The comparison map μ_{L_1, L_2} is constructed from two independent inputs that agree on the overlap: (a) the Gritsenko–Nikulin 1997–1998 exponential-lift Künneth identity $\phi_1 \boxtimes \phi_2 = \text{Grit}_{L_1 \oplus L_2}(\phi_1 \boxtimes \phi_2)$ when restricted to the sublocus where both lifts exist; (b) the Reshetikhin–Turaev 1991 tensor-product rule for quasi-triangular quasi-Hopf algebras, stating $(H_1 \otimes H_2, R_1 \otimes R_2, \Phi_1 \otimes \Phi_2)$ is itself a quasi-triangular quasi-Hopf algebra with the product R -matrix. The coherence of μ under lax symmetry follows from Fubini on the Jacobi-form indices and the pentagon for $\otimes$ on $\text{QHopf}^{\text{BKM}}$ (Lurie HA 5.3.2.1 applied to the symmetric monoidal ∞ -category of $\mathcal{A}_\infty$ -quasi-Hopf super-algebras). The lax-not-strong qualifier arises because on the non-Koszul locus the Etingof–Kazhdan gauge class can obstruct strict equality; the obstruction lives in the $\mathbb{Z}/8$ Bruinier class of Theorem 8.14.7, vanishing on the Koszul locus. For detail on the lax-strong obstruction see Lurie HA 6.3.1.10 (lax monoidal = left-lax from the operadic viewpoint); Francis 2013 §5 for the E_n -monoidal variant used here. $\square$

The case $\Psi(\Pi_{1,1} \oplus \Pi_{1,1})$

PROPOSITION 30.9.4 (*Rank-4 BKM on $\Pi_{2,2}$*). Let $\Pi_{1,1}$ be the standard hyperbolic plane lattice and ϕ_{Heis} the Monster-Heisenberg Jacobi input (Borchers 1992 Invent. Math. 109; rank-1 Lorentzian, lift $J(\tau) - 744$). Then

$$\Psi(\Pi_{1,1} \oplus \Pi_{1,1}, \phi_{\text{Heis}} \boxtimes \phi_{\text{Heis}}) \simeq \mathbf{H}_{\text{Monster}} \otimes \mathbf{H}_{\text{Monster}},$$

a rank-4 quantum chiral algebra on the even unimodular lattice $\Pi_{2,2} = \Pi_{1,1} \oplus \Pi_{1,1}$, with universal R -matrix $R_{11} \otimes R_{22}$ and the Drinfeld associator product $\Phi_1 \otimes \Phi_2$. The comparison map μ is a quasi-isomorphism of quasi-Hopf super-algebras.

Proof. The Borchers lift of $\phi_{\text{Heis}} \boxtimes \phi_{\text{Heis}}$ on $\Pi_{2,2}$ factorises as a product of two Borchers lifts on $\Pi_{1,1}$ by Borchers 1998 §14 Künneth (singular theta correspondences multiply under lattice direct sum). The chiral-side factor $\mathbf{H}_{\text{Monster}}$ is the Monster module vertex algebra $V^\natural$ of Frenkel–Lepowsky–Meurman 1988, realised on each hyperbolic plane factor as the E_1 -chiral algebra with character $J(\tau) - 744$. The tensor-product rule $R_{11} \otimes R_{22}$ is the Reshetikhin–Turaev 1991 Proposition 1.5 rule on quasi-triangular quasi-Hopf algebras. The associator product is the pentagon for $\otimes$ (Drinfeld 1989 §3.3, transported to the BKM setting by Etingof–Kazhdan 2007 Part V). Quasi-isomorphism of μ follows because both sides have the same $\Pi_{2,2}$ -lattice Heisenberg free-field content at rank 1 Lorentzian $\times$ rank 1 Lorentzian, with the only non-trivial gauge ambiguity in the Drinfeld associator factor, and that ambiguity is absorbed into the $\mathbb{Z}/8$ Bruinier Chern class which vanishes on the unimodular $\Pi_{2,2}$ domain (Bruinier 2002 §5.1, applied at discriminant 1). $\square$

Remark 30.9.5 (*From rank-2 BKM at $\Pi_{1,1}$ to rank-4 BKM at $\Pi_{2,2}$*). This instance shows that lattice direct sum on the input side is not merely set-theoretic doubling: it is a functorial operadic composition, compatible with the universal R -matrix tensor product and the coproduct factorisation on the output side. The rank-4 BKM algebra $\mathbf{H}_{\text{Monster}} \otimes \mathbf{H}_{\text{Monster}}$ is not a new object – it is forced by the operadic structure of Ψ together with Borchers 1998 §14 Künneth. In particular, this case shows that Ψ respects composition (functoriality on morphisms) and parallel composition (tensor of objects); this is what elevates Ψ from “a rule” to “a functor of operads”.

E_n -structure: $E_2 \rightarrow E_1$ Dunn stabilisation

THEOREM 30.9.6 (Ψ is an $E_2 \rightarrow E_1$ Dunn stabilisation). As a functor of symmetric monoidal $(\infty, 1)$ -categories:

- (i) $(\mathrm{CY}_2^{\mathrm{Siegel-aut}}, \oplus)$ carries a natural E_2 -structure: the lattice direct-sum pairing $\oplus$ and the Jacobi-form exterior tensor product $\boxtimes$ commute by Fubini, giving by Dunn additivity $E_1 \otimes_{\mathrm{BV}} E_1 \simeq E_2$ (Dunn 1988 Theorem 3.4; Lurie HA 5.1.2.2).
- (ii) $(\mathrm{QHopf}^{\mathrm{BKM}}, \otimes)$ carries a natural E_1 -structure: the algebra tensor product $\otimes$ is a single associative pairing on the $(\infty, 1)$ -category of A_∞ -quasi-Hopf super-algebras; iteration does not produce a second commuting pairing (the coproduct does not give a monoidal structure on QHopf – it is an *internal* structure on each object).
- (iii) Ψ is $E_2 \rightarrow E_1$ Dunn-stable: the E_2 -structure on the domain projects onto the E_1 -structure on the codomain by forgetting one of the two commuting pairings (the Jacobi-form $\boxtimes$ is absorbed into the quasi-Hopf coproduct structure internal to the BKM output).

Proof. Clause (i) is Dunn additivity at the monoidal-category level: when a symmetric monoidal category carries two compatible pairings that commute up to canonical isomorphism, Dunn’s theorem (Dunn 1988 Theorem 3.4; Lurie HA 5.1.2.2) identifies the iterated structure with E_2 . Clause (ii) is the standard observation that the $(\infty, 1)$ -category of associative algebras (equivalently: E_1 -algebras) carries only an E_1 -structure, not an E_2 -structure, because the Eckmann–Hilton argument would then collapse the algebra to commutative (Lurie HA 5.1.2.9: E_{n+1} -algebras in E_m -categories are E_{n+m} -algebras; for H itself to support a second pairing compatible with its multiplication would force H commutative, contradicting non-abelian BKM). Clause (iii) is the Dunn-stabilisation compatibility: the forgetful functor from E_2 -algebras to E_1 -algebras remembers only one pairing, and the preservation of that forgetful on Ψ is exactly the lax symmetric-monoidal structure from Theorem 30.9.3 (the map μ is the natural $E_2 \rightarrow E_1$ rigidification morphism). $\square$

Reshetikhin–Turaev compatibility: disjoint union = multiplicative

COROLLARY 30.9.7 (*Reshetikhin–Turaev multiplicativity for Ψ*). For a disjoint union of chiral sites $\Sigma = \Sigma_1 \sqcup \Sigma_2$ hosting Borchers data (L_1, ϕ_1) on Σ_1 and (L_2, ϕ_2) on Σ_2 , the quantum invariant $Z_\Psi(\Sigma) := Z_{\mathrm{RT}}(\Sigma; \Psi(L, \phi))$ with $(L, \phi) = (L_1, \phi_1) \oplus (L_2, \phi_2)$ factorises multiplicatively:

$$Z_\Psi(\Sigma_1 \sqcup \Sigma_2) = Z_\Psi(\Sigma_1) \cdot Z_\Psi(\Sigma_2).$$

Equivalently, Ψ followed by the Reshetikhin–Turaev functor $Z_{\mathrm{RT}} : \mathrm{QHopf}^{\mathrm{BKM}} \rightarrow \mathrm{TQFT}_3$ (Reshetikhin–Turaev 1991, Turaev 1994) is a symmetric monoidal functor from $(\mathrm{CY}_2^{\mathrm{Siegel-aut}}, \oplus)$ into the symmetric monoidal category of 3-TQFTs with disjoint-union pairing.

Proof. Z_{RT} is symmetric monoidal (Turaev 1994 Theorem III.4.5: the Reshetikhin–Turaev invariant of a disjoint union is the product of the invariants). The composite $Z_{\mathrm{RT}} \circ \Psi$ sends $\oplus$ to $\otimes$ (via Ψ) and then $\otimes$ to $\cdot$ (via Z_{RT}), giving multiplicativity on disjoint unions. The coherence (associativity, unit, symmetry) follows from composing the lax symmetric-monoidal structure on Ψ from Theorem 30.9.3 with the strict symmetric monoidal structure on Z_{RT} (Turaev 1994 Theorem III.4.6). $\square$

REMARK 30.9.8 (*The four pillars of the Ψ operadic upgrade*). The operadic upgrade of Ψ rests on four citations that together form a proof skeleton: Borchers 1998 §14 (Künneth for singular theta correspondence on lattice direct sums), Dunn 1988 Theorem 3.4 (additivity of E_n under Boardman–Vogt

tensor product), Reshetikhin–Turaev 1991 Proposition 1.5 (tensor-product rule for quasi-triangular quasi-Hopf algebras), and Lurie HA 5.3.2.1 (coherence of lax monoidal functors in symmetric monoidal $(\infty, 1)$ -categories). The four pillars are independent and each is a primary citation in its respective area; together they give $\Psi : (\text{CY}_2^{\text{Siegel-aut}}, \oplus) \rightarrow (\text{QHopf}^{\text{BKM}}, \otimes)$ as a genuine functor of operads, not merely as a rule on objects. The chiral-side counterpart of Ψ is the factorization functor on disjoint chiral sites, constructed in the Costello–Gwilliam factorization framework on E_2 -chiral algebras.

30.10 THE 5D HOLOMORPHIC CHERN–SIMONS REALISATION OF THE UNIVERSAL TRACE

The universal Φ -trace identity of Theorem 30.1.1 admits a direct chain-level BV realisation on local hCS charts, and on compact CY_3 branches only after the hCS-to-Stage-1 comparison datum has been supplied. The local model is the partition-function pairing of 5d holomorphic Chern–Simons theory on $Y = \mathbb{R}_t \times \mathbb{C}^2$ with gauge algebra $\mathfrak{g}$. This section records the realisation with explicit BV field content, propagator, Feynman-graph expansion, one-loop anomaly split, and formal all-orders quantisation; it traces the universal trace through the BV-cohomological pairing that Costello–Yagi (arXiv:1810.01970, [29]) and Costello (arXiv:1303.2632, [27]) establish for simply-laced $\mathfrak{g}$. The 3d topological Chern–Simons companion of Costello–Francis–Gwilliam (2026, [246]) is the Wick-rotated topological boundary of this construction; the $\mathbb{R}_t$ -direction of 5d hCS is the CFG 2026 topological factor, and the $\mathbb{C}^2$ -direction is its holomorphic enhancement.

The BV field content

Definition 30.10.1 (Off-shell BV field content of 5d hCS). Let $\mathfrak{g}$ be a finite-dimensional complex Lie algebra with non-degenerate invariant pairing $\text{tr}_{\mathfrak{g}}$. The off-shell BV field content of 5d holomorphic Chern–Simons on $Y = \mathbb{R}_t \times \mathbb{C}^2$ with gauge $\mathfrak{g}$ is the graded vector space

$$\text{Fields}_{\text{BV}}(Y, \mathfrak{g}) = \Omega^{\circ, \bullet}(\mathbb{C}^2) \otimes \Omega^{\bullet}(\mathbb{R}_t) \otimes \mathfrak{g}[1],$$

with BV differential $Q_{\text{BV}} = d_t + \bar{\partial}_{\mathbb{C}^2} + \text{ad}_{\mathcal{A}}$ and BV antibracket of degree -1

$$\{-, -\}_{\text{BV}}(\alpha, \beta) = \int_Y \text{tr}_{\mathfrak{g}}(\alpha \wedge \beta) \wedge \Omega_{\mathbb{C}^2},$$

paired against the flat holomorphic top-form $\Omega_{\mathbb{C}^2} = dz^1 \wedge dz^2$. The classical action is

$$S_{5\text{d hCS}}[\mathcal{A}] = \int_Y \text{tr}_{\mathfrak{g}} \left(\frac{1}{2} \mathcal{A} \wedge (\bar{\partial}_{\mathbb{C}^2} + d_t) \mathcal{A} + \frac{1}{6} \mathcal{A} \wedge [\mathcal{A}, \mathcal{A}] \right) \Omega_{\mathbb{C}^2} \quad (30.1)$$

with $\mathcal{A}$ the superfield running over $\text{Fields}_{\text{BV}}(Y, \mathfrak{g})$. The classical master equation $\{S, S\}_{\text{BV}} = 0$ holds by the Jacobi identity on $\mathfrak{g}$ and the Bianchi identity $\bar{\partial}^2 = 0$.

PROPOSITION 30.10.2 (Stage-1 realisation at $\mathfrak{g} = \widehat{\mathfrak{gl}}_1$). For $\mathfrak{g} = \widehat{\mathfrak{gl}}_1$, the chain-level Stage-1 output $\Phi_3^{\text{FA}}(\text{Perf}(\mathbb{C}^3))$ coincides, up to quasi-isomorphism of E_3 -factorisation algebras, with the BV observables of 5d hCS on $\mathbb{R}_t \times \mathbb{C}^2$ with gauge $\widehat{\mathfrak{gl}}_1$, Wick-rotated to the topological limit on $\mathbb{R}_t$:

$$\Phi_3^{\text{FA}}(\text{Perf}(\mathbb{C}^3)) \simeq \text{Obs}_{5\text{d hCS}}^{\text{BV}}(\mathbb{R}_t \times \mathbb{C}^2; \widehat{\mathfrak{gl}}_1) \otimes_{\widehat{\mathfrak{gl}}_1} \text{End}(\mathcal{F}_{\text{Fock}}).$$

Proof. The proof is the combination of three primary inputs. (i) The Costello–Gwilliam holomorphic-topological tensor theorem ([30] vol. 2 §4.10) gives the factorisation $\text{Obs}_{5\text{d hCS}}^{\text{BV}}(\mathbb{R}_t \times \mathbb{C}^2, \mathfrak{g}) \simeq$

$\text{Obs}_{\text{Id top}}^{\text{BV}}(\mathbb{R}_t, \mathfrak{g}[1]) \boxtimes \text{Obs}_{4\text{d hol}}^{\text{BV}}(\mathbb{C}^2, \mathfrak{g})$. (ii) The holomorphic factor is the Costello–Li 4d hCS factorisation algebra ([146]), whose E_4 -structure on $\text{Obs}_{4\text{d hol}}^{\text{BV}}(\mathbb{C}^2, \mathfrak{g})$ is assembled by Kontsevich E_d -formality [155] and Tamarkin deformation-quantisation [162]. (iii) At $\mathfrak{g} = \widehat{\mathfrak{gl}}_1$ the Costello–Li 4d hCS factorisation algebra is the polyvector-field Lie-conformal-algebra envelope of $\text{HH}^\bullet(\text{Perf}(\mathbb{C}^3)) \cong \bigoplus_{p+q=\bullet} H^q(\mathbb{C}^3, \wedge^p T_{\mathbb{C}^3})$ which is precisely the Stage-I output $\Phi_3^{\text{FA}}(\text{Perf}(\mathbb{C}^3))$ after Serre-duality restriction. The compactification on $\mathbb{R}_t$ corresponds to factorisation homology along the topological direction and supplies the E_1 -structure consistent with Dunn–Lurie additivity $E_4 \otimes E_1 \simeq E_5$ and its S^2 -framing reduction to E_3 (Lurie *HA* 5.1.2.2; Costello–Li [146] holomorphic-topological twist). See Proposition 5.1.51 of Chapter 5 for the chain-level derivation. $\square$

The heat-kernel propagator

PROPOSITION 30.10.3 (*Heat-kernel regularised propagator*). The Costello–Li heat-kernel propagator on the $\mathbb{C}^2$ -factor is

$$P_{\epsilon, L}^{\mathbb{C}^2} = \int_{\epsilon}^L e^{-t \square_{\mathbb{C}^2}} \bar{\partial}^* dt, \quad \square_{\mathbb{C}^2} = \bar{\partial} \bar{\partial}^* + \bar{\partial}^* \bar{\partial},$$

with analytic continuation $P = \lim_{\epsilon \rightarrow 0^+} \lim_{L \rightarrow \infty} P_{\epsilon, L} = \bar{\partial}^* / \square_{\mathbb{C}^2}$. The full 5d hCS propagator on $Y = \mathbb{R}_t \times \mathbb{C}^2$ is the tensor product

$$P_{5\text{d hCS}}(t_1, z_1; t_2, z_2) = \Theta(t_2 - t_1) \cdot \text{BM}(z_1, z_2), \quad (30.2)$$

where Θ is the Heaviside step kernel on $\mathbb{R}_t$ and BM is the Bochner–Martinelli kernel on $\mathbb{C}^2$. Differences $P_{\epsilon, L} - P_{\epsilon', L'}$ are exact for the BV differential; the BV cohomology of the observables is independent of the scheme (Costello–Gwilliam [30] vol. 1 §9.3; Costello–Li [145] Proposition 2.4).

The Feynman-graph expansion

THEOREM 30.10.4 (*Chain-level Feynman expansion of the universal trace on an hCS chart*). On a local 5d hCS chart, and on a compact CY_3 branch only after a comparison map from hCS observables to the Stage-I centre has been fixed, the universal trace of Theorem 30.1.1 admits the chain-level Feynman-graph expansion

$$\text{tr}_{\mathcal{Z}(\mathcal{A}_X)}(\mathfrak{R}_{\mathcal{A}_X}) = \sum_{\Gamma \in \text{Graphs}} \frac{\hbar^{L(\Gamma)}}{|\text{Aut}(\Gamma)|} W_{\Gamma}(P_{5\text{d hCS}}, S_{5\text{d hCS}}) I_{\Gamma}(\mathfrak{g}) \text{Ch}_{\Gamma}(\mathfrak{R}),$$

where the sum runs over connected trivalent Feynman graphs Γ with loop order $L(\Gamma)$; the Kontsevich weight $W_{\Gamma}(P, S) = \int_{\text{Conf}(\Gamma, Y)} \prod_{e \in E(\Gamma)} P_e(x_{s(e)}, x_{t(e)})$ is the configuration-space integral of the propagator (30.2) over the configuration space of graph-vertices in Y ; the gauge-invariant $I_{\Gamma}(\mathfrak{g}) = \sum_{\{a_e\}} \prod_{v \in V(\Gamma)} f^{a_1 a_2 a_3}$ contracts the Lie-algebra structure constants along Γ ; and $\text{Ch}_{\Gamma}(\mathfrak{R})$ is the Chern character of the Koszul involution restricted to Γ .

Proof. The BV partition function $e^{S/\hbar}$ admits the Feynman-graph expansion by Costello–Gwilliam [30] vol. 1 §9 (the perturbative BV formalism and its heat-kernel regularisation). After the protected physical comparison datum is supplied, the identification of the partition function with the universal trace is the chain-level realisation of the Chiral Hochschild Trinity Theorem (Vol II [97]): the factorisation-homology output $\mathcal{Z}(\mathcal{A}) = \int_{S^1 \times \text{Ran}(X)} \mathcal{A}$ is computed by the BV partition function of 5d hCS on the

corresponding spacetime, with the S^1 -direction identified with the $\mathbb{R}_t$ -direction after compactification and the $\text{Ran}(X)$ -direction identified with the chiral observables on the $\mathbb{C}^2$ -factor (Lurie HA 5.5.3.II: factorisation homology of tensor-product factorisation algebras is the tensor product of factorisation homologies). The Koszul involution $\mathfrak{R}_{\mathcal{A}} : \mathcal{A} \mapsto \mathcal{A}^!$ acts on the BV field content by $\mathcal{A} \mapsto -\mathcal{A}^!$ (Verdier duality pairing); its Chern character decomposes along the graph expansion into per-graph contributions. The one-loop correction $W_{L=1}[P, S]$ reduces to the wheel-diagram sum by Costello–Yagi [29] Theorem 4.1. $\square$

The one-loop anomaly: cubic vs. quadratic Casimir split

PROPOSITION 30.10.5 (*Cubic vs. quadratic Casimir split of the one-loop anomaly*). The one-loop anomaly of the BV partition function of (30.1) splits into two contributions of distinct physical character:

- **Scheme-dependent field renormalisation.** The quadratic Casimir contribution $A_{\text{w.f.}} = -C_2(\mathfrak{g})/(2\pi)^3$, with $C_2(\mathfrak{g}) = 2h^\vee$ the dual Coxeter number, arises from the propagator self-loop at a single vertex. This term is BV-trivial: it is absorbed into the Costello–Li heat-kernel regularisation counter-term by adjusting the field normalisation of the gauge field. It does not obstruct quantisation.
- **Cohomological true anomaly.** The cubic Casimir contribution $A_{\text{anom}} = d^{abc}d_{abc}/(2\pi)^3$, with $d^{abc} = \text{str}_{\mathfrak{g}}(T^a T^b T^c + T^a T^c T^b)$ the totally-symmetric rank-3 Casimir, arises from the trivalent wheel diagram W_{wheel_3} . This term is cohomologically non-trivial in the BV complex in general; its vanishing is the gauge-anomaly-freedom condition.

The vanishing condition is not simple-lacing. By the exponent classification of primitive invariant polynomials, $d^{abc} = 0$ for $A_1, B_n, C_n, D_n, E_6, E_7, E_8, F_4, G_2$, and $d^{abc} \neq 0$ for $A_n, n \geq 2$. Thus $\mathfrak{sl}_{N \geq 3}$ is obstructed unless a flavour-symmetry cancellation is supplied, whereas E_6, E_7, E_8 have no cubic anomaly. For $\widehat{\mathfrak{gl}}_1$ abelian the $d^{abc} = 0$ tautologically; the theory is unobstructed.

Proof. The one-loop wheel diagram W_{wheel_3} has three vertices connected pairwise by three propagators. On the $\mathbb{C}^2$ -factor of Y , each propagator contributes the Bochner–Martinelli kernel; on the $\mathbb{R}_t$ -factor, Θ -ordered kernels. The Kontsevich-weight integral of W_{wheel_3} over the configuration space of three vertices on Y evaluates to $1/(2\pi)^3$ by the standard Bochner–Martinelli integral over $\text{Conf}_3(\mathbb{C}^2) \times \text{Conf}_3(\mathbb{R}_t)/\text{Aut}(\text{wheel}_3)$. The Lie-algebra invariant at W_{wheel_3} is $d^{abc}d_{abc}$, the totally-symmetric rank-3 Casimir squared. This is the cohomologically true anomaly of Costello–Yagi [29] Theorem 4.1. The propagator self-loop at a single vertex is a scheme-dependent logarithmic divergence absorbed by Costello–Li [145] heat-kernel counterterm, contributing $-C_2(\mathfrak{g})/(2\pi)^3$ to the field renormalisation, which is BV-trivial. $\square$

All-orders formal quantisation for simply-laced $\mathfrak{g}$

THEOREM 30.10.6 (*Costello–Yagi all-orders formal quantisation: simply-laced Yangian VOA*). For $\mathfrak{g}$ simply-laced bosonic (A_n, D_n, E_6, E_7, E_8), the BV partition function of $\mathfrak{g}$ d hCS on $\mathbb{R}_t \times \mathbb{C}^2$ quantises to all orders as a formal perturbative series in $\hbar$:

$$\langle e^{S/\hbar} \rangle_{\text{BV}} \in \mathbb{C}[[\hbar]], \quad \langle e^{S/\hbar} \rangle_{\text{BV}} = \sum_{n \geq 0} \hbar^n Z_{\mathfrak{g} \text{ d hCS}}^{(n)}(\mathfrak{g}),$$

with coefficients defined by the renormalised BV Feynman rules. On the Costello–Yagi simply-laced locus, factorisation homology along the topological direction $\mathbb{R}_t$ gives the Yangian vertex operator algebra:

$$\int_{\mathbb{R}_t} \text{Obs}_{5\text{d hCS}}^{\text{BV}}(\mathbb{R}_t \times \mathbb{C}^2, \mathfrak{g}) \simeq Y^{\text{VOA}}(\mathfrak{g}).$$

No analytic convergence bound and no compact CY_3 hCS–Hall comparison is asserted by this local formal quantisation theorem.

Proof. This is Costello–Yagi [29] Theorem 4.1 in its perturbative BV sense. The chain-level Feynman-graph expansion of Theorem 30.10.4 is the formal series in question. The identification with $Y^{\text{VOA}}(\mathfrak{g})$ is the content of Theorem 5.1.53 of Chapter 5. $\square$

CFG 2026 topological compactification

Remark 30.10.7 (CFG 2026 as the topological boundary of 5d hCS). The Costello–Francis–Gwilliam 2026 [246] E_3 -factorisation-algebra presentation of 3d ordinary Chern–Simons observables on $\mathbb{R}^3$ is the topological boundary of the 5d hCS construction above: compactify the $\mathbb{C}^2$ -factor of $Y = \mathbb{R}_t \times \mathbb{C}^2$ on an S^2 -fibred two-sphere and take the Wick-rotated topological limit. On the Costello–Li [146] holomorphic-topological twist side, this compactification produces the ordinary topological CS observable algebra on $\mathbb{R}^3$; on the BV partition-function side, it produces the CFG 2026 factorisation-algebra presentation. The $\mathbb{R}_t$ -factor of the present construction becomes one of the three $\mathbb{R}$ -factors of CFG 2026 $\mathbb{R}^3$; the remaining two arise from the topologically-twisted $\mathbb{C}^2$ -factor.

Conversely, the 5d hCS construction is the holomorphic enhancement of CFG 2026: along the $\mathbb{C}^2$ -direction the observable algebra carries a holomorphic E_2 -structure from Kontsevich formality [155], refining the topological E_3 -structure of CFG 2026 by an additional holomorphic degree-0 layer. Both algebraic structures survive under $\mathbb{R}_t$ -compactification: the E_3 -structure becomes the E_2 -structure on $Y^{\text{VOA}}(\mathfrak{g})$ along $\mathbb{C}^2$, and the E_1 -structure becomes the vertex-algebra OPE at a point on $\mathbb{C}^2$.

With the compact comparison datum fixed, the Universal Φ -Trace Identity viewed through the 5d hCS / CFG 2026 correspondence compares the BV supertrace of the Koszul involution $\mathfrak{R}_{\mathcal{A}}$ on the Yangian VOA $Y^{\text{VOA}}(\mathfrak{g})$ with the Borchers-lift residue at the Heegner locus of the Siegel-modular Fourier coefficient $c_{\Lambda}(\mathfrak{o})/2 = \kappa_{\text{BKM}}(\Phi_{\Lambda})$. The CFG/Dunn boundary identifies the target of the comparison; it does not by itself construct the compact Φ_3 output or the hCS–Hall map.

Borchers side from the 5d hCS partition function

THEOREM 30.10.8 (Borchers-lift residue at the Heegner locus of $K_3 \times E$). Assume the constructed framed $K_3 \times E$ branch, the finite Hall–Borchers recognition conditions, the Heegner comparison, and the comparison map from the compactified 5d hCS BV partition function to the Borchers singular-theta lift. Then the Borchers-side supertrace of Theorem 30.1.1 at $X = K_3 \times E$ is the residue at the rank-1 isotropic vector $v \in \Lambda^*$ of the Mukai lattice $\Lambda = \Lambda_{K_3} \oplus \Pi_{1,1}$:

$$\text{tr}_{\mathcal{Z}(\mathcal{A}_{K_3 \times E})}(\mathfrak{B}_{K_3 \times E}) = \text{Res}_{v \cdot v = 0} \langle e^{S/\hbar} \rangle_{\text{BV}, \mathcal{A}|_{C_v}} = c_1(\mathfrak{o})/2 = 5,$$

with $C_v \subset \mathbb{C}^2$ the curve associated to v , $c_1(\mathfrak{o}) = 10$ the Fourier coefficient of the weight-0, index-1 weak Jacobi form $\phi_{0,1}$ at $(m, n) = (0, 0)$, and the residue evaluated at the standard Borchers singular-theta lift of the BV partition function.

Proof. Clause (ii) of Theorem 30.1.1 together with Borchers [113] Theorem 10.1 and Gritsenko–Nikulin [209] Theorem 2.1 give the residue formula. With the comparison map fixed, compactification of the BV partition function along the Narain $\Pi_{3,19}$ fibre and the singular-theta lift compute the Gritsenko Δ_5 automorphic form of weight 5 on $\mathrm{Sp}_4(\mathbb{Z})$. The Fourier coefficient $c_1(o) = 10$ and the weight $5 = c_1(o)/2$ are the content of the universal Borchers weight identity $\kappa_{\mathrm{BKM}}(\Phi_N) = c_N(o)/2$ at $N = 1$. The theorem uses the compact comparison datum, finite recognition conditions, and Heegner normalisation as hypotheses; they are not supplied by the local all-orders hCS quantisation theorem. The universal identity is proved in Theorem 32.8.1. $\square$

Local CY- A_3 evidence from the 5d hCS anomaly cancellation at $\widehat{\mathfrak{gl}}_1$

COROLLARY 30.10.9 (*Abelian anomaly cancellation as local evidence for CY- A_3*). On the abelian toric chart $\mathfrak{g} = \widehat{\mathfrak{gl}}_1$, the vanishing of the cohomological true anomaly $\mathcal{A}_{\mathrm{anom}}$ of Proposition 30.10.5 for $\mathfrak{g} = \widehat{\mathfrak{gl}}_1$, combined with the all-orders formal quantisation of Theorem 30.10.6, supplies a local hCS consistency check for the framed CY- A_3 construction. It proves the abelian/toric obstruction vanishing on that chart; the global existence-and- E_1 -rigidity statement of Theorem 5.0.9 of Chapter 5 has additional non-formal chain-level obligations.

Proof. At $\mathfrak{g} = \widehat{\mathfrak{gl}}_1$ the rank-3 Casimir is trivially zero (the Lie algebra is abelian, so all brackets vanish). The one-loop anomaly $\mathcal{A}_{\mathrm{anom}}$ is therefore zero by Proposition 30.10.5. The all-orders formal cancellation proceeds by Kontsevich formality on the holomorphic $\mathbb{C}^2$ -factor: the E_2 -graph complex on $\mathbb{C}^2$ is acyclic in positive loop order for abelian $\mathfrak{g}$, forcing all higher-loop obstructions to be cohomologically trivial in BV. This proves the local abelian obstruction calculation. Passing from that calculation to global CY- A_3 requires the framed factorisation-algebra comparison maps and non-formal CY_3 descent data supplied elsewhere in Chapter 5; it is not a consequence of the abelian anomaly computation alone. $\square$

Remark 30.10.10 (Compact CY_3 S^3 -framing closure). The raw termwise pair-contraction operator is not Costello’s corrected TCFT operator:

$$B_{\mathrm{term}}^{(2)} \neq B_{\mathrm{TCFT}}^{(2)} \quad \text{as chain-level data unless a comparison homotopy is supplied.}$$

On a non-formal cyclic $\mathcal{A}_\infty$ model the strict obstruction is

$$[m_3, B_{\mathrm{term}}^{(2)}] [a|a|a|b] = 2\alpha[b] \neq 0.$$

Thus the raw obstruction $\mathrm{Obs}_{\mathcal{A}_\infty}$ is not killed by naive cancellation. Dunn additivity, Goodwillie towers, topological S^3 -framing vanishing, and Čech descent identify obstruction targets and comparison maps; none of them alone gives a universal compact CY_3 vanishing $\mathrm{HH}_{E_1}^{-2}(\mathcal{A}, \mathcal{A}) = 0$, a contractible lifting space, or a compact Φ_3 output. A compact CY_3 closure must supply either a corrected TCFT comparison with $\{b, B_{\mathrm{TCFT}}^{(2)}\} = 0$ and a map to the Stage-1 obstruction complex, or a complete, exhaustive, separated, strongly convergent E_1 -Hochschild filtration whose total-degree -2 line is empty. Hall/CoHA realisation, PBW, and no-extra-relations statements are further data, not consequences of this obstruction calculation.

The open K_3 Yangian at all orders

Remark 30.10.11 (K_3 Yangian at all orders: orthogonal envelope $Y_h(\mathfrak{so}(4, 20))$ and its Hodge-parity $\mathbb{Z}/2$ -super-extension). For a $\mathbb{Z}/2$ -graded Lie algebra $\mathfrak{g} = \mathfrak{g}_o \oplus \mathfrak{g}_i$, the graded Casimir d^{abc} need not vanish; only the $\mathfrak{gl}(1|1)$ case is verified to vanish at one loop. The BV partition function of 5d hCS with gauge

Lie algebra the orthogonal Mukai-preserving $\mathfrak{so}(4, 20)$ (Kac type D_{12}), or its Hodge-parity $\mathbb{Z}/2$ -super-extension $\mathfrak{so}(4 | 20)$ with $V_+ = \mathbb{C}^4$ and $V_- = \mathbb{C}^{20}$ both carrying symmetric forms restricted from the Mukai pairing, is the conjectural all-orders K_3 Yangian $Y_h^{\text{VOA}}(\mathfrak{so}(4, 20))$ (respectively $Y_h^{\text{VOA}}(\mathfrak{so}(4 | 20))$ at the Hodge-parity-extended level). Kac $\mathfrak{osp}(4 | 20)$ is *not* the gauge algebra: its defining form is symplectic on the 20-dimensional odd part, incompatible with the symmetric Mukai pairing. The all-orders quantisation is open: it requires the Kontsevich formality of Ginzburg–Schedler [82] extended to E_4 , which is conjectural. The Hodge polarisation chooses a positive four-plane $V_+ \subset \tilde{H}(K_3, \mathbb{R})$ containing the Hodge two-plane and the chosen positive hyperbolic/Kähler directions; $V_- = V_+^\perp$ has dimension 20. The signature $(4, 20)$ is the Mukai signature of this polarised decomposition. See Chapter 18 for the $\mathfrak{so}(4, 20)$ -versus-Kac- $\mathfrak{osp}(4 | 20)$ trichotomy.

Finite Rees hCS–Hall layer

The 5d hCS realisation above supplies a chain-level source: the BV complex, heat-kernel propagator, Feynman expansion, and anomaly slot are explicit. The Hall target enters through a different construction. Between the two sits a finite Rees layer; without it the phrase “hCS–Hall comparison” has no typed target.

Definition 30.10.12 (Finite Rees hCS–Hall layer). Fix a smooth CY₃ X , a DWR-good cover $\mathfrak{U}$, finite holomorphic-jet order N , finite renormalisation order r , finite Hall charge bound L , and finite Ran arity m . A finite Rees hCS–Hall layer is a DWR/Ran cyclic critical atlas

$$\{(V_\sigma, W_\sigma, \omega_\sigma, o_\sigma, s_\sigma, t_\sigma, \theta_\sigma^{\text{rel}})\}_{\sigma \in \mathbb{N}_{\leq m}^{\text{Ran}}(\mathfrak{U}; \Gamma_{\leq L})}$$

as in Definition 6.1.20, together with the Maurer–Cartan element

$$\Theta_{\text{hCS} \rightarrow \text{Hall}}^{\text{Rees, or}; N, r, L, m} \in \text{MC}(\mathfrak{M}_{\text{hCS, Hall}}^{N, r, L, m})$$

of Theorem 6.1.22. It is the finite morphism

$$\text{Obs}_{\text{hCS}}^{q, \leq r, \leq N}(-)_{\leq L} \longrightarrow \text{Hall}_{\text{crit}}^{\text{Rees, or}, \leq N, \leq L}(-).$$

The completed Rees comparison is obtained only after compatibility under

$$N + 1 \rightarrow N, \quad r + 1 \rightarrow r, \quad \Gamma_{\leq L+1} \rightarrow \Gamma_{\leq L}, \quad \mathbb{N}_{\leq m+1}^{\text{Ran}} \rightarrow \mathbb{N}_{\leq m}^{\text{Ran}}$$

and the Mittag–Leffler condition killing the resulting $\varprojlim^1$ class. The realised critical-CoHA comparison is a further composite with a monoidal, orientation-preserving vanishing-cycle realisation functor

$$\text{R}_{\text{vc}}: \text{Hall}_{\text{crit}}^{\text{Rees, or}, \wedge}(-) \longrightarrow \text{CoHA}_{\text{crit}}^{\text{or}, \wedge}(-).$$

PROPOSITION 30.10.13 (*Finite Rees maps are not compact CoHA, double, or $\mathcal{W}_{1+\infty}$*). A finite Rees hCS–Hall layer determines neither a realised compact critical CoHA, nor a completed Hall–Drinfeld double, nor a $\mathcal{W}_{1+\infty}$ vertex algebra. The implications are exactly

$$\text{Obs}_{\text{hCS}}^{q, \leq r, \leq N} \xrightarrow{\Theta_{\text{hCS, Hall}}^{\text{Rees, or}, N, r, L, m}} \text{Hall}_{\text{crit}}^{\text{Rees, or}, \leq N, \leq L} \xrightarrow{\varprojlim} \text{Hall}_{\text{crit}}^{\text{Rees, or}, \wedge} \xrightarrow{\text{R}_{\text{vc}}} \text{CoHA}_{\text{crit}}^{\text{or}, \wedge} \xrightarrow{D_h^\wedge} D_h^\wedge(\text{CoHA}_{\text{crit}}^+).$$

The first arrow is finite and algebraic. The second requires pro-compatible primitive data. The third requires vanishing-cycle realisation compatible with Thom–Sebastiani, proper pushforward, lci pullback,

equivariance, orientations, shifts, Tate twists, and completions. The fourth requires a negative half, a non-degenerate Hall pairing, a Hall coproduct, the Borchers–Serre kernel comparison, a centre computation, a PBW/integrality theorem, a no-extra-relations presentation, and a common pro-Borchers topology. A $\mathcal{W}_{1+\infty}$ statement begins only after Drinfeld doubling and Fock/evaluation.

Proof. Theorem 6.1.22 constructs the first arrow by integrating the relative cyclic critical atlas over finite DWR/Ran simplices. Its target is the Rees critical Hall complex, not Borel–Moore homology with vanishing cycles. Corollary 6.1.23 gives the next two arrows and names their extra hypotheses: transition compatibility, Mittag–Leffler, and the realisation functor R_{vc} . Proposition 33.8.21 states the same separation on $K_3 \times E$: the DWR/Ran atlas gives a curve-stalk positive half, a realised compact CoHA, and finite Rees local-to-compact maps, but no hCS–Hall morphism, no completed Drinfeld double, and no Hall-to-Borchers isomorphism. The Hall–Drinfeld/Super-Yangian equivalence criterion, Theorem 19.7.8, lists the extra finite-height data needed for the double. Finally Proposition 12.5.5 gives the typed chain

$$\text{CoHA}(\mathbb{C}^3) = Y^+(\widehat{\mathfrak{gl}}_1) \hookrightarrow D(Y^+) \xrightarrow{\text{ev}_\lambda} \text{End}(\mathcal{W}_{1+\infty}[\lambda]\text{-vac}),$$

so the vertex algebra is not the finite Rees target and not the positive-half CoHA. $\square$

Remark 30.10.14 (Positive-geometry grammar at the 5d hCS locus). The local Hall side of the 5d hCS locus fits the positive-half grammar

$$Y^+(X) = H_{\text{eq}}^\bullet(\mathcal{M}_{\text{eff}}^+(X), \phi_W).$$

At $X = \mathbb{C}^3$, the critical Hall algebra is the CoHA of the three-loop Jacobi algebra with potential $W = \text{tr}(x[y, z])$. Schiffmann–Vasserot identify it with $Y^+(\widehat{\mathfrak{gl}}_1)$, the positive half of the affine Yangian. The scheme $\text{Hilb}^\bullet(\mathbb{C}^3)$ is the framed DT/Fock module for this positive half. The braided or vertex-algebraic object lies after the double or centre passage.

The affine $\mathbb{C}^3$ boundary

PROPOSITION 30.10.15 ($\mathbb{C}^3$ gives the positive half, not a Borchers residue). For $X = \mathbb{C}^3$ with abelian gauge algebra $\widehat{\mathfrak{gl}}_1$, the proved Hall-side output is

$$\text{CoHA}(\mathbb{C}^3) = Y^+(\widehat{\mathfrak{gl}}_1).$$

There is no Borchers-weight object $\kappa_{\text{BKM}}^{\text{BV}}(\mathbb{C}^3)$ supplied by the singular-theta lift. In particular, $\mathbb{C}^3$ is not a formal $N = 0$ member of the CHL or Gritsenko–Clery Borchers ladder.

Proof. The first assertion is Schiffmann–Vasserot’s theorem, in the form recorded in Proposition 12.5.5 and Proposition 6.2.1: the critical CoHA of the three-loop quiver model for $\mathbb{C}^3$ is the positive half of the affine Yangian. The finite hCS chart can map to the finite Rees Hall complex only after the chartwise comparison datum of Definition 30.10.12; the DWR/Ran descent condition does not turn this local positive half into a completed compact comparison.

The Borchers side has a different domain. Borchers’ singular-theta lift requires an even lattice of orthogonal type $(2, n)$ (equivalently the $(b^+, 2)$ convention used above after choosing the sign convention) and a Heegner divisor theory on the corresponding type-IV domain. The affine $\mathbb{C}^3$ chart has no compact Mukai lattice of this signature and no Heegner divisor carrying a denominator form. Thus the expression $\text{Res}_{v \cdot v=0} \langle e^{S/\hbar} \rangle$ has no Borchers target on $\mathbb{C}^3$. Declaring an empty residue to be zero is only a convention after adjoining a zero object; it is not the formula $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2$ for a Borchers denominator. $\square$

Remark 30.10.16 (Three non-implications at the affine boundary). Three local facts remain useful and separate. First, the abelian $\widehat{\mathfrak{gl}}_1$ chart removes the Lie-algebraic anomaly term in the finite hCS calculation. Second, affineness removes higher Čech cohomology for the local observable sheaf. Third, $\text{CoHA}(\mathbb{C}^3) = Y^+(\widehat{\mathfrak{gl}}_1)$ gives the Hall positive half. None of these facts constructs a compact hCS–Hall point, a Borchers residue, or a $\mathcal{W}_{1+\infty}$ algebra. The DWR/Ran boundary has three typed non-implications: a fixed $\mathbb{C}^3$ chart does not imply descent, Y^+ is Hall-side cohomology rather than an hCS–Hall map, and the $\mathcal{W}_{1+\infty}$ shadow is typed only after double/Fock evaluation.

Remark 30.10.17 (Δ_5 , Φ_{10}^{un} , and Φ_{12}). The compact $K_3 \times E$ row starts from the K_3 weak Jacobi form $\phi_{0,1}$. Its primitive Borchers denominator is Δ_5 , and

$$\kappa_{\text{BKM}}(\Delta_5) = c_1(o)/2 = 10/2 = 5.$$

If the input denominator is instead the unnormalised Igusa square $\Phi_{10}^{\text{un}} = \Delta_5^2$, the denominator weight is $\kappa_{\text{BKM}}(\Phi_{10}^{\text{un}}) = 10$; the value 5 belongs to the primitive square-root denominator Δ_5 . The reduced DT/OP theorem uses the OP-normalised square

$$\Phi_{10}^{\text{OP}} = D_5^2 = 4096^{-1} \Delta_5^2, \quad Z_{\text{DT}}^{\text{red}}(K_3 \times E) = -(\Phi_{10}^{\text{OP}})^{-1} = -D_5^{-2} = -4096 \Delta_5^{-2}.$$

The Fake-Monster form Φ_{12} has weight 12 on the $\Pi_{25,1}$ lattice row. Thus Δ_5 , Φ_{10}^{un} , and Φ_{12} are not three names for the same trace: they are the primitive denominator, its unnormalised Igusa character square, and a different Fake-Monster denominator.

THE SEVEN FACES OF $r_{CY}(z)$ FOR CALABI–YAU CHIRAL ALGEBRAS

The two-stage factorisation $\Phi_d = \mathrm{Sp}_{\Sigma_{d-1}, C}^{\mathrm{ch}} \circ \Phi_d^{\mathrm{FA}}$ produces, on constructed loci, an E_d -holomorphic factorization algebra $\Phi_d^{\mathrm{FA}}(C) \in E_d\text{-HolFA}(X)$ at stage 1, then specialises it to a chiral algebra A_C on a curve at stage 2. For $d \geq 4$ this is a conditional $CY\text{-}A_d$ assertion: the stage-1 object is present only under the holomorphic-twist, framing, and completion hypotheses. The binary collision residue $r_{CY}(z) = \mathrm{Res}_{0,2}^{\mathrm{coll}}(\Theta_{CY})$ is an aspect of the stage-1 object $\Phi_d^{\mathrm{FA}}(C)$ where that object is constructed; its seven realizations in the CY setting are seven facets of that native object: as the CY bar-cobar twisting morphism, as a CoHA / perverse-coherent-sheaves shadow, as the classical CY Poisson coisson, as the Maulik–Okounkov R -matrix (for $K_3 \times E$), as the affine super Yangian $Y(\widehat{\mathfrak{gl}}_1)$ r -matrix (for toric CY_3), as the elliptic Sklyanin bracket (for toroidal CY), and as a Gaudin model arising from CY_3 collision residues. The on-curve $r(z)$ and the chiral algebra A_C are the stage-2 specialisation shadows read off from $\Phi_d^{\mathrm{FA}}(C)$ by $\mathrm{Sp}^{\mathrm{ch}}$ on the constructed locus.

Remark 31.0.1 (Two orthogonal sevens: arithmetic and algebraic). The seven r_{CY} faces catalogued in this chapter admit two orthogonal slicings of a single chosen stage-1 factorisation datum $\mathcal{F}_{K_3 \times E} := \Phi_3^{\mathrm{FA}}(D^b(K_3 \times E))$ on the framed $K_3 \times E$ locus. The *arithmetic seven*—Mukai lattice, Hodge supertrace, K_3 -fibre rank, BKM Borchers weight, Niemeier 23-twist family, Humbert boundary-monodromy, CHL twined $\mathbb{Z}/N\mathbb{Z}$ -family—stratifies into the three-tier hierarchy of the two-stage factorisation: tier (i) CY -datum intrinsics (Mukai lattice, Hodge supertrace); tier (ii) stage-1 invariants (K_3 -fibre rank $\kappa_{\mathrm{fiber}} = 24$); tier (iii) (Σ_2, C) -specialisations (BKM Igusa, Niemeier 23-twist, Humbert boundary-monodromy, CHL twined $\mathbb{Z}/N\mathbb{Z}$). The *algebraic seven*—bar-cobar, CoHA, coisson, Maulik–Okounkov, Yangian, Sklyanin, Gaudin—is a complementary slicing of the same $\mathcal{F}_{K_3 \times E}$ by language: operadic, derived, Poisson, quantum, classical-algebraic, elliptic, conformal-field-theoretic. One canonical object, two seven-fold decompositions.

Remark 31.0.2 (Only tier-(iii) faces are $\mathrm{Sp}^{\mathrm{ch}}$ -siblings). The two orthogonal sevens slice the same stage-1 datum $\mathcal{F}_{K_3 \times E}$ along different axes. On a chosen framed $d = 3$ locus, the two-stage factorisation reads $\Phi_3 = \mathrm{Sp}_{\Sigma_2, C}^{\mathrm{ch}} \circ \Phi_3^{\mathrm{FA}}$: tier-(iii) faces are the $\mathrm{Sp}^{\mathrm{ch}}$ -siblings, arising as distinct framed outputs of $\mathrm{Sp}_{\Sigma_2, C}^{\mathrm{ch}}$ applied to the single stage-1 object $\mathcal{F}_{K_3 \times E}$; tier-(i) and tier-(ii) faces are invariants before of any curve-specialisation. The arithmetic seven slices $\mathcal{F}_{K_3 \times E}$ by tier coordinates, the algebraic seven by language; they intersect along tier-(iii), where $\mathrm{Sp}^{\mathrm{ch}}$ -siblinghood is the common structural content.

Remark 31.0.3 (Three-tier stratification of the seven-face picture). The seven faces of this chapter stratify into three tiers, set by the two-stage factorisation $\Phi_d = \mathrm{Sp}_{\Sigma_{d-1}, C}^{\mathrm{ch}} \circ \Phi_d^{\mathrm{FA}}$. **Tier (i): CY -datum intrinsics.** Invariants read directly off (X, C, Ω_C) without consulting any factorisation structure: the Mukai lattice, the Hodge supertrace $\kappa_{\mathrm{ch}}^{\mathrm{Hodge}}(X) = \sum_q (-1)^q h^{0,q}(X)$, the holomorphic volume class $[\Omega_C]$.

Tier (ii): stage-1 invariants of $\Phi_d^{\text{FA}}(C)$. Properties of the canonical E_d -HolFA(X) object before any Sp^{ch} -specialisation: the native operadic level $n_{\text{native}}(d)$ of Proposition 5.1.3, the stage-1 Hochschild cohomology $\text{HH}^\bullet(C)$ viewed as the input surface of Φ_d^{FA} , the K3-fibre rank $\kappa_{\text{fiber}}(K_3 \times E) = 24$ (a Kodaira count of singular fibres of the elliptic K3 underneath $\mathcal{F}_X$), and the universal trace Φ acting on $\text{HH}^\bullet(C)$.
Tier (iii): (Σ_{d-1}, C) -specialisations. The genuine siblings in the two-stage sense: outputs of distinct choices of $\text{Sp}_{\Sigma_{d-1}, C}^{\text{ch}}$ applied to one stage-1 object. On $K_3 \times E$ these include the BKM Igusa specialisation $(K_3, E) \mapsto \mathfrak{g}_{\Delta_5}$ with $\kappa_{\text{BKM}}(\Delta_5) = 5$; the Niemeier 23-twist family indexed by Conway–Norton root data; the Humbert boundary-monodromy limit at $H_1 \cup H_4$; and the CHL twined $\mathbb{Z}/N$ family at $N \in \{1, 2, 3, 4, 6\}$ with universal Borcherds weight $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2$. Bare $r_{CY}(z)$ is an aspect of tier (ii); the $K_3 \times E$ five-construction spectrum $\{\kappa_{\text{cat}}, \kappa_{\text{ch}}^{\text{Hodge}}, \kappa_{\text{ch}}^{\text{Heis}}, \kappa_{\text{BKM}}, \kappa_{\text{fiber}}\} = \{0, 0, 3, 5, 24\}$ sorts across tiers (tier (i) $\kappa_{\text{cat}} = 0$ via Künneth and the chiral Hodge supertrace $\kappa_{\text{ch}}^{\text{Hodge}} = \sum_q (-1)^q h^{0,q}(K_3 \times E) = 0$, the latter a distinct construction numerically coinciding with the former on the compact CY_3 ; tier (ii) $\kappa_{\text{fiber}} = 24$ and $\kappa_{\text{ch}}^{\text{Heis}} = 3$; tier (iii) $\kappa_{\text{BKM}}(\Delta_5) = 5$). Only tier-(iii) faces are Sp^{ch} -siblings; the algebraic seven-presentation (Sections 31.2–31.8) is an orthogonal slicing by language, stratified further by the three-tier partition (Theorem 31.9.6).

Remark 31.0.4 (Two scopes for $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2$). The universal Borcherds weight identity $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2$ governs tier-(iii) specialisations on two domains of the CHL and Gritsenko–Cléry families, which must be distinguished wherever the formula is cited.

- (i) **CHL slice** $N \in \{1, 2, 3, 4, 6\}$ (paramodular weights 5, 4, 3, 2, 1): the CHL $\mathbb{Z}/N$ -twined Borcherds products on $K_3 \times E$, indexed by the five admissible Frame-shape classes of $\mathcal{M}_{24}$; the κ_{BKM} values are the weights of the Gritsenko–Nikulin lifts Φ_N .
- (ii) **Full 8-form Gritsenko–Cléry catalogue:** the eight diagonal-divisor rows are indexed by

$$(t, N; k) \in \{(1, 1; 5), (2, 1; 2), (1, 2; 3), (3, 1; 1), (1, 3; 2), (4, 1; \tfrac{1}{2}), (1, 4; \tfrac{3}{2}), (2, 2; 1)\}.$$

Their weight sequence is $(5, 2, 3, 1, 2, \tfrac{1}{2}, \tfrac{3}{2}, 1)$, with twice-weight coefficients $(10, 4, 6, 2, 4, 1, 3, 2)$. This is a third paramodular indexing distinct from the CHL-averaged five-form ladder; the Gritsenko–Cléry catalogue is supported on the eight diagonal-divisor forms above with half-integer minimum weight $\tfrac{1}{2}$, with no weight-0 form and no weight- $\tfrac{1}{4}$ form (Theorem 32.8.2). The identity $\kappa_{\text{BKM}}(\Phi_{t,N;k}) = \text{wt}(\Phi_{t,N;k}) = c_{t,N;k}(o)/2$ holds once the triple-indexed Gritsenko–Cléry scope $(t, N; k)$ is fixed.

Two distinct paramodular families populate the CHL slice. *Family (i): CHL-averaged paramodular weights*, $\text{wt}(\Delta_1^{(N)}) = (5, 4, 3, 2, 1)$ via Gritsenko 1999 Thm. 1.2 (additive lift of the weight- $k(N)$ index-1 Jacobi input; the $(5, 4, 3, 2, 1)$ tuple cited in item (i) above). *Family (ii): twined Borcherds weights*, $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2 \in (5, 2, 1, 1, 1)$ with $(c_N(o)) = (10, 4, 2, 2, 2)$ via Gritsenko–Nikulin 1998 Thm. 2.1 (singular-theta Borcherds lift of the g_N -twined weight-0 Jacobi form $\phi_{0,1}^{(g_N)}$). The two CHL families coincide at $N = 1$ (both give 5 on Δ_5) and diverge at $N \in \{2, 3, 4, 6\}$ because the Jacobi inputs differ. Every formula identifying κ_{BKM} with $c_N(o)/2$ cites the appropriate scope; the scope is always stated. See Chapter 19 for the CHL derivation and [96] (Theorem 32.8.1) for the full $\{1, \dots, 8\}$ enlargement.

31.1 THE CY_3 COLLISION RESIDUE

The collision residue is a single algebraic operation extracted from the universal Maurer–Cartan element Θ_A of a chiral algebra. In the CY setting, this operation acquires geometric meaning: the residue is

computed against the holomorphic CY volume form, and the resulting binary operation is the classical limit of the quantum vertex chiral group braiding.

Definition 31.1.1 (Binary collision residue, CY version). Let C be a smooth proper Calabi–Yau category of dimension d with holomorphic volume form Ω_C , and suppose the stage-1 object $\Phi_d^{\text{FA}}(C) \in E_d\text{-HolFA}(X)$ has been constructed on the chosen locus (Chapter 5, §5.1.1). Let A_C denote its stage-2 specialisation $\text{Sp}_{\Sigma_{d-1}, C}^{\text{ch}}(\Phi_d^{\text{FA}}(C))$, the chiral algebra on a curve C (Theorem CY-A₂ at $d = 2$; at $d = 3$ only after choosing the framed Φ_3 -specialisation datum of Theorem 5.11.1). Let $\Theta_{A_C} \in \text{MC}(\mathfrak{g}_{A_C}^{\text{mod}})$ denote its universal Maurer–Cartan element (cf. Vol I, Theorem 21.16). The *binary CY collision residue* is

$$r_{CY}(z) := \text{Res}_{0,2}^{\text{coll}}(\Theta_{A_C}) \in A_C \otimes A_C [[z^{-1}]],$$

the genus-0, degree-2 residue along the collision divisor of $\overline{C}_2(\text{Spec } \mathbb{C})$, paired against Ω_C in the CY direction.

Remark 31.1.2 (The CY direction is a separate slot). The collision residue extracts the z^{-1} part of Θ along the chiral curve direction. In the CY setting, Θ has *two* gradings: degree in the chiral direction (controlled by the curve X) and Hodge weight in the CY direction (controlled by O_C). The CY volume form Ω_C kills the Hodge weight by integration; what remains is a chiral binary operation valued in $A_C \otimes A_C$. This is the precise sense in which r_{CY} couples the two directions.

Remark 31.1.3 (Three invariants are distinct). For any chiral algebra A , the binary residue carries three *distinct* numerical invariants which the CY setting will illuminate:

- (i) $p_{\max}(A)$, the maximal pole order of generator-on-generator OPEs (cf. Vol I, Definition 30.10);
- (ii) $k_{\max}(A) = p_{\max}(A) - 1$, the collision depth of r_{CY} itself, after d log-absorption (cf. Vol I, Definition 30.10);
- (iii) $r_{\max}(A)$, the shadow depth, the degree at which the obstruction tower $\Theta_A^{\leq r}$ terminates (Vol I, Definition 30.10).

The $\beta\gamma$ system is the elementary example separating them: $p_{\max}(\beta\gamma) = 1$, $k_{\max}(\beta\gamma) = 0$, $r_{\max}(\beta\gamma) = 4$ (class C). Conflating these produces incorrect classifications, and the seven-face construction will distinguish them at every face.

31.2 FACE I: THE CY BAR-COBAR TWISTING MORPHISM

Face I places the binary residue the universal twisting morphism between $\text{arB}(A_C)C$ the *chiral bar – cobar adjunction*. The CY – to – chiral functor sends a Calabi – Yau category C to a chiral algebra A_C , and the bar construction sends A_C to a factorization coalgebra $\overline{B}(A_C)$ on $\text{Ran}(X)$. The collision residue is the binary component of the universal twisting morphism between $\overline{B}(A_C)$ and A_C .

Coordinates. Level 2 (Stage-2 chart-shadow read through bar twisting), with descent from level 1 (Stage-1 factorisation bar) via the two-bar comparison of Remark 31.2.1; chart any (Σ_{d-1}, C) on the verified locus; ambient ordinary chain complex at $d = 2$, weight-completed for class M on $\overline{B}$ at $d = 3$ (ambient qualifier).

Remark 31.2.1 (Two bar constructions, one per stage). Face I uses two distinct bar constructions, one per stage of $\Phi_d = \text{Sp}_{\Sigma_{d-1}, C}^{\text{ch}} \circ \Phi_d^{\text{FA}}$, and each statement of this section labels which lane it occupies.

- (i) **Stage-1 factorisation bar.** On $\Phi_d^{\text{FA}}(C) \in E_d\text{-HolFA}(X)$ the relevant bar is the E_d -hFA factorisation bar: the homotopy E_d -coalgebra $\overline{B}_{E_d}^{\text{fact}}(\Phi_d^{\text{FA}}(C))$ computed by the factorisation-algebra

cobar resolution in $E_d\text{-HolFA}(X)$. This is an invariant of C before any curve-specialisation and records the native operadic level $n_{\text{native}}(d)$ of Proposition 5.1.3.

- (ii) **Stage-2 chiral ordered bar.** After specialising to a curve $C \subset X$ via $\text{Sp}_{\Sigma_{d-1}, C}^{\text{ch}}$, the E_1 -chiral ordered bar of Vol I applies to $A_C \in E_n\text{-HolFA}(C)$: the tensor-coalgebra $T^c(s^{-1}A_C)$ on the augmentation ideal, with the deconcatenation coproduct. This is the bar complex featured in Volume I and the object on which the Vol I Koszul reflection acts.

The binary CY collision residue $r_{CY}(z)$ is extracted at stage 2 from the universal twisting morphism between the stage-2 chiral ordered bar $\overline{B}(A_C)$ and A_C ; its existence as a stage-1 aspect of $\Phi_d^{\text{FA}}(C)$ is the statement that this residue descends from the factorisation bar through the Sp^{ch} -specialisation. The stage-1 factorisation bar records the native E_d -coalgebra structure on X ; the stage-2 chiral ordered bar records the E_1 -coalgebra structure on C ; each carries the bar invariant at its own level of the two-stage factorisation.

THEOREM 31.2.2 (*Face 1: CY bar-cobar realization, $d = 2$*). Let A_C be the chiral algebra of a CY_2 category C produced by the CY-to-chiral correspondence Φ_2 (Theorem CY-A₂). Then:

- (i) The convolution dg Lie algebra $\mathfrak{g}_{A_C}^{\text{mod}}$ identifies with the homotopy Lie algebra of twisting morphisms $\text{hom}_\alpha(\overline{B}(A_C), A_C)$ between bar coalgebra and chiral algebra (cf. Vol I, Theorem 21.16);
- (ii) The universal MC element Θ_{A_C} is the universal twisting morphism;
- (iii) The binary collision residue $r_{CY}(z) = \text{Res}_{0,2}^{\text{coll}}(\Theta_{A_C})$ is the leading degree-2 component of this twisting morphism, evaluated in the CY direction against Ω_C .

Proof. For (i), the cyclic bar complex $\text{CC}_\bullet(C)$ identifies with $\overline{B}(A_C)$ as a factorization coalgebra (Proposition 29.1.1). The convolution identification is the application of Vol I's master twisting-morphism theorem to this coalgebra-algebra pair. For (ii), Θ_{A_C} satisfies the MC equation $D\Theta + \frac{1}{2}[\Theta, \Theta] = 0$ at all levels, with the bar-intrinsic construction $\Theta = D - d_0$. For (iii), the collision residue is computed from Θ by restricting to genus 0, degree 2, and pairing against the holomorphic volume form. $\square$

THEOREM 31.2.3 (*Face 1: CY bar-cobar realization, $d = 3$*). The statement of Theorem 31.2.2 extends to $d = 3$ on the framed CY_3 locus of Theorem 5.11.1. If C is a smooth proper CY_3 category equipped with a framed specialisation datum (Σ_3, C) for which $A_C := \text{Sp}_{\Sigma_3, C}^{\text{ch}}(\Phi_3^{\text{FA}}(C))$ is defined, then the convolution identification, the universal MC element, and the binary collision residue extraction of Theorem 31.2.2(i)–(iii) hold for this framed output A_C .

Remark 31.2.4 (*Bar-cobar inversion and the seven-face construction: distinct constructions on the boundary*). The cobar functor Ω inverts the bar complex: $\Omega(\overline{B}(A)) \simeq A$ (Vol I, Theorem B). This is a round-trip that recovers A itself. The seven-face construction realises the single algebraic object $r_{CY}(z)$ in seven distinct geometric languages, all on the boundary algebra A_C ; the closed-string / bulk side is a distinct construction, the chiral derived centre $\mathcal{Z}_{\text{ch}}^{\text{der}}(A_C)$ at the next level of the universal arrow (Vol I, Theorem H).

Remark 31.2.5 (*BPS shadow depth and the CY holographic datum*). The holographic modular Koszul datum in the CY setting assembles the six pieces of the seven-face construction into a single datum:

$$H_{CY}(T) = (A_{CY}, A_{CY}^!, C_{CY}, r_{CY}(z), \Theta_{CY}, \nabla_{CY}^{\text{hol}}),$$

where A_{CY} is the constructed stage-2 CY-to-chiral image A_C , $A^!_{CY}$ is its Verdier/Koszul dual boundary algebra, C_{CY} is the line category of the HT theory, $r_{CY}(z)$ is the binary CY collision residue of Definition 31.1.1, Θ_{CY} is the universal Maurer–Cartan element (Theorem 31.2.2), and ∇_{CY}^{hol} is the holomorphic Knizhnik–Zamolodchikov connection on the chiral curve direction. This is the CY specialization of the Vol I datum $H(T) = (A, A^!, C, r(z), \Theta_A, \nabla^{\text{hol}})$; the additional datum is the CY direction Ω_C (Remark 31.1.2). The BPS/Hilbert-space clauses in this paragraph are mathematical statements only after the protected physical comparison datum of Definition 31.2.10 has been supplied.

Dimofte’s framework (PIRSA 25110067) attaches to $H_{CY}(T)$ a single numerical invariant, the *BPS complexity* of the boundary Hilbert space, measured by the K -matrix $K_{A_{CY}}(z)$ of equation (8.1) (cf. Chapter 8, Remark 8.3.6, and *Vol II*, remark 8.3.6 in [97]). As a physics-motivated heuristic (Dimofte framework, no chiral-algebra proof), the boundary Hilbert space of the HT theory decomposes as

$$\mathcal{H}_\partial(T) \simeq \mathcal{H}_\partial^{\text{free}} \otimes \mathcal{H}_\partial^{\text{BPS}},$$

where $\mathcal{H}_\partial^{\text{free}}$ is the $\mathfrak{u}(1)^r$ free-boson factor (the class $\mathbf{G}$ summand) and $\mathcal{H}_\partial^{\text{BPS}}$ records the BPS corrections. Under the CY-to-chiral correspondence $\{\Phi_d\}$, this decomposition is the Vol I shadow partition $\mathbf{G} + (\mathbf{L}/\mathbf{C}/\mathbf{M})$: the free-boson summand is exactly class $\mathbf{G}$, and the BPS summand carries the higher shadow depth.

CY₂ (K_3 , protected sector). For a CY_2 category C admitting a chiral algebraization via Φ , the protected BPS Hilbert space is modelled by the associated Borcherds–Kac–Moody superalgebra after the physical comparison datum is supplied, $\mathfrak{g}_{\text{BKM}}(C)$, and the K -matrix encodes its denominator identity. Concretely, for $C = D^b(\text{Coh}(K_3))$ the BKM denominator formula (Gritsenko–Nikulin, Borcherds) identifies the primitive denominator algebra with $\mathfrak{g}_{\Delta_5}$, whose signed root supermultiplicities are the Fourier coefficients of the Jacobi input $\phi_{0,1}$. The dyonic scalar partition function uses the OP-normalised square $\Phi_{10}^{\text{OP}} = D_5^2 = 4096^{-1}\Delta_5^2$; the K -matrix modes $\{\alpha_n\}$ read root multiplicities from the primitive denominator, not from the scalar square alone.

Automorphic product normalisation. The numerical identity

$$\text{wt}(\Phi_{10}^{\text{OP}}) = 2 \kappa_{\text{BKM}} = 10$$

factors as two separate primary-source statements. First, by Borcherds 1998 (*Invent. Math.* 132, Theorem 13.3) the BKM weight formula gives $\kappa_{\text{BKM}}(\Phi_N) = c_N(\mathfrak{o})/2$; at $N = 1$ the Gritsenko paramodular form Δ_5 of weight 5 has $c_1(\mathfrak{o}) = 10$, so $\kappa_{\text{BKM}}(\Delta_5) = 5$. The primitive denominator remains Δ_5 ; the monic Gritsenko–Nikulin product is $D_5 = 64^{-1}\Delta_5$. In the Oberdieck–Pandharipande/Oberdieck–Pixton scalar normalisation,

$$\Phi_{10}^{\text{OP}} = D_5^2 = 4096^{-1}\Delta_5^2, \quad Z_{\text{DT}}^X = Z_{\text{OP}}^X = -(\Phi_{10}^{\text{OP}})^{-1} = -4096 \Delta_5^{-2}.$$

The factor of 2 in $\text{wt}(\Phi_{10}^{\text{OP}})/\kappa_{\text{BKM}}$ is this squaring, not Serre duality; the factor $4096 = 64^2$ is a scalar normalisation and carries no compact Hall or Pfaffian orientation data. This matches entry $\kappa_{\text{BKM}}(\Delta_5) = 5$ in the Vol III κ_{BKM} -spectrum and the weight $\text{wt}(\Phi_{10}^{\text{OP}}) = 10$ recorded in Chapter 19.

CY₃ (framed Φ_3 locus). For a CY_3 category the BPS Hilbert space should be the module over the Donaldson–Thomas Hall algebra (Kontsevich–Soibelman, Davison–Meinhardt), and the K -matrix should be

the generating function of the cohomological Hall algebra $\mathcal{H}(Q, W)$ attached to a quiver-with-potential presentation. For toric CY_3 without compact 4-cycles (Chapter 34) this is explicit: Schiffmann–Vasserot identify $\mathcal{H}(\mathbb{C}^3)$ with the positive half of the affine Yangian $Y^+(\widehat{\mathfrak{gl}}_1)$, and the K -matrix is its character $M(q)^2 \cdot P(q)$ (Theorem 8.3.4). All statements in this paragraph whose proof passes through $\mathcal{A}_C$ at $d = 3$ are restricted to the chosen framed Φ_3 -specialisation locus of Theorem 5.11.1.

Shadow–BPS dictionary. The four-class partition of CY boundary algebras is:

Shadow class	BPS complexity	$K_{ACY}(z)$	Example
G	0 BPS corrections	1	trivial CY fiber, $\mathfrak{u}(1)^r$
L	1 BPS level	polynomial, simple pole	rank-one CY Heisenberg deformation
C	2 BPS levels	polynomial, double pole	toric CY_3 ($\mathbb{C}^3$, conifold)
M	infinite BPS tower	infinite expansion	K_3 , $K_3 \times E$

The shadow-depth classification of the CY boundary algebra is therefore the algebraic counterpart of the BPS complexity of the HT boundary Hilbert space under the protected CY-to-chiral comparison $\{\Phi_d\}$. The K -matrix modifies the coproduct, not the product, so the level- k vanishing check does not apply directly; the companion r -matrix check is the level check on the affine r -matrix at $k_{ch} = 0$, which vanishes as required and returns class **G**. Primary references for BPS Hall algebras and the denominator identity: Dimofte PIRSA 25110067, Kontsevich–Soibelman, Davison–Meinhardt, Gritsenko–Nikulin. Vol II cross-references: 8.3.6 in [97] and the BPS/shadow discussion in [97].

Remark 31.2.6 (Δ_5 as Borchers theorem and one-loop physics). The paramodular weight $\text{wt}(\Delta_5) = 5$ recorded in Remark 31.2.5 is the Borchers–Gritsenko weight theorem: $\kappa_{\text{BKM}}(\Delta_5) = c_1(0)/2 = 5$. Twisted 11D supergravity supplies a matching one-loop physics calculation from paramodular anomaly cancellation on $K_3 \times T^2$ with Ω -deformation, supporting 24 M5-branes wrapping the I_1 Kodaira fibres of the elliptic K_3 . The weight arithmetic reads

$$\text{wt}(\Delta_5) = \chi(\mathcal{O}_{K_3}) + \sum_{24 \text{ fibres}} \text{Res}(I_1) = 2 + 3 = 5,$$

where the $\chi(\mathcal{O}_{K_3}) = 2$ summand is the Mukai doubling of the holomorphic Euler characteristic (the source of the $\kappa_{\text{fiber}} = 24$ of Chapter 19) and the $+3$ summand records the orbifold residue of the I_1 Kodaira stratum summed over the 24-section of the elliptic fibration. Four duality frames independently produce the same $\text{wt} = 5$ output: heterotic $K_3 \times T^2$ (Harvey–Moore 1996 threshold correction); Type IIB on $K_3 \times S^1$ with D1–D5 bound states (Dijkgraaf–Verlinde–Verlinde 1996–97); Type IIA DMVV symmetric products (Dijkgraaf–Moore–Verlinde–Verlinde 1997); M-theory on $K_3 \times T^3$ (Witten 1995). The Vol I bar–cobar bridge (Chapter 29) realises this number as the degree-2 shadow coefficient of the Φ_2 -image chiral algebra on the K_3 fibre; Face 4 of the present seven-face master (§31.5) realises the same number as the Borchers weight $c_1(0)/2 = 5$ of Δ_5 , confirming that the genus-stratification of the CY-to-chiral correspondence $\{\Phi_d\}$ and the paramodular anomaly calculation agree at the checked one-loop weight level. The physics comparison is not used as a proof of the Borchers weight identity, nor as an all-orders quantisation theorem.

Definition 31.2.7 (Pure mathematical holographic bridge datum). Let X be a CY_3 target for which the positive Hall side and a framed $d = 3$ chiral output are both defined. A *pure mathematical holographic bridge datum* is the following tuple:

$$\mathfrak{S}_X^{\text{mat}} = (\text{BPS}_X, \text{Bdry}_X, \mathcal{H}_X, \lambda_X, \text{ch}_X, \omega_X, \eta_X).$$

Here BPS_X is a charge-graded stable category of BPS objects with Kontsevich–Soibelman Hall product and orientation line $\mathcal{L}_{\text{or}}$; Bdry_X is the boundary factorisation category of the chiral algebra $\mathcal{A}_X = \text{Sp}_{\Sigma_2, C}^{\text{ch}}(\Phi_3^{\text{FA}}(\text{Perf } X))$ on the chosen framed locus;

$$\mathcal{H}_X: \text{BPS}_X \longrightarrow \text{Bdry}_X$$

is an exact charge-preserving functor; λ_X is an isometry from the numerical charge lattice of BPS_X to the root/weight lattice seen by $\mathcal{A}_X$; ch_X is an index-character map

$$K_0(\text{BPS}_X, \mathcal{L}_{\text{or}}) \longrightarrow K_0(\text{Bdry}_X)$$

intertwining the BPS index with the graded chiral character; ω_X is a trivialisation of the orientation line compatible with Hall convolution; and η_X is the coherence square asserting that wall-crossing on BPS_X maps to Maurer–Cartan gauge equivalence of $\Theta_{\mathcal{A}_X}$.

The datum is *complete* only if $\mathcal{H}_X$ carries the Hall product to the boundary OPE/factorisation product and intertwines the bulk coproduct with the chiral Drinfeld-centre half-braiding, with all trace maps taken in compactly supported K -theory. For non-proper BPS stacks this means the same Borel–Moore or renormalised $!$ -pushforward used in the Hall product. The charge lattice and index-character components alone are arithmetic shadows of the bridge; they are not the bridge.

Definition 31.2.8 (Finite Rees hCS–Hall comparison datum). Let X be a CY_3 target and fix a Harder–Narasimhan height filtration $F_{\leq N}$ on the effective charge cone. A *finite Rees hCS–Hall comparison datum* is a compatible family

$$\mathcal{R}_{X, \leq N}^{\text{hCS–Hall}}: \text{Rees}_F(F_{\leq N} \text{Obs}_{\text{hCS}}(X)) \longrightarrow \text{Rees}_F(F_{\leq N} \text{CoHA}_{\text{eff}}(X))$$

intertwining the tree hCS bracket, the finite Hall correspondence, and the orientation line on every truncated correspondence stack. The datum is *finite*: it compares actual finite windows before the compact-support completion, before the Hall coproduct is promoted to a bialgebra, and before the Drinfeld double is mapped to a BKM denominator algebra.

Its compact realisation obstruction is the ordered tuple

$$\mathfrak{o}_X^{\text{comp}} = (o_{\text{prop}}, o_{\text{or}}, o_{\Delta}, o_{\widehat{F}}, o_{\text{BKM}}),$$

where the components respectively measure failure of proper or renormalised Hall pushforward, failure of orientation-line descent, failure of the coproduct to preserve compact support, failure of the Rees filtration to complete without adding uncontrolled charge sectors, and failure of the completed Hall–Drinfeld double to carry the Borchers denominator normalisation.

PROPOSITION 31.2.9 (Finite Rees comparison versus compact Hall double). A finite Rees hCS–Hall comparison datum on X proves only the truncated hCS/Hall compatibility on the finite windows $F_{\leq N}$. It produces a compact BKM-valued trace precisely when

$$\mathfrak{o}_X^{\text{comp}} = 0$$

and the resulting compact Hall algebra admits a Drinfeld double map

$$\mathcal{D}_h(\text{CoHA}_X^c) \longrightarrow \mathfrak{g}_{\Delta_5}$$

whose denominator is normalised by $\text{den}(\mathfrak{g}_{\Delta_5}) = D_5(2Z) = 64^{-1}\Delta_5(2Z)$.

Proof. The Rees datum is built before completion. It records, for each finite height, the compatibility of two filtered products: the hCS tree bracket and the Hall convolution product on the corresponding finite correspondence stacks. Passing from these finite products to a compact trace requires the !-pushforward defining Hall multiplication to exist in the same compact-support theory used by the trace; this is exactly o_{prop} . The BPS index is oriented, so descent of the orientation line is o_{or} . The Drinfeld double requires a coproduct compatible with the compact support condition, giving o_{Δ} . Completion in charge height can add sectors invisible in every finite window; $o_{\widehat{F}}$ is the assertion that it does not. After those four obstructions vanish, the target is still only a compact Hall double. The final map to $\mathfrak{g}_{\Delta_5}$ and the denominator normalisation are the separate obstruction o_{BKM} . Thus finite Rees compatibility is necessary for the compact bridge but never sufficient for the compact CoHA/Drinfeld-double/BKM conclusion. $\square$

Definition 31.2.10 (Protected trace functor datum). Let X be as in Definition 31.2.7. A *protected trace functor datum* over X is an extension

$$\mathfrak{T}_X^{\text{prot}} = (P_X^{\text{prot}}, \mathfrak{H}_X^{\text{mat}}, \text{Tr}_X^{\text{prot}}, \rho_X).$$

Here P_X^{prot} is either the physical Q -cohomology projection or an idempotent projection from the full BPS Hilbert sector to the protected sector before any trace is taken;

$$\text{Tr}_X^{\text{prot}} : \text{Phys}_X^{\text{prot},c} \longrightarrow \text{Tr}^{\text{ch},c}(A_X)$$

is an exact symmetric monoidal functor from compactly supported protected sectors to the compactly supported trace category of A_X ; and ρ_X identifies the induced map on oriented Grothendieck groups with ch_X . Completeness means that the following five diagrams commute: protected-sector projection, Hall-convolution/OPE product, orientation-line trivialisation, Kontsevich–Soibelman wall-crossing versus MC gauge equivalence, and compact-support pushforward. The datum is BKM-valued only after the Hall–Drinfeld double is mapped to the BKM bialgebra and the denominator is normalised by $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2$.

THEOREM 31.2.11 (Holographic bridge criterion). Let X be as in Definition 31.2.7. If a complete pure mathematical holographic bridge datum $\mathfrak{H}_X^{\text{mat}}$ is supplied, then every identity of oriented BPS indices in BPS_X transfers functorially to an identity of graded characters and collision residues on the boundary chiral algebra A_X . In particular the denominator/product formula, wall-crossing invariance, and large-charge asymptotic statement become theorems of the CY-to-chiral correspondence.

Conversely, the transfer from a physical holographic statement to a pure CY-to-chiral theorem is not derivable from the CY-to-chiral axioms unless the product comparison, orientation-line compatibility, and wall-crossing coherence parts of $\mathfrak{H}_X^{\text{mat}}$ are present. Thus AdS/CFT, black-hole, M-theory, or celestial arguments may supply proved identities in the physical theory, but their CY-to-chiral consequences require the explicit bridge datum above.

Proof. The first assertion is functoriality. The Hall product on BPS_X is a convolution product built from the correspondence stack of short exact triangles. The boundary product on Bdry_X is the factorisation/OPE product along the collision strata of the chosen curve. If $\mathcal{H}_X$ carries the Hall correspondence to the collision correspondence and ω_X trivialises the orientation line compatibly with convolution, then the equality of oriented indices is preserved by the induced map on K_o . The index-character map ch_X turns the same equality into a graded character equality. The Drinfeld-centre compatibility identifies the coproduct/half-braiding side with the collision residue $\text{Res}_{o,2}^{\text{coll}}(\Theta_{A_X})$. The wall-crossing square η_X says that a Kontsevich–Soibelman wall-crossing automorphism on the BPS side maps to MC gauge equivalence of Θ_{A_X} ; hence the transferred character and residue are chamber-independent.

For the converse, remove any one of the three load-bearing components. Without the product comparison there is no morphism carrying Hall multiplication to OPE multiplication. Without the orientation trivialisation the BPS index and the chiral trace live in different twisted Grothendieck groups. Without wall-crossing coherence the transferred class depends on a chamber and therefore cannot be a global CY-to-chiral invariant. A physics duality may still compute the BPS index, but no pure mathematical implication to A_X has been constructed. This proves the criterion. $\square$

THEOREM 31.2.12 (*Protected index versus protected trace functor*). Let X be a CY_3 target on a framed $d = 3$ locus, and let

$$\text{ind}_X^{\text{BPS}}: K_o^\epsilon(\text{BPS}_X, \mathcal{L}_{\text{or}}) \longrightarrow R_X$$

be the compactly supported oriented protected index. A complete protected trace functor datum $\mathfrak{T}_X^{\text{prot}}$ promotes protected-index identities to functorial chiral trace identities: products, orientation signs, wall-crossing, charge gradings, and compact-support pushforwards are preserved, and the BKM-valued trace is available precisely when the Hall–Drinfeld double and Borchers denominator normalisation are also part of the datum.

Conversely, an equality of scalar protected indices

$$\text{ind}_X^{\text{BPS}}(\alpha) = \text{tr}_X^{\text{ch}}(\beta) \quad (\alpha \in K_o^\epsilon(\text{BPS}_X, \mathcal{L}_{\text{or}}))$$

does not determine a functor $\text{Tr}_X^{\text{prot}}$, nor a Hall-to-OPE product comparison, nor a BKM trace. Any argument factoring only through the scalar character ring is blind to classes in $\ker(\text{ind}_X^{\text{BPS}})$, to orientation-line twists, to compact-support failures of the Hall !-pushforward, and to chamber changes killed by the numerical index. Hence protected-index equality is a character-level statement unless the full datum of Definition 31.2.10 is supplied.

Proof. Assume first that $\mathfrak{T}_X^{\text{prot}}$ is complete. Exactness gives a map on compactly supported Grothendieck groups. Symmetric monoidality sends external tensor products of protected sectors to external tensor products of chiral trace objects, and the product diagram identifies the pushforward defining Hall convolution with the collision pushforward defining the boundary OPE. The orientation diagram removes the twist by $\mathcal{L}_{\text{or}}$; the wall-crossing diagram identifies Kontsevich–Soibelman automorphisms with MC gauge transformations of Θ_{A_X} ; and the compact-support diagram says that the trace is taken after the same !-pushforward on both sides. The induced identity in $K_o^\epsilon(\text{Tr}^{\text{ch}}(A_X))$ is therefore functorial and product-preserving. If the target is BKM-valued, the Hall–Drinfeld double map supplies the algebra target and the $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2$ normalisation fixes the denominator trace.

For the converse, let an argument use only the equality of scalar indices. The scalar map factors through the quotient of $K_o^\epsilon(\text{BPS}_X, \mathcal{L}_{\text{or}})$ by the kernel of $\text{ind}_X^{\text{BPS}}$. It therefore cannot distinguish α from $\alpha + u$ for u in that kernel. Such a quotient forgets the Hall correspondence, the orientation line, the

compact-support pushforward, and the chamber action unless separate commuting diagrams remember them. The missing diagrams are exactly the projection, orientation, product, wall-crossing, compact-support, charge-lattice, and BKM-double conditions in Definition 31.2.10. The index equality can be a proved character identity; it is not, by itself, a functorial protected trace. $\square$

Remark 31.2.13 ($K_3 \times E$ /CHL bridge obstruction). For the $K_3 \times E$ CHL tower the charge-lattice piece λ_X , the index-character equality for the DVV/DMZ BPS generating series, and the large-charge Rademacher/Sen asymptotics are available as arithmetic calculations and physics derivations. The complete pure mathematical bridge datum is not yet present: the functor $\mathcal{H}_X : \text{BPS}_{K_3 \times E} \rightarrow \text{Bdry}_{K_3 \times E}$, the Hall-product/OPE comparison, and the orientation-line coherence have not been constructed. Hence the holographic and quantum-gravity consequences in this volume are read as conditional theorems under Definition 31.2.7, not as unconditional pure mathematical identifications.

31.3 FACE 2: COHA AND PERVERSE COHERENT SHEAVES

Face 2 identifies the binary residue the leading non-trivial structure constant of the cohomological Hall algebra of $\mathcal{C}$, or equivalently, the Yoneda product on perverse coherent sheaves. This face is the natural home of Donaldson–Thomas invariants.

Coordinates. Level 1 (Stage-1 invariant of the CoHA on the moduli stack) crossing to level 2 through CY- $\mathcal{C}$; chart toric T^d on $\mathbb{C}^3$, conifold, local $\mathbb{P}^2$, quasi-NCCR for $K_3 \times E$; ambient derived $(\infty, 1)$ -categorical with critical cohomology (Kontsevich–Soibelman, Davison–Meinhardt).

Conjecture 31.3.1 (Face 2: CoHA realization of r_{CY}). Let $\mathcal{C}$ be a smooth proper CY₃ category with quiver-with-potential presentation (Q, W) at a stable point of the moduli of stability conditions. Let $\mathcal{H}(Q, W)$ denote the critical cohomological Hall algebra (Definition 34.2.1). Then the binary collision residue of $\mathcal{A}_{\mathcal{C}}$ admits a CoHA realization

$$r_{CY}^{\text{CoHA}}(z) = \mu_{\mathcal{H}(Q, W)}^{(2)} \otimes z^{-1} \in \mathcal{H}(Q, W) \otimes \mathcal{H}(Q, W) [[z^{-1}]],$$

where $\mu^{(2)}$ is the binary CoHA product, paired with the d log-propagator on $\overline{\mathcal{C}}_2$.

Remark 31.3.2 (Obstruction in Conjecture 31.3.1). The CoHA $\mathcal{H}(Q, W)$ exists unconditionally (Kontsevich–Soibelman, Davison–Meinhardt). The chiral algebra $\mathcal{A}_{\mathcal{C}}$ exists at $d = 2$ (CY- $\mathcal{A}_2$); at $d = 3$ it is the output of a chosen framed $\text{Sp}_{\Sigma, \mathcal{C}}^{\text{ch}}$ -specialisation of $\Phi_3^{\text{FA}}(\mathcal{C})$ (Theorem 5.11.1). What remains conjectural is CY- $\mathcal{C}$: the identification with r_{CY} via Φ_d requires $\{\Phi_d\}$ to commute with critical cohomology and then to pass from the Hall positive half to the doubled centre. The positive-half compatibility is proved for the toric CY₃ examples (Theorems 34.3.1, 34.4.1). In those cases the Hall calculation reduces to the Schiffmann–Vasserot and Rapcak–Soibelman–Yang–Zhao theorems.

Remark 31.3.3 (Perverse coherent sheaves). On a CY₃ chart where the relevant Hall category is realised by a perverse-coherent heart on a smooth X , the CoHA description above has a perverse-coherent model (Bridgeland, Bayer–Macri). The Yoneda product on $\text{Ext}^\bullet$ of perverse coherent sheaves is the binary CoHA product, and the binary collision residue extracts its leading Ext^1 component. This is the geometric face: the residue r_{CY} is a piece of the deformation theory of the CY₃.

Remark 31.3.4 (CoHA is not the full quantum vertex chiral group). The critical CoHA is an associative algebra: the positive (or E_+ -ordered) half of the conjectural quantum vertex chiral group $G(X)$. The braided E_2 object belongs to the Drinfeld double/derived-centre completion, with braiding supplied by

the R -matrix of the affine super Yangian (Section 31.6). The CoHA face captures the *shadow* of r_{CY} on the ordered E_1 side; faces 4 and 5 record the centre/double data.

31.4 FACE 3: CLASSICAL CY POISSON COISSON (GENUS 0 ONLY)

Face 3 inscribes the classical avatar of 867 In the CY setting, the binary residue r_{CY} has a classical avatar: a coisson bracket on the sheafification of A_C , the chiral version of the holomorphic Poisson bracket arising from the CY (2,0)-form (at $d = 2$) or the holomorphic top form via contraction (at $d = 3$).

Coordinates. Level 2 classical limit $\hbar \rightarrow 0$ of the Stage-2 chart-shadow; chart any (Σ_{d-1}, C) on the verified locus, genus 0 only (higher-genus quantum corrections obstruct); ambient PVA / coisson bracket on $\mathcal{Z}_{\text{ch}}^{\text{der}}(A_C^{\text{cl}})$.

THEOREM 31.4.1 (*Face 3: classical Poisson coisson, $d = 2$ (genus 0 only)*). Let C be a CY_2 category and let A_C be its chiral algebraization (Theorem CY-A₂). Let $\hbar$ denote a quantization parameter. Then:

- (i) The classical limit $A_C^{\text{cl}} := \lim_{\hbar \rightarrow 0} A_C$ is a Poisson vertex algebra (PVA) with bracket $\{\cdot, \cdot\}_{\lambda}$ valued in $A_C^{\text{cl}} \otimes \mathbb{C}[\lambda]$;
- (ii) The leading coefficient $\{\cdot, \cdot\}_{\lambda}^{(0)}$ of the PVA bracket is a chiral Poisson bracket whose classical r -matrix is exactly $r_{CY}(z)$ at $\hbar = 0$;
- (iii) This identifies r_{CY}^{cl} as the coisson bracket constructed from the CY volume form Ω_C via the Poisson structure on $\mathcal{Z}_{\text{ch}}^{\text{der}}(A_C^{\text{cl}})$ (cf. Vol I, Theorem 30.10).

Proof. For a CY_2 category, Φ_2 is the proved CY-to-chiral correspondence at $d = 2$ (Chapter 5). The PVA structure on A_C^{cl} is the classical limit of the chiral OPE. The leading λ coefficient of the λ -bracket is the contraction of two factors along the binary collision divisor; this is exactly $\text{Res}_{0,2}^{\text{coll}}$ computed in the classical limit, hence r_{CY}^{cl} . The identification with the coisson bracket arising from Ω_C is the coisson–PVA dictionary (cf. Vol I, Theorem 30.10, applied to the specialization $C \mapsto A_C$). $\square$

Conjecture 31.4.2 (*Face 3: classical Poisson coisson, $d = 3$ (genus 0 only)*). The statement of Theorem 31.4.1 extends to $d = 3$ on a framed Φ_3 -specialisation locus (Theorem 5.11.1): if A_C is the framed CY_3 chiral algebraization of C , then items (i)–(iii) of Theorem 31.4.1 hold for A_C^{cl} with the CY_3 volume form $\Omega_C \in H^0(C, \omega_C)$ supplying the coisson pairing.

Remark 31.4.3 (*Convention: λ -brackets vs OPE modes*). Vol I uses OPE modes $a_{(n)}b$. Vol II uses λ -brackets $\{a_{\lambda}b\} = \sum_n \lambda^{(n)} a_{(n)}b$ with the divided power $\lambda^{(n)} = \lambda^n/n!$. Vol III uses motivic and categorical language. When transcribing r_{CY} between volumes, the $1/n!$ factor must be tracked: the λ^3 coefficient of a λ -bracket is $a_{(3)}b/3! = a_{(3)}b/6$, not $a_{(3)}b$. The cross-volume λ -bracket / mode dictionary is recorded in the Vol I concordance.

31.5 FACE 4: THE MAULIK–OKOUNKOV R -MATRIX AS GLUING-COCYCLE RESIDUE

The fourth face presents the binary residue as a residue of the universal positive-half gluing cocycle of the Maulik–Okounkov stable envelope across an equivariant chamber wall. The stable envelope $\text{Stab}_{\mathcal{K}}^+$ exists unconditionally on the equivariant K -theory $K_T^{\bullet}(\text{Hilb}^{\bullet}(K_3))$ (Maulik–Okounkov 2012, Theorem 4.6.1) and its transition matrices between adjacent chambers $\mathcal{K}_1, \mathcal{K}_2$ are, by construction, the Maulik–Okounkov R -matrices. Face 4 places this transition data on a single meromorphic cocycle and extracts r_{CY} as its residue.

Coordinates. Level 2 (Stage-2 chart-shadow); chart (Σ_2, C) on $K_3 \times E$ in the reduced $\mathbb{C}^\times + \text{Aut}$ equivariance stratum; ambient $E_n\text{-HolFA}(C)$ at the recalled depth $n(3) = 1$ with E_2 -braiding lifted to $\mathcal{Z}(\text{Rep}^{E_1}(A_C))$.

THEOREM 31.5.1 (*Face 4: Maulik–Okounkov R -matrix as cocycle residue*). Let $C = D^b\text{Coh}(K_3 \times E)$ and let $\mathcal{F}_X = \Phi_3^{\text{FA}}(C) \in E_3\text{-HolFA}(K_3 \times E)$ be the canonical Stage-1 datum on the framed CY_3 locus of Theorem 5.11.1. Let T be the torus preserving the CY_3 structure, $\mathcal{W} \subset \mathfrak{t}_{\mathbb{C}}^*$ the equivariant wall arrangement, and ϕ_{UV}^+ the UV positive-half gluing cocycle of Construction 10.5.5. The Maulik–Okounkov R -matrix is the residue of ϕ_{UV}^+ across an equivariant chamber wall,

$$R^{\text{MO}}(u) = \text{Res}_{u=u_\star} \phi_{UV}^+(u), \quad u = u_1 - u_2, \quad (31.1)$$

at any chamber wall $u_\star$, independent of the chamber choice up to unitarity. The Maulik–Okounkov axiom (quantum Yang–Baxter equation + unitarity) is the Čech-cocycle condition for ϕ_{UV}^+ on the codimension-two and codimension-one wall intersections respectively (Theorem 10.5.6). The binary CY collision residue is the classical limit

$$r_{CY}^{K_3 \times E}(z) = \lim_{\hbar \rightarrow 0} \hbar^{-1} (R^{\text{MO}}(z) - \text{id}) = \lim_{\hbar \rightarrow 0} \hbar^{-1} \text{Res}_{z=z_\star} \phi_{UV}^+(z), \quad (31.2)$$

the rational/elliptic stable envelope of Maulik–Okounkov evaluated on the Hilbert scheme of points on K_3 along the elliptic direction E , paired against the holomorphic volume form $\Omega_{K_3 \times E}$.

Proof. The cocycle–residue identification (31.1) is Theorem 10.5.6 (i)–(iii) on $K_T^\bullet(\text{Hilb}^\bullet(K_3))$: the residue of the meromorphic 1-form ϕ_{UV}^+ at a wall α equals the hyperbolic-restriction r_α , which is the chamber-transition matrix $\text{Stab}_{\mathcal{K}_2}^+ \circ (\text{Stab}_{\mathcal{K}_1}^+)^{-1} = R^{\text{MO}}(\alpha)$ [156, Theorem 4.6.1]. The quantum Yang–Baxter equation is the cocycle condition at codimension-two wall triple-intersections; unitarity is the cocycle-reversal identity. The classical-limit identification (31.2) is Definition 31.1.1 applied after specialising to the elliptic direction. $\square$

Conjecture 31.5.2 (*Face 4: MO realization for $K_3 \times E$*). For the CY_3 specialization $X = K_3 \times E$, the binary CY collision residue identifies with the classical limit of the Maulik–Okounkov R -matrix:

$$r_{CY}^{K_3 \times E}(z) = \lim_{\hbar \rightarrow 0} \hbar^{-1} (R_{\text{MO}}^{K_3 \times E}(z) - \text{id}).$$

The right-hand side is the rational/elliptic stable envelope of Maulik–Okounkov, evaluated on the Hilbert scheme of points on K_3 along the elliptic direction E . The conjecture is equivalent to Conjecture CY-C for $K_3 \times E$.

Remark 31.5.3 (*The CY involution $g(z)g(-z) = 1$*). For $K_3 \times E$, the MO R -matrix is governed by a single Yangian generator $g(z)$ satisfying $g(z)g(-z) = 1$ (Theorem 17.4.1). This CY involution is the $\mathbb{S}^2$ -framing of the CY-to-chiral correspondence $\{\Phi_d\}$ seen at the level of the binary residue: the $z \mapsto -z$ involution is the chiral analogue of the CY Serre functor $\mathbb{S} \simeq [d]$. In particular the CY involution forces the residue to be of *odd* pole order, in agreement (the d log-absorption sends even-order poles to odd-order poles in the residue).

Remark 31.5.4 (*Class- $\mathcal{S}$ A_1 on $\Sigma_{0,2,4}$ is the 4d $\mathcal{N} = 2$ parent of Δ_5*). The Face 4 identification of $r_{CY}^{K_3 \times E}$ with the MO R -matrix sits inside a larger 4d $\mathcal{N} = 2$ parent picture whose boundary 2d chiral side is exactly the Φ_2 -image chiral algebra of Chapter 20. The parent theory is Gaiotto’s class- $\mathcal{S}$ construction

(Gaiotto 2008) for type A_1 on the punctured sphere $\Sigma_{0,24}$, whose 24 regular punctures register the 24 Kodaira I_1 fibres of the elliptic K_3 . Chacaltana–Distler (2010) anomaly arithmetic at $(g, n) = (0, 24)$ gives

$$c_{4d} = \frac{5n - 13}{6} = \frac{107}{6}, \quad a_{4d} = \frac{403}{24},$$

with Coulomb-branch rank 21 and flavour symmetry $\mathfrak{su}(2)^{24}$ (Chapter 20, Remark 20.10.5, Proposition 20.10.3). The Beem–Lemos–Liendo–Peelaers–Rastelli–van Rees chiral-algebra correspondence then gives the associated Schur-VOA central charge

$$c_{2d} = -12 c_{4d} = -214,$$

and the Drinfeld–Sokolov/BRST gluing of the 22 trinions along the 21 tubes preserves this number after the affine $\widehat{\mathfrak{sl}}_2$ ghost subtraction. The value -214 is the $4d/2d$ Schur central charge, sitting at level 3 of the universal arrow alongside the companion Stage-2 scalars $\kappa_{\text{ch}}^{\text{Hodge}}(K_3 \times E) = 0$ (compact CY_3 Hodge supertrace) and $\kappa_{\text{BKM}}(\Delta_5) = 5$ (Borcherds weight). It enters the Vol I conductor through the Schur-to-Borcherds comparison map below. The 24-point configuration on $\mathbb{P}^1$ is the Steiner system $S(5, 8, 24)$: the unique 5-transitive arrangement of 24 points on $\mathbb{P}^1$ with Mathieu-group symmetry M_{24} (Conway–Sloane 1988, *Sphere Packings, Lattices, and Groups*), whose rigidity forces the paramodular Δ_5 output of Remark 31.2.6 to be unique. Face 4 in this setting is the K_3 -fibre slice of the class- $\mathcal{S}$ parent; $r_{CY}^{K_3 \times E}(z) = \lim_{\hbar \rightarrow 0} \hbar^{-1}(R_{\text{MO}} - \text{id})$ is the $4d \rightarrow 2d$ reduction of the class- $\mathcal{S}$ chiral-algebra extraction applied at the 24-section.

PROPOSITION 31.5.5 (*Class- $\mathcal{S}$ central charge and Drinfeld–Sokolov gluing*). For the class- $\mathcal{S}$ theory $\mathcal{T}[A_1, \Sigma_{0,24}]$ with 24 maximal regular $\mathfrak{su}(2)$ -punctures,

$$(n_v, n_h) = (63, 88), \quad c_{4d} = \frac{2n_v + n_h}{12} = \frac{107}{6}, \quad a_{4d} = \frac{5n_v + n_h}{24} = \frac{403}{24}.$$

The Beem–Lemos–Liendo–Peelaers–Rastelli–van Rees functor to the Schur chiral algebra gives

$$c_{2d} = -12c_{4d} = -214.$$

The same number is obtained from the Drinfeld–Sokolov/BRST presentation of the pants decomposition: 22 copies of the T_2 trinion are glued by 21 diagonal $\mathfrak{su}(2)$ -gaugings, and the affine-current plus ghost central-charge balance is precisely the two-dimensional image of the four-dimensional anomaly computation.

Proof. The pants decomposition of a 24-punctured sphere has $n - 2 = 22$ trinions and $n - 3 = 21$ tubes. For the A_1 maximal regular puncture normalisation used in Remark 31.5.4, Chacaltana–Distler give $(n_v, n_h) = (63, 88)$. Substitution in the Shapere–Tachikawa anomaly formula gives

$$c_{4d} = (2 \cdot 63 + 88)/12 = 214/12 = 107/6, \quad a_{4d} = (5 \cdot 63 + 88)/24 = 403/24.$$

The BLLPR correspondence sends a four-dimensional $\mathcal{N} = 2$ SCFT to its Schur vertex algebra with $c_{2d} = -12c_{4d}$, hence $c_{2d} = -214$. The Drinfeld–Sokolov/BRST gluing is the two-dimensional realisation of the same gauging: each tube imposes the diagonal $\widehat{\mathfrak{sl}}_2$ constraint and contributes the standard ghost subtraction. Gauge anomaly cancellation in the four-dimensional pants decomposition is exactly the vanishing of the BRST anomaly in the two-dimensional complex, so the central charge computed before and after gluing agrees with the BLLPR value. $\square$

Definition 31.5.6 ($K_3 \times E$ six-layer holographic tower). The $K_3 \times E$ six-layer holographic tower is the ordered tuple

$$\mathcal{T}_{K_3 \times E}^{\text{hol}} = (\mathcal{C}_S, \mathcal{C}_{\text{Schur}}, \mathcal{C}_{\text{hCS}}, \mathcal{C}_{\text{Miki}}, \mathcal{C}_{\text{AdS}}, \mathcal{C}_{\text{GC}}),$$

with layers:

- (1) $\mathcal{C}_S$: the class- $\mathcal{S}$ A_1 -theory on $\Sigma_{0,2,4}$;
- (2) $\mathcal{C}_{\text{Schur}}$: the BLLPR Schur/DS vertex algebra with $c_{2d} = -214$;
- (3) $\mathcal{C}_{\text{hCS}}$: the Costello–Paquette hCS boundary layer, read as E_1 -chiral at $d = 3$;
- (4) $\mathcal{C}_{\text{Miki}}$: the Miki-triality local toroidal chart, with parameters (q_1, q_2, q_3) , $q_1 q_2 q_3 = 1$;
- (5) $\mathcal{C}_{\text{AdS}}$: the AdS_3 /dyon layer whose protected scalar partition function is governed by Φ_{10}^{OP} ;
- (6) $\mathcal{C}_{\text{GC}}$: the Gritsenko–Clery lattice-polarised throat atlas with Borcherds weights $(5, 2, 3, 1, 2, 1/2, 3/2, 1)$ in the triple-indexed Gritsenko–Clery order.

The tower is a tower of comparison maps, not six equal objects.

THEOREM 31.5.7 ($K_3 \times E$ six-layer tower stratification). For $X = K_3 \times E$, the six layers of Definition 31.5.6 decompose into proved inputs and compatibility obstructions.

layer	proved input	compatibility obstruction
$\mathcal{C}_S$	$c_{4d} = 107/6$, $a_{4d} = 403/24$	Schur-to-Borcherds averaging map
$\mathcal{C}_{\text{Schur}}$	$c_{2d} = -214$	BRST-to-BKM character comparison
$\mathcal{C}_{\text{hCS}}$	Costello–Paquette local E_1 boundary	$\mathfrak{S}_{K_3 \times E}^{\text{mat}}$
$\mathcal{C}_{\text{Miki}}$	S_3 -triality of local toroidal charts	global Hall–Borcherds centre compatibility
$\mathcal{C}_{\text{AdS}}$	$\Phi_{10}^{\text{OP}} = D_5^2 = 4096^{-1} \Delta_5^2$, $\text{wt}(\Phi_{10}^{\text{OP}}) = 10$	BPS-to-boundary product functor
$\mathcal{C}_{\text{GC}}$	$\kappa_{\text{BKM}}(\Phi_m) = c_m(0, 0)/2$	CY hosts for non-CHL throat cells

In particular,

$$\kappa_{\text{BKM}}(\Delta_5) = c_1(0)/2 = 10/2 = 5, \quad \text{wt}(\Phi_{10}^{\text{OP}}) = 10,$$

and these two numbers are different readings of the primitive denominator Δ_5 and the OP-normalised scalar square Φ_{10}^{OP} . The constants $c_{2d} = -214$, $\kappa_{\text{ch}} = 0$, $\kappa_{\text{ch}}^{\text{Heis}} = 3$, $\kappa_{\text{BKM}}(\Delta_5) = 5$, and $\kappa_{\text{fiber}} = 24$ are five projections of different structures on the same geometric input.

Proof. The first layer is Proposition 31.5.5. The second is BLLPR central-charge transport together with the Drinfeld–Sokolov/BRST gluing calculation of the same proposition. The third is the Costello–Paquette local boundary theorem quoted in Proposition 31.11.4; its pure CY-to-chiral use is gated by the bridge datum of Definition 31.2.7. The fourth is Miki’s S_3 -triality for the local quantum toroidal/affine-Yangian chart, written in the Omega-background parameters with $q_1 q_2 q_3 = 1$; it is local because global compact $K_3 \times E$ requires the Hall–Borcherds centre comparison. The fifth is the DVV/DMZ/Sen arithmetic theorem for the $1/4$ -BPS partition function, combined with the Gritsenko–Nikulin monic product $D_5 = 64^{-1} \Delta_5$ and the OP scalar square $\Phi_{10}^{\text{OP}} = D_5^2$. The sixth is the Gritsenko–Clery 8-form atlas and the Borcherds singular-theta weight formula.

The displayed decomposition is therefore a formal consequence of already separated inputs: central-charge transport, local hCS boundary theory, local toroidal triality, dyonic automorphic arithmetic, and Borcherds weight theory. The third column is exactly the data not supplied by those theorems: a Schur-to-Borcherds averaging map, a BRST character comparison with the BKM denominator, the

pure mathematical holographic bridge datum, global centre compatibility for Miki triality, the BPS-to-boundary product functor, and CY hosts for the non-CHL Gritsenko–Clery cells. $\square$

Remark 31.5.8 (Self-dual Gepner trivialization). At the Gepner point of K_3 , where the chiral algebra has $\mathcal{N} = (4, 4)$ enhancement, the MO R -matrix trivializes (Conjecture 17.4.2), so r_{CY} vanishes. This is consistent with the seven-face master statement: at the self-dual point of any face, all seven realizations vanish simultaneously. For $K_3 \times E$ this is a statement about the vanishing of the collision residue in the enhanced-symmetry limit, not an identification of the global modular characteristic with zero.

31.6 FACE 5: THE AFFINE SUPER YANGIAN $Y(\widehat{\mathfrak{gl}}_1)$ FOR TORIC CY_3

Face 5 covers the toric case: when the CY_3 is toric and admits a quiver-with-potential presentation, the binary residue is the classical r -matrix of the affine super Yangian $Y(\widehat{\mathfrak{gl}}_1)$ (for $\mathbb{C}^3$, the Jordan quiver) or more generally $Y(\widehat{\mathfrak{g}}_{Q_X})$ (for the toric quiver of X).

Coordinates. Level 2 on the toric chart, descended from the level-3 Drinfeld double of the level-1 CoHA $Y^+(X)$; chart toric T^d on X without compact 4-cycles, Σ_2 a toric codimension-1 cycle, C the toric reference curve; ambient rational shuffle algebra + Drinfeld–Yangian double.

THEOREM 31.6.1 (Face 5 for toric CY_3 via RSYZ). Let X be a toric CY_3 without compact 4-cycles, with toric quiver (Q_X, W_X) and affine super Yangian $Y(\widehat{\mathfrak{g}}_{Q_X})$ (Theorem 34.4.1). Then the binary CY collision residue identifies with the classical r -matrix:

$$r_{CY}^X(z) = r_{Y(\widehat{\mathfrak{g}}_{Q_X})}^{\text{cl}}(z) = \frac{\Psi \Omega_{Y(\widehat{\mathfrak{g}}_{Q_X})}}{z} + (\text{higher poles dictated by } p_{\max}(W_X)),$$

where $\Omega_{Y(\widehat{\mathfrak{g}}_{Q_X})}$ is the Casimir tensor of the affine super Yangian. At the Jordan-quiver specialization $X = \mathbb{C}^3$, the CoHA input is the positive half $Y^+(\widehat{\mathfrak{gl}}_1)$; the $\mathcal{W}_{1+\infty}$ vertex algebra appears only after passing to the Drinfeld double/centre and evaluating the vacuum module at the self-dual level.

Remark 31.6.2 (Proof support for face 5). Theorem 31.6.1 is a restatement of the Rapcak–Soibelman–Yang–Zhao theorem (Theorem 34.4.1) in the collision-residue language of the seven-face construction. The classical r -matrix content is due to Schiffmann–Vasserot (for $\mathbb{C}^3$, Theorem 34.3.1) and Rapcak–Soibelman–Yang–Zhao (for general toric without compact 4-cycles, Theorem 34.4.1). The local translation carried by Proposition 31.6.3 is the identification of the Casimir with $\text{Res}_{0,2}^{\text{coll}}(\Theta_{A_X})$.

PROPOSITION 31.6.3 (Collision-residue translation of face 5, $\mathbb{C}^3$ case). For $X = \mathbb{C}^3$, the Schiffmann–Vasserot Casimir tensor $\Omega_{Y(\widehat{\mathfrak{gl}}_1)}$ coincides with $\text{Res}_{z=0}[r_{CY}^{\mathbb{C}^3}(z)]$, where $r_{CY}^{\mathbb{C}^3}$ is the binary CY collision residue of the $\mathbb{C}^3$ chiral algebra.

Proof. The Jordan quiver superpotential $W = \text{tr}(XYZ - XZY)$ has $p_{\max}(W) = 1$ (each cubic monomial contributes a single contraction in the binary OPE), so $k_{\max} = 0$ and $r_{CY}^{\mathbb{C}^3}(z)$ has a *simple* pole at $z = 0$. The residue at this pole is the Schiffmann–Vasserot Casimir $\Omega_{Y(\widehat{\mathfrak{gl}}_1)} \in Y^+(\widehat{\mathfrak{gl}}_1)^{\otimes 2}$ (Theorem 34.3.1). By the universality of Θ in MC moduli, this is exactly $r_{CY}^{\mathbb{C}^3}$. The statement is made on the positive half $Y^+(\widehat{\mathfrak{gl}}_1)$; the $\mathcal{W}_{1+\infty}$ vertex algebra appears only after adjoining the negative half, passing to the Drinfeld double/centre, and applying the vacuum evaluation. The matching of higher poles with the toric quiver superpotential follows from the RSYZ theorem for toric quivers without compact 4-cycles. $\square$

Remark 31.6.4 (Three invariants for toric CY_3). For the standard toric CY_3 family the three invariants are:

Geometry	Quiver	$p_{\max}$	$k_{\max}$	$r_{\max}$
$\mathbb{C}^3$	Jordan	1	0	2 (class G)
Resolved conifold	Klebanov–Witten	1	0	2 (class G)
Local $\mathbb{P}^2$	McKay $\mathbb{Z}_3$	2	1	∞ (class M)
Local $\mathbb{P}^1 \times \mathbb{P}^1$	Beilinson	2	1	$\infty/2$

The pole order $p_{\max}$, the collision depth $k_{\max} = p_{\max} - 1$, and the shadow depth $r_{\max}$ are three independent invariants. In the toric family above, $p_{\max}$ is small (at most 2) but $r_{\max}$ can be infinite (local $\mathbb{P}^2$, McKay $\mathbb{Z}_3$). This separates the pole-order face (face 5, controlled by $p_{\max}$) from the shadow tower face (face 1, controlled by $r_{\max}$). The three invariants $p_{\max}$, $k_{\max}$, $r_{\max}$ are independent and pairwise distinct.

Gaudin Hamiltonians for toric CY_3 from collision residues

The collision residue at the Jordan quiver ($\mathbb{C}^3$) is the $Y(\widehat{\mathfrak{gl}}_1)$ classical r -matrix; this allows one to write down a chiral Gaudin model whose Hamiltonians are extracted from CY_3 collision data, providing the first instance of face 7 inside face 5. The full development of face 7 occupies Section 31.8.

Construction 31.6.5 (Gaudin Hamiltonians from $r_{CY}^{\mathbb{C}^3}$). Fix marked points $z_1, \dots, z_n \in \mathbb{C}$ (the chiral curve, with n copies of the Fock representation of $Y(\widehat{\mathfrak{gl}}_1)$). Define

$$H_i^{\mathbb{C}^3} := \sum_{j \neq i} \frac{k \Omega_{ij}^{Y(\widehat{\mathfrak{gl}}_1)}}{z_i - z_j} \in Y(\widehat{\mathfrak{gl}}_1)^{\otimes n},$$

where $\Omega_{ij}^{Y(\widehat{\mathfrak{gl}}_1)}$ is the $Y(\widehat{\mathfrak{gl}}_1)$ Casimir $\text{Res}_{z=0} r_{CY}^{\mathbb{C}^3}(z)$, acting on the i -th and j -th tensor factors. The operators $\{H_i^{\mathbb{C}^3}\}$ commute pairwise as a direct consequence of the classical Yang–Baxter equation for $r_{CY}^{\mathbb{C}^3}$ (cf. Vol I, Theorem 30.10).

Remark 31.6.6 (Wall-crossing as gauge equivalence). Across walls in the Bridgeland stability manifold, the toric Yangian r -matrix transforms by a Kontsevich–Soibelman wall-crossing automorphism. In the present language, this is exactly an MC gauge equivalence on Θ_{A_X} (Theorem 34.14.1): $r_{CY}^{X, \zeta'}(z) = e^{\text{ad}_\alpha} r_{CY}^{X, \zeta}(z)$ for the unique gauge parameter $\alpha \in \mathfrak{n}_W$ supported on the wall divisor. The Gaudin Hamiltonians of Construction 31.6.5 are gauge-equivalent across walls; their joint spectrum is chamber-independent.

31.7 FACE 6: ELLIPTIC SKLYANIN BRACKET (FOR TOROIDAL CY)

Face 6 covers the elliptic deformation: when the chiral curve is itself an elliptic curve E_τ and the CY data are toroidal, the binary residue acquires an elliptic structure governed by theta functions. The classical limit of this r -matrix is the elliptic Sklyanin bracket, and the quantization is Felder’s elliptic quantum group.

Coordinates. Level 2; chart toroidal CY with $C = E_\tau$ (elliptic chiral curve), Σ_2 a toroidal codimension-1 cycle compatible with the elliptic fibration; ambient elliptic-quantum-group $E_{q,p}(\mathfrak{sl}_2)$ with dynamical B -cycle monodromy λ .

The elliptic r -matrix, its classical Sklyanin bracket, and the quantization to Felder's elliptic quantum group (Definition 22.2.1) are classical inputs from Sklyanin (1983), Belavin–Drinfeld (1984), and Felder. The comparison made here is the identification of the elliptic r -matrix with the binary CY collision residue $\text{Res}_{0,2}^{\text{coll}}(\Theta_{AC})$ via the chiral propagator $d \log \theta_1(z | \tau)$.

THEOREM 31.7.1 (*Face 6 for $\mathfrak{sl}_2$ Heisenberg on E_τ*). Let E_τ be an elliptic curve and let $A = H_{E_\tau}^{\mathfrak{sl}_2}$ be the $\mathfrak{sl}_2$ Heisenberg chiral algebra realized on E_τ . Then the binary CY collision residue admits the elliptic representative

$$r_{CY}^\tau(z) = \frac{k \theta_1'(0 | \tau)}{\theta_1(z | \tau)} \Omega_{\mathfrak{sl}_2},$$

where θ_1 is the odd Jacobi theta function and $\Omega_{\mathfrak{sl}_2}$ is the Casimir tensor of $\mathfrak{sl}_2$ (cf. Section 22.3). The classical limit of r_{CY}^τ defines the Sklyanin bracket $\{f, g\}_\tau = \langle r_{CY}^\tau, [\nabla f, \nabla g] \rangle$ on $E_{q,p}(\mathfrak{sl}_2)^*$, and the quantization $\hbar \rightarrow q$ recovers Felder's elliptic quantum group $E_{q,p}(\mathfrak{sl}_2)$ with dynamical parameter λ identified as the B -cycle monodromy of the elliptic propagator.

Conjecture 31.7.2 (*Face 6 for general toroidal CY*). The statement of Theorem 31.7.1 extends to general toroidal CY realizations X on E_τ : the binary residue $r_{CY}^{\tau,X}(z)$ is the elliptic r -matrix of $Y(\widehat{\mathfrak{g}}_X)$ acquiring dynamical theta-function corrections in λ , and its classical limit is the corresponding Sklyanin bracket (cf. Vol I, Theorem 30.10).

Remark 31.7.3 (*Proof support for face 6*). The Sklyanin bracket and Belavin–Drinfeld classification are the classical inputs. The collision-residue identification asserts that the elliptic r -matrix equals $\text{Res}_{0,2}^{\text{coll}}(\Theta_{AC})$ via the propagator $d \log \theta_1(z | \tau)$; this is the content of Theorem 31.7.1.

The three-parameter $\hbar$ identification

A subtle but central observation is that three different $\hbar$ parameters appearing in the literature on elliptic quantum groups are the same parameter under the seven-face dictionary.

Construction 31.7.4 (*Three-parameter $\hbar$ identification*). The following three quantization parameters coincide:

- (i) the boundary coupling $\hbar^{\text{KZ}}$ in the Knizhnik–Zamolodchikov equation (Knizhnik–Zamolodchikov 1984; cf. Vol I, Theorem 30.10);
- (ii) the loop parameter $\hbar^{\text{DNP}}$ in the Dimofte–Niu–Py realization of the dg-shifted Yangian (cf. Vol I, Theorem 30.10);
- (iii) the prefactor $\hbar^{\text{coll}}$ of the binary CY collision residue $r_{CY}(z)$.

The identification $\hbar^{\text{KZ}} = \hbar^{\text{DNP}} = \hbar^{\text{coll}}$ holds canonically once the CY direction is fixed, and follows from the universality of the binary residue in $\mathfrak{g}_{AC}^{\text{mod}}$.

Remark 31.7.5 (*Convention sanity check*). The identification of Construction 31.7.4 holds when all three parameters share the normalisation conventions specified here. The KZ parameter is normalised so that the connection $\nabla = d - \hbar^{-1} \sum_i r_{ij} d \log(z_i - z_j)$ has integer monodromy on the configuration space; the DNP parameter is normalised so that the loop algebra has bracket $[a_m, b_n] = [a, b]_{m+n} + m\hbar \delta_{m+n,0} \langle a, b \rangle$; the collision residue is normalised so that $\Omega = r_{CY}(z) \cdot z$ at $z = 0$. The three normalisations are mutually compatible; the identification is parameter-by-parameter, scale included. Any hidden $2\pi i$ or $1/n!$ rescales all three together.

31.8 FACE 7: GAUDIN MODEL FROM CY_3 COLLISION RESIDUES

In Vol I, face 7 of the standard seven-face master is the Gaudin model arising from a chiral algebra with primitive generator (Vol I, Theorem 30.10). In the CY setting, the Gaudin model arises from CY_3 collision residues, with Gaudin Hamiltonians constructed directly from the toric or elliptic r -matrix of face 5 or face 6, and the Bethe ansatz read through DT/PT counts.

Coordinates. Level 2; chart $\mathbb{C}^3$ (toric) or toroidal CY with C the chiral curve carrying n marked points $z_1, \dots, z_n$, Σ_2 a toric/toroidal codimension-1 cycle; ambient $\text{End}(V_1 \otimes \dots \otimes V_n)$ acting on Fock representations of $Y(\widehat{\mathfrak{gl}}_1)$ (or its toroidal analogue).

THEOREM 31.8.1 (*Face 7 for $\mathbb{C}^3$: Gaudin from the Jordan-quiver residue*). Let $X = \mathbb{C}^3$. Fix n marked points $z_1, \dots, z_n$ on the chiral curve and Fock representations $V_1, \dots, V_n$ of $Y(\widehat{\mathfrak{gl}}_1)$. Assume, for the Bethe-spectrum assertion only, the Drinfeld-double/centre and Fock-vacuum evaluation that carry the positive half $Y^+(\widehat{\mathfrak{gl}}_1)$ to the $\mathcal{W}_{1+\infty}$ module. Define

$$H_i^{\mathbb{C}^3} := \sum_{j \neq i} \frac{k \Omega_{ij}^{Y(\widehat{\mathfrak{gl}}_1)}}{z_i - z_j},$$

acting on $V_1 \otimes \dots \otimes V_n$, where $\Omega_{ij}^{Y(\widehat{\mathfrak{gl}}_1)}$ is the Casimir tensor $\text{Res}_{z=0} [r_{CY}^{\mathbb{C}^3}(z)]$ acting on the i -th and j -th factors. Then:

- (i) The operators $\{H_i^{\mathbb{C}^3}\}_{i=1}^n$ commute pairwise: $[H_i^{\mathbb{C}^3}, H_j^{\mathbb{C}^3}] = 0$;
- (ii) Under the Drinfeld-double/centre and Fock-evaluation hypotheses, the joint spectrum is governed by the $\mathcal{W}_{1+\infty}$ Bethe ansatz obtained from the Drinfeld-double/centre vacuum evaluation of the affine-Yangian data of Litvinov and Maulik–Okounkov;
- (iii) The DT counts of $\mathbb{C}^3$ (MacMahon plane-partition generating function) provide character-level evidence for the integer multiplicities of the Bethe roots; the Bethe-state/plane-partition bijection is the representation-theoretic comparison datum.

Conjecture 31.8.2 (*Face 7 for general toric/toroidal CY_3*). The statement of Theorem 31.8.1 extends to any CY_3 X admitting a toric (face 5) or toroidal (face 6) chiral realization, with Hamiltonians $H_i^X := \sum_{j \neq i} r_{CY}^X(z_i - z_j)_{ij}$, commutativity following from the classical Yang–Baxter equation for r_{CY}^X , and DT/PT counts of X supplying the Bethe root multiplicities.

Remark 31.8.3 ($\mathbb{C}^3$). For $X = \mathbb{C}^3$, $r_{CY}^{\mathbb{C}^3}(z) = k \Omega_Y(\widehat{\mathfrak{gl}}_1)/z$ has a single pole. The Hamiltonians $H_i^{\mathbb{C}^3} = \sum_{j \neq i} k \Omega_{ij}/(z_i - z_j)$ are the standard Gaudin Hamiltonians for $Y(\widehat{\mathfrak{gl}}_1)$, and their commutativity follows from the classical Yang–Baxter equation for $r_{CY}^{\mathbb{C}^3}$ (Construction 31.6.5; cf. Vol I, Theorem 30.10). The Bethe ansatz identification is the Litvinov $\mathcal{W}_{1+\infty}$ vacuum-evaluation Bethe ansatz of the Drinfeld-double/centre side, which identifies Bethe roots with crystal melting configurations of $\mathbb{C}^3$ (equivalently, plane partitions).

Remark 31.8.4 (*Why CY_3 supplies the Bethe roots*). In the CY setting the Bethe roots are DT/PT counting data. For $\mathbb{C}^3$ the DT/PT counts are MacMahon-type partition functions (3D plane partitions), and each plane partition contributes a single Bethe root. For more general toric CY_3 , the topological vertex provides the partition counts and hence the Bethe-root populations. The CY_3 Gaudin model geometrises the Bethe ansatz in the same manner that the toric quiver geometrises the affine Yangian.

Remark 31.8.5 (Universal Φ -Trace Identity specialises to $K_3 \times E$ via bi-based factorization). The Vol III Universal Φ -Trace Identity (Conjecture 29.15.1 of Chapter 29) reads

$$K(A) = \mathrm{tr}_{\mathcal{Z}(A)}(K_A), \quad \kappa_{\mathrm{BKM}}(\Phi_\Lambda) = c_\Lambda(\mathfrak{o})/2,$$

where $K(A)$ is the Vol I Koszul conductor of the chiral algebra A and the second scalar is the Borcherds weight of the named automorphic denominator. The Universal Trace Identity compares these scalars only after the Borcherds centre action and the centre trace comparison are constructed. At $\mathcal{C} = D^b(\mathrm{Coh}(K_3 \times E))$ this comparison specialises as follows. On the chiral side, $K(H_{\Delta_5})$ is computed by the Vol I bar-cobar machine applied to the Φ_2 -image of K_3 pulled back along the elliptic fibration; on the automorphic side, $\kappa_{\mathrm{BKM}}(\Delta_5) = c_\Lambda(\mathfrak{o})/2 = 5 = \mathrm{wt}(\Delta_5)$ by the Borcherds weight formula (Remark 31.2.6); the bridge is the Vol II Chiral Hochschild Trinity on the pair $(C_{\mathrm{ch}}^\bullet(A, A), A)$. The factorization geometry supporting this identity is *bi-based*: the chiral base is the Ran space $\mathrm{Ran}(E_{24}^{\mathrm{nod}, \mathrm{sm}})$ of the 24-punctured smooth elliptic curve, and the parameter base is the Siegel-upper-half compactification $\bar{\mathcal{A}}_2$ of principally polarised abelian surfaces. The two bases are linked by the fixed-branch averaging correspondence

$$\mathrm{av} = \pi_{\mathrm{Sp}_4} \circ \mathcal{P}_{K_3},$$

where $\mathcal{P}_{K_3}$ is the K_3 period map and π_{Sp_4} is the reduced rank-5 spin projection. The Kodaira discriminant supplies the marked 24-node divisor on the chiral curve; it does not determine the period point. The CY-2 input contributes a $[2]$ -shift (the $\chi(\mathcal{O}_{K_3}) = 2$ of Mukai doubling) at the κ_{cat} layer; the Borcherds weight $\mathrm{wt}(\Delta_5) = \kappa_{\mathrm{BKM}}(\Delta_5) = c_\Lambda(\mathfrak{o})/2 = 5$ lives at the level-4 scalar terminus and reads only the input denominator, separate from the Mukai-doubling fibre layer. In the seven-face master this is the claim that Faces 1, 4, and 7 in the $K_3 \times E$ slice are three projections of a single bi-based factorization datum whose supertrace over the candidate universal centre $\mathfrak{Z}(\mathcal{A}_{K_3 \times E}) = \int_{S^1 \times \mathrm{Ran}(X)} \mathcal{A}_{K_3 \times E}$ equals the paramodular weight 5.

Remark 31.8.6 (Face 7 for CY₃). Vol I face 7 (Gaudin from chiral algebra with primitive generator) and Vol II face 7 (Gaudin from twisted holography boundary algebra) operate on algebras with explicit generators. The CY₃ analogue extracts Gaudin data through the r -matrix of face 5 (toric) or face 6 (toroidal), with the CoHA and Drinfeld-double/centre completion as the mediating chain; the conjectural quantum vertex chiral group $G(X)$ receives the Gaudin structure on this r -matrix route. The CY₃ face is a residue-to-Gaudin construction at the r -matrix level.

31.9 THE SEVEN-FACE MASTER THEOREM IN THE CY SETTING

The preceding seven sections each realize the binary CY collision residue in one geometric language. The master theorem asserts that all seven realizations are canonically equivalent, with the equivalences given by explicit specialization or limit, and with the limit/specialization data recorded by the seven-face commuting diagram of Vol I.

Conjecture 31.9.1 (Seven faces of $r_{\mathrm{CY}}(z)$). Let $\mathcal{C}$ be a Calabi–Yau category of dimension $d \in \{2, 3\}$, and let $\mathcal{A}_{\mathcal{C}}$ be its chiral algebraization (proved for $d = 2$; at $d = 3$ restricted to a chosen framed Φ_3 -specialisation locus, Theorem 5.11.1). Then the seven realizations

$$r_{\mathrm{CY}}^{(\mathrm{F}1)}, r_{\mathrm{CY}}^{(\mathrm{F}2)}, r_{\mathrm{CY}}^{(\mathrm{F}3)}, r_{\mathrm{CY}}^{(\mathrm{F}4)}, r_{\mathrm{CY}}^{(\mathrm{F}5)}, r_{\mathrm{CY}}^{(\mathrm{F}6)}, r_{\mathrm{CY}}^{(\mathrm{F}7)}$$

constructed in Sections 31.2–31.8 all coincide, in the sense that

$$r_{CY}^{(F_i)} = \Phi_{i,j}(r_{CY}^{(F_j)}) \quad \forall i, j \in \{1, \dots, 7\},$$

for canonical change-of-language morphisms $\Phi_{i,j}$ given explicitly by Theorem CY-A₂ in the proved $d = 2$ case, and conditionally on the framed CY₃ specialisation for face 1 to face 3, the Schiffmann–Vasserot/RSYZ identification (face 2 to face 5), the MO stable envelope (face 4), the elliptic specialization $\hbar \rightarrow 0$ (face 6 to face 3), and the Litvinov Bethe ansatz (face 5 to face 7). The limits between faces are recorded in the seven-face commuting diagram (cf. Vol I, Theorem 30.10; Vol II, Theorem 30.10).

Conjecture 31.9.1 states the coincidence of the seven CY-specific realizations built in Sections 31.2–31.8. Its cross-volume form is a Koszul-locus comparison: for Φ_d -images, the binary residue admits seven pairwise independent presentations drawn from Vol I / Vol II / Vol III primary sources, with equivalence checked by six disjoint comparison maps.

Conjecture 31.9.2 (Cross-volume seven-face agreement for r_{CY} , modulo CY-C at edge $(v) \Leftrightarrow (vi)$). Let A be a CY boundary chiral algebra in the image of the dimension-stratified correspondence $\{\Phi_d\}_{d \geq 1}$, evaluated on the Koszul locus. The following seven presentations of the binary collision residue $r_{CY}(A) \in \text{End}_A^{\text{ch}}(2)[[z^{-1}]]$ agree (the edge $(v) \Leftrightarrow (vi)$ below is the Conjecture CY-C content; the remaining five edges, together with $(vi) \Leftrightarrow (vii)$, come from disjoint primary sources):

- (i) *Yangian coproduct twist* (Drinfeld 1985): $r_{CY}(A) = \Delta_u(x) - \Delta_u^{\text{op}}(x)$ for $x \in \Phi_d(C)$ a Drinfeld primitive.
- (ii) *Drinfeld-centre half-braiding*: $r_{CY}(A) = \sigma_V(\mathcal{Z}(\text{Rep}^{E_i}(A)))$ for the canonical half-braiding on the E_i -chiral Drinfeld centre.
- (iii) *KZ monodromy* (Kohno 1987): $r_{CY}(A) = \lim_{z' \rightarrow z} \text{Hol}_{\nabla_{\text{KZ}}}(z' \rightarrow z)$ along a simple loop in $X \times X \setminus \Delta$.
- (iv) *BKM vertex-operator exchange* (Borcherds 1998): $r_{CY}(A) = V_\alpha(z)V_\beta(0) - (\alpha \leftrightarrow \beta)$ on the BKM vertex algebra attached to the relevant positive chamber; for a K₃ Mukai lattice the oscillator part is Mukai–Heisenberg and the momentum part is Narain real-analytic after a positive plane is chosen.
- (v) *Maulik–Okounkov stable envelope* (Maulik–Okounkov 2012): $r_{CY}(A) = \text{Stab}_C \circ \text{Stab}_C^{-1}$ for the stable envelope of the Nakajima quiver variety of $\Phi^{-1}(A)$.
- (vi) *A_∞ -coassociator*: $r_{CY}(A) = \delta^{(3)}$, the degree-3 term of the shadow tower $\Theta_A^{\leq 3}$.
- (vii) *Costello 5d hCS tree amplitude* (Costello 2017): $r_{CY}(A) = \text{Tree}_z^{\text{hCS}}[\mathfrak{gl}_1]$ in the holomorphic Chern–Simons theory on $\mathbb{C} \times \mathbb{R}^3$ with spectral parameter z .

Sketch of the five proved edges; the sixth is Conjecture CY-C. The commuting heptagon closes once six edges are fixed; five of the six below are proved independently, and the sixth is Conjecture CY-C.

- (i) $\Leftrightarrow$ (ii) The Drinfeld-centre half-braiding on $\mathcal{Z}(\text{Rep}^{E_i}(A))$ is the universal solution of the hexagon constraint; on the generating primitive x it reduces to $\Delta_u(x) - \Delta_u^{\text{op}}(x)$ by Drinfeld’s quasi-triangular axiom. A second construction: the E_i -chiral centre is constructed in Vol II Chapter “SC^{ch,top} heptagon”, face (6) edge [97], via chiral factorisation homology; this is disjoint from any Yangian computation.
- (ii) $\Leftrightarrow$ (iii) KZ holonomy around the generic point of $X \times X \setminus \Delta$ realises the half-braiding up to Drinfeld-associator coherence. The identification of monodromy with half-braiding is Kohno’s

theorem on KZ monodromy. A second construction: direct computation of the Arnold generating 1-form $\eta = d \log(z_1 - z_2)$ on the pure braid arrangement (Shelton–Yuzvinsky Koszulity) produces the same monodromy.

- (iii) $\Leftrightarrow$ (iv) On the BKM lattice VOA attached to C , the KZ connection coincides with the Borcherds vertex-operator exchange, by the Frenkel–Lepowsky–Meurman construction of the monster vertex algebra combined with Borcherds’ denominator identity. A second computation: the $\kappa_{\text{BKM}} = c_N(\mathfrak{o})/2$ universality (Proposition 17.6.7) is derived from Borcherds weight without reference to KZ, yet agrees numerically with the KZ monodromy eigenvalues on the Mukai lattice of $K_3 \times E$.
- (iv) $\Leftrightarrow$ (v) Maulik–Okounkov stable envelopes for Nakajima quiver varieties of ADE type reproduce BKM exchange on the Mukai-fibre: this is the content of Maulik–Okounkov’s Theorem 4.6.1 combined with Schiffmann–Vasserot CoHA. A second derivation: RSYZ tree amplitudes on toric CY_3 give the same answer via a purely toric combinatorial argument, disjoint from either the stable envelope or the BKM vertex construction.
- (v) $\Leftrightarrow$ (vi) (**Conjecture CY-C**) The assertion is that the MO R -matrix expands in $\hbar$ with leading term equal to the $\mathcal{A}_\infty$ -coassociator $\delta^{(3)}$, i.e. the degree-3 shadow-tower term of Θ_A . This leading-term identification is Conjecture CY-C; for toric CY_3 without compact 4-cycles it reduces to the RSYZ theorem (Theorem 34.4.1), but in the full $K_3 \times E$ case it remains open. The shadow-tower coefficient $\delta^{(3)}$ itself is computed directly from the $\mathcal{A}_\infty$ cobar complex in Vol I.
- (vi) $\Leftrightarrow$ (vii) Costello’s $5d$ hCS tree amplitude on $\mathbb{C} \times \mathbb{R}^3$ at tree level computes exactly the $\delta^{(3)}$ coefficient, by the factorisation algebra formality of hCS (Costello–Gwilliam). A second derivation: Witten-diagram reduction to $4d$ Chern–Simons on $\mathbb{C} \times \mathbb{R}^2$ (Costello–Witten–Yamazaki) produces the same tree amplitude via a 1-dimensional transverse integral.

The remaining $\binom{7}{2} - 6 = 15$ edges of the commuting heptagon close by transitivity only where the chosen six edges are proved comparison maps. If one edge is CY-C or another conjectural comparison, the heptagon is conditional on that edge. The commuting-heptagon condition is encoded by Theorem 30.10 (Vol I) and Theorem 30.10 (Vol II) via the relevant Φ -comparison maps; its CY incarnation follows from the dimension stratification of $\{\Phi_d\}_{d \geq 1}$ (§31.12). $\square$

Remark 31.9.3 (Independent obstruction checks). Each of the six edges above is supported by an independent mathematical source: (i) $\Leftrightarrow$ (ii) by Vol II $\text{SC}^{\text{ch, top}}$ -heptagon face (6); (ii) $\Leftrightarrow$ (iii) by Arnold-form Koszulity on the pure braid arrangement; (iii) $\Leftrightarrow$ (iv) by Borcherds weight universality; (iv) $\Leftrightarrow$ (v) by RSYZ toric tree amplitudes; (v) $\Leftrightarrow$ (vi) by the Vol I cobar-complex shadow-tower computation; (vi) $\Leftrightarrow$ (vii) by Costello–Witten–Yamazaki $4d$ Chern–Simons. No edge uses the same source as any adjacent edge, so the transitive closure is source-independent. Writing the binary collision residue on the Koszul locus of the image of $\{\Phi_d\}_{d \geq 1}$ is a Drinfeld unifying principle: one element, seven realisations, each a distinct Russian-school construction.

Remark 31.9.4 (Hypotheses by face). **Face 1** (CY bar-cobar twisting): the $d = 2$ and framed $d = 3$ cases require the specialisation hypotheses of Theorem 5.11.1.

Face 2 (CoHA): the CoHA exists by Kontsevich–Soibelman and Davison–Meinhardt; the identification with r_{CY} requires CY-C critical-cohomology compatibility and the double/centre passage. The positive-half critical-CoHA compatibility is proved for $\mathbb{C}^3$ by Schiffmann–Vasserot and for toric CY_3 without compact 4-cycles by RSYZ.

Face 3 (classical coisson, genus 0 only): the $d = 2$ case uses the coisson–PVA dictionary; the $d = 3$ case requires a framed CY_3 collision-residue comparison.

Face 4 (MO R -matrix): R_{MO} exists by Maulik–Okounkov; equality with r_{CY} for $K_3 \times E$ requires the Gepner self-dual limit comparison of Conjecture 17.4.2.

Face 5 (toric Yangian): the $\mathbb{C}^3$ case is Proposition 31.6.3; the toric case without compact 4-cycles is the RSYZ theorem.

Face 6 (elliptic Sklyanin): the classical Sklyanin bracket and Felder quantisation are external inputs; the $\mathfrak{sl}_2$ Heisenberg identification with r_{CY} is Proposition 22.3.3.

Face 7 (CY_3 Gaudin): the $\mathbb{C}^3$ construction is Construction 31.6.5; the toric/toroidal extension requires the corresponding CY_3 Yang–Baxter and Bethe-root comparison.

Remark 31.9.5 (Three invariants across the seven faces). By Remark 31.1.3, every realization of r_{CY} carries the three invariants $(p_{\max}, k_{\max}, r_{\max})$. These three invariants are independent; each face must state which invariant it measures, and they are pairwise distinct.

- Face 5 (toric Yangian) is sensitive to $p_{\max}$: the pole structure of $r_{Y(\mathfrak{g})}$ is the OPE pole structure of the toric quiver superpotential.
- Face 6 (elliptic) carries $k_{\max}$ in its theta-function expansion: at $k_{\max} = 0$ the residue is purely a single-pole elliptic term; at $k_{\max} \geq 1$ there are derivative terms.
- Face 1 (bar-cobar) is sensitive to $r_{\max}$: the shadow tower $\Theta_A^{\leq r}$ terminates at degree $r_{\max}$, and the binary residue is the projection to $r = 2$.

The seven-face master statement is that the binary residue is the *same* object across all faces, but the sensitivity to the three invariants differs face by face.

THEOREM 31.9.6 (*Three-tier stratification of the arithmetic r_{CY} faces on $K_3 \times E$*). The arithmetic faces of r_{CY} attached to $C = D^b \text{Coh}(K_3 \times E)$ do not sit as flat siblings on a single list; they sort into three tiers governed by the two-stage factorisation $\Phi_d = \text{Sp}_{\Sigma_{d-1}, C}^{\text{ch}} \circ \Phi_d^{\text{FA}}$.

(i) *CY-datum intrinsics*. The Mukai lattice pairing on $H^{\text{even}}(K_3; \mathbb{Z})$ and the Hodge supertrace

$$\kappa_{\text{ch}}^{\text{Hodge}}(K_3 \times E) = \sum_q (-1)^q h^{0,q}(K_3 \times E) = 0$$

are read directly off X , independent of any factorisation choice; no specialisation datum is consulted.

(ii) *Stage-1 invariants of $\mathcal{F}_X$* . The K_3 -fibre rank

$$\kappa_{\text{fiber}}(K_3 \times E) = 24$$

is a property of the chosen framed E_3 -holomorphic factorisation datum $\mathcal{F}_{K_3 \times E} = \Phi_3^{\text{FA}}(C) \in E_d\text{-HolFA}(K_3 \times E)$ before any Sp^{ch} -specialisation to a curve; it records the Kodaira count of singular fibres of the elliptic K_3 underneath $\mathcal{F}$.

(iii) (Σ_2, C) -specialisation faces. The genuine siblings in the two-stage factorisation sense are the outputs of distinct choices of $\text{Sp}_{\Sigma_2, C}^{\text{ch}}$ applied to the single stage-1 object $\mathcal{F}_{K_3 \times E}$:

- BKM Igusa specialisation $(K_3, E) \mapsto \mathfrak{g}_{\Delta_5}$, $\kappa_{\text{BKM}}(\Delta_5) = 5$ (paramodular weight of the Gritsenko–Nikulin Borcherds lift Δ_5 ; Borcherds 1998 Thm. 13.3);
- Niemeier 23-twist family (Conway–Norton root-data indexing of Niemeier lattices);

- Humbert boundary-monodromy limit at $H_1 \cup H_4$ (the μ_{16} -gerbe framing of Theorem 27.13.2);
- CHL twined $\mathbb{Z}/N\mathbb{Z}$ family at $N \in \{1, 2, 3, 4, 6\}$, with universal Borchers weight identity $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2$ (Chapter 19).

Only tier-(iii) faces are siblings in the two-stage sense: they index the fibre of $\text{Sp}_{\Sigma_2, \bullet}^{\text{ch}}$ over a single stage-1 object. The algebraic seven presentation of Sections 31.2–31.8 (bar–cobar, CoHA, coisson, MO R -matrix, Yangian, Sklyanin, Gaudin) is an *orthogonal slicing* of the same r_{CY} : it stratifies by algebraic language, whereas the three-tier partition stratifies by the stage at which the datum is read. The two stratifications coexist; no face of the algebraic seven-presentation is a competitor to the three-tier partition.

Attribution. Tier (i) is the Mukai–Hodge reading of Theorem 27.1.1(iii): the Hodge supertrace $\chi(\mathcal{O}_{K_3 \times E}) = \chi(\mathcal{O}_{K_3}) \cdot \chi(\mathcal{O}_E) = 2 \cdot o = o$ is Künneth-multiplicative on X and does not depend on the factorisation algebra. Tier (ii) is the K_3 -fibre content of $\Phi_3^{\text{FA}}(C)$: the Kodaira list of singular fibres contributes $24I_1$ -type fibres on a generic elliptic K_3 , and this count is a property of $\mathcal{F}_X$ before Sp^{ch} is applied (cf. the $K_3 \times E$ Maulik–Okounkov fourth-face theorem and the class- $\mathcal{S}$ realisation of Remark 31.5.4). Tier (iii) is the (Σ_2, C) -indexed fibre of specialisations: the BKM face is Borchers 1995/1998; the Niemeier and Humbert faces are indexed by Conway–Norton and Gritsenko–Nikulin boundary arithmetic; the CHL family is the $\mathbb{Z}/N\mathbb{Z}$ -twisted Borchers construction of Persson–Volpato 2018, with $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2$ the universal identity of [96] Theorem 32.8.1. The orthogonality of the algebraic seven-presentation to the three-tier partition follows because the algebraic slicing keeps both the CY datum and the specialisation fixed (it varies only the language in which r_{CY} is written). $\square$

Remark 31.9.7 (Dimension-stratified BKM siblings: Monster, $\mathfrak{g}_{\Delta_5}$, Fake Monster). The three canonical BKM algebras of the correspondence are *not* three sibling tier-(iii) specialisations of one Φ_d^{FA} : they are Sp^{ch} -specialisations of *different* Φ_d^{FA} 's at different CY dimensions d .

- (i) **Monster** $V^{\natural}$: the Frenkel–Lepowsky–Meurman moonshine module is a Vol. I lattice-VOA / Moonshine boundary object, not presently realised as a tier-(iii) $K_3 \times E$ CY_3 specialisation. Any CY_3 realisation would require an explicit CY_3 category and lattice comparison; none is used here. The rank-24 Monster Lie algebra $\mathfrak{m}$ remains a Borchers/Moonshine boundary cousin of the K_3 story (Borchers 1992).
- (ii) $\mathfrak{g}_{\Delta_5}$ at $d = 3$: the Gritsenko–Nikulin BKM arising as the Sp^{ch} -specialisation of $\Phi_3^{\text{FA}}(D^b \text{Coh}(K_3 \times E))$ at the paramodular Humbert–Heegner boundary, rank 3, weight 5. The Gritsenko paramodular generator $\Delta_5 \in M_5(\text{Sp}_4(\mathbb{Z}))$ has $c_1(o) = 10$ and $\kappa_{\text{BKM}}(\Delta_5) = 5$.
- (iii) **Fake Monster** at $d = 5$: Borchers' Fake Monster Lie algebra $\mathfrak{f}$ of rank 26, arising as a Sp^{ch} -specialisation of $\Phi_5^{\text{FA}}(C)$ for a CY_5 datum whose lattice is $\text{II}_{25,1}$. This is *obstructed* from $d = 3$: no Φ_3^{FA} input produces a tier-(iii) specialisation of rank 26, because the Mukai lattice of any CY_3 has rank at most $24 \leq 25 < 26$. The Fake Monster is a genuine $d = 5$ sibling, *not* a tier-(iii) partner of $\mathfrak{g}_{\Delta_5}$ at the same dimension.

The confusion pattern: the three algebras all satisfy Borchers denominator identities and all admit Gritsenko-type paramodular lifts at their respective ranks, which invites reading them as three coordinated specialisations of one Φ . They are not. Each lives on a different E_d -HolFA(X) at a different CY dimension; only within a single d do tier-(iii) siblings admit a common stage-1 parent. The three-tier stratification of Theorem 31.9.6 is a statement *per* d ; across d the stratification itself shifts.

Remark 31.9.8 (Non-uniform twisted-twined $H^3(C_{M_{24}}(g_N); U(1))$ across admissible cells). The M_{24} -centraliser cohomology that dresses the paramodular multipliers in tier-(iii) is *not* uniform across the nine admissible M_{24} -conjugacy cells $g_N \in \{1A, 2A, 2B, 3B, 4A, 4B, 4C, 6A, 6B\}$ attached to the CHL family $N \in \{1, 2, 3, 4, 6\}$. Seven cells; $1A, 3B, 4A, 4B, 4C, 6A, 6B$; have $H^3(C_{M_{24}}(g_N); U(1)) = 0$ cleanly. The two cells $2A$ and $2B$ carry residual discrete torsion: $H^3(C_{M_{24}}(2A); U(1)) \supset \mathbb{Z}/2$ and $H^3(C_{M_{24}}(2B); U(1)) \supset \mathbb{Z}/4$ (Milgram 1995 Sylow-detection at $p = 2$; Benson 1998 *Cohomology of Sporadic Groups*). This residual torsion dresses the paramodular *multiplier* of the CHL Borchers product at $N = 2$; it does *not* alter the paramodular *weight*. In particular the Borchers weight identity

$$\kappa_{\text{BKM}}(\Phi_2) = c_2(o)/2 = 4$$

is cocycle-free: the discrete torsion acts on the multiplier system but commutes with the $c_N(o)/2$ -weight projection. This is the precise sense in which tier-(iii) faces share a common weight law (Theorem 31.9.6(iii), final bullet) while carrying non-uniform cocycle data; the two data types factor through different projections of the Borchers lift.

31.10 CROSS-VOLUME BRIDGE

Part IV of Vol III mirrors the seven-face construction developed in Vols. I and II. The common skeleton is the seven-face construction; the variation is in which face is most concrete.

Remark 31.10.1 (The three seven-face masters). The three volumes each devote a part to the seven-face construction, with the same architecture but different ground objects:

- (1) *Vol I, the seven-face part:* the binary collision residue of a chiral algebra on a curve, in seven languages: bar-cobar twisting, primitive generator, classical r -matrix, KZ connection, Gaudin model, Bethe ansatz, dg-shifted Yangian (cf. Vol I, Theorem 30.10).
- (2) *Vol II, the seven-face part:* the binary collision residue of a holomorphic-topological quantum group, in seven languages: open-string brace algebra, derived center, twisted holography boundary, line defect, Wilson line R -matrix, soft graviton coupling, Yangian double (cf. Vol II, Theorem 30.10).
- (3) *Vol III, this chapter:* the binary CY collision residue of a Calabi–Yau chiral algebra, in seven CY-specific languages: CY bar-cobar, CoHA / perverse coherent sheaves, classical CY Poisson coisson, MO stable envelope, affine super Yangian for toric CY_3 , elliptic Sklyanin for toroidal CY, Gaudin from CY_3 (Conjecture 31.9.1 above).

The three master theorems are compatible through the installed comparison maps: under the CY-to-chiral correspondence $\{\Phi_d\}$, face i of Vol III maps to a specialization of face i of Vol I, and similarly for Vol II, precisely at the level governed by Theorem 28.10.1. The CY setting is the most constrained: each face acquires geometric content that the abstract chiral algebra setting does not see (DT counts, plane partitions, crystal melting, MO stable envelopes).

Remark 31.10.2 (The CY direction is the new slot). Compared with Vol I and Vol II, the CY seven-face master contains the additional CY direction Ω_C . In Vol I the binary residue lives on $\overline{C}_2(X) \times \mathfrak{g}^{\otimes 2}$; in Vol II it lives on $\overline{C}_2(X) \times \text{open-sector}^{\otimes 2}$; in Vol III it lives on $\overline{C}_2(X) \times C^{\otimes 2}$, with the CY volume form supplying the pairing on $C^{\otimes 2}$. The CY direction makes face 4 (MO) and face 7 (CY_3 Gaudin) geometric: they live on quiver varieties whose definition requires the CY structure.

Remark 31.10.3 ($\kappa_{\text{ch}}(\mathcal{A})$ is a face-by-face invariant). The modular characteristic $\kappa_{\text{ch}}(\mathcal{A}_C)$ depends on the construction, not on the geometry alone. For $K_3 \times E$, the $\kappa_\bullet$ -spectrum has five values from five distinct

constructions: $\kappa_{\text{cat}} = \chi(\mathcal{O}_{K_3 \times E}) = 2 \cdot 0 = 0$ (Künneth; the K_3 -fiber value $\chi(\mathcal{O}_{K_3}) = 2$ is a distinct *fiber* invariant, not κ_{cat} of the total space) and $\kappa_{\text{fiber}} = 24$ are *manifold invariants* (topological, independent of any construction), while $\kappa_{\text{ch}}^{\text{Heis}} = 3$ (the Heisenberg-level additive reading of the framed Φ_3 -image; the Hodge-supertrace reading $\kappa_{\text{ch}}^{\text{Hodge}}(\mathcal{A}_{K_3 \times E}) = \sum_q (-1)^q h^{0,q}(K_3 \times E) = 0$ is the complementary manifold invariant of Theorem 32.4.5) and $\kappa_{\text{BKM}} = 5$ (from the Borchers weight $c_1(0)/2$ on the primitive denominator Δ_5 , while $\Phi_{10}^{\text{OP}} = D_5^2 = 4096^{-1} \Delta_5^2$ has weight 10) are *construction-dependent invariants* arising from distinct constructions, not from four applications of Φ . Each value sits on a different face: κ_{ch} on face 1 (bar-cobar of the chiral de Rham complex), κ_{cat} on face 2 (holomorphic Euler characteristic), κ_{fiber} on face 3 (classical lattice VOA limit), κ_{BKM} on face 4 (MO/Igusa). The $\kappa_{\bullet}$ -spectrum is the imprint of the geometry on the seven-face master: $\kappa_{\text{ch}}(\mathcal{A})$ depends on the full algebra (not on its Virasoro subalgebra alone), and in the CY setting depends on the full construction (not on the underlying CY manifold alone).

Remark 31.10.4 (Outlook: an eighth face?). The standard seven-face master is closed: there are exactly seven languages in which the binary residue lives, corresponding to the seven edges of the Vol I commuting diagram. The natural question in the CY setting: does the deformation-quantization face (Khan–Zeng 3d PVA sigma model) constitute an eighth? At present this face reduces to a combination of face 3 (classical coisson) and face 7 (Gaudin from CY_3), with the deformation-quantization parameter playing the role of the loop parameter in face 7. An independent eighth face would require a CY-specific structure not visible in the seven-face commuting diagram; it remains open whether the 3d $\mathcal{N} = 2$ holomorphic-twisted theory provides such a structure.

Remark 31.10.5 (Three faces of 8 on the K_3 branch). The integer 8 appears three times inside the CY holographic datum at $C = D^b(\text{Coh}(K_3 \times E))$, in three independent incarnations of the B-family rigidity scalar. This scalar is separate from the Borchers weight $\kappa_{\text{BKM}}(\Delta_5) = c_1(0)/2 = 5$ and from the OP-normalised scalar square $\text{wt}(\Phi_{10}^{\text{OP}}) = 10$.

- (i) *Mukai doubling*: the Mukai pairing on the full cohomology lattice $H^{\text{even}}(K_3; \mathbb{Z})$ has signature $(4, 20)$, and the positive-signature 4-dimensional sublattice doubles to an $\mathbb{I}^{4+}$ -summand of the Mukai lattice of the Steiner system in Remark 31.5.4; the doubling from 4 to 8 is the Mukai doubling of $\chi(\mathcal{O}_{K_3}) = 2$.
- (ii) *Humbert surface*: the relevant Humbert datum is the chosen branch of the Δ_5 Heegner divisor, usually written H_1 in the genus-two normalisation. Its local exponent has an order-eight normalisation in the comparison used here.
- (iii) *Lusztig*: the Lusztig special-piece decomposition of the $\mathfrak{su}(2)^{24}$ flavour symmetry of the class- $\mathcal{S}$ parent (Remark 31.5.4) has a distinguished stratum of codimension 8 whose stabiliser is M_{24} .

The three occurrences are comparison data on the fixed K_3 branch. They do not imply a canonical equation $\hbar^2 \cdot K^{\kappa_{\text{ch}}} = -1$; the symbol $\hbar$ is a formal deformation parameter until a logarithm of the root of unity and a normalisation of the associator have been chosen. The comparison records an order-eight constraint, not a doubled or averaged Borchers weight.

The genus-1 extension, identifying the KZB connection with the elliptic r -matrix on the torus E_τ , is proved for affine KM in Vol I, Chapter [96].

31.11 TWISTED M-THEORY AS THE STAGE-I FIELD-THEORY BULK OF Φ_3

The seven faces all live on the boundary chiral side $\mathcal{A}_C$ or its Stage-I $\Phi_3^{\text{FA}}(C)$ predecessor. The present section reads the same factorisation datum from the field-theoretic bulk side: as the holomorphic factor of twisted 11d supergravity on $X \times \mathbb{R}^5$ in the Omega-background, compactified to 5d holomorphic Chern–Simons on $X \times \mathbb{R}_t$ and holographically expected to map to the E_1 -chiral boundary on $C \subset X$ via the Costello–Paquette extension of twisted holography to 3d HT gauge theory after the protected comparison datum is supplied. Each arrow is chain-level; the E_n -level at every stage is read off the factorisation-homology cochains. The twisted-M-theory bulk is the Stage-I field-theory bulk; the slot-3 chiral bulk object of the holographic datum is the chiral derived centre $Z_{\text{ch}}^{\text{der}}(A)$, equivalently chiral Hochschild cochains of the specialised boundary algebra, living at level 3 of the universal arrow.

Perturbative reduction: twisted M-theory to 5d hCS

PROPOSITION 31.11.1 (*Perturbative reduction of twisted 11d SUGRA to 5d hCS*). (Costello 2016, arXiv:1610.04144, Thm. 4.1.) The perturbative BV factorisation algebra of twisted 11d supergravity on $\mathbb{C}^3 \times \mathbb{R}^5$ with Omega-background on a $\mathbb{R}^2 \subset \mathbb{R}^5$ plane is equivalent, as a BV factorisation algebra on the surviving slab $\mathbb{C}^3 \times \mathbb{R}_t$, to 5d holomorphic Chern–Simons on $\mathbb{C}^3 \times \mathbb{R}_t$ with gauge algebra $\widehat{\mathfrak{gl}}_\infty$. The Omega-background localises the $\mathbb{R}^2$ -rotation plane to its fixed point; the residual 5d hCS action on $\mathbb{C}^3 \times \mathbb{R}_t$ is

$$S_{5\text{d hCS}}[\mathcal{A}] = \int_{\mathbb{C}^3 \times \mathbb{R}_t} \Omega_{\mathbb{C}^3} \wedge \text{tr} \left(\mathcal{A} \wedge \bar{\partial}_{\mathbb{C}^3} \mathcal{A} + \mathcal{A} \wedge d_t \mathcal{A} + \frac{2}{3} \mathcal{A} \wedge \mathcal{A} \wedge \mathcal{A} \right),$$

with gauge algebra $\widehat{\mathfrak{gl}}_\infty$ tracking the M2/M5 perturbative reductions of the 11d parent. Restriction of the gauge algebra to rank r corresponds to compactifying on a 4-manifold carrying r M5-branes.

Remark 31.11.2 (*Compact CY_3 reduction and paramodular arithmetic on $K_3 \times E$*). The compactification of Proposition 31.11.1 on $X = K_3 \times E$ replaces $\mathbb{C}^3$ by the compact CY_3 and introduces 24 M5-branes wrapping the I_1 Kodaira fibres of the elliptic K_3 . The protected one-loop comparison target of the resulting 5d hCS theory on $(K_3 \times E) \times \mathbb{R}_t$ contributes the paramodular weight $\text{wt}(\Delta_5) = \kappa_{\text{BKM}}(\Delta_5) = c_1(o)/2 = 5$ as the one-loop forced output of paramodular anomaly cancellation once the physical trace comparison is supplied (Remark 31.2.6). The number $\chi(O_{K_3}) = 2$ remains the K_3 -fibre Hodge Euler characteristic, while the Kodaira residues belong to the anomaly calculation rather than to an additive $\kappa_\bullet$ formula. Four independent duality frames (heterotic $K_3 \times T^2$ Harvey–Moore 1996; Type IIB $K_3 \times S^1$ DVV 1996–1997; Type IIA symmetric products DMVV 1997; M -theory $K_3 \times T^3$ Witten 1995) confirm the same arithmetic numerically.

Chain-level E_3 bulk observables via holomorphic-topological factorisation

THEOREM 31.11.3 (*E_3 chain-level realisation of $\Phi_3^{\text{FA}}(C)$ via twisted-M-theory*). Let X be a smooth CY_3 with holomorphic volume form Ω_X and let $\mathfrak{g}$ be a reductive gauge Lie algebra. Assume X is restricted to a formal/toric Costello–Gwilliam chart, or more generally that the framed Φ_3^{FA} chain model has been constructed. This is a local chain-level assertion on the stated chart; arbitrary compact non-formal CY_3 s require their own holomorphic-factorisation models. Under the holomorphic-topological tensor theorem of Costello–Gwilliam Vol. II §4.10 (arXiv:2210.13036), the bulk local observables of twisted M-theory on $X \times \mathbb{R}^2$ factor as a chain-level tensor product

$$\text{Obs}_{\text{loc}}^{\text{tw-M}}(X \times \mathbb{R}^2) \simeq \text{Obs}^{\text{4d hol}}(X, \mathfrak{g}) \boxtimes \text{Obs}^{\text{id top}}(\mathbb{R}_t) \boxtimes \text{Obs}^{\text{id top}}(\mathbb{R}_s),$$

where the two topological $\mathbb{R}$ -factors carry E_1 -structure each and the holomorphic X -factor carries E_4 -structure via Kontsevich–Tamarkin 4d formality on the Gerstenhaber bracket of degree -3 on $\mathrm{HH}^\bullet(\mathrm{Perf} X)$. Restricting to the holomorphic E_3 -subfactor obtained by compactifying one $\mathbb{R}$ -factor and reading the $\mathbb{R}_s$ -transverse slab gives

$$\Phi_3^{\mathrm{FA}}(\mathrm{Perf} X) \simeq \int_{\mathbb{R}_s} \mathrm{Obs}_{\mathrm{loc}}^{\mathrm{tw-M}}(X \times \mathbb{R}^2) \in E_d\text{-HolFA}(X).$$

On this stated locus, this identifies the constructed $\Phi_3^{\mathrm{FA}}(\mathrm{Perf} X)$ model with the holomorphic factor of the 5d hCS BV observable factorisation algebra on $X \times \mathbb{R}_t$.

Proof. The 5d hCS action is linear in the $\mathbb{R}_t$ -direction: $\mathcal{A} \wedge d_t \mathcal{A}$ contributes a first-order t -derivative. The classical BV complex on $X \times \mathbb{R}_t$ is therefore a tensor product $(\Omega^{\bullet, \bullet}(X) \otimes \mathfrak{g}[1], \bar{\partial}_X) \otimes (\Omega^\bullet(\mathbb{R}_t), d_t)$ with the antibracket respecting the factorisation. Costello–Gwilliam Vol. II §4.10 promotes this tensor decomposition at the cochain level to a tensor decomposition of BV factorisation algebras. The holomorphic factor is Costello–Li 4d hCS on X (arXiv:1606.00365) with E_4 -structure from Kontsevich E_d -formality. The topological factor is the E_1 -algebra $C_{\mathrm{Lie}}^*(\mathfrak{g}[1])$; factorisation homology $\int_{\mathbb{R}_t}$ is the enveloping algebra $U(\mathfrak{g}[[\hbar]])$ by Francis 2013 (arXiv:1303.0305) Theorem 2.29. Restriction to Stage-I reads only the holomorphic factor; this is $\Phi_3^{\mathrm{FA}}(\mathrm{Perf} X)$ of Chapter 5 §5.1.1. $\square$

Costello–Paquette boundary: the E_1 -chiral algebra is the boundary of 3d HT gauge theory

Why twisted holography at $d = 3$ requires the Costello–Paquette extension rather than the Costello–Gaiotto 4d-HT framework: the sphere-OPE datum of a VOA lives in $H^\bullet(\mathrm{Ran}(\mathbb{A}^1), \mathrm{Fact}_{E_2})$, whose one-dimensional E -factor contribution $H^1(E, \mathbb{C})$ is the Omega-deformation parameter rather than the sphere-OPE structure. Direct transplantation would produce a VOA that does not exist; the boundary of a 3d HT theory is E_1 -chiral (locally constant on $C \subset X$), not E_2 -chiral. This is the chain-level reason why $\Phi_3(D^b \mathrm{Coh}(K_3 \times E))$ is an E_1 -chiral bialgebra, not a VOA.

PROPOSITION 31.II.4 (*Costello–Paquette E_1 -chiral boundary at $d = 3$*). Let $X = K_3 \times E$, let $Y_3^{\mathrm{HT}}(X)$ denote the 3d holomorphic-topological gauge theory on $X \times \mathbb{R}_+$, and let $\mathcal{A}_\partial^{E_1}$ denote its locally-constant boundary factorisation algebra on $C = E \subset X$. Assuming the Stage-I Φ_3^{FA} model, Costello–Paquette’s boundary theorem (Costello–Paquette 2020, arXiv:2001.02177 Thm. 4.7), and the protected hCS boundary comparison, then:

$$\Phi_3(D^b \mathrm{Coh}(X)) \simeq \mathcal{A}_\partial^{E_1}(Y_3^{\mathrm{HT}}(X)) \quad \text{on } C = E \subset X,$$

with Ω -deformation parameter ε set by the elliptic period $\oint_\gamma \omega_E \in H^1(E, \mathbb{C})$. The identification is E_1 -monoidal, not E_2 -braided; the r -matrix r_{CY} is an E_1 -commutator shadow, not a braiding coefficient of a modular tensor category. The mode algebra $\mathrm{Modes}(\mathcal{A}_\partial^{E_1})$ is an associative algebra (not a vertex algebra); the pairing is the linearised E_1 -commutator, not the full Borchers OPE.

Remark 31.II.5 (The E_2 -data hides on the derived centre). The E_2 -chiral lift of $\Phi_3(D^b \mathrm{Coh}(X))$ lives on the Drinfeld centre $\mathcal{Z}(\mathrm{Rep}^{E_1}(\Phi_3(D^b \mathrm{Coh}(X))))$, one level up from the boundary algebra. The Borchers product $\Phi_{10}^{\mathrm{OP}} = D_5^2 = 4096^{-1} \Delta_5^2$ is the OP-normalised protected scalar target of $Y_3^{\mathrm{HT}}(X)$ on $X \times S^1$, not the character of $\Phi_3(D^b \mathrm{Coh}(X))$ itself. Under the same protected comparison, the

primitive genus-2 denominator $\Delta_5(Z) \in M_5(\mathrm{Sp}_4(\mathbb{Z}))$ is the chiral-half genus-2 shadow of the E_1 -mode character

$$\Delta_5(Z) = \mathrm{ch}_{g=2}^{\mathrm{modes}}(\mathcal{A}_\partial^{E_1})(Z) = \mathrm{Tr}_{\mathcal{A}_\partial^{E_1}}^{E_1} \left(e^{2\pi i(\tau L_0 + z J_0 + \sigma \bar{L}_0)} \right), \quad Z = \begin{pmatrix} \tau & z \\ z & \sigma \end{pmatrix} \in \mathbb{H}_2,$$

with period matrix Z encoding the $\Omega_{K_3 \times E}$ -expansion directions (τ, σ) and the coupling z . The weight 5 of Δ_5 is the conformal anomaly of the E_1 -mode trace normalised by the Weyl vector ρ with $(\rho, \rho) = -3/2$.

Costello–Yagi as (Σ_2, C) -specialisation of Φ_3^{FA}

PROPOSITION 31.11.6 (*Costello–Yagi as tier-(iii) specialisation of $\Phi_3^{\mathrm{FA}}(\mathrm{Perf} \mathbb{C}^3)$*). (Composite of Theorem 31.11.3 with Costello–Yagi 2018 arXiv:1810.01970 Thm. 4.1.) Let $X^{\mathrm{germ}} = \mathbb{C}^3 = \mathbb{C}^2 \times \mathbb{C}$ and fix the specialisation datum $(\Sigma_2, C) = (\mathbb{C}^2\text{-germ}, \mathbb{C}\text{-germ})$. For $\mathfrak{g}$ simply-laced bosonic (ADE: A_n, D_n, E_6, E_7, E_8), the (Σ_2, C) -specialisation of the Stage-1 object of Theorem 31.11.3 is the Yangian VOA:

$$\mathrm{Sp}_{\mathbb{C}^2, \mathbb{C}}^{\mathrm{ch}}(\Phi_3^{\mathrm{FA}}(\mathrm{Perf} \mathbb{C}^3)) \simeq Y^{\mathrm{VOA}}(\mathfrak{g}) \quad \text{to all orders in } \hbar.$$

Convergence (not merely asymptotic) is supplied by Kontsevich–Tamarkin E_d -formality on the holomorphic $\mathbb{C}^2$ -factor: the one-loop wheel $\mathrm{Tr}(A \partial A \partial A \partial A)$ anomaly is proportional to the symmetric rank-3 Casimir $d_{\mathfrak{g}}^{abc}$, which vanishes for the simple types whose exponent list has no 2, and is non-zero for $A_n, n \geq 2$. The identification is thus the $(\Sigma_2, C) = (\mathbb{C}^2\text{-germ}, \mathbb{C}\text{-germ})$ -specialisation of Φ_3^{FA} on $\mathbb{C}^3$, a tier-(iii) datum in the stratification of Theorem 31.9.6.

Remark 31.11.7 (Scope discipline: simply-laced bosonic only). The Costello–Yagi all-orders theorem quantises only the simply-laced bosonic case. This scope is not the same as cubic-Casimir vanishing: B_n, C_n, F_4, G_2 have $d^{abc} = 0$ by exponent absence, while $\mathfrak{sl}_{N \geq 3}$ has non-zero d^{abc} . Non-simply-laced bosonic and super-Lie $(\widehat{\mathfrak{gl}}(m|n))$ with $m \neq n$: non-zero super-symmetric rank-3 Casimir) remain open at all orders. The $\mathfrak{sl}_2$ case is unobstructed; $\mathfrak{sl}_{N \geq 3}$ is obstructed with anomaly splitting into a scheme-dependent field-renormalisation term $A_{\mathrm{w.f.}} = -C_2/(2\pi)^3$ (BV-trivial counter-term) and a cohomological true anomaly $A_{\mathrm{anom}} = d^{abc} d_{abc}/(2\pi)^3$. The two-author Costello–Yagi (arXiv:1810.01970) is the source; it is distinct from the three-author Costello–Gaiotto–Yagi (arXiv:2103.01835) on twisted supergravity dualities. Conflation is a primary-literature attribution error.

κ_{ch} as chain-level conformal anomaly of the E_1 -mode trace

PROPOSITION 31.11.8 (κ_{ch} as E_1 -mode conformal anomaly on $K_3 \times E$). Let $X = K_3 \times E$ and let $\mathcal{A}_\partial^{E_1}$ be the E_1 -chiral boundary algebra of Proposition 31.11.4. Assume the boundary comparison of that proposition. Then:

- (i) The Heisenberg-level additive reading equals the Weyl-vector- normalised conformal anomaly:

$$\kappa_{\mathrm{ch}}^{\mathrm{Heis}}(A_{K_3 \times E}) = -2(\rho, \rho) = 3, \quad (\rho, \rho) = -3/2.$$

- (ii) The Hodge-supertrace reading is the Künneth-multiplicative total-space value:

$$\kappa_{\mathrm{ch}}^{\mathrm{Hodge}}(A_{K_3 \times E}) = \sum_q (-1)^q h^{0,q}(K_3 \times E) = \chi(\mathcal{O}_{K_3}) \cdot \chi(\mathcal{O}_E) = 2 \cdot 0 = 0.$$

- (iii) Both values are Φ_3^{FA} -invariant (tier-(i) and tier-(ii) of Theorem 31.9.6), independent of the (Σ_2, C) -specialisation. They differ because they read different projections of the E_1 -mode trace: (i) the Heisenberg subalgebra of $\mathcal{A}_\partial^{E_1}$; (ii) the full mode trace on the compact total space.

Proof. For (i), Costello–Paquette 2020 Thm. 4.7 identifies the central charge of the E_1 -mode trace on a 3d HT boundary with the Weyl-vector- normalised conformal anomaly. On the K_3 -fibre side of $K_3 \times E$, the Weyl vector of the BKM $\mathfrak{g}_{\Delta_5}$ satisfies $(\rho, \rho) = -3/2$ (Gritsenko–Nikulin 1998 Thm. 2.1); the Heisenberg central charge reads $-2(\rho, \rho) = 3$. For (ii), the Künneth multiplicativity is $\chi(\mathcal{O}_{X \times Y}) = \chi(\mathcal{O}_X)\chi(\mathcal{O}_Y)$; $\chi(\mathcal{O}_E) = 0$ gives $\chi(\mathcal{O}_{K_3 \times E}) = 0$. For (iii), both are tier-(i)/(ii) by the three-tier stratification theorem. $\square$

Remark 31.II.9 (Five-value invariant spectrum on $K_3 \times E$ under the twisted-M-theory reading). The five-value invariant spectrum $\{0, 0, 3, 5, 24\}$ on $K_3 \times E$ reads, chain-level, as five *distinct* constructions:

- $\kappa_{\text{cat}}(K_3 \times E) = 0$: Künneth-multiplicative total-space invariant, $\chi(\mathcal{O}_{K_3}) \cdot \chi(\mathcal{O}_E) = 2 \cdot 0 = 0$.
- $\kappa_{\text{ch}}^{\text{Hodge}}(K_3 \times E) = 0$: compact total-space Hodge supertrace, Serre at odd $d = 3$ (distinct construction layer from κ_{cat}).
- $\kappa_{\text{ch}}^{\text{Heis}} = 3$: E_1 -mode Heisenberg central charge (tier-(i)), via Weyl-vector pairing $-2(\rho, \rho)$.
- $\kappa_{\text{BKM}}(\Delta_5) = 5$: Borchers weight $c_1(0)/2$ at $N = 1$ (tier-(iii)), Borchers 1998 Thm. 13.3; the one-loop paramodular arithmetic of Remark 31.II.2 is a physical derivation of the same Borchers-weight value, not an additive decomposition into the other $\kappa_{\bullet}$ invariants.
- $\kappa_{\text{fiber}} = 24$: K_3 Mukai-lattice rank on the elliptic fibration (tier-(ii)), Kodaira 24 I_1 -fibres.

None of these is a VOA central charge of $\Phi_3(D^b \text{Coh}(X))$ itself: that identification conflates E_1 -mode-trace conformal anomaly (chain-level allowed) with E_2 -chiral central charge of a VOA (absent at $d = 3$, as $\mathcal{A}_{\mathcal{J}}^{E_1}$ is E_1 -chiral, not E_2).

Bulk–boundary dictionary (chain-level)

The chain-level correspondences assembled above compress into the following dictionary, each entry realising one read of $\Phi_3^{\text{FA}}(C)$ from the bulk twisted-M-theory side.

Bulk (twisted M-theory)	Boundary (E_1 -chiral)	Reads on Φ_3
twisted 11d SUGRA on $X \times \mathbb{R}^5$	E_1 -mode algebra on C	$\Phi_3(D^b \text{Coh}(X))$
Ω -background on $\mathbb{R}^2 \subset \mathbb{R}^5$	elliptic period of E	Stage-I: Φ_3^{FA}
M5-brane on I_1 Kodaira fibre	Kodaira residue +3	tier-(ii): $\kappa_{\text{fiber}} = 24$
M2-brane tadpole arithmetic	paramodular weight 5	tier-(iii): $\kappa_{\text{BKM}}(\Delta_5) = 5$
Mukai doubling $\chi(\mathcal{O}_{K_3}) = 2$	Hodge supertrace on K_3 -fibre	$\kappa_{\text{ch}}^{\text{Heis}} = 3$
S^2 -trace on bulk E_3 observables	genus-2 $\Delta_5(Z)$ shadow	E_2 -centre $\mathcal{Z}(\text{Rep}^{E_1})$
5d hCS on $\mathbb{C}^3 \times \mathbb{R}_t$, $\mathfrak{g}$ ADE	$Y^{\text{VOA}}(\mathfrak{g})$ on germ $\mathbb{C}$	Costello–Yagi as (Σ_2, C) - Sp^{ch}

Every row is chain-level: no VOA structure on the boundary at $d = 3$, no central-charge-as- κ_{ch} conflation, no Δ_5 -as-character confusion. Face 4 (MO R -matrix for $K_3 \times E$) and Face 5 (affine super-Yangian for toric CY_3) project onto the bottom two rows; Face 7 (CY_3 Gaudin) projects onto the sixth row through the E_2 -centre.

Coherence with Costello–Francis–Gwilliam topological envelope

PROPOSITION 31.II.10 (Coherence with the CFG topological envelope). Let $M^3 = \mathbb{R}_t \times \mathbb{C}$ denote the topological slab of $X \times \mathbb{R}_t$ after transverse holomorphic quotient (reducing X onto the $\mathbb{C}$ -direction;

for $X = \mathbb{C}^3$ this is the projection onto one holomorphic coordinate; for $X = K_3 \times E$, onto the E -direction).

- (i) The Costello–Francis–Gwilliam 2026 envelope $\mathcal{U}^{\text{CFG}}(\mathfrak{g}, M^3)$ is an E_3 -pre-factorisation algebra on M^3 , sheafifying to a genuine E_3 -factorisation algebra by Weiss-cover descent (Costello–Gwilliam Vol. I Def. 6.1.0.6).
- (ii) Holomorphic compactification of 5d hCS on $X \times \mathbb{R}_t$ along X reduces the E_4 -holomorphic factor to its $H^\bullet(X)$ -cohomology (Costello–Li 2016 Prop. 5.2, with one-loop coefficient $\alpha_{\text{BCOV}} = \chi(X)/24 \cdot [\Omega_X]^{\circ,1}$ vanishing on $K_3 \times E$ by $\chi(K_3 \times E) = 0$), absorbing the X -holomorphic data into the gauge algebra $\widehat{\mathfrak{gl}}_\infty$ of Costello 2016.
- (iii) The two envelopes agree on their common Gerstenhaber/BV core: both select the Kontsevich–Tamarkin E_3 -formality output of the Gerstenhaber bracket of degree -3 on $\text{HH}^\bullet(\text{Perf } X)$ at the Costello–Li $\text{GRT}_1(\mathbb{Q})$ -point.

The twisted-M-theory construction *geometrises* the CFG envelope by supplying the CY_3 -datum input and the gauge algebra $\widehat{\mathfrak{gl}}_\infty$ from the iid parent; conversely, the CFG envelope provides the E_3 -operadic structure canonically.

Remark 31.11.11 (The bulk-boundary picture is Sp^{ch} -natural across (Σ_2, C)). The (Σ_2, C) -specialisation fibres of $\Phi_3^{\text{FA}}(\text{Perf } X)$ produce tier-(iii) siblings in the two-stage factorisation sense; the twisted-M-theory reading naturalises the choice by identifying (Σ_2, C) with a holomorphic sub-4-cycle of X (for $X = \mathbb{C}^3$: $\Sigma_2 = \mathbb{C}^2$ -germ; for $X = K_3 \times E$: $\Sigma_2 = K_3$ -fibre) together with a reference curve $C \subset X$ transverse to Σ_2 . Each (Σ_2, C) realises a distinct boundary theory $\mathcal{A}_\partial^{E_1}$ under Costello–Paquette, and hence a distinct face in the tier-(iii) seven-face slice. The six routes to $G(K_3 \times E)$ of Chapter 23 are six (Σ_2, C) -specialisations of one Stage-1 object (Remark 31.0.2), not six applications of Φ_3 ; the twisted-M-theory reading identifies each with a distinct choice of sub-4-cycle and reference curve inside the compact CY_3 .

Cross-references across the seven-face construction

The twisted-M-theory reading intersects the seven faces as follows.

Face 1 (CY bar-cobar). The bar complex $\overline{B}(\mathcal{A}_C)$ coacts on the holomorphic factor of Theorem 31.11.3; the binary CY collision residue $r_{CY}(z) = \text{Res}_{0,2}^{\text{coll}}(\Theta_{\mathcal{A}_C})$ is the degree-2 component of the universal twisting morphism between the E_1 -chiral mode bar $\overline{B}(\mathcal{A}_\partial^{E_1})$ and $\mathcal{A}_\partial^{E_1}$.

Face 4 (MO R -matrix for $K_3 \times E$). The Maulik–Okounkov stable-envelope R -matrix $R_{\text{MO}}^{K_3 \times E}(z)$ is the bulk E_3 -observable trace of the Ω -deformed boundary E_1 -chiral mode algebra against the configuration space of two marked points on C ; the classical limit $\lim_{\hbar \rightarrow 0} \hbar^{-1}(R_{\text{MO}} - \text{id})$ is the $r_{CY}^{K_3 \times E}$ of Conjecture 31.5.2.

Face 5 (affine super Yangian for toric CY_3). Proposition 31.11.6 identifies the $(\mathbb{C}^2$ -germ, $\mathbb{C}$ -germ)-specialisation of $\Phi_3^{\text{FA}}(\text{Perf } \mathbb{C}^3)$ with the Yangian VOA $Y^{\text{VOA}}(\mathfrak{g})$ for simply-laced bosonic $\mathfrak{g}$; tied to Theorem 31.6.1 via the Rapcak–Soibelman–Yang–Zhao CoHA identification.

Face 7 (Gaudin from CY_3). The Drinfeld-centre E_2 -shadow of Remark 31.11.5 is the bulk-side source of the Gaudin Hamiltonians: the E_2 -centre acts on the Fock-representation tensor product through

the (Σ_2, C) -framed factorisation homology integral, yielding the commuting Hamiltonians of Theorem 31.8.1 via the Ω -background coupling to the reference curve.

Seven-face master. Faces 1–7 project onto distinct slices of the bulk E_3 -observable pre-factorisation algebra $\text{Obs}_{\text{loc}}^{\text{tw-M}}(X \times \mathbb{R}^2)$ under different choices of specialisation datum (Σ_2, C) and different centre-complementarity operations. This is the seven-face content of Conjecture 31.9.1 read from the bulk side: one chosen framed stage-1 $\Phi_3^{\text{FA}}(C)$; seven tier-(iii) boundary projections via $\text{Sp}_{\Sigma_2, C}^{\text{ch}}$; one family of bulk observables in twisted M-theory.

31.12 EXPLICIT CROSS-VOLUME BRIDGES

The CY holographic datum $H_{CY}(T) = (A_{CY}, A_{CY}^!, C_{CY}, r_{CY}(z), \Theta_{CY}, \nabla_{CY}^{\text{hol}})$ of Remark 31.2.5 is the CY incarnation of the Vol I holographic datum $H(T) = (A, A^!, C, r(z), \Theta_A, \nabla^{\text{hol}})$. The seven CY faces constructed above are compared with load-bearing Vol I / Vol II structures through explicit Φ -maps. Four bridges carry the load.

Bridge to Vol I Koszul Reflection ([96]). The Vol I bar-cobar adjunction $(\Omega_X, \bar{B}_X)$ on $\text{Kosz}(X)$ defines an involutive Koszul reflection $\mathfrak{R}_A: A \mapsto A^!$. Under the CY-to-chiral correspondence $\{\Phi_d\}$ (CY- A_2 proved at $d = 2$ as Φ_2 ; the $d = 3$ statement restricted to the framed Φ_3 locus of Theorem 5.11.1), Face 1 (CY bar-cobar twisting morphism, §31.2) IS the Φ -image of the Koszul reflection: the binary CY collision residue $r_{CY}(z) = \text{Res}_{0,2}^{\text{coll}}(\Theta_{A_C})$ is the leading degree-2 component of the universal twisting morphism between $\bar{B}(A_C)$ and A_C . The arrow:

$$r_{CY}(z) = \Phi_*(\text{Res}_{0,2}^{\text{coll}}(\mathfrak{R}_{\Phi(C)})).$$

Bridge to Vol III 32.4.5. The Vol III dimension-stratified κ_{ch} formula (Theorem 32.4.5 of [96]) identifies $\kappa_{\text{ch}}(A_C)$ with the Hodge supertrace $\sum_q (-1)^q h^{o,q}(X)$ for compact CY_d . Under the seven faces:

- Face 1 (bar-cobar): κ_{ch} is the degree-2 shadow invariant $S_2 = \kappa_{\text{ch}}$ (convention-independent; the $c/12$ coefficient sometimes seen in λ -bracket conventions is $(c/2)/3! = \kappa_{\text{ch}}/6$, not S_2 itself).
- Face 2 (CoHA): κ_{ch} is the dimension shift of the perverse-coherent shadow.
- Face 4 (MO): the K_3 -fibered case gives $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2$ via the Borchers weight (17.6.7; see also Remark 31.10.3 above).

The five-construction $\kappa_{\bullet}$ -spectrum $\{\kappa_{\text{cat}}, \kappa_{\text{ch}}^{\text{Hodge}}, \kappa_{\text{ch}}^{\text{Heis}}, \kappa_{\text{BKM}}, \kappa_{\text{fiber}}\}$ splits into manifold invariants (topological, Φ -invariant: $\kappa_{\text{cat}}, \kappa_{\text{fiber}}$) and construction-dependent invariants (face-dependent: the chiral Hodge supertrace $\kappa_{\text{ch}}^{\text{Hodge}} = \sum_q (-1)^q h^{o,q}(\cdot)$ as the canonical chiral-side reading, $\kappa_{\text{ch}}^{\text{Heis}}$ on Face 1, κ_{BKM} on Face 4); the distinction is preserved at every cross-reference.

Bridge to Vol II universal holography master ([97]). Vol II universal celestial holography establishes that the $\text{SC}^{\text{ch,top}}$ -structure on the bulk-boundary pair $(C_{\text{ch}}^{\bullet}(A, A), A)$ equals chiral factorization homology, with shadow-tower coefficients matching the soft-factor hierarchy. The CY image is the seven-face master: under Φ , the seven CY incarnations of $r_{CY}(z)$ correspond to seven projections of the Vol II $\text{SC}^{\text{ch,top}}$ -structure on $(C_{\text{ch}}^{\bullet}(A_C, A_C), A_C)$. The Universal Trace Identity (Conjecture 29.15.1, §29.15 of the bar-cobar bridge chapter) predicts that the supertrace of the Koszul reflection on the candidate universal centre $\mathfrak{Z}(A_C) := \int_{S^1 \times \text{Ran}(X)} A_C$ has two Stage-2 scalar shadows: the Vol I κ_{ch} -conductor

$K(A_C)$ and, on the K_3 -fibered $\mathfrak{g}_\Lambda$ branch, the Borchers weight characteristic $\kappa_{\text{BKM}}(\Phi_\Lambda) = c_\Lambda(o)/2$. These numbers need not be equal. The comparison datum of 29.15.1 is a morphism from the Koszul reflection to the Borchers centre action after both objects have been constructed; it is not a formal pushforward supplied by the theta lift. With that datum fixed, the seven-face master is a projection of one universal involution.

Remark 31.12.1 (Bi-based factorization realises $\text{SC}^{\text{ch},\text{top}}$ on the Hochschild pair). The Vol II $\text{SC}^{\text{ch},\text{top}}$ -structure on $(C_{\text{ch}}^\bullet(A_C, A_C), A_C)$ is not a structure on $\tilde{B}(A_C)$ alone (which is an E_1 coassociative coalgebra; the bar coalgebra is not itself an $\text{SC}^{\text{ch},\text{top}}$ -coalgebra); $\text{SC}^{\text{ch},\text{top}}$ emerges on the bulk–boundary pair in which the chiral Hochschild cochain algebra is paired with A_C through the Chiral Hochschild Trinity (Vol II). For $C = D^b(\text{Coh}(K_3 \times E))$ the pair is bi-based: the boundary A_C is factorised over the chiral base $\text{Ran}(E_{24}^{\text{nod},\text{sm}})$ (Remark 31.8.5) and the bulk $C_{\text{ch}}^\bullet(A_C, A_C)$ is factorised over the parameter base $\tilde{\mathcal{A}}_2$ through the projected K_3 -period correspondence. Under this bi-based factorization, the seven-face projections of Remark 31.9.5 are the seven ways of slicing the $\text{SC}^{\text{ch},\text{top}}$ -heptagon:

- Face 1 (bar–cobar) projects the chiral base;
- Face 4 (MO stable envelope) projects the parameter base via the K_3 period point and the reduced spin projection;
- Face 7 (CY₃ Gaudin) projects the joint base given by the marked Kodaira divisor and the projected period correspondence, with Bethe roots of the chiral side compared to lattice points of the Borchers automorphic side only after this correspondence has been fixed.

The assertion is that each projection preserves the Universal Φ -Trace Identity of Remark 31.8.5. The proved value-level input is the Borchers weight $\kappa_{\text{BKM}}(\Delta_5) = 5$. The assertion that the Koszul reflection supertrace on $\mathfrak{Z}(A_C)$ equals this value in every slice is the universal-trace comparison and requires the stated projection compatibility.

Bridge to Vol I climax + universal conductor + shadow quadrichotomy. The three Vol I master structures map face-by-face under Φ :

- *Climax* ([96]): $\tilde{d}_X = \text{KZ}^*(\nabla_{\text{Arnold}})$ controls Face 1 (bar–cobar) at the level of the bar differential.
- *Universal conductor* ([96]): $K(A_C) = -c_{\text{ghost}}(\text{BRST}(A_C))$ provides the single scalar invariant attached to each face (face-dependent $\kappa_\bullet$ -values agree under appropriate normalisation).
- *Shadow quadrichotomy* ([96]): the G/L/C/M shadow class of A_C controls which faces are nonvanishing and at what degree (Remark 31.9.5: p_{max} for Face 5, k_{max} for Face 6, r_{max} for Face 1).

Each bridge is a Φ -comparison of a Vol I or Vol II structure, carries the distinction between manifold-level and construction-level invariants, and replaces any informal “X gives Y” with an explicit comparison arrow.

31.13 CY HOLOGRAPHIC DATUM MASTER AT THE K_3 BASE

Remark 31.13.1 (CY holographic datum master at the K_3 base). The CY holographic datum master diagram on the K_3 base has the source datum

$$\mathcal{H}^{\text{CY}}(K_3) = (D^b\text{Coh}(K_3), D^b\text{Coh}(K_3)^!, \text{Hoch}^\bullet(K_3), \Omega_{\text{Calabi–Yau}}, \Theta^{\text{CY}}, \nabla^{\text{GM}}),$$

and, conditional on the CY-to-chiral comparison, the boundary-linear Hall–Borcherds bridge data, and the chosen $\mathrm{Sp}_{\Sigma_2, C}^{\mathrm{ch}}$ -specialisation, targets the chiral holographic datum master

$$\mathcal{H}^{\mathrm{ch}}(\mathbf{H}_{\Delta_5}) = (\mathbf{H}_{\Delta_5}, \mathbf{H}_{\Delta_5}^{(!)}, \mathcal{Z}_{\mathrm{ch}}^{\mathrm{der}}(\mathbf{H}_{\Delta_5}) \simeq \mathcal{C}_{\mathrm{ch}}^{\bullet}(\mathbf{H}_{\Delta_5}, \mathbf{H}_{\Delta_5}), R_{\mathrm{Sieg}, \mathrm{dyn}}, \Theta_{\mathbf{H}_{\Delta_5}}, \nabla_{\tilde{\mathcal{A}}_2}^{\mathrm{KZB}}).$$

The ordered bar complex $B_{\mathrm{ch}}^{\mathrm{ord}}(\mathbf{H}_{\Delta_5})$ is the chain model used to construct $\Theta_{\mathbf{H}_{\Delta_5}}$ and the binary residue $R_{\mathrm{Sieg}, \mathrm{dyn}}$; it is not the bulk slot. The Gauss–Manin connection ∇^{GM} on the CY side is required, under the same bridge datum, to match the KZB connection on the chiral side through the projected K₃ period correspondence $\pi_{\mathrm{Sp}_4} \circ \mathcal{P}_{K_3}$; no literal morphism $K_3 \hookrightarrow \tilde{\mathcal{A}}_2$ is supplied by the base datum alone. The six-tuple master equation $D \cdot \Theta + \frac{1}{2}[\Theta, \Theta] = 0$ is the conditional compatibility equation on the two sides, not an unconditional consequence of the K₃ base datum alone. Cross-ref Vol. I, §[96] (Vol I), and Vol. III, Chapter 20.

Part V

The Calabi–Yau Landscape

Definition 31.13.2 (Equivariance strata of $\text{CY}_d\text{-Cat}$ at the Stage-2 chart). The Stage-2 chart datum factors as

$$\text{equivariance stratum} \times (\Sigma_{d-1}, C) \times \text{boundary vacuum } b \times \text{admissibility window}.$$

The four equivariance strata of $\text{CY}_d\text{-Cat}$ are:

- *Toric T^d .* X admits an effective algebraic T^d -action with isolated fixed points; the Stage-1 factorisation algebra $\Phi_d^{\text{FA}}(C)$ is computed via T^d -equivariant localisation on X , while the K-theoretic critical CoHA on the T^d -fixed locus supplies the Hall positive-half comparison for the Stage-2 chiral output. Worked $d = 3$ examples: $\mathbb{C}^3$ (Schiffmann–Vasserot CoHA($\mathbb{C}^3$) = $Y^+(\widehat{\mathfrak{gl}}_1)$, Theorem 34.3.1), local $\mathbb{P}^2 = \text{Tot}(\omega_{\mathbb{P}^2})$ via the $[\mathbb{C}^3/\mathbb{Z}_3]$ McKay quiver and Bridgeland–King–Reid equivalence (Theorem 34.11.1; Beasley–Plesser cubic superpotential $W = \text{tr}(XYZ - XZY)$ on the Beilinson 9-arrow quiver), resolved conifold $\widetilde{X}_{\text{con}} = \text{Tot}(\mathcal{O}(-1)^{\oplus 2} \rightarrow \mathbb{P}^1)$ via the Czech atlas $U_+, U_- = \mathbb{C}^3$ with Klebanov–Witten potential $W_{\pm} = \text{tr}(x[y, z])$ (Theorem 34.0.1) and the Szenđrői 2-vertex global NCCR with reduced topological Euler $\chi(\widetilde{X}_{\text{con}}) = 2$ and Maulik–Nekrasov–Okounkov–Pandharipande partition function $Z^{\text{DT}} = M(-q)^2 \prod_{k \geq 1} (1 - Q(-q)^k)^k$.
- *Reduced $\mathbb{C}^\times + \text{Aut}$.* X admits a $\mathbb{C}^\times$ -action on a fibre or transverse cycle together with a finite automorphism group fixing the CY structure; the central stratum at $d = 3$ is $K_3 \times E$, with a reduced elliptic-translation action on E and the K_3 polarisation automorphisms acting on the K_3 factor. At $(\Sigma_2, C) = (K_3, E)$ the Stage-2 specialisation produces the K_3 BKM superalgebra $\mathfrak{g}_{\Delta_5}$ on the rank-3 hyperbolic lattice $U \oplus \langle -2 \rangle$ (Gritsenko–Nikulin 1998, *IMRN* 1998 no. 11, 525–547; Borchers 1998, *Invent. Math.* 132, 491–562), with Stage-2 Borchers-weight identity $\kappa_{\text{BKM}}(\Delta_5) = c_1(o)/2 = 5$. The full $K_3 \times E$ five-spectrum from five distinct constructions (Remark 26.32.2) is

$$\{\kappa_{\text{cat}}, \kappa_{\text{ch}}^{\text{Hodge}}, \kappa_{\text{ch}}^{\text{Heis}}, \kappa_{\text{BKM}}(\Delta_5), \kappa_{\text{fiber}}\}(K_3 \times E) = \{0, 0, 3, 5, 24\}.$$

Sibling reduced-stratum entries: abelian threefold E^3 with $\kappa_{\text{cat}}(E^3) = 0$ and full automorphism torus T^3 acting on the universal cover; elliptic K_3 fibration $X \rightarrow \mathbb{P}^1$ with E -translation along each fibre.

- *Orbifold inertia $I(X/G)$.* $X = Y/G$ for a finite $G \subset \text{SU}(d)$ acting on a smooth Calabi–Yau Y , with the inertia stack $I(X)$ supplying the chart datum. At $d = 3$, $\mathbb{C}^3/\Gamma$ for $\Gamma \subset \text{SU}(3)$ finite produces the McKay critical CoHA on the Bridgeland–King–Reid crepant resolution $G\text{-Hilb}(\mathbb{C}^3)$ (Bridgeland–King–Reid 2001, *J. Amer. Math. Soc.* 14, 535–554). The Mathieu-moonshine sibling at $d = 2$ is the orbifold K_3 elliptic genus enriched by M_{24} (Eguchi–Ooguri–Tachikawa 2010, *Exp. Math.* 20, 91–96); the Conway/Leech sibling at $d = 4$ via the fermionic Conway module $V^{\mathfrak{f}}_{\mathfrak{h}}$ with Co_0 -action (Frenkel–Lepowsky–Meurman 1988 *Vertex Operator Algebras and the Monster*, Academic Press; Duncan 2007, *Duke Math. J.* 139, 255–315).
- *Lattice-polarised period domain.* X has reduced period map into a type-IV symmetric domain Ω_L for an even lattice L of signature $(2, n)$; the Stage-2 chiral output is a Borchers lift on Ω_L . At $d = 3$, the quintic $X_5 \subset \mathbb{P}^4$ has period in $\Omega_{H^3(X_5)}$ of signature $(2, 100)$; Z -manifolds and abelian quotients (Kummer, Borcea–Voisin) inherit lattice-polarised period from their parents. At $d = 5$, the Fake-Monster sibling lives on $\text{II}_{25,1} \subset \text{II}_{26,2}$ via Borchers 1992 (Chapter 40).

The four strata are the chart classes treated in Vol III. They do not classify all possible Stage-2 inputs.

Cross-stratum sibling census across d . The Stage-2 output of Φ_d at the canonical reference curve C produces a sibling family across CY dimension:

d	representative X	Stage-2 chiral output on C	lattice / chart data
1	E (elliptic curve)	H_1 (free Heisenberg lattice VOA)	$\tilde{H}(E, \mathbb{Z}) = U \oplus U$ (rank 2)
2	K_3	$Y_h(\mathfrak{so}(4, 20))$ (Mukai-self-mirror)	$\tilde{H}(K_3, \mathbb{Z}) = U^4 \oplus E_8(-1)$
3	$K_3 \times E$	$\mathfrak{g}_{\Delta_5}$ (K_3 BKM, Hall–Drinfeld double)	$U \oplus \langle -2 \rangle$ (rank 3, sign. (2))
3	$V^{\natural}$ (Monster moonshine module)	$\mathbb{M}$ -action on $V^{\natural}$ (Borcherds Monster Lie algebra)	$\Pi_{1,1}$ Cartan rank 2 (not 26)
4	Conway / Leech bridge $V^{f^{\natural}}$	$N = 1$ Conway moonshine module (Co_0)	Λ_{Leech} (rank 24, Niemeier)
5	$K_3 \times K_3 \times E$ conditional comparison	$\mathfrak{g}^{\text{FM}}$ (Fake Monster, Borcherds 1990)	$\Pi_{25,1}$ external; $E_5 \simeq E_2 \otimes E_3$

At $d = 1$ the chiral target is E_{∞} -native; at $d = 2$ it is E_2 (the K_3 Yangian face of Part III); at $d \geq 3$ it is E_1 via the Dunn–Lurie additivity $E_3 \simeq E_2 \otimes E_1$ (Lurie, *Higher Algebra*, 5.1.2.6). The Borcherds–Monster Cartan rank is 2 on $\Pi_{1,1}$, not 26 on $\Pi_{25,1}$; the rank-26 object is the Fake Monster at $d = 5$. The iterated tensor decomposition $E_5 \simeq E_2 \otimes E_2 \otimes E_1$ gives only the operadic route; the $K_3 \times K_3 \times E$ host remains conditional on the primitive $\Pi_{25,1}$ -embedding and the $d = 5$ Hall comparison (Chapter 40).

Two distinct fives, one common cell. The CY landscape carries two five-element scalar collections that share one entry but are otherwise distinct.

The $K_3 \times E$ five $\{0, 0, 3, 5, 24\}$ enumerates five readings of *one CY datum* through five distinct constructions: κ_{cat} Künneth-multiplicative on the total space; $\kappa_{\text{ch}}^{\text{Hodge}} = \Xi(K_3 \times E) = 0$ the Hodge supertrace (Theorem 32.2.1, $\Xi(E) = 0$ kills the product); $\kappa_{\text{ch}}^{\text{Heis}} = 3 = \dim_{\mathbb{C}}(K_3 \times E)$ the Heisenberg–Mukai specialisation (Vol I Theorem D); $\kappa_{\text{BKM}}(\Delta_5) = c_1(0)/2 = 5$ the primitive Borcherds weight of Gritsenko’s paramodular cusp form Δ_5 ; $\kappa_{\text{fiber}}(K_3) = \text{rank}(\tilde{H}(K_3, \mathbb{Z})) = 24$ the Mukai lattice rank of the K_3 fibre. The five values inhabit five distinct cohomology theories on a single Calabi–Yau threefold; no two coincide by definition.

The G/L/C/M/B five-archetype landmark $\{0, 8, 13, 250/3, 98/3\}$ enumerates the derived-centre complementarity ceiling $K^{\kappa_{\text{ch}}}(A) = \kappa_{\text{ch}}(A) + \kappa_{\text{ch}}(A^{\natural})$ across *five different chiral-algebra archetypes*: Heisenberg ($\text{G}, K^{\kappa_{\text{ch}}} = 0$), affine Kac–Moody ($\text{L}, K^{\kappa_{\text{ch}}} = 0$), $\beta\gamma_{\lambda}$ ($\text{C}, K^{\kappa_{\text{ch}}} = 0$), Virasoro Vir_c with Verdier partner Vir_{26-c} ($\text{M}, K^{\kappa_{\text{ch}}} = 13$), principal $\mathcal{W}_3^k$ via Drinfeld–Sokolov ($\text{M}, K^{\kappa_{\text{ch}}} = 250/3$; Bershadsky–Polyakov on the non-principal $\mathfrak{sl}_3$ orbit, $K^{\kappa_{\text{ch}}} = 98/3$). The fifth archetype B is the Mukai-doubling face on K_3 , with $K^{\kappa_{\text{ch}}} = 8 = 2c_+(\text{Mukai}(K_3))$ (Vol I derived-centre complementarity theorem, parts (b)–(c) [96]).

The two fives intersect on a single cell. The $K_3 \times E$ five carries no $K^{\kappa_{\text{ch}}} = 8$ entry; the G/L/C/M/B five carries the B-row $K^{\kappa_{\text{ch}}} = 8$ as the K_3 Mukai-doubling value. The K_3 Mukai-doubling $K^{\kappa_{\text{ch}}} = 8$ is the common cell: the B-row archetype above sits on the K_3 fibre of the $K_3 \times E$ chart, and its Mukai–Heisenberg realisation $\kappa_{\text{ch}}^{\text{Mukai}} = 4 = K^{\kappa_{\text{ch}}}/2$ is the same fibre datum read at half complementarity. The two fives are otherwise non-overlapping. The $\kappa_{\text{cat}} = 0$ entry of the $K_3 \times E$ five counts a total-space Euler characteristic; the G-row $K^{\kappa_{\text{ch}}} = 0$ of the archetype five counts a Heisenberg complementarity sum.

Per-dimension Hodge Supertrace (Theorem 32.4.5). The constructed- Φ_d Hodge-supertrace $\kappa_{\text{ch}}^{\text{Hodge}}(\mathcal{A}_X) = \Xi(X) = \sum_{q=0}^d (-1)^q h^{0,q}(X)$ fixes the Stage-2 shadow invariant on every compact X in

the constructed locus. The dimension stratifies by Beauville–Bogomolov holonomy:

d	family	$\kappa_{\text{ch}}^{\text{Hodge}}(\mathcal{A}_X)$	target E_n	stratum (Thm 32.3.1)
1	E (elliptic curve)	0	E_∞ native / E_1^{curve}	(I) odd- d
2	K_3	2	E_2	(II) strict CY, $\text{SU}(2) = \text{Sp}(1)$
2	abelian surface	0	E_2	(III) holomorphic-symplectic
2	bielliptic	0	E_2	(III) (étale $\mathbb{Z}/n$ quotient)
2	Enriques	1	E_2	torsion canonical $\omega_X^{\otimes 2} = \mathcal{O}_X$ (free $\mathbb{Z}/2$ quotient of K_3)
3	quintic $X_5 \subset \mathbb{P}^4$	0	E_1	(I) odd- d , strict CY
3	$K_3 \times E$	0	E_1	(I) odd- d , five-spectrum above
3	E^3	0	E_1	(I) odd- d
3	local $\mathbb{P}^2$	$3/2$	E_1	non-compact; chain-level McKay
3	conifold $\tilde{X}_{\text{con}}$	1	E_1	non-compact; direct $\mathbb{P}^1$ cycle
4	sextic $\text{CY}_4 \subset \mathbb{P}^5$	2	E_1	(II) strict CY
4	$K_3^{[2]}$	3	E_1	(III) hyper-Kähler $n+1=3$
4	$K_3 \times K_3$	4	E_1	p_1 -twisted cascade
4	T^8	0	E_1	maximal abelian
5	generic CY_5	0	E_1	(I) odd- d , universal Serre
5	$K_3 \times K_3 \times E$	0	E_1	(I) odd- d , conditional Fake-Monster comparison

Three caveats are marked. The conifold is not a local surface, so $\kappa_{\text{ch}}^{\text{loc}} = \chi(S)/2$ fails (Corollary 32.7.1); the chain-level reading uses the Klebanov–Witten Kronecker quiver and gives $\kappa_{\text{ch}}^{\text{loc}}(\mathcal{A}_{\tilde{X}_{\text{con}}}) = 1$. $K_3 \times K_3$ is p_1 -twisted with non-trivial obstruction class $p_1(T_{K_3 \times K_3}) \in H^4(K_3 \times K_3, \mathbb{Z})$, so the naive E_4 cascade breaks at the E_3 level. Generic CY_5 means $h^{p,q}(X) = \delta_{p,q}$ outside the Hodge diamond's symmetry; isolated loci carry extra classes (Theorem 32.6.2, Universal Serre Cancellation).

Beauville–Bogomolov tri-stratum. Compact Calabi–Yau manifolds with $h^{1,0} = 0$ partition into three holonomy strata (Theorem 32.3.1, Beauville 1983, *J. Differential Geom.* 18, 755–782):

stratum	condition	$\kappa_{\text{ch}}^{\text{Hodge}}(\mathcal{A}_X)$
(I) odd- d	d odd, $\omega_X = \mathcal{O}_X$	0 by Serre pairing $h^{0,q} = h^{0,d-q}$
(II) strict CY even- d	$\text{Hol}(X) = \text{SU}(d)$, $h^{2,0} = 0$	2
(III) holomorphic-symplectic	$\text{Hol}(X) = \text{Sp}(n)$, $d = 2n$	$n+1$ on $K_3^{[n]}$

Strata (II) and (III) overlap exactly at $d = 2$, where $\text{SU}(2) = \text{Sp}(1)$ and both strata assign $\Xi(K_3) = 2$; for $d \geq 4$ the strata are disjoint. Stratum (I) absorbs every odd- d entry of the dimension table above; stratum (II) absorbs the strict even- d entries (sextic $\subset \mathbb{P}^5$, decic $\subset \mathbb{P}(1^5, 5)$, Enriques double cover); stratum (III) absorbs the hyper-Kähler entries (K_3 , $K_3^{[n]}$, Beauville–Donagi $F(Y)$).

Other Calabi–Yau category constructions.

- *Matrix factorisations.* For $W: \mathbb{A}^n \rightarrow \mathbb{A}^1$ with isolated critical point at the origin, $\text{MF}(W)$ is a CY_{n-2} category (Orlov 2009, *Russian Math. Surveys* 64 no. 3, 537–553); the ADE classification at $n = 4$ produces CY_2 structures connecting to Drinfeld–Sokolov $\mathcal{W}_N$. Chapter 36.
- *Fukaya categories.* $\text{Fuk}(X)$ with A_∞ -structure from J -holomorphic disks (Fukaya–Oh–Ohta–Ono 2009); the symplectic input to Φ_d via the Landau–Ginzburg / CY correspondence. Chapter 37.

- *Super-Yangian general rank.* $Y_h(\mathfrak{sl}(m \mid n))^{\text{ch}}$ with super-Riccati recurrence and rank-stratified shadow class; the parity-sign recurrence yields super-complementarity $\kappa_{\text{ch}}^{\text{Mukai}}(Y) + \kappa_{\text{ch}}^{\text{Mukai}}(Y^\dagger) = \max(m, n)$ on the small-rank cases proved (Section 38.5; Wang–Wen–Jing 2022, *J. Algebra* 596, 313–345). Chapter 38.
- *Wall-crossing CoHA and bar coalgebra.* The Kontsevich–Soibelman wall-crossing identity at the bar level on $B^{\text{ord}}(\text{MH}(C))$ (Kontsevich–Soibelman 2008, arXiv:0811.2435, Theorem 1); the chiral upgrade of the motivic Hall pentagon to a bar-level identity. Chapter 35.
- *Quantum group representations.* Kazhdan–Lusztig theory at roots of unity (where $\text{Rep}_q(\mathfrak{g})$ is non-semisimple and the modular tensor category structure is non-trivial), affine Yangians, critical CoHAs. The representation categories Rep^{E_2} are the targets of the CY-C derived-centre comparison. Chapter 39.

The landscape closes with the existence-obstruction theorem beyond $K_3 \times E$: the single-chart NCCR obstruction (Theorem 26.1.1) and the Serre-equivariant quasi-NCCR substitute (Definition 26.1.2).

THE κ_{ch} STRATIFICATION BY CY DIMENSION

The two-stage factorisation functor

$$\Phi_d = \text{Sp}_{\Sigma_{d-1}, C}^{\text{ch}} \circ \Phi_d^{\text{FA}} : \text{CY}_d\text{-Cat} \longrightarrow E_d\text{-HolFA}(X) \longrightarrow E_n\text{-HolFA}(C)$$

(see [96], Definitions 5.1.1–5.1.17) assigns to a CY_d category C first a holomorphic factorisation algebra $\Phi_d^{\text{FA}}(C)$ on the CY_d target X , then a chiral algebra $\text{Sp}_{\Sigma_{d-1}, C}^{\text{ch}}(\Phi_d^{\text{FA}}(C))$ on a curve. In this chapter the Hodge-supertrace computations are unconditional Hodge theory; their interpretation as κ_{ch} of a chiral output is proved on the constructed $d \leq 3$ loci and is conditional for $d \geq 4$. The specialisation is factorisation homology over Σ_{d-1} . Five scalar invariants of distinct provenance attach to this two-stage datum; four inhabiting the main text (κ_{ch} , κ_{cat} , κ_{BKM} , κ_{fiber}) plus the one-loop Costello–Li BCOV curving coefficient $\kappa_{\text{ch}, \text{BV}}$ valued on the compactly-supported side; and no two coincide in general. The discipline of never conflating them is the unit of analysis of this chapter.

Definition 32.0.1 (The four $\kappa_{\bullet}$ -invariants). For a CY_d manifold X with CY_d category $C = D^b(\text{Coh}(X))$, the following four scalar invariants, jointly denoted $\kappa_{\bullet} \in \{\kappa_{\text{ch}}, \kappa_{\text{cat}}, \kappa_{\text{BKM}}, \kappa_{\text{fiber}}\}$, are defined.

- (i) $\kappa_{\text{ch}}(\mathcal{A}_X)$. The degree-two shadow coefficient of the chiral algebra $\mathcal{A}_X = \Phi_d(C)$, computed as the Hodge supertrace on compact CY_d at even d :

$$\kappa_{\text{ch}}(\mathcal{A}_X) = \Xi(X) := \sum_{q=0}^d (-1)^q h^{0,q}(X) \quad (\text{Theorem 32.2.1}).$$

Native to the $\Phi_d^{\text{FA}}(C)$ stage; at odd d read chain-level (Remark 32.0.2).

- (ii) $\kappa_{\text{cat}}(C) = \chi(\mathcal{O}_X)$. The categorical Euler characteristic of the structure sheaf, Künneth-multiplicative on products: $\kappa_{\text{cat}}(X \times Y) = \kappa_{\text{cat}}(X) \cdot \kappa_{\text{cat}}(Y)$. Native to the variety X , independent of the Φ_d^{FA} stage.
- (iii) $\kappa_{\text{BKM}}(\Phi) = c(o)/2$. The weight of a Borchers product Φ , equal to half the constant term $c(o)$ of the Borchers-input principal part (Theorem 32.8.1). Attached to the Sp^{ch} specialisation cycle, not to the Φ_d^{FA} output.
- (iv) κ_{fiber} . The rank or Euler characteristic of the fibering data attached to the Sp^{ch} map; for a $K3$ fibration it is the Mukai-lattice rank 24 of the fibre.
- (v) $\kappa_{\text{ch}, \text{BV}}(\mathcal{A}_X)$. The Costello–Li one-loop BCOV curving coefficient at $\beta\gamma$ -ghost central charge $c = -2$, valued on compact X in $H^1(X, \mathcal{O}_X)$ against the $\beta\gamma$ -ghost supertrace sign and on non-compact X in $H_c^1(X, \mathcal{O}_X)$ (or equivalently, via Alexander duality, in the boundary trace on the link ∂X). Concretely, the Atiyah–BCOV dilaton cocycle is the class

$$\alpha_{\text{BCOV}} = \frac{\chi_{\text{top}}(X)}{24} \cdot \text{tr At}(T_X) \in H^1(X, \mathcal{O}_X),$$

where $\text{At}(T_X) \in \text{Ext}^1(T_X, T_X \otimes \Omega_X^1)$ is the Atiyah class and tr is the trace pairing $\Omega_X^1 \otimes T_X \rightarrow \mathcal{O}_X$; for strict CY, although $c_1(T_X) = 0$ in $H^{1,1}(X)$, the Dolbeault component $\text{tr At}(T_X) \in H^{0,1}(X, \mathcal{O}_X)$ need not vanish (the $c_1 = 0$ CY condition lives in $H^{1,1}$, not in $H^{0,1}$; the two are distinct Hodge components of the Chern-class data). The class is computed via the Atiyah-class extension of the tangent sheaf (Kapranov math/9811023) and pairs through the BV one-loop Quantum Master Equation of Costello–Li (arXiv:1606.00365 Prop. 5.2) with the $\beta\gamma$ -ghost zero mode ω_{ghost} to produce the BCOV dilaton free energy of BCOV (hep-th/9309140 Eq. (5.11)). Native to the stratum-(ii–iv) BCOV sector on $\Phi_d^{\text{FA}}(C)$; vanishes on stratum-(i) toric cells with zero-dimensional T -fixed locus by the Atiyah-retraction $X \simeq X^T$ collapsing $\text{At}(T_X)$ to the T -weight-balanced zero class (Kapranov math/9811023). Scope: $\kappa_{\text{ch}, \text{BV}}$ targets $H^1(X, \mathcal{O}_X)$ on compact X and $H_c^1(X, \mathcal{O}_X)$ on non-compact X , *not* $H^\bullet(C)$; it is a first-principles Atiyah-class-of- T_X coefficient on the geometric target, not a Hochschild invariant of the category.

These are five construction-distinct invariants of a single CY datum (C, X) ; four are native to the main text (κ_{ch} , κ_{cat} , κ_{BKM} , κ_{fiber}) and the fifth $\kappa_{\text{ch}, \text{BV}}$ is activated when the one-loop BCOV curving is non-trivial; i.e. when the dilaton cocycle $\text{tr At}(T_X)$ survives as a nonzero class in $H^1(X, \mathcal{O}_X)$ on compact X , or equivalently when the boundary link ∂X of a non-compact X supports a nontrivial $\beta\gamma$ -ghost zero mode. Any identity relating two or more of the five is a theorem about the specific construction; no pair coincides by definition.

Odd- d failure via Serre involution. At odd d the Serre involution $\sigma: q \mapsto d - q$ acts on $h^{\circ, \bullet}(X)$ with character $(-1)^d = -1$, so Serre duality $h^{\circ, q} = h^{\circ, d-q}$ pairs each $q < d/2$ with its sign-opposite partner and the pairs cancel uniformly: $\Xi(X) = 0$ for every compact CY_d at odd d (Theorem 32.3.1, stratum (I)). The Hodge-supertrace formula $\kappa_{\text{ch}}^{\text{Hodge}}(\mathcal{A}_X) = \Xi(X)$ is vacuous on this stratum and must be replaced by direct chain-level computation: $\kappa_{\text{ch}}^{\text{loc}}(\text{loc } \mathbb{P}^2) = 3/2$ via the $\mathbb{Z}/3$ -McKay quiver (Theorem 34.11.1) and $\kappa_{\text{ch}}^{\text{loc}}(\text{conifold}) = 1$ via direct McKay (Corollary 32.7.1) are the two canonical chain-level readings at $d = 3$ that expose the Serre-silent algebraic content. Hence: at even d , κ_{ch} is the Hodge supertrace; at odd d , κ_{ch} reads chain-level through the McKay quiver or the direct shadow computation of the relevant non-compact toric CY_3 .

Canonical $K_3 \times E$ five-spectrum. The Calabi–Yau threefold $K_3 \times E$ carries the canonical five-valued spectrum

$$\{\kappa_{\text{cat}}, \kappa_{\text{ch}}^{\text{Hodge}}, \kappa_{\text{ch}}^{\text{Heis}}, \kappa_{\text{BKM}}(\Delta_5), \kappa_{\text{fiber}}\}(K_3 \times E) = \{0, 0, 3, 5, 24\}$$

from five distinct constructions on the same Calabi–Yau datum.

- $\kappa_{\text{cat}}(K_3 \times E) = \chi(\mathcal{O}_{K_3}) \cdot \chi(\mathcal{O}_E) = 2 \cdot 0 = 0$ by Künneth multiplicativity for coherent cohomology (Hartshorne, Chapter III, Proposition 8.5).
- $\kappa_{\text{ch}}^{\text{Hodge}}(K_3 \times E) = \Xi(K_3 \times E) = 0$ via $\Xi(K_3 \times E) = \Xi(K_3) \cdot \Xi(E) = 2 \cdot 0$ on the Hodge supertrace, with $\Xi(E) = 1 - 1 = 0$ killing the product.
- $\kappa_{\text{ch}}^{\text{Heis}}(K_3 \times E) = 3$ from the Heisenberg–Mukai specialisation, with the Mukai-enhanced Hodge supertrace giving $\kappa_{\text{ch}}^{\text{Heis}}(K_3) = 2$ on the K_3 fibre and $\kappa_{\text{ch}}^{\text{Heis}}(E) = 1$ on the elliptic factor (Remark 32.5.9).
- $\kappa_{\text{BKM}}(\Delta_5) = c_1(0)/2 = 5$ from the Borchers weight of Gritsenko’s paramodular cusp form Δ_5 (Theorem 32.8.1).
- $\kappa_{\text{fiber}}(K_3) = \text{rank}(\tilde{H}(K_3, \mathbb{Z})) = 24$ the Mukai-lattice rank of the K_3 fibre.

The five values inhabit five distinct cohomology theories on a single Calabi–Yau threefold; no two coincide by definition. The two zeros $\kappa_{\text{cat}} = 0$ and $\kappa_{\text{ch}}^{\text{Hodge}} = 0$ vanish for distinct reasons: Künneth on the structure-sheaf Euler for the first, Serre cancellation on the elliptic factor for the second. The value 2 is the K_3 fibre $\kappa_{\text{cat}}(K_3) = \chi(\mathcal{O}_{K_3}) = 1 + 1$ and not a total-space entry; misreading the fibre as the total space is the confusion the five-invariant discipline forestalls.

Universal Borchers weight at two scopes. The identity $\kappa_{\text{BKM}}(\Phi) = c(0)/2$ holds in two canonical parametrisations of the paramodular simplest-divisor family. *Scope (A): chiral-half BKM-denominator ladder.* On the five-entry diagonal ladder $N \in \{1, 2, 3, 4, 6\}$; the orders with an elliptic curve automorphism of matching order fixing the origin; the Gritsenko–Nikulin 1995 Pt II Theorem 2.1 construction (additive lift of the g_N -twined weight-0 weak Jacobi form $\phi_{0,1}^{(g_N)}$) yields paramodular cusp forms $\Delta_{k(N)}^{(N)}$ of weights $\text{wt}(\Delta_{k(N)}^{(N)}) = k(N) = (5, 4, 3, 2, 1)$ with $(c_N(0)) = (10, 8, 6, 4, 2)$; this is the chiral-half convention deployed in Theorem 32.8.1 below. *Scope (A) extends to the Mukai-admissible orders $N \in \{5, 7, 8\}$ via Gritsenko 1994 Proposition 3.1 with $\text{Sp}_4(\mathbb{Z})$ -paramodular weight $(2, 1, 1)$ (Corollary 32.8.7); at $N \in \{5, 7, 8\}$ the missing datum is a smooth $K_3 \times E$ CHL quotient of matching order.* *Scope (B): Gritsenko–Cléry 2008 Theorem 1.4 classification.* The eight dd-modular forms with divisor equal to the diagonal $\mathcal{H}_1 \subset \mathbb{H}_2$ of vanishing order 1 on $\Gamma_t(N)$, indexed by triples $(t, N; k) \in \{(1, 1; 5), (2, 1; 2), (1, 2; 3), (3, 1; 1), (1, 3; 2), (4, 1; \frac{1}{2}), (1, 4; \frac{3}{2}), (2, 2; 1)\}$, each satisfying $\kappa_{\text{BKM}}(F_{t,N}) = \text{wt}(F_{t,N}) = k_{t,N}$ by the cusp-weighted Borchers automorphic product formula of Gritsenko–Cléry 2008 Theorem 3.1 (Theorem 32.8.2). Six integer-weight entries live on $\Gamma_t(N)$ -paramodular subgroups; two half-integer-weight entries carry multiplier systems of orders 8 and 4 respectively, using the Shimura 1975 holomorphic- square-root convention, not a metaplectic cover of $\text{Sp}_4(\mathbb{Z})$. The two scopes coincide at $(t, N) = (1, 1)$ (the common entry $F_{1,1} = \Delta_5$, weight 5) and otherwise enumerate distinct Borchers products on distinct paramodular groups. The twice-weight tuple of the GC catalogue is $(10, 4, 6, 2, 4, 1, 3, 2)$, not the CHL constant table $(10, 8, 6, 4, 2)$. Scalar-square identities therefore have to be read row-by-row with their own levels, covers, branches, and denominator data; they do not identify the CHL $N \in \{2, 3, 4\}$ ladder with the GC $(1, N)$ rows.

Refutation of the additive identity. The additive identity

$$\kappa_{\text{BKM}}(\Phi_N) = \kappa_{\text{ch}}^{\text{Hodge}}(\mathcal{A}_{X_N}) + \chi(\mathcal{O}_{\text{fiber}_N})$$

fails at every $N \in \{1, 2, 3, 4, 6\}$: at $N = 1$, LHS = 5 while RHS = $0 + 0 = 0$; at $N = 2$, LHS = 4 while RHS = $1 + 0 = 1$. The apparent decomposition $5 = 2 + 3$ at $N = 1$ (K_3 fibre $\chi(\mathcal{O}_{K_3}) = 2$ plus Heisenberg–Mukai $\kappa_{\text{ch}}^{\text{Heis}} = 3$) is a coincidence of two distinct readings, not a structural identity; the universal formula is $\kappa_{\text{BKM}}(\Phi_N) = c_N(0)/2$ throughout, with κ_{BKM} read off the Borchers weight of the paramodular form, not summed from supertraces on the product.

Root cause at odd d . The invariant κ_{ch} is additive under direct sums but not under fibre products: for $X = Y \times_Z W$ of CY dimensions $(\dim Y, \dim W, \dim Z)$, the Hodge supertrace $\Xi(X)$ is not determined by $\Xi(Y), \Xi(W), \Xi(Z)$ alone at odd fibre-product dimension. The same fact forces the chain-level reading at odd d : on compact CY_d with d odd, Serre cancellation collapses every Φ -output Hodge column uniformly to $\Xi = 0$ regardless of the algebraic richness of $\mathcal{A}_X$, and the true invariant is the chain-level McKay shadow of the non-compact toric model or the direct Hochschild computation on the quiver (Remark 32.0.2).

Canonical conifold row and the Polyakov ghost-mode balance. On the non-compact CY_3 frontier, the resolved conifold $X_{\text{con}} = \text{Tot}(\mathcal{O}(-1)^{\oplus 2} \rightarrow \mathbb{P}^1)$ carries the canonical four-subscript row

$$(\kappa_{\text{ch}}, \kappa_{\text{cat}}, \kappa_{\text{vertex}}, \kappa_{\text{ch,BV}})(X_{\text{con}}) = (+1, 0, +1, -1)$$

(Theorem 32.7.2). The fifth invariant $\kappa_{\text{ch,BV}}$ is the Costello–Li one-loop BCOV curving coefficient against the $\beta\gamma$ -ghost supertrace sign at $\beta\gamma$ -system central charge $c = -2$ (Costello–Li arXiv:1606.00365 Prop. 5.2; BCOV hep-th/9309140 Eq. (5.11); the $c = -2$ $\beta\gamma$ -system is the Kausch hep-th/9510149 holomorphic avatar of the critical-dimension argument); on compact X with $H^1(X, \mathcal{O}_X) \neq 0$ it is the Atiyah-dilaton pairing $(\chi_{\text{top}}(X)/24) \cdot \text{tr At}(T_X) \in H^1(X, \mathcal{O}_X)$ integrated against the $\beta\gamma$ -ghost zero mode, and on non-compact X whose ambient $H^1(X, \mathcal{O}_X)$ and $H_c^1(X, \mathcal{O}_X)$ both vanish (e.g. the resolved conifold, §32.7) it is the ζ -regularised $\beta\gamma$ Casimir energy on the Sasaki–Einstein boundary link ∂X . The three apparent conifold values $+1, 0, -1$; the DT count on the compact curve class, the structure-sheaf Euler on the non-compact total space, and the Costello–Li one-loop BV curving as Casimir energy on the Sasaki–Einstein boundary link $T^{\text{tr}} \cong S^2 \times S^3$ of the conifold (Klebanov–Witten hep-th/9807080); inhabit three distinct cohomology theories (Kontsevich–Soibelman DT/motivic, ordinary $H^*(X, \mathcal{O}_X)$, and $\beta\gamma$ -ghost vacuum-energy on ∂X), and the Polyakov ghost-mode balance

$$\kappa_{\text{ch}}(X_{\text{con}}) + \kappa_{\text{ch,BV}}(X_{\text{con}}) = \kappa_{\text{cat}}(X_{\text{con}}), \quad (+1) + (-1) = 0,$$

registers critical-dimension ghost cancellation in the $\beta\gamma$ -ghost system at $c = -2$ (Polyakov 1981 *Gauge Fields and Strings* Ch. 9 critical-dimension paradigm; $c = -2$ avatar via Kausch hep-th/9510149), instantiated on non-compact CY_3 via Costello–Li holomorphic BV quantisation. The balance is a G-class non-compact CY_3 theorem, not the Theorem C ceiling $\kappa_{\text{ch}} + \kappa_{\text{ch}}^! \in \{0, 8, 13, 250/3, 98/3\}$ and not a universal identity across strata; see Remark 32.7.3 for the precise scope.

This chapter evaluates the Hodge supertrace dimension by dimension for $d \in \{1, 2, 3, 4, 5\}$ and stratifies the comparison between κ_{ch} and κ_{cat} by Beauville–Bogomolov holonomy type.

Remark 32.0.2 (Odd- d κ_{ch} reads chain-level). At odd complex dimension d the Hodge-supertrace identification $\kappa_{\text{ch}}(\mathcal{A}_X) = \Xi(X)$ collapses to 0 by Serre, and the substantive algebraic content of $\mathcal{A}_X$ is read instead through the chain-level McKay quiver attached to the non-compact toric CY_3 model (or directly through the Hochschild cohomology of the path algebra). At $d = 3$ the two canonical chain-level readings are:

- *Local* $\mathbb{P}^2 = \text{Tot}(\omega_{\mathbb{P}^2})$. The $\mathbb{Z}/3$ -McKay quiver of $\mathbb{C}^3/\mathbb{Z}_3$ (three arrows, three nodes) gives $\kappa_{\text{ch}}(\mathcal{A}_{\text{loc } \mathbb{P}^2}) = \frac{1}{2}\chi_{\text{top}}(\mathbb{P}^2) = 3/2$ via the compactly-supported Dolbeault supertrace on the base (Theorem 34.11.1).
- *Resolved conifold* $\text{Tot}(\mathcal{O}(-1)^{\oplus 2} \rightarrow \mathbb{P}^1)$. The Kronecker quiver with two arrows in each direction gives $\kappa_{\text{ch}}(\mathcal{A}_{\text{conifold}}) = 1$ via direct McKay (Corollary 32.7.1).

Both values are Serre-silent on the $h^{\circ, \bullet}$ column – the local $\mathbb{P}^2$ has $h^{\circ, \bullet}$ column not well-defined as a compact CY datum, and the conifold contribution 1 comes from the single compact cycle $\mathbb{P}^1$ rather than from a Hodge sum.

32.1 SETUP: κ_{ch} , $\chi(\mathcal{O}_X)$, AND THE HODGE SUPERTRACE

Let X be a compact Calabi–Yau manifold of complex dimension d , so that $\omega_X \simeq \mathcal{O}_X$ and the Serre functor on $D^b(\text{Coh}(X))$ is the shift $[d]$. Write $h^{p,q} = h^{p,q}(X) = \dim_{\mathbb{C}} H^q(X, \Omega_X^p)$ for its Hodge

numbers and $\chi_p = \chi_p(X) = \sum_q (-1)^q h^{p,q}$ for its holomorphic Euler characteristics (the $p = 0$ case recovers $\chi(\mathcal{O}_X)$).

Fix the CY-to-chiral correspondence Φ_d and write $\mathcal{A}_X = \Phi_d(D^b(\text{Coh}(X)))$ for the chiral algebra associated to X . The *algebraization scalar* $\kappa_{\text{ch}}(\mathcal{A}_X)$ is the degree-two shadow invariant of Vol I: the coefficient of $[b \mid b]$ in the quadratic piece of the Maurer–Cartan obstruction on $B^{\text{ord}}(\mathcal{A}_X)$. It is an algebraization invariant: a second algebraization of the same topological CY_d manifold can produce a different κ_{ch} . The companion invariants $\kappa_{\text{cat}}(X)$ and $\kappa_{\text{fiber}}(X)$ are topological manifold invariants; κ_{BKM} depends on the Borchers frame shape.

Three candidate comparators

We compare κ_{ch} against three Hodge-derived scalars:

- The *holomorphic Euler characteristic* $\chi(\mathcal{O}_X) = \sum_q (-1)^q h^{0,q}(X) = \chi_0(X)$.
- The *Hodge-filtered supertrace* of the structure sheaf column

$$\Xi(X) := \sum_{q=0}^d (-1)^q h^{0,q}(X).$$

Because $h^{0,q}$ counts antiholomorphic forms of pure type $(0, q)$, $\Xi(X)$ and $\chi(\mathcal{O}_X)$ agree as numbers. The distinction is structural: the κ_{ch} route produces the supertrace $\Xi(X)$ via the chiral bar complex on the $(0, \bullet)$ column, agreeing with $\chi(\mathcal{O}_X)$ on inputs where Serre cancellation has not already collapsed the latter. The notation Ξ records the supertrace view; the identification $h^{0,q} = h^{d,d-q}$ via Serre then expresses Ξ in terms of $\chi(\mathcal{O}_X)$ when both are in scope.

- The *explicit algebraic Hochschild sum* $\text{HH}_{\text{alg}}(X) = \sum_{p,q} (-1)^{p-q} h^{p,q}(X)$. This is the signed Hodge sum appearing in the HKR–Calderaru formula; on compact Kähler X one has $(-1)^{p-q} = (-1)^{p+q}$, so $\text{HH}_{\text{alg}}(X) = \sum_p (-1)^p \chi_p(X) = \chi_{\text{top}}(X)$.

Theorem 32.2.1 identifies κ_{ch} with the supertrace $\Xi(X)$, computed from the chiral/categorical side through the $(0, q)$ anti-holomorphic column independently of Kodaira vanishing or Serre cancellation. The Serre antisymmetry $h^{0,q} = h^{0,d-q}$ then acts at odd d : pairwise cancellation in the supertrace forces $\kappa_{\text{ch}} = 0$, separating it from the $\chi(\mathcal{O}_X)$ -track which is itself zero on the same input.

Running examples and their Hodge columns

For every CY manifold below, we record d , the column $(h^{0,0}, h^{0,1}, \dots, h^{0,d})$, and the topological Euler characteristic.

Family	d	Column $h^{\circ, \bullet}$	χ_{top}	κ_{ch}	Side
Elliptic curve E	1	(1, 1)	0	0	Φ_d^{FA}
K_3 surface	2	(1, 0, 1)	24	2	Φ_d^{FA}
Abelian surface $E \times E$	2	(1, 2, 1)	0	0	Φ_d^{FA}
Bielliptic surface	2	(1, 1, 0)	0	0	Φ_d^{FA}
Quintic threefold	3	(1, 0, 0, 1)	-200	0	Φ_d^{FA}
$K_3 \times E$	3	(1, 1, 1, 1)	0	0	Φ_d^{FA}
E^3	3	(1, 3, 3, 1)	0	0	Φ_d^{FA}
Local $\mathbb{Q}^2 = \text{Tot}(\omega_{\mathbb{Q}^2})$	3	open toric column	$\chi_{\text{top}}(\mathbb{Q}^2) = 3$	3/2	Φ_d^{FA}
Resolved conifold $\text{Tot}(\mathcal{O}(-1)^{\oplus 2} \rightarrow \mathbb{Q}^1)$	3	open toric	-	1	Φ_d^{FA}
CY ₄ sextic $\subset \mathbb{Q}^5$	4	(1, 0, 0, 0, 1)	2610	2	Φ_d^{FA}
Septic CY ₅ , $X_7 \subset \mathbb{Q}^6$	5	(1, 0, 0, 0, 0, 1)	;	0	Φ_d^{FA}
$K_3 \times X_5$ (quintic)	5	(1, 0, 1, 1, 0, 1)	0	0	Φ_d^{FA}
Generic strict CY ₅	5	(1, 0, 0, 0, 0, 1)	;	0	Φ_d^{FA}
<i>Specialisation-side invariants (not Φ_d^{FA} outputs):</i>					
$\kappa_{\text{cat}}(X) = \chi(\mathcal{O}_X)$	all d	manifold	-	(topological)	variety
$\kappa_{\text{BKM}}(\Phi_N) = c_N(\mathfrak{o})/2$	3	Borcherds	-	(automorphic)	Sp^{ch}
κ_{fiber}	3	fibre rank	-	(lattice)	Sp^{ch} cycle

Column key: “Side” records whether the invariant is native to the Φ_d^{FA} factorisation-algebra stage (all rows above the rule) or to the $\text{Sp}_{\Sigma_{d-1}, C}^{\text{ch}}$ specialisation stage (rows below). κ_{ch} values above are computed via the Hodge supertrace $\Xi(X) = \sum_q (-1)^q h^{\circ, q}(X)$ (Theorem 32.2.1); they do not depend on which Sp^{ch} specialisation is chosen. The three specialisation-side invariants are construction-dependent: they change when the Borcherds lift or fibre changes, while κ_{ch} does not.

These values are the numerical core of the stratification theorem. The κ_{ch} column is populated by Künneth multiplicativity of the Hodge supertrace, $\Xi(X \times Y) = \Xi(X) \cdot \Xi(Y)$ (the value at $t = -1$ of the Poincaré polynomial of the $h^{\circ, \bullet}$ column is a homomorphism from products of compact Kähler manifolds to $\mathbb{Z}$), and by the independent supertrace evaluation for non-product families (quintic, local $\mathbb{Q}^2$, sextic). On the product entries of the table above at least one factor carries $\Xi = 0$, so Künneth multiplicativity and the naive additive rule $\Xi(X \times Y) = \Xi(X) + \Xi(Y)$ happen to give the same value; the two diverge on products with both factors even-dimensional and supertrace-nonzero (e.g., $K_3 \times K_3$: multiplicative $2 \cdot 2 = 4$, additive $2 + 2 = 4$ coincides; $K_3 \times K_3^{[2]}$: multiplicative $2 \cdot 3 = 6$, additive $2 + 3 = 5$ disagrees). The coincidences $\kappa_{\text{ch}} = \chi(\mathcal{O}_X)$ hold only for $(d, h^{1,0}) = (2, 0)$: K_3 sits alone as the honest match.

LEMMA 32.1.1 (*Künneth multiplicativity of the Hodge supertrace*). For compact Kähler manifolds X and Y ,

$$\Xi(X \times Y) = \Xi(X) \cdot \Xi(Y).$$

Proof. The Künneth formula for sheaf cohomology gives $H^q(X \times Y, \mathcal{O}_{X \times Y}) = \bigoplus_{i+j=q} H^i(X, \mathcal{O}_X) \otimes H^j(Y, \mathcal{O}_Y)$, hence $h^{\circ, q}(X \times Y) = \sum_{i+j=q} h^{\circ, i}(X) \cdot h^{\circ, j}(Y)$. Summing with signs,

$$\Xi(X \times Y) = \sum_q (-1)^q \sum_{i+j=q} h^{\circ, i}(X) h^{\circ, j}(Y) = \left(\sum_i (-1)^i h^{\circ, i}(X) \right) \left(\sum_j (-1)^j h^{\circ, j}(Y) \right) = \Xi(X) \cdot \Xi(Y).$$

□

Lemma 32.1.1 reads the table: $\Xi(K_3 \times E) = \Xi(K_3) \cdot \Xi(E) = 2 \cdot 0 = 0$; $\Xi(E^3) = 0^3 = 0$; $\Xi(K_3 \times K_3) = 4$; $\Xi(K_3 \times K_3 \times E) = 0$.

32.2 THE HODGE SUPERTRACE IDENTIFICATION

THEOREM 32.2.1 (κ_{ch} is the Hodge supertrace of the $h^{\circ, \bullet}$ column). The Hodge supertrace is an unconditional Hodge-theoretic invariant. Its interpretation as κ_{ch} is asserted only on the constructed Φ_d -locus, in particular on the CY- $\mathcal{A}_d$ locus for $d \geq 4$. Let X be a compact Calabi–Yau manifold of complex dimension d and let $\mathcal{A}_X = \Phi_d(D^b(\text{Coh}(X)))$ be the chiral algebra of Theorem 5.11.1 (for $d = 3$) or the analogous CY- $\mathcal{A}_d$ construction (for other d , conditional for $d \geq 4$). Then, on that constructed locus,

$$\kappa_{\text{ch}}(\mathcal{A}_X) = \Xi(X) = \sum_{q=0}^d (-1)^q h^{\circ, q}(X),$$

while $\Xi(X)$ itself is an unconditional Hodge-theoretic supertrace. At $d = 2$ with $h^{1,0}(X) = 0$ the right-hand side collapses to $\chi(\mathcal{O}_X)$, recovering Proposition 5.3.13.

Proof. The argument has three components.

Arrow 1. HKR and the CY trace. By Theorem 16.1.3, the Hochschild homology of $D^b(\text{Coh}(X))$ decomposes as

$$\text{HH}_{\bullet}(D^b(\text{Coh}(X))) \simeq \bigoplus_{p+q=\bullet} H^q(X, \Omega_X^p),$$

intertwining the Connes B -operator on the left with the de Rham differential on the right up to the Caldararu twist. The CY structure determines the negative cyclic lift $\text{HC}_d^-(D^b(\text{Coh}(X)))$ of the trace class, which is the S^d -framing datum required by Φ_d .

Arrow 2. The shadow scalar from HC_d^- . The Vol I shadow construction evaluates the degree-two shadow S_2 of $\mathcal{A}_X$ on the composition $\text{HC}_d^- \rightarrow \text{HH}_{\bullet} \rightarrow \bigoplus_{p+q} H^q(\Omega^p)$. The r -matrix on $\mathcal{A}_X$ is the Mukai pairing (Proposition 16.1.2), graded by the Hodge filtration $F^{\bullet}$ on $\text{HH}_{\bullet}$. By construction κ_{ch} is the value of S_2 on the first graded piece $F^0/F^{-1} \cong \bigoplus_q H^q(X, \mathcal{O}_X)$, the structure-sheaf column $(0, \bullet)$. The higher Hodge columns $H^q(X, \Omega_X^p)$ with $p \geq 1$ enter the full categorical trace on $\text{HH}_{\bullet}$ and contribute to κ_{ch} through the graded projection to F^0/F^{-1} ; the chiral shadow is the $(0, \bullet)$ filtered piece of this projection. When the middle columns $h^{1,0}, h^{2,0}, \dots$ vanish, Hodge symmetry $h^{p,q} = h^{q,p}$ collapses the $(0, q)$ supertrace to $\chi(\mathcal{O}_X)$.

Arrow 3. Supertrace through the $(0, q)$ column. The surviving $p = 0$ column contributes $H^q(X, \mathcal{O}_X)$ with sign $(-1)^q$, the cohomological sign from the chiral bar complex. Summing over q , $\kappa_{\text{ch}}(\mathcal{A}_X) = \sum_q (-1)^q h^{\circ, q}(X) = \Xi(X)$.

The three components together establish the supertrace identity unconditionally at Φ -generic parameters. At $d = 2$ with $h^{1,0} = 0$ the column $(1, 0, 1)$ gives $\Xi(K_3) = 2 = \chi(\mathcal{O}_{K_3})$ and we recover Proposition 5.3.13. Outside that scope $\chi(\mathcal{O}_X) = 0$ is forced by Serre (Lemma 32.2.3), and the same supertrace identity gives $\Xi(X) = \kappa_{\text{ch}}(\mathcal{A}_X) = 0$ on compact odd-dimensional CY inputs. Non-zero odd-dimensional

scalars belong to distinct shadow, BCOV, Heisenberg, or BKM lanes, not to the compact Hodge supertrace. $\square$

Remark 32.2.2 (Stage-I supertrace scope: κ_{ch} vs. $\kappa_{\text{ch,BV}}$). Theorem 32.2.1 identifies $\kappa_{\text{ch}}(\mathcal{A}_X)$ with the Hodge supertrace $\Xi(X)$ of the $h^{\circ,\bullet}$ column: the Stage-I shadow on $\Phi_d^{\text{FA}}(\mathcal{C})$ against ordinary $H^q(X, \mathcal{O}_X)$. The one-loop BCOV curving coefficient $\kappa_{\text{ch,BV}}$ is a separate Stage-I datum, living on the dilaton-class cohomology: $H^1(X, \mathcal{O}_X)$ via the dilaton cocycle $\text{tr At}(T_X)$ on compact X , and the ζ -regularised $\beta\gamma$ Casimir energy on the boundary link ∂X at $c = -2$ on non-compact X . It sources from the Costello–Li holomorphic BV action (arXiv:1606.00365), distinct from Ξ . On compact CY_d where the actual dilaton class vanishes (the quintic, the four $d = 4$ families of Section 32.5, and the $d = 5$ families of Section 32.6), the dilaton cocycle $\text{tr At}(T_X)$ vanishes in $H^1(X, \mathcal{O}_X)$ and $\kappa_{\text{ch,BV}} = 0$, so the two invariants coincide numerically by zero. For $K_3 \times E$ and E^3 , $h^{\circ,1}$ is respectively 1 and 3; the compact Hodge supertrace still vanishes by Serre/Künneth, but the argument is not an $h^{\circ,1} = 0$ argument. The scope separation is substantive on the non-compact CY_3 frontier where the boundary link ∂X supports a nontrivial $\beta\gamma$ -ghost zero mode; e.g. the conifold with link $T^{1,1} \simeq S^2 \times S^3$, and local $\mathbb{Q}^2$ with link $S^5/\mathbb{Z}_3$; so $\kappa_{\text{ch,BV}} \neq 0$ through the boundary-link ζ -regularised Casimir pairing. The canonical conifold row $(+1, 0, +1, -1)$ of Theorem 32.7.2 exhibits the non-trivial balance $\kappa_{\text{ch}} = -\kappa_{\text{ch,BV}}$ per the Polyakov $c = -2$ ghost-cancellation identity on G-class non-compact CY_3 with single compact curve class; the two invariants remain two separate Stage-I data evaluated against two distinct cohomology theories.

LEMMA 32.2.3 (Serre-enforced vanishing of $\chi(\mathcal{O}_X)$ at odd d). For any compact Calabi–Yau X of odd complex dimension d , $\chi(\mathcal{O}_X) = 0$. The proof is Serre pairwise cancellation: $h^{\circ,q}(X) = h^{\circ,d-q}(X)$ and, for d odd, $(-1)^q + (-1)^{d-q} = 0$ for every pair $(q, d-q)$ with $q \neq d-q$; there is no middle term. See Griffiths–Harris, *Principles of Algebraic Geometry*, Ch. 0

Remark 32.2.4 (Why the identification $\kappa_{\text{ch}} = \chi(\mathcal{O}_X)$ survives only at $(d, h^{1,0}) = (2, 0)$). The supertrace $\Xi(X)$ and the number $\chi(\mathcal{O}_X)$ are computationally identical (both are $\sum_q (-1)^q h^{\circ,q}$). The distinction is that the supertrace is a well-defined invariant of the CY category (it is the degree-two shadow $S_2(\mathcal{A}_X)$ passing through HC_d^-), whereas the phrase “ $\chi(\mathcal{O}_X)$ ” invokes Serre cancellation whenever d is odd. At E with $(d, h^{\circ,\bullet}) = (1, (1, 1))$ the Serre pairing $h^{\circ,0} = h^{\circ,1} = 1$ cancels the two contributions in the written-out sum, so $\Xi(E) = 1 - 1 = 0 = \chi(\mathcal{O}_E)$; the independent chiral computation $\kappa_{\text{ch}}(\mathcal{A}_E) = 0$ agrees, coming from the abelian π_1 -cohomology of E , not from a pairing with the vacuum. Supertrace and chiral calculation agree at the elliptic curve ($0 = 0$); the supertrace value records a cancellation between the two nonzero entries of the $h^{\circ,\bullet}$ column. K_3 sits at the unique even- q -only locus: every nonzero entry of $h^{\circ,\bullet}(K_3)$ lies at even q , and the supertrace records a sum of two nonzero contributions ($1 + 1 = 2$). This locates $(d, h^{1,0}) = (2, 0)$ as the structural home of the K_3 chiral algebra.

32.3 DIMENSION-BY-DIMENSION STRATIFICATION

The Hodge-filtered supertrace formula (Theorem 32.2.1) collapses the entire CY-D landscape into three structural strata, discriminated by the parity of d and by the presence of a holomorphic-symplectic form. This unifies Theorem B at $d = 2$ (K_3), the $d = 3$ case study $K_3 \times E$, the $d = 4$ sextic and hyperkähler examples, the $d = 5$ Universal Serre Cancellation, and every higher-dimensional example below.

THEOREM 32.3.1 (CY-D tri-stratum theorem). Let X be a compact CY_d manifold with Hodge column $h^{\circ,\bullet}(X) = (h^{\circ,0}, h^{\circ,1}, \dots, h^{\circ,d})$. The Hodge-filtered supertrace $\Xi(X) := \sum_{q=0}^d (-1)^q h^{\circ,q}(X)$ takes one of three forms, determined by the parity of d and the holomorphic-symplectic structure of X :

- (I) *Odd d stratum.* If d is odd, then $\Xi(X) = 0$ for every compact CY_d . Mechanism: Serre duality $h^{\circ,q} = h^{\circ,d-q}$ pairs every term with its sign-opposite, and d odd means there is no middle term ($q = d/2$ is non-integral); pairs cancel uniformly.
- (II) *Even d strict-CY stratum.* If d is even and X has holonomy exactly $SU(d)$ (so $h^{\circ,k} = 0$ for $0 < k < d$; the unique global holomorphic form is the Calabi–Yau volume), then $\Xi(X) = 2$. Examples: sextic fourfold in $\mathbb{P}^5$, decic 5-fold in $\mathbb{P}(1^5, 5)$, and every strict CY of even dimension.
- (III) *Even d holomorphic-symplectic stratum.* If d is even and X is irreducible holomorphic-symplectic (holonomy $Sp(d/2)$, with $h^{\circ,k} = 1$ for every even $0 \leq k \leq d$ and $h^{\circ,k} = 0$ for k odd), then $\Xi(X) = (d/2) + 1$. In particular: $K_3^{[n]}$ at $d = 2n$ has $\Xi = n + 1$, recovering $\Xi(K_3) = 2$ at $n = 1$ and $\Xi(K_3^{[2]}) = 3$ at $n = 2$.

Strata (II) and (III) overlap precisely when $SU(d) = Sp(d/2)$, which occurs only at $d = 2$ (where $SU(2) = Sp(1)$; both strata assign $\Xi(K_3) = 2$). For $d \geq 4$ the strata are disjoint, and together with (I) they exhaust the Beauville–Bogomolov classification of compact CY holonomies on connected simply-connected X with $h^{1,0} = 0$.

Proof. Stratum (I) is direct Serre cancellation: for d odd, $h^{\circ,q} = h^{\circ,d-q}$ pairs each $q < d/2$ with $d - q > d/2$, contributing $(-1)^q + (-1)^{d-q} = (-1)^q + (-1)^{d-q}$; since $(-1)^{d-q} = (-1)^d (-1)^{-q} = -(-1)^q$ for d odd, each pair contributes 0. No middle term exists since $d/2$ is non-integral.

Stratum (II) uses the strict-CY definition: for X with holonomy exactly $SU(d)$, the holonomy representation on Ω^q has no trivial summand for $0 < q < d$, so $h^{\circ,q} = 0$ in this range. The only nonzero $h^{\circ,q}$ are $q = 0$ (constants) and $q = d$ (the Calabi–Yau volume form). A second holomorphic form at $q = d/2$ would reduce the holonomy to $Sp(d/2)$, placing X in stratum (III) instead. Hence $\Xi(X) = h^{\circ,0} + (-1)^d h^{\circ,d} = 1 + 1 = 2$, since d is even.

Stratum (III) uses the holomorphic-symplectic Hodge structure of Beauville–Bogomolov: for X irreducible holomorphic-symplectic of complex dimension $d = 2n$, the holomorphic-symplectic form σ and its powers σ^k for $k = 0, 1, \dots, n$ generate the only nonzero $h^{\circ,q}$ with q even. Specifically $h^{\circ,2k} = 1$ for $0 \leq k \leq n$ and $h^{\circ,q} = 0$ for q odd. The supertrace is $\Xi = \sum_{k=0}^n h^{\circ,2k} = n + 1 = (d/2) + 1$.

Mutual exclusivity follows from Beauville–Bogomolov: every compact Kähler CY manifold with $c_1 = 0$ admits a finite étale cover that decomposes as $T^d \times \prod_i HK_i \times \prod_j Y_j$ where T^d is a torus, HK_i are irreducible holomorphic-symplectic, and Y_j are strict CYs. Restricting to $h^{1,0} = 0$ (the universal hypothesis on the present chapter) eliminates the torus factor; restricting to one Bogomolov factor gives one of the three strata exclusively. $\square$

Remark 32.3.2 (The κ_{ch} landscape has structure only at even d). Stratum (I) collapses the entire odd- d landscape to the single value $\kappa_{\text{ch}}(\mathcal{A}_X) = 0$. The algebraic richness of the chiral output $\mathcal{A}_X$ at odd d lives on other invariants — shadow-tower depth, BCOV partition function, Maulik–Okounkov stable-envelope R -matrix — each computing its own structural content beyond the linear Hodge supertrace. The κ_{ch} landscape proper sits at even d , distributed across strata (II) and (III) by the holomorphic-symplectic form.

This is the structural reason that the K_3 chiral algebra at $d = 2$ is the canonical exemplar: the two stratifying formulas agree on K_3 . Stratum (III) gives $\Xi = (d/2) + 1 = 2$ at $d = 2, n = 1$. Stratum (II) with the K_3 column $h^{\circ,\bullet}(K_3) = (1, 0, 1)$ and the $h^{\circ,d/2} = h^{\circ,1} = 0$ middle term gives $\Xi = 1 + (-1)^1 \cdot 0 + 1 = 2$. Both routes land on the same value because K_3 is simultaneously strict CY (holonomy $SU(2)$) and irreducible holomorphic-symplectic (holonomy $Sp(1) = SU(2)$), an accident of low dimension: $SU(2) = Sp(1)$. In higher even dimension the two holonomy classes are distinct and the two stratum formulas

diverge, with stratum (II) giving 2 (at vanishing middle holomorphic form) and stratum (III) giving $n + 1$ for $K_3^{[n]}$.

COROLLARY 32.3.3 (*BCOV F_g vanishing across all even d*). Theorems 32.5.2 ($d = 4$) and 32.6.2 ($d = 5$) are the chain-level expressions of Theorem 32.3.1: the BCOV F_g holomorphic anomaly equation respects the underlying Serre symmetry of stratum (I) and the holomorphic-symplectic Hodge structure of stratum (III), so the supertrace is the COMPLETE answer in both strata. At stratum (II), the BCOV F_g contribution is similarly forced to zero by the constancy $F_1 = \chi/24$ on the BTT moduli of strict CYs.

32.4 SHADOW-CLASS STRATIFICATION BY CY HOLONOMY

Theorem 32.3.1 controls the scalar $\kappa_{\text{ch}}(\mathcal{A}_X)$ by the Hodge column $h^{\circ, \bullet}$. A complementary, logically independent question is: what is the *shadow class* $\text{Cl}(\mathcal{A}_X) \in \{G, L, C, M\}$ of the chiral algebra $\mathcal{A}_X = \Phi_d(D^b(\text{Coh}(X)))$ per stratum? The shadow class is determined by the higher shadow coefficients $(S_3, S_4, \dots)$ (the OPE-pole structure of the chiral r -matrix), not by $\kappa_{\text{ch}} = S_2$ alone. The classification below uses the Vol I shadow-depth hierarchy $G < L < C < M$ indexed by $r_{\text{max}} \in \{2, 3, 4, \infty\}$ together with the Vol III closed $\kappa_{\bullet}$ menu.

THEOREM 32.4.1 (*CY- D shadow-class stratification by holonomy*). The statement is read at the level of the tree-level Hodge-supertrace input to the shadow tower. It is supplied unconditionally for $d \in \{1, 2, 3\}$ by CY- A_2 and by the ∞ -categorical CY- A_3 resolution of Theorem 5.11.1; for $d \geq 4$ it assumes the CY- A_d construction. The BCOV F_g -instanton promotion in stratum (I_{BCOV}) is unconditional on the cited cases (quintic, sextic-double cover at $d = 3$); compact non-product non-toric CY₃ with a verified non-vanishing leading Gopakumar–Vafa invariant supplies the promotion case by case. Let X be a compact CY _{d} manifold with $h^{1,0}(X) = 0$ and $\mathcal{A}_X = \Phi_d(D^b(\text{Coh}(X)))$, all statements at generic parameters of Φ and ambient-qualified per stratum below:

- (I_{tree}) *Odd d stratum, tree level.* If d is odd, the Hodge-supertrace input to the shadow tower is $S_2 = \Xi(X) = 0$ by Serre pairwise cancellation. This statement does not compute the higher shadow coefficients $S_3, S_4, \dots$; those require OPE/BRST/BCOV input beyond the linear Hodge supertrace. The tree-level shadow class is therefore G only on the additional vanishing locus for the higher tree coefficients.
- (I_{BCOV}) *Odd d stratum, BCOV-promoted.* At compact odd- d CY with nontrivial Gopakumar–Vafa spectrum, the BCOV instanton corrections promote the shadow class to M (depth $r_{\text{max}} = \infty$). The quintic $X_5 \subset \mathbb{P}^4$ realizes this promotion: classical $S_4 = 0$ gives tree-level class L once the $\sigma_3 = 5$ triple-intersection Yukawa is retained, but the Gopakumar–Vafa genus-zero invariants n_d^0 are nonzero for every $d \geq 1$, driving $S_4^{\text{instanton}} \neq 0$ and hence class M (Proposition 29.9.7, with the quintic $\kappa_{\text{ch}}^{\text{BCOV}} = \chi/24 = -25/3$ separately; see Remark 32.4.2 below for the supertrace-vs-BCOV disambiguation).
- (II) *Even d , strict CY stratum.* If X has holonomy exactly $\text{SU}(d)$ (strict CY, $h^{\circ, k} = 0$ for $0 < k < d$), then the tree-level algebra $\mathcal{A}_X$ is the rank-2 lattice VOA on the holomorphic $(0, 0)$ and $(0, d)$ sector (the vacuum and the Calabi–Yau volume form), which is a free-field algebra. Free-field algebras have $S_3 = S_4 = 0$ and shadow class G with $r_{\text{max}} = 2$. Sextic $X_6 \subset \mathbb{P}^5$ and decic $\subset \mathbb{P}(1^5, 5)$ (with $\kappa_{\text{ch}}^{\text{Hodge}} = 2$) are canonical class- G representatives.
- (III) *Even $d = 2n$, holomorphic-symplectic stratum.* If X is irreducible holomorphic-symplectic (holonomy $\text{Sp}(n)$), then $h^{\circ, 2k} = 1$ for $0 \leq k \leq n$ and the tree-level algebra $\mathcal{A}_X$ is the rank- $(n + 1)$ lattice VOA generated by the σ^k tower (the $n + 1$ powers of the holomorphic-symplectic form).

This is a free-field algebra: $S_3 = S_4 = 0$, shadow class G , $r_{\max} = 2$. K_3 ($n = 1$), $K_3^{[n]}$, and the Beauville–Donagi Fano variety of lines $F(Y)$ on a cubic fourfold are canonical class- G representatives, with $\kappa_{\text{ch}} = n + 1$. At $n = 1$ (K_3), strata (II) and (III) coincide and both yield class G on the Φ_2 -output vertex algebra, consistent with the Mukai–Heisenberg vertex-algebra computation (Chapter 17, $S_3 = S_4 = 0 \Rightarrow \Delta = 0 \Rightarrow \text{class } G$).

The tree-level shadow class is thus uniformly G across every compact CY_d stratum (I_{tree}), (II), (III). Promotion to higher shadow classes requires either (a) compact odd- d BCOV F_g instanton corrections (I_{BCOV}), (b) non-compact toric promotion via McKay quiver $\mathbb{Z}/N$ -symmetry (see Theorem 34.11.1: local $\mathbb{P}^2$ is class M with $r_{\max} = \infty$ by $\mathbb{Z}/3$ -McKay), or (c) K_3 *sigma-model* enhancement of the Φ_2 -output Heisenberg vertex algebra to an $\widehat{\mathfrak{su}}_2^{\oplus n}$ subalgebra at level 1 (Kummer point, Chapter 17: enhanced subalgebra is class L with $r_{\max} = 3$).

Proof. We prove each stratum separately.

Stratum (I_{tree}). At odd d with $h^{1,0} = 0$, the Hodge column $(1, h^{0,1}, \dots, h^{0,1}, 1)$ paired by Serre produces, at tree level (before BCOV F_g corrections), a free-field lattice VOA structure on $\mathcal{A}_X$: the paired generators $\{1, \omega_d\}$ at degrees 0 and d , together with the Serre-dual pairs $\{\eta_q, \eta_{d-q}\}$ at intermediate degrees $q \in \{1, \dots, d-1\}$, mutually commute at tree level because (a) Serre duality pairs η_q with η_{d-q} in a degree-zero pairing $\langle \eta_q, \eta_{d-q} \rangle = \int_X \eta_q \wedge \eta_{d-q} = \text{vol}_X$, giving a symplectic (d odd, so η -pair is in antisymmetric position) rank-2 block per pair, and (b) cross-pairs between distinct q, q' vanish by bigrading conservation. The total structure is a rank- $(d+1)$ symplectic lattice VOA on the rootless free-field branch, which is free-field (Frenkel–Ben-Zvi *Vertex algebras and algebraic curves* 2001 Chapter 3, free-field lattice VOA construction). Free-field lattice VOAs have $S_3 = S_4 = 0$ (no cubic or quartic OPE pole; every OPE has at most a double pole by free-field Wick contraction), so $\Delta = 8\kappa_{\text{ch}}S_4 = 0$ and the shadow class is G with $r_{\max} = 2$. Equivalently: $\kappa_{\text{ch}} = 0$ from the Serre-cancellation of $\Xi(X)$ (stratum (I) of Theorem 32.3.1), and the higher shadow coefficients are zero from the free-field structure. The two inputs (vanishing scalar; free-field higher) converge on class G .

Stratum (I_{BCOV}). At compact odd- d CY with nontrivial Gopakumar–Vafa spectrum, the BCOV holomorphic-anomaly equation (Bershadsky–Cecotti–Ooguri–Vafa 1994, Theorem 11.1) propagates to the shadow tower via $S_4^{\text{instanton}} = \sum_{d \geq 1} n_d^0 / \kappa_{\text{ch}}^{\text{BCOV}}$ (Proposition 29.9.7, clause (iii)). For the quintic: $n_1^0 = 2875 \neq 0$ (Candelas–de la Ossa–Green–Parkes 1991), forcing $S_4^{\text{instanton}} \neq 0$ and hence class M with $r_{\max} = \infty$. The class- M conclusion applies conditionally: (i) to the quintic unconditionally, via the explicit nonzero $n_1^0 = 2875$ computation; (ii) to compact non-product CY_3 families with a nonvanishing leading Gopakumar–Vafa invariant at degree 1 or at some higher degree for which the BCOV mirror-symmetry series is known to be nontrivial. Each such case proceeds by an explicit GV-invariant verification; universal nonvanishing of the GV spectrum across all compact non-product CY_3 is an open conjecture, treated case-by-case here. The open frontier of Remark 32.7.5 is the locus of compact non-product non-toric CY_3 awaiting an independent GV-nonvanishing witness.

The BCOV promotion produces the leading shadow-tower coefficient. For the quintic it proves the first LCS obstruction coefficient $S_{4,1}^{\text{inst}} = 2875/(-25/3) = -345$, with leading sign $(\kappa_{\text{ch}}^{\text{BCOV}})^3 S_{4,1}^{\text{inst}} > 0$. The Booth–Lazarev vanishing theorem operates at a separate level: the residual sewing obstruction $O_3^{\text{BL}} \in \varprojlim_g^1 \mathcal{A}^{\text{sew},g}$ vanishes through the full BCOV Borel sign lemma on the entire genus tower; the Ran-space obstruction $O_1^{\text{BL}} \in H^1(\text{Ran}(C), \text{Aut}_{\otimes}(\text{Gen}_{\text{BL}}))$ is the Smith-recognition complex. Each obstruction carries its own vanishing locus, with the scalar shadow calculation supplying the leading-order check.

Stratum (II). At strict CY_d with holonomy exactly $\text{SU}(d)$ (even d), the nontrivial Hodge column is $\{h^{\circ,0}, h^{\circ,d}\} = \{1, 1\}$ with $h^{\circ,k} = 0$ for $0 < k < d$. The chiral algebra $\mathcal{A}_X$ at tree level is generated by the $H^0(X, \mathcal{O}_X) = \mathbb{C}$ vacuum $|0\rangle$ and the $H^d(X, \mathcal{O}_X) = \mathbb{C}\omega$ volume form, giving a Fock-module structure of Heisenberg type: the pair $(|0\rangle, \omega)$ generates a rank-1 Heisenberg VOA $\mathcal{H}_1$ via the mode expansion of $\omega(z) = \sum_n \omega_n z^{-n-1}$ with canonical commutation $[\omega_m, \omega_n] = m\delta_{m+n,0}$ (the standard Heisenberg relation, Frenkel–Ben-Zvi 2001 Proposition 2.2.1). The shadow tower of a Heisenberg VOA $\mathcal{H}_k$ has $\kappa_{\text{ch}} = k$, $S_3 = 0$ (no cubic pole: Heisenberg OPE is $\omega(z)\omega(w) \sim k/(z-w)^2$, a pure double pole with no cubic term), and $S_4 = 0$ (no quartic pole either). The critical discriminant $\Delta = 8\kappa_{\text{ch}}S_4 = 0$ gives class G with $r_{\text{max}} = 2$ (Vol I shadow-class- G criterion: $S_3 = S_4 = 0 \Leftrightarrow \Delta = 0$ and shadow tower terminates at degree 2). The Hodge supertrace $\kappa_{\text{ch}} = \Xi(X) = 2$ from Stratum (II) of Theorem 32.3.1 identifies the Heisenberg level $k = 2$. The sextic $X_6 \subset \mathbb{P}^5$, decic $\subset \mathbb{P}(1^5, 5)$, and every higher even- d strict CY realize this Heisenberg pattern at tree level.

Stratum (III). At irreducible holomorphic-symplectic X of complex dimension $d = 2n$, the Hodge column has $h^{\circ,2k} = 1$ for $0 \leq k \leq n$ and $h^{\circ,q} = 0$ otherwise (Beauville–Bogomolov decomposition). The chiral algebra $\mathcal{A}_X$ at tree level is generated by the $n+1$ classes $\sigma^k \in H^{\circ,2k}(X, \mathbb{C})$ ($k = 0, \dots, n$) with corresponding bosonic modes $\sigma^k(z) = \sum_m \sigma_m^k z^{-m-1}$. The Fujiki relations (Fujiki *Hodge structures on hyperkähler manifolds*, Publ. Inst. Math. IHES 1987, cubic Fujiki constant c_X) give the pairing $\int_X \sigma^k \wedge \bar{\sigma}^{n-k} = c_X \cdot \text{vol}(X)$ pairwise, and orthogonality for distinct Hodge weights (k, k') with $k + k' \neq n$. The induced mode commutator is $[\sigma_m^k, \sigma_p^{n-k}] = m \cdot c_X \cdot \delta_{m+p,0}$ (pure Heisenberg central-charge relation with σ^k and σ^{n-k} forming a conjugate pair), and $[\sigma_m^k, \sigma_p^{k'}] = 0$ for $k + k' \neq n$. This is exactly the defining commutator of the rank- $(n+1)$ Heisenberg VOA $\mathcal{H}^{\otimes(n+1)}$ at level c_X (equivalently: $n+1$ mutually-commuting free-boson generators, each a copy of $\mathcal{H}_{c_X}$). The shadow coefficients of a tensor product of free-boson VOAs are $S_3 = S_4 = 0$ and $\kappa_{\text{ch}} = \sum_{k=0}^n c_X = (n+1)c_X$ at the standard normalization $c_X = 1$, recovering $\kappa_{\text{ch}} = n+1$ from Stratum (III) of Theorem 32.3.1. The critical discriminant $\Delta = 0$ gives class G with $r_{\text{max}} = 2$. K_3 ($n = 1$, rank-2 Heisenberg tensor), $\text{K}_3^{[2]}$ ($n = 2$, rank-3 Heisenberg tensor), and the Beauville–Donagi cubic-4-fold lines $F(Y) \sim_{\text{deform}} \text{K}_3^{[2]}$ (Beauville–Donagi 1985) all realize this pattern; the full rank-24 Mukai–Heisenberg vertex algebra on K_3 of Chapter 17 is an enlargement to the full Mukai lattice but the class- G conclusion is preserved ($S_3 = S_4 = 0 \Rightarrow \Delta = 0 \Rightarrow$ class G).

Overall conclusion. The tree-level shadow class is G uniformly across strata. Promotion mechanisms (a) compact odd- d BCOV, (b) non-compact toric McKay $\mathbb{Z}/N$ -symmetry, (c) K_3 -sigma-model enhancement are the three documented routes out of class G ; each is explicit in the indicated chapter or stratum. $\square$

Remark 32.4.2 (Disambiguation: $\kappa_{\text{ch}}^{\text{Hodge}}$ vs $\kappa_{\text{ch}}^{\text{BCOV}}$ at the quintic). The quintic threefold carries two distinct invariants that each go by the name κ_{ch} ; the Φ -output invariant must be distinguished from the construction-level invariant.

- (i) $\kappa_{\text{ch}}^{\text{Hodge}}(\mathcal{A}_{X_5}) = \Xi(X_5) = 0$, the Hodge supertrace of the $(0, \bullet)$ column $(1, 0, 0, 1)$: vanishes by Serre (Theorem 32.2.1).
- (ii) $\kappa_{\text{ch}}^{\text{BCOV}}(\mathcal{A}_{X_5}) = \chi(X_5)/24 = -25/3$, the BCOV F_1 one-loop free energy divided by the universal Euler coefficient: nonzero, fractional (Proposition 29.9.5).

Both are “ κ_{ch} ” of “the quintic chiral algebra”, but they are invariants of *different constructions*: (1) is the supertrace trace on HC_3^- of the shadow tower of $\mathcal{A}_{X_5} = \Phi_3(D^b(\text{Coh}(X_5)))$ (the categorical Φ_3 output), while (2) is the BCOV-genus-1 coefficient of the topological-string partition function on the

quintic (a separately constructed worldsheet invariant). These two invariants are both legitimate and both denoted κ_{ch} in the standard literature (Vol III [96] at Proposition 29.9.5 for the BCOV route, and this chapter Section 32.3 for the Hodge supertrace route), but they are not the same number and are distinct. Six routes to $G(K_3 \times E)$ are six different constructions, not six Φ applications; the same discipline applies here: $\kappa_{\text{ch}}^{\text{Hodge}}$ and $\kappa_{\text{ch}}^{\text{BCOV}}$ are two-route analogs at the quintic.

The shadow-class stratification of Theorem 32.4.1 uses the Hodge supertrace input (tree level, stratum (I_{tree})), and promotes to class M via BCOV instanton corrections to S_4 (stratum (I_{BCOV})). The two routes converge on the same shadow-class outcome at the quintic (class M) but differ on the degree-2 scalar: $\kappa_{\text{ch}}^{\text{Hodge}} = 0$ from stratum- (I_{tree}) Serre cancellation, $\kappa_{\text{ch}}^{\text{BCOV}} = -25/3$ from F_1 -constant-map formula.

COROLLARY 32.4.3 (*Shadow class and CY dimension: the universal compact class- G signature at tree level*). Assume the tree-level Φ_d -shadow is constructed in the sense of Theorem 32.4.1. For every compact CY_d with $h^{1,0} = 0$, the tree-level shadow class $\text{Cl}^{\text{tree}}(\mathcal{A}_X)$ is G uniformly across $d \in \{2, 3, 4, 5\}$. (At $d = 1$, the $h^{1,0} = 0$ scope is vacuous: every elliptic curve has $h^{1,0} = 1$, so there is no compact $d = 1$ CY with $h^{1,0} = 0$ to classify; the $d = 1$ entry is treated separately at Theorem 32.4.5 via the $\Xi(E) = 0$ Serre cancellation.) The tree-level shadow depth is $r_{\text{max}}^{\text{tree}} = 2$ throughout the $d \in \{2, 3, 4, 5\}$ scope. Higher shadow classes L, C, M appear only through (a) compact odd- d BCOV F_g instanton promotion, (b) non-compact toric McKay $\mathbb{Z}/N$ -enhancement, or (c) K3-sigma-model $\widehat{\mathfrak{su}}_2^{\oplus n}$ enhancement. Equivalently: the CY dimension d alone does not determine the shadow class; the shadow class is determined by the compactness, the holonomy, and the presence/absence of a promotion mechanism, not by d directly.

Proof. Strata (I_{tree}) , (II), (III) of Theorem 32.4.1 each yield class G at tree level, and the three strata exhaust the compact CY_d landscape with $h^{1,0} = 0$ per Beauville–Bogomolov (Theorem 32.3.1). Hence class G is universal at tree level across d . The three documented promotion mechanisms are enumerated in the last paragraph of Theorem 32.4.1; each is conditional on auxiliary data (BCOV instanton spectrum, McKay quiver symmetry, K3 sigma-model enhancement) beyond the raw CY dimension. $\square$

Remark 32.4.4 (*Cross-volume implication: Vol I four-class landscape*). The Vol I four-class landscape $\{G, L, C, M\}$ is populated by four archetype vertex algebras: Heisenberg $\mathcal{H}_k$ (class G), affine Kac–Moody $V_k(\mathfrak{g})$ (class L), $\beta\gamma$ (class C), Virasoro Vir_c (class M). The Vol III Φ_d -output stratification of Theorem 32.4.1 realizes class G universally at tree level; classes L, C, M are accessed only through the three promotion mechanisms. In particular:

- Class L (affine Kac–Moody) is accessed from Φ_d only via the K3 $N = 4$ sigma-model enhancement to $\widehat{\mathfrak{su}}_2^{\oplus n}$ at level 1 on the Kummer point (Chapter 17).
- Class C ($\beta\gamma$) is accessed from Φ_d only at non-compact local surfaces (Theorem 34.11.1: local $\mathbb{P}^2$ via the $\beta\gamma$ boundary algebra is class C at $r_{\text{max}} = 4$; see also the conifold bichamber computation of Chapter 34).
- Class M (Virasoro-type) is accessed via BCOV instanton corrections at compact odd- d CY (quintic, $K_3 \times E$, non-product CY_3) or via the K3 sigma-model full $N = 4$ superconformal enhancement (Chapter 17, full sigma model class M).

This population pattern is the Vol III-specific analog of the Vol I averaging-map principle: the averaging map $\text{av} : \mathfrak{g}^{E_1} \rightarrow \mathfrak{g}^{\text{mod}}$ collapses every standard chiral algebra into one of four archetypes; the Φ_d -output tree-level algebra $\mathcal{A}_X$ lands on the Heisenberg archetype (class G) uniformly, and higher classes require ambient-category enhancement beyond the bare Φ_d output.

THEOREM 32.4.5 (*Stratification of κ_{ch} by $(d, h^{\bullet})$*). On the constructed Φ_d -locus, with the $d \geq 4$ entries read under CY- A_d , the following table is the Hodge-supertrace stratification. Let X be a compact CY $_d$ and $\mathcal{A}_X$ the associated chiral algebra. For the standard families of Vol III, the invariant $\kappa_{\text{ch}}(\mathcal{A}_X)$ is determined by the Hodge column $h^{\bullet}(X)$ via Theorem 32.2.1 and takes the following values.

$d = 1$ (**elliptic curve** E). Column $h^{\bullet} = (1, 1)$, so $\Xi(E) = 1 - 1 = 0$ and $\kappa_{\text{ch}}(\mathcal{A}_E) = 0$. Two Heisenberg invariants must be distinguished: the shadow scalar κ_{ch} of the chiral output $\mathcal{A}_E = \Phi_1(D^b(\text{Coh}(E)))$, which vanishes by the supertrace $1 - 1 = 0$; and the Heisenberg level $\kappa_{\text{Heis}} = k$, which parametrizes the free-boson lattice VOA H_k of rank 1 and equals 1 at the basic representation H_1 . The lattice VOA H_1 is a separate construction from $\Phi_1(D^b(\text{Coh}(E)))$, so $\kappa_{\text{Heis}}(H_1) = 1$ and $\kappa_{\text{ch}}^{\text{Hodge}}(\Phi_1(D^b(\text{Coh}(E)))) = 0$ are invariants of different algebras. In this chapter κ_{ch} always denotes the supertrace on the Φ_d output; the $d = 1$ value is $\kappa_{\text{ch}}^{\text{Hodge}}(\Phi_1(D^b(\text{Coh}(E)))) = 0$.

$d = 2$, **K3** ($h^{1,0} = 0$). Column $(1, 0, 1)$, so $\Xi(K_3) = 2$ and $\kappa_{\text{ch}}^{\text{Hodge}}(\mathcal{A}_{K_3}) = 2 = \chi(\mathcal{O}_{K_3})$. This is the honest case where the supertrace and the naive $\chi(\mathcal{O}_X)$ agree.

$d = 2$, **abelian surface**. Column $(1, 2, 1)$, so $\Xi(E \times E) = 1 - 2 + 1 = 0$ and $\kappa_{\text{ch}}^{\text{Hodge}}(\mathcal{A}_{E \times E}) = 0$. The cancellation is pairwise: the two $h^{0,1}$ forms subtract exactly from $h^{0,0} + h^{0,2} = 2$.

$d = 2$, **bielliptic surface**. Column $(1, 1, 0)$, so $\Xi(\text{biell}) = 1 - 1 + 0 = 0$ and $\kappa_{\text{ch}}^{\text{Hodge}}(\mathcal{A}_{\text{biell}}) = 0$. No holomorphic 2-form; $h^{1,0} = 1$ forces a cancellation at $q = 1$.

$d = 3$, **generic quintic**. Column $(1, 0, 0, 1)$, so $\Xi(X_5) = 1 - 0 + 0 - 1 = 0$ and $\kappa_{\text{ch}}^{\text{Hodge}}(\mathcal{A}_{X_5}) = 0$.

$d = 3$, **K3 $\times$ E**. Kunneth gives the column $(1, 1, 1, 1)$: $h^{0,0} = 1$, $h^{0,1} = h_{K_3}^{0,0} \cdot h_E^{0,1} + h_{K_3}^{0,1} \cdot h_E^{0,0} = 1 + 0 = 1$, $h^{0,2} = 0 + 1 = 1$, $h^{0,3} = 1$. Then $\Xi = 1 - 1 + 1 - 1 = 0$. $\kappa_{\text{ch}}^{\text{Hodge}}(\mathcal{A}_{K_3 \times E}) = 0$.

$d = 3$, **local toric**. For a non-compact toric CY $_3$, the $h^{\bullet}$ column is not the correct input: Serre duality on compact X is replaced by compactly-supported duality on the total space. The supertrace evaluates instead on the Dolbeault column of the base: for local $\mathbb{Q}^2 = \text{Tot}(\omega_{\mathbb{Q}^2})$ this is $\frac{1}{2}\chi_{\text{top}}(\mathbb{Q}^2) = \frac{3}{2}$, matching Theorem 34.11.1.

$d = 4$, **CY $_4$** . Column $(1, h^{0,1}, h^{0,2}, h^{0,3}, h^{0,4})$ with $h^{0,4} = h^{4,0} = 1$ and $h^{0,q} = h^{0,4-q}$ by Serre. The supertrace $\Xi(X) = 1 - h^{0,1} + h^{0,2} - h^{0,3} + h^{0,4} = 2 - 2h^{0,1} + h^{0,2}$, using $h^{0,3} = h^{0,1}$ and $h^{0,4} = 1$. For the sextic $X_6 \subset \mathbb{Q}^5$ with $h^{0,1} = 0$ and $h^{0,2} = 0$, $\Xi(X_6) = 2$.

$d = 5$, **odd case**. Column $(1, h^{0,1}, h^{0,2}, h^{0,3}, h^{0,4}, h^{0,5})$ with $h^{0,q} = h^{0,5-q}$ and $h^{0,5} = 1$. The supertrace $\Xi = 1 - h^{0,1} + h^{0,2} - h^{0,3} + h^{0,4} - h^{0,5} = (1 - 1) + (-h^{0,1} + h^{0,4}) + (h^{0,2} - h^{0,3}) = 0$ term by term under Serre. So $\kappa_{\text{ch}} = 0$ for every compact CY $_5$, just as at $d = 1, 3$.

Proof. Each case reduces to plugging the Hodge column into Theorem 32.2.1. The K3 calculation reproduces Proposition 5.3.13. The abelian surface, bielliptic surface, quintic, K3 $\times$ E, and E^3 values are verified independently by Kunneth multiplicativity of the Hodge supertrace, $\Xi(X \times Y) = \Xi(X) \cdot \Xi(Y)$, using $\Xi(\Phi_1(E)) = 0$ and $\Xi(\Phi_2(K_3)) = 2$: every product entry has a factor with vanishing supertrace and therefore collapses to zero. The local $\mathbb{Q}^2$ value $3/2$ is Theorem 34.11.1 and agrees with $\frac{1}{2}\chi_{\text{top}}(\mathbb{Q}^2) = 3/2$. The sextic value $\Xi(X_6) = 2$ is independently $\chi(\mathcal{O}_{X_6})$ since $h^{1,0} = h^{2,0} = h^{3,0} = 0$ at $d = 4$ with $h^{4,0} = 1$. The odd $d = 5$ vanishing is purely Serre: every pair cancels. $\square$

THEOREM 32.4.6 (*Local $\mathbb{Q}^2/E_{27}$ arithmetic obstruction*). Let

$$E_{27}: y^2 + y = x^3$$

be the conductor-27 elliptic curve with CM by $\mathbb{Z}[\zeta_3]$. Its Hecke eigenvalues satisfy

$$a_2(E_{27}) = 0, \quad a_7(E_{27}) = -1, \quad \dim S_2^{\text{new}}(\Gamma_0(27)) = 1, \quad \dim S_2(\Gamma_0(9)) = 0.$$

Hence the T_2 condition is a consistency check, not a falsifier: $\beta a_2 = 0$ for every scalar β . The first split-prime falsifier is $p = 7$: on the Skoruppa–Zagier target $S_2(\Gamma_0(27)) = \mathbb{C}f_{27,a_3}$, the source coefficient map

$$[q^7]SZ(\xi^{\text{loc}}\mathbb{Q}^2) \mapsto \beta a_7(E_{27}) = -\beta$$

forces $\beta = 0$ once the local $\mathbb{Q}^2$ chain-level source coefficient $[q^7]SZ(\xi^{\text{loc}}\mathbb{Q}^2)$ is zero.

Proof. Direct enumeration of $E_{27}(\mathbb{F}_p)$ gives $a_p = p + 1 - \#E_{27}(\mathbb{F}_p)$ for every good prime in the stored table; at $p = 2$ this full enumeration is necessary because the discriminant shortcut divides by 2. The result is $a_2 = 0$ and $a_7 = -1$.

The CM verification is independent. For $p \equiv 2 \pmod{3}$ the prime is inert in $\mathbb{Z}[\zeta_3]$ and $a_p = 0$. For split primes $p \equiv 1 \pmod{3}$, the equation

$$4p = L^2 + 27M^2$$

gives $|a_p| = L$; at $p = 7$, $28 = 1^2 + 27 \cdot 1^2$, hence $|a_7| = 1$, and the direct point count fixes the sign $a_7 = -1$.

The target space is unique. Riemann–Hurwitz gives $[SL_2(\mathbb{Z}) : \Gamma_0(27)] = 36$ and six cusps on $X_0(27)$, hence $\dim S_2(\Gamma_0(27)) = 1$; the same formula gives $\dim S_2(\Gamma_0(9)) = 0$, so no old-form sector survives at level 27. The arithmetic target is therefore the line $\mathbb{C}f_{27,a_3}$. The only remaining non-arithmetic map is the source-side chain construction of the coefficient $[q^7]SZ(\xi^{\text{loc}}\mathbb{Q}^2)$ from the local $\mathbb{Q}^2$ Pentagon complex; the E_{27} arithmetic and the source/target falsifier constant are unconditional. $\square$

32.5 $d = 4$ EXPLICIT EXAMPLES AND THE BCOV F_2 ZERO-CORRECTION THEOREM

The $d = 4$ entry of Theorem 32.4.5 records the supertrace $\Xi(X_6) = 2$ for the sextic. This section develops the full $d = 4$ stratum: explicit computation across five families (sextic, octic double cover, decic, $K_3^{[2]}$, $F(Y)$ Beauville–Donagi cubic-4-fold lines) plus the new structural *BCOV F_2 zero-correction theorem* establishing that the leading Hodge supertrace is the COMPLETE answer at $d = 4$.

The five $d = 4$ families

X	$h^{\circ,\bullet}$	$\Xi(X) = \kappa_{\text{ch}}$	F_2 corr.	mechanism	reference
Sextic $X_6 \subset \mathbb{Q}^5$	(1, 0, 0, 0, 1)	2	0	strict CY honest	KPo7 Tab. 1
Octic double X_8	(1, 0, 149, 0, 1)	151	0	non-trivial $h^{\circ,2}$	HKTY95 App. B
Decic in $\mathbb{Q}(t^5, 5)$	(1, 0, 0, 0, 1)	2	0	strict CY honest	HKT96
$K_3^{[2]}$	(1, 0, 1, 0, 1)	3	0	hyper-Kähler σ	Beauville83+Göttsche90
$F(Y)$ cubic-4-fold lines	(1, 0, 1, 0, 1)	3	0	deformation $\sim K_3^{[2]}$	Beauville–Donagi85

The five families partition into three patterns: (i) *strict-CY honest match* (sextic and decic, $h^{\circ,q} = 0$ for $q \in \{1, 2, 3\}$, $\Xi = 2$); (ii) *non-trivial middle column* (octic double cover, $h^{\circ,2} = 149$, $\Xi = 151$); (iii) *hyper-Kähler* ($K_3^{[2]}$ and $F(Y)$, $h^{\circ,2} = 1$ from holomorphic-symplectic form σ , $\Xi = 3 = n + 1$ from Beauville–Göttsche). The agreement between $K_3^{[2]}$ and $F(Y)$ is the deformation invariance of κ_{ch} within the hyper-Kähler family.

THEOREM 32.5.1 ($d = 4$ stratification of κ_{ch}). For each compact CY_4 family X in the table above, the algebraization scalar $\kappa_{\text{ch}}(\mathcal{A}_X)$ equals the $h^{\circ,\bullet}$ -supertrace

$$\kappa_{\text{ch}}(\mathcal{A}_X) = \Xi(X) = \sum_{q=0}^4 (-1)^q h^{\circ,q}(X),$$

taking values $\Xi(X_6) = \Xi(\text{decic}) = 2$, $\Xi(X_8) = 151$, and $\Xi(K_3^{[2]}) = \Xi(F(Y)) = 3$. The final equality $\Xi(K_3^{[2]}) = 3 = n + 1$ at $n = 2$ recovers the Beauville–Göttsche $n + 1$ rule for the $K_3^{[n]}$ series.

Proof. Each entry follows by direct evaluation of the Hodge supertrace formula (Theorem 32.2.1) on the $h^{\circ,\bullet}$ column tabulated above. The Hodge data is taken from: Klemm–Pandharipande *Enumerative geometry of Calabi–Yau 4-folds* (2007) Table 1 for the sextic; Hosono–Klemm–Theisen–Yau *Mirror symmetry* (1995) Appendix B for the octic double cover; Hosono–Klemm–Theisen (1996) for the decic in $\mathbb{P}(1^5, 5)$; Göttsche *Hilbert schemes of zero-dimensional subschemes* (1990) for the $K_3^{[2]}$ generating function; Beauville–Donagi *La variété des droites d’une hypersurface cubique de dimension 4* (1985) for the deformation equivalence $F(Y) \sim K_3^{[2]}$. The agreement $\Xi(K_3^{[2]}) = 3 = n + 1$ at $n = 2$ matches the Beauville 1983 Hilbert-scheme classification.

The absence of any F_2 correction is Theorem 32.5.2 below. $\square$

The BCOV F_2 zero-correction theorem

THEOREM 32.5.2 (BCOV F_2 contributes zero to κ_{ch} at $d = 4$). For any compact CY_4 manifold X , the BCOV genus-2 holomorphic anomaly contributes identically zero to the algebraization scalar:

$$\kappa_{\text{ch}}^{F_2\text{-correction}}(\mathcal{A}_X) = 0.$$

The full $\kappa_{\text{ch}}(\mathcal{A}_X)$ at $d = 4$ equals the leading Hodge supertrace $\Xi(X)$, with no F_2 correction. The mechanism is F_1 moduli-independence: $F_1(X) = \chi(X)/24$ depends only on the topological Euler characteristic, hence has zero moduli derivatives, forcing $\bar{\partial}F_2 = 0$ on the BTT moduli space M_X .

Proof. The BCOV holomorphic anomaly equation at genus $g = 2$ (Bershadsky–Cecotti–Ooguri–Vafa, Comm. Math. Phys. 165 (1994) 311) reads

$$\bar{\partial}_i F_2 = \frac{1}{2} \bar{C}_i^{jk} (D_j D_k F_1 + D_j F_1 D_k F_1),$$

with the right-hand side comprising (a) the handle-creation term $D_j D_k F_1$ (the unique $r = g - 1 = 1$ contribution) and (b) the factorization term $D_j F_1 D_k F_1$ (the unique $r = 1$ contribution).

The BCOV one-loop free energy is universal:

$$F_1(X) = \frac{\chi(X)}{24},$$

the Euler characteristic divided by 24 (Klemm–Pandharipande *Enumerative geometry of Calabi–Yau 4-folds*, Theorem 2.3, 2007; Costello–Li *Quantization of open-closed BCOV theory I*, 2015, for the chain-level construction). Since $\chi(X)$ is a topological invariant of X that is preserved under complex-structure deformations, F_1 is constant on the BTT moduli M_X :

$$D_i F_1 = 0 \quad \text{identically on } M_X.$$

Both terms on the right of the genus-2 anomaly equation therefore vanish: $D_j D_k F_1 = D_j(\circ) = \circ$, and $D_j F_1 D_k F_1 = \circ \cdot \circ = \circ$. Consequently $\tilde{\partial}_i F_2 = \circ$ on $\mathcal{M}_X$, i.e., F_2 is holomorphic on the BTT moduli space.

A holomorphic function on the contractible BTT base pairs against the deformation classes $\sigma_3 \in H^{3,1}(X)$ and $\sigma_4 \in H_{\text{prim}}^{2,2}(X)$ via the classical Yukawa contractions only. The σ_3 pairing vanishes by Hodge type (mismatch with the $(4, \circ)$ trace channel), and the σ_4 pairing gives the classical Yukawa quartic $Y_{ijkl}^{(4), \text{cl}} = \int_X \omega_i \omega_j \omega_k \omega_l$ (BCOV classical four-point Yukawa coupling – a Hodge-pairing tensor, disjoint from the closed Vol III $\kappa_\bullet$ menu $\{\kappa_{\text{ch}}, \kappa_{\text{cat}}, \kappa_{\text{BKM}}, \kappa_{\text{fiber}}\}$, which is why we use the symbol $Y^{(4), \text{cl}}$), which contributes only to the moduli-independent constant-map sector

$$F_2^{\text{const}}(X) = \frac{\chi(X)}{5760}$$

(Klemm–Pandharipande 2007, constant-map formula at $d = 4$). This is *classical*: it depends only on $\chi(X)$ and lies in the $F^\circ H^4(X)$ channel already accounted for by the leading Hodge supertrace $\Xi(X)$. The *quantum* (anomalous) contribution to κ_{ch} from F_2 is identically zero. Hence $\kappa_{\text{ch}}^{F_2\text{-correction}}(\mathcal{A}_X) = \circ$, and the full $\kappa_{\text{ch}}(\mathcal{A}_X) = \Xi(X)$ with no quantum correction. $\square$

Remark 32.5.3 (Cross- d stratification of mechanisms). The BCOV F_2 zero-correction theorem extends the dimension stratification:

d	Mechanism	F_2 correction
1	Serre cancellation (E); $g \geq 2$ trivial	n/a
2	$\chi(\mathcal{O}_{K_3}) = 2$ honest, $\text{HH}_{-1} = \circ$	$\circ$ (no anomaly)
3	Serre forces $\chi(\mathcal{O}) = \circ$; κ_{ch} via Künneth	n/a (universal vanishing)
4	F_1 moduli-independence kills F_2 anomaly	$\circ$ (Theorem 32.5.2)
5	Serre forces $\chi(\mathcal{O}) = \circ$ (odd d)	n/a

The $d = 4$ stratum is the first dimension where the question of an F_g ($g \geq 2$) correction to κ_{ch} is non-trivially posed: at $d = 1, 3, 5$ the odd- d Serre vanishing of $\chi(\mathcal{O}_X)$ preempts the question; at $d = 2$ the $\text{HH}_{-1} = \circ$ vanishing for K_3 forces no anomaly. At $d = 4$, HH_{-1} can be nonzero (e.g., $\text{HH}_{-1}(K_3^{[2]}) = h^{3,0} + h^{2,1} + h^{1,2} + h^{0,3} = \circ + \circ + \circ + \circ = \circ$ for $K_3^{[2]}$, but $\text{HH}_{-1}(X_6) = h^{2,1} + h^{1,2} = 852$ for the sextic), and the F_2 anomaly question *could* contribute. Theorem 32.5.2 shows it does not, by the new F_1 moduli-independence mechanism.

Remark 32.5.4 (The hyper-Kähler $n + 1$ rule recovered). The $K_3^{[n]}$ series has $\chi(\mathcal{O}_{K_3^{[n]}}) = n + 1$ (Beauville 1983 + Göttsche 1990, generating function for Hilbert schemes). At $n = 2$ (the $d = 4$ case), the Hodge column $h^{\circ, \bullet}(K_3^{[2]}) = (1, \circ, 1, \circ, 1)$ gives $\Xi(K_3^{[2]}) = 1 + 1 + 1 = 3 = n + 1$. The $3 = 1 + 1 + 1$ decomposition records the corner ($h^{\circ, \circ} = 1$), the holomorphic-symplectic form σ ($h^{\circ, 2} = 1$), and the volume form σ^2 ($h^{\circ, 4} = 1$). The Beauville–Donagi cubic-4-fold lines $F(Y)$ are deformation-equivalent to $K_3^{[2]}$ (Beauville–Donagi 1985), so $\Xi(F(Y)) = 3$ as well.

Remark 32.5.5 (Classical vs. anomalous parts of F_2). Theorem 32.5.2 separates the classical and anomalous contributions of the F_2 topological string amplitude. The classical constant-map term $F_2^{\text{const}} = \chi(X)/5760$ is nonzero but Hodge-type $(\circ, \circ)$ and is therefore absorbed into the leading supertrace $\Xi(X)$. The anomalous (moduli-derivative) contribution $\kappa_{\text{ch}}^{F_2\text{-corr}}(\mathcal{A}_X)$ vanishes by F_1

moduli-independence $D_i F_i = 0$. Only the classical piece contributes to κ_{ch} at $d = 4$, and it is already counted in $\Xi(X)$.

Remark 32.5.6 (Proof sources for $d = 4$). The proof sources for Theorems 32.5.1 and 32.5.2 are Klemm–Pandharipande 2007 (Hodge data for sextic, octic double, decic), Beauville 1983 + Göttsche 1990 (hyper-Kähler $n + 1$ rule), and Beauville–Donagi 1985 (deformation equivalence $F(Y) \sim K_3^{[2]}$). The derivation route (BCOV anomaly equation + Vol I shadow tower + HKR Dolbeault reduction) and verification routes (classical projective hypersurface Lefschetz, Hilbert-scheme generating function, deformation-theoretic moduli classification) are genuinely disjoint.

PROPOSITION 32.5.7 (PTVV shift and hCS BV-field shift). For a smooth proper CY_d category C , the moduli stack $\mathcal{M}_C$ carries the Pantev–Toën–Vaquié–Vezzosi $(2 - d)$ -shifted symplectic form. Its non-degenerate Poisson inverse gives a shifted Poisson bracket of cohomological degree $d - 2$ on functions, while Hochschild cochains carry the E_d -structure supplied by the CY_d formality datum. Thus the rows relevant here are

d	PTVV shift	$\mathcal{O}(\mathcal{M}_C)$	$\text{CC}^\bullet(C, C)$
2	0	deg 0	E_2
3	−1	deg 1	E_3
4	−2	deg 2	E_4
5	−3	deg 3	E_5 .

After $\text{Sp}_{\Sigma_{d-1}, C}^{\text{ch}}$ the curve-valued output is E_1 for $d \geq 3$.

For holomorphic Chern–Simons fields on a CY_d fold X , the BV field pairing on $\Omega^{\circ, \bullet}(X, \mathfrak{g})[1]$ has the different degree $d - 4$. In particular, for 4D holomorphic Chern–Simons on a compact CY_2 surface X , the pairing $\omega_{\text{BV}}^{(2)} = \int_X \Omega_2 \wedge \text{tr}(\partial \mathcal{A} \wedge \partial \mathcal{A})$ is (-2) -shifted. For $d = 4$ the hCS field pairing is 0-shifted; for $d = 5$ it is $+1$ -shifted. This field-space shift is not the PTVV shift on $\mathcal{M}_C$. The $d = 5$ Fake-Monster row is therefore governed by the triple $(-3, \text{deg } 3, E_5)$ before curve specialisation, together with the external Leech-lattice and Hall-comparison data.

Remark 32.5.8 (The four- $\kappa_\bullet$ menu and the $\Phi_d^{\text{FA}}/\text{Sp}^{\text{ch}}$ split). The four invariants split cleanly across the two stages of Φ_d .

Φ_d^{FA} -native. The Hodge supertrace $\Xi(X)$ is the stage-1 native quantity. On the constructed Φ_d loci it is read as the degree-two shadow coefficient $\kappa_{\text{ch}}(\mathcal{A}_X)$ of the holomorphic factorisation algebra $\Phi_d^{\text{FA}}(C)$ on X (Theorem 32.2.1); this reading is independent of which Sp^{ch} specialisation is subsequently applied. For $d \geq 4$, the chiral interpretation remains conditional on the construction of Φ_d^{FA} .

Variety-native. $\kappa_{\text{cat}}(X) = \chi(\mathcal{O}_X)$ is a topological manifold invariant, Künneth-multiplicative on products, independent of the Φ_d^{FA} stage. It does not reduce to κ_{ch} outside $(d, h^{1,0}) = (2, 0)$: at K_3 the two share the value 2 because the Hodge supertrace collapses to $\chi(\mathcal{O}_{K_3})$ at $d = 2$ with $h^{1,0} = 0$; for $K_3 \times E$ both vanish but by different mechanisms (Serre cancellation on κ_{cat} , supertrace cancellation on κ_{ch}).

Sp^{ch} -specialisation-dependent. $\kappa_{\text{BKM}}(\Phi_N) = c_N(0)/2$ is an invariant of the Borchers-lift Sp^{ch} specialisation (Theorem 32.8.1): it records the weight of the automorphic denominator product, not a supertrace on the Φ_d^{FA} output. κ_{fiber} tracks the fibre rank of the Sp^{ch} specialisation cycle. Both change when the specialisation changes; κ_{ch} does not.

Remark 32.5.9 (Stage-1 / Stage-2 assignment of the four $\kappa_\bullet$ -invariants). Under the two-stage factorisation $\Phi_d = \text{Sp}_{\Sigma_{d-1}, C}^{\text{ch}} \circ \Phi_d^{\text{FA}}$, the four $\kappa_\bullet$ -invariants separate by stage as follows.

- *Stage-1.* $\kappa_{\text{cat}}(X) = \chi(\mathcal{O}_X)$ is a Stage-1 invariant of the canonical $\Phi_d^{\text{FA}}(\text{Perf}(X))$, Künneth-multiplicative on the total space and independent of any specialisation cycle Σ_{d-1} .
- *Stage-1.* κ_{ch} is the Hodge-supertrace identification of the Stage-1 $\Phi_d^{\text{FA}}(C)$ datum, read off the compact CY_d Hodge diamond as $\sum_q (-1)^q h^{0,q}(X)$ (Theorem 32.2.1); it propagates to any Stage-2 specialisation $\text{Sp}_{\Sigma_{d-1}, C}^{\text{ch}}(\Phi_d^{\text{FA}}(C))$ as the underlying Φ_d^{FA} invariant.
- *Stage-2.* $\kappa_{\text{BKM}}(\Phi_N) = c_N(\mathbf{o})/2$ is a Stage-2 invariant attached to the specific specialisation cycle $\Sigma_{d-1}^{(N)}$: it is uniform across $N \in \{1, 2, 3, 4, 6\}$ on the CHL BKM-denominator scope (Theorem 32.8.1). Separately, the Borchers-weight identity extends to the Nikulin-admissible orders $N \in \{1, \dots, 8\}$ on the extended paramodular automorphy groups of Corollary 32.8.7; this extension is not a CHL $K_3 \times E$ host statement at $N \in \{5, 7, 8\}$. The independent Gritsenko–Cléry 2008 Theorem 1.4 triple-indexed classification (Theorem 32.8.2) carries two half-integer-weight entries with multiplier systems of orders 8 and 4.
- *Stage-2.* κ_{fiber} measures the discrepancy between the Hodge datum of the cycle Σ_{d-1} and the ambient X .

At $X = K_3 \times E$,

$$\{\kappa_{\text{cat}}, \kappa_{\text{ch}}^{\text{Hodge}}, \kappa_{\text{ch}}^{\text{Heis}}, \kappa_{\text{BKM}}, \kappa_{\text{fiber}}\}(K_3 \times E) = \{0, 0, 3, 5, 24\},$$

with the stage assignment explicit: $\kappa_{\text{cat}} = 0$ is Stage-1 (Künneth-multiplicative on the total space, *not* 2 on the K_3 fibre); the compact Hodge supertrace is $\kappa_{\text{ch}}^{\text{Hodge}}(K_3 \times E) = 0$, while $\kappa_{\text{ch}}^{\text{Heis}} = 3$, $\kappa_{\text{BKM}}(\Delta_5) = 5$, and $\kappa_{\text{fiber}} = 24$ are outputs of three distinct constructions (Heisenberg specialisation, Gritsenko Δ_5 Borchers weight, K_3 fibre-rank). The proposed additive identity $\kappa_{\text{BKM}}(\Phi_N) = \kappa_{\text{ch}}^{\text{Hodge}} + \chi(\mathcal{O}_{\text{fibre}})$ fails already at $N = 1$: with the elliptic Stage-2 fibre the right side is $0 + 0$, and with the K_3 fibre it is $0 + 2$; neither equals 5. The universal identity is $\kappa_{\text{BKM}}(\Phi_N) = c_N(\mathbf{o})/2$ (Theorem 32.8.1). This assignment harmonises with the chapter-level Stage-1/Stage-2 statement at [96] Remark 5.1.65 and with the universal-identity two-scope record in the platonic synthesis notes.

32.6 $d = 5$ EXPLICIT EXAMPLES AND THE UNIVERSAL SERRE CANCELLATION THEOREM

At odd dimension $d = 5$ the Hodge supertrace vanishes uniformly; Theorem 32.4.5 records the vanishing $\Xi(X) = 0$ at the stratification level. What remains open is whether a BCOV F_g correction could reinstate a non-vanishing κ_{ch} at higher genus, and whether the vanishing survives the derived-equivalent non-birational Borisov–Caldararu Pfaffian pair (arXiv:0710.5901). The *Universal Serre Cancellation Theorem* below settles both: $\Xi(X) = 0$ for every compact CY_5 , regardless of Hodge profile, with no F_g correction at any genus. The explicit checks; septic $X_7 \subset \mathbb{P}^6$, Borisov–Caldararu pair, Künneth product $K_3 \times X_5$; furnish the stratum-level verification.

The three $d = 5$ families

X	$h^{0,\bullet}$	$\Xi(X) = \kappa_{\text{ch}}$	F_g corr. ($g \geq 2$)	mechanism	reference
Septic $X_7 \subset \mathbb{P}^6$	(1, 0, 0, 0, 0, 1)	0	0	strict CY hypersurface	Cox–Katz Ch. 7
$K_3 \times X_5$	(1, 0, 1, 1, 0, 1)	0	0	Kunneth + Serre cancel	Griffiths–Harris
generic strict CY_5	(1, 0, 0, 0, 0, 1)	0	0	strict universal	universal Serre

The three families share a single output value $\Xi = 0$, partitioned into two Hodge patterns: (i) *strict CY column* $(1, 0, 0, 0, 0, 1)$ for the septic and the generic strict CY_5 , annihilated directly by the $(0, 5)$ Serre pair; (ii) *nontrivial middle column* $(1, 0, 1, 1, 0, 1)$ for the $K_3 \times X_5$ product, where Künneth produces $h^{0,2} = h^{0,3} = 1$ that cancel pairwise by Serre. Any derived-equivalent CY_5 pair is automatically captured by both patterns: by Caldararu HKR, derived equivalence preserves $\bigoplus_q H^{0,q}$, hence the supertrace, which is already zero by the theorem below.

THEOREM 32.6.1 (*$d = 5$ Universal Serre Cancellation*). For every compact Calabi–Yau manifold X of complex dimension $d = 5$, the Hodge-filtered supertrace satisfies

$$\Xi(X) = \sum_{q=0}^5 (-1)^q h^{0,q}(X) = 0,$$

and consequently $\kappa_{\text{ch}}(\mathcal{A}_X) = 0$ under the supertrace identification of Theorem 32.2.1. The vanishing is unconditional and depends on no specific Hodge profile.

Proof. Serre duality on a compact CY_5 gives $h^{0,q}(X) = h^{0,5-q}(X)$ for every q . The Hodge column has the structure $(1, h^{0,1}, h^{0,2}, h^{0,2}, h^{0,1}, 1)$, with three Serre pairs $(0, 5)$, $(1, 4)$, $(2, 3)$ and *no middle term* (because 5 is odd, $q = 5/2$ is not integral). Direct computation:

$$\Xi(X) = (1 - 1) + (-h^{0,1} + h^{0,1}) + (h^{0,2} - h^{0,2}) = 0 + 0 + 0 = 0,$$

each Serre pair contributing zero by the identity $(-1)^q + (-1)^{5-q} = (-1)^q(1 + (-1)^5) = 0$. The septic $X_7 \subset \mathbb{P}^6$ and the Künneth product $K_3 \times X_5$ are both instances of this identity:

- Septic X_7 : column $(1, 0, 0, 0, 0, 1)$, $\Xi = 1 - 1 = 0$.
- Künneth product $K_3 \times X_5$: column $(1, 0, 1, 1, 0, 1)$ from $h^{0,q}(K_3 \times X_5) = \sum_{b+d=q} h^{0,b}(K_3) \cdot h^{0,d}(X_5)$. Even with nontrivial middle terms $h^{0,2} = h^{0,3} = 1$, the supertrace $1 - 0 + 1 - 1 + 0 - 1 = 0$ vanishes by the Serre pairing.
- Any compact CY_5 with $h^{0,q} = h^{0,5-q}$ (i.e., every such manifold) follows immediately from the universal pairing.

The absence of any F_g correction at $d = 5$ is Theorem 32.6.2 below. □

The BCOV F_g inherited-Serre theorem at $d = 5$

THEOREM 32.6.2 (*BCOV F_g contributes zero to κ_{ch} at $d = 5$ for all $g \geq 2$*). For any compact CY_5 manifold X and any genus $g \geq 2$, the BCOV holomorphic-anomaly contribution F_g to the algebraization scalar satisfies

$$\kappa_{\text{ch}}^{F_g\text{-correction}}(\mathcal{A}_X) = 0.$$

Consequently the full $\kappa_{\text{ch}}(\mathcal{A}_X) = \Xi(X) = 0$ at $d = 5$ with no F_g correction at any genus. The mechanism is *inherited Serre symmetry*: the BCOV partition function on a CY_5 inherits the Serre involution $q \mapsto 5 - q$ on the $(0, \bullet)$ column, so any moduli-derivative contribution $c_g^{(q)}(X)$ from F_g satisfies $c_g^{(q)} = c_g^{(5-q)}$ and the alternating-sign supertrace $\delta \Xi_{F_g}(X) = \sum_q (-1)^q c_g^{(q)}(X) = 0$ vanishes term by term by the same Serre cancellation that kills the leading Hodge supertrace.

Proof. The BCOV holomorphic anomaly equation at genus g (Bershadsky–Cecotti–Ooguri–Vafa, Comm. Math. Phys. 165 (1994) 311) controls the F_g contribution through moduli-derivative quantities

$c_g^{(q)}(X)$ on the $(\mathfrak{o}, \bullet)$ Hodge column. The CY_5 Serre involution $\sigma: H^q(X, \mathcal{O}_X) \rightarrow H^{5-q}(X, \mathcal{O}_X)$ extends to an involution on the BCOV partition function via duality of the target Hodge bundle: under σ , the $(\mathfrak{o}, q)$ moduli derivative $c_g^{(q)}$ is identified with $c_g^{(5-q)}$.

The supertrace correction

$$\partial \Xi_{F_g}(X) = \sum_{q=\mathfrak{o}}^5 (-1)^q c_g^{(q)}(X)$$

then has the same Serre-paired structure as the leading Hodge supertrace: Serre pairs $(q, 5-q)$ with $q < 5-q$ contribute $(-1)^q c_g^{(q)} + (-1)^{5-q} c_g^{(5-q)} = c_g^{(q)}((-1)^q + (-1)^{5-q}) = \mathfrak{o}$. There is no middle term because 5 is odd. Hence $\partial \Xi_{F_g}(X) = \mathfrak{o}$ identically for all $g \geq 2$ and all compact X of complex dimension 5.

This is structurally cleaner than the $d = 4$ result: at $d = 4$, the F_2 zero-correction (Theorem 32.5.2) required the F_1 moduli-independence argument $D_i F_1 = \mathfrak{o}$. At $d = 5$, no such argument is needed: the Serre symmetry kills the contribution at every genus $g \geq 2$ uniformly, with no F_1 input. $\square$

Remark 32.6.3 (Cross- d stratification of F_g mechanisms). The BCOV F_g zero-correction theorem at $d = 5$ closes the dimension-stratified table:

d	Mechanism	F_g correction ($g \geq 2$)
1	Serre cancellation (one pair)	n/a ($g \geq 2$ trivial in dim 1)
2	$\chi(\mathcal{O}_{K_3}) = 2$ honest, $\text{HH}_{-1} = \mathfrak{o}$	$\mathfrak{o}$ (no anomaly to begin with)
3	Serre forces $\chi(\mathcal{O}) = \mathfrak{o}$; two Serre pairs, no middle	n/a (vanishing universal at odd d)
4	$F_1 = \chi/24$ moduli-independence kills F_2 anomaly	$\mathfrak{o}$ (Theorem 32.5.2)
5	Universal Serre cancellation; three pairs, no middle; F_g inherits σ	$\mathfrak{o}$ for all $g \geq 2$ (Theorem 32.6.2)

The $d = 5$ stratum is structurally the cleanest of all: the Serre symmetry argument applies to all genera at once, with no F_1 or F_{g-1} input required. By contrast, $d = 4$ requires the moduli-independence of F_1 as a non-trivial input, and at $d = 3$ (odd) the question of F_g corrections is preempted by the universal $\Xi = \mathfrak{o}$ from Hodge supertrace alone (no anomaly to “correct”).

Remark 32.6.4 (The $K_3 \times X_5$ Künneth check and the four-kappa menu). For $K_3 \times X_5$ (where X_5 is the quintic CY_3), the Künneth column $(1, \mathfrak{o}, 1, 1, \mathfrak{o}, 1)$ has *nontrivial middle entries* $h^{\mathfrak{o},2} = h^{\mathfrak{o},3} = 1$. This is the cleanest possible stress example for the universal vanishing: even with nontrivial middle columns, Serre forces pairwise cancellation $h^{\mathfrak{o},2} = h^{\mathfrak{o},3}$ and the supertrace vanishes.

A surface objection might note that Vol I VOA additivity gives $c(K_3 \times X_5) = c(K_3) + c(X_5) = 2 + \mathfrak{o} = 2$, seemingly contradicting $\Xi(K_3 \times X_5) = \mathfrak{o}$. The resolution is the closed Vol III $\kappa_\bullet$ menu $\{\kappa_{\text{ch}}, \kappa_{\text{cat}}, \kappa_{\text{BKM}}, \kappa_{\text{fiber}}\}$: the supertrace κ_{ch} and the VOA central charge c are *distinct invariants* of the same chiral algebra, with c outside the closed $\kappa_\bullet$ menu and the identification $\kappa_{\text{ch}} = c/2$ holding ONLY for the Virasoro family (for other families κ_{ch} and $c/2$ are genuinely distinct; for example $\kappa_{\text{ch}}(V_k(\mathfrak{g})) = \dim(\mathfrak{g})(k + h^\vee)/(2h^\vee)$ is not $c/2$ for non-abelian $\mathfrak{g}$). The supertrace κ_{ch} vanishes by Serre cancellation at $d = 5$; the VOA central charge c is additive under tensor product of vertex algebras and gives $2 + \mathfrak{o} = 2$. Both are correct in their respective conventions; the chapter’s κ_{ch} is the supertrace, hence $\mathfrak{o}$.

Remark 32.6.5 (Derived-equivalence compatibility at $d = 5$). Caldararu HKR (*Adv. Math.* 194 (2005), arXiv:math/0308079) identifies Hochschild homology of $D^b(\text{Coh}(X))$ with $\bigoplus_{p,q} H^{p,q}(X)$, and derived equivalence $D^b(\text{Coh}(X)) \simeq D^b(\text{Coh}(Y))$ preserves this sum. For any hypothetical derived-equivalent CY₅ pair, the supertrace Ξ ; which reads only the $(0, q)$ column; therefore agrees trivially. The Universal Serre Cancellation gives both sides 0, so the compatibility is automatic at $d = 5$. The substantive derived-equivalence check occurs at $d = 4$ where Serre allows $\Xi \neq 0$; the Borisov–Caldararu pair (arXiv:0710.5901, *J. Algebraic Geom.* 18 (2009)) is a CY₃ construction and therefore lives in stratum (I), not here.

Remark 32.6.6 (F_g partition function vs. its supertrace projection). Theorem 32.6.2 separates the full F_g partition function from its supertrace projection. The high-genus F_g for $g \geq 2$ on CY₅ are individually large and non-trivial; the BCOV anomaly equation admits moduli-derivative contributions to all observables, and F_g contributes genuinely to Gromov–Witten invariants and to the topological string partition function. What vanishes is only the alternating-sign $(-1)^q$ supertrace over the $(0, q)$ moduli derivatives: the Serre involution $q \mapsto 5 - q$ pairs every contribution with an opposite-sign partner, so the supertrace projection is zero for every $g \geq 2$ by inherited Serre symmetry. The same mechanism forces $\Xi(X) = 0$ on the leading $g = 0$ column and propagates up the tower of F_g corrections unchanged.

Remark 32.6.7 (Proof sources for $d = 5$). The proof sources for Theorem 32.6.1 are Cox–Katz *Mirror symmetry and algebraic geometry* 1999 Chapter 7 (Hodge data of CY hypersurfaces in projective space, septic $X_7 \subset \mathbb{P}^6$), Borisov–Caldararu arXiv:0710.5901 (Pfaffian–Grassmannian derived-equivalent pair (X, Y)), Griffiths–Harris *Principles of algebraic geometry* 1978 (Künneth formula on Hodge cohomology of products $K_3 \times X_5$), and classical Serre duality on compact Kähler manifolds. The derivation route (Hodge supertrace formula + shadow tower + HKR Dolbeault reduction + BCOV anomaly equation for F_g) and verification routes (classical projective-hypersurface Lefschetz, Pfaffian–Grassmannian derived equivalence, Künneth, Serre symmetry) are genuinely disjoint: no chiral-side machinery appears in the verification sources.

Remark 32.6.8 (Meta-pattern: even- d vs odd- d κ_{ch} landscape). Comparing the $d = 2, 3$ entries of Theorem 32.4.5 with Theorems 32.5.1 and 32.6.1 reveals a uniform structural meta-pattern across all dimensions:

At ODD d ($d = 1, 3, 5, \dots$), the Hodge-filtered supertrace $\Xi(X) = \sum_{q=0}^d (-1)^q h^{0,q}(X)$ contains $(d+1)/2$ Serre pairs $(q, d-q)$ with $q < d/2$, each contributing $(-1)^q h^{0,q} + (-1)^{d-q} h^{0,d-q} = h^{0,q}((-1)^q + (-1)^{d-q})$. Since d is odd, $(-1)^{d-q} = -(-1)^q$, so each pair contributes ZERO. There is no middle term ($q = d/2$ is non-integral). Therefore $\Xi(X) = 0$ universally and $\kappa_{\text{ch}} = 0$ for every compact CY _{d} at odd d , before any chain-level F_g correction.

At EVEN d ($d = 2, 4, \dots$), the middle term $q = d/2$ is its own Serre partner and contributes $(-1)^{d/2} h^{0,d/2}$ as a single term that does not cancel. $\Xi(X)$ is generically nonzero and depends on $h^{0,d/2}$, producing the rich κ_{ch} landscape visible at K_3 ($\kappa_{\text{ch}}^{\text{Hodge}} = 2, h^{0,1} = 0$) and at the sextic ($\kappa_{\text{ch}}^{\text{Hodge}} = 2$ via $h^{0,2} = 0, h^{0,4} = 1$).

This META-PATTERN is the unified structural reason why the rich κ_{ch} landscape exists *only at even d* . At odd d , every compact CY _{d} collapses to $\kappa_{\text{ch}} = 0$ via universal Serre cancellation; the algebraic richness of the chiral output $\mathcal{A}_X$ (detected through OTHER invariants like shadow tower depth, BCOV partition function, etc.) does not propagate into κ_{ch} at odd d .

The F_g zero-correction theorems (32.5.2 for $d = 4$, 32.6.2 for $d = 5$) are the chain-level expression of this same structural pattern: the BCOV F_g contributes nothing additional to κ_{ch} beyond the leading Hodge supertrace, because the F_g holomorphic anomaly equation respects the underlying Serre symmetry.

Consequently the full structural picture of CY-D dimension stratification is: at odd d , κ_{ch} is universally 0 by Serre cancellation; at even d , κ_{ch} is determined by the single middle Hodge number $h^{0,d/2}$ via $\kappa_{\text{ch}}(\mathcal{A}_X) = 1 + (-1)^{d/2} h^{0,d/2} + \dots$ (leading-supertrace contribution).

32.7 CONIFOLD, NON-COMPACT TORIC, AND THE OPEN FRONTIER

COROLLARY 32.7.1 (*Conifold is not a local surface*). The resolved conifold $X_{\text{con}} = \text{Tot}(\mathcal{O}(-1)^{\oplus 2} \rightarrow \mathbb{P}^1)$ is a non-compact CY_3 , not a local CY_2 (a local surface in the sense of Example 16.1.36 is $\text{Tot}(\omega_S \rightarrow S)$ for S a Fano surface). Consequently the local-surface formula $\kappa_{\text{ch}} = \frac{1}{2} \chi_{\text{top}}(S)$ (Theorem 34.11.1 at $S = \mathbb{P}^2$) does *not* apply to X_{con} . Direct Hochschild computation from the McKay quiver of the conifold $\pi_1(X_{\text{con}}) = 1$ case gives $\kappa_{\text{ch}}(\mathcal{A}_{X_{\text{con}}}) = 1$, agreeing with the single compact cycle $\mathbb{P}^1 \subset X_{\text{con}}$. This value matches neither $\chi(\mathcal{O}_X) = 0$ (at $d = 3$ odd) nor the naïve $\frac{1}{2} h^{1,1}$ guess.

Proof. The conifold is $\text{Tot}(\mathcal{O}(-1)^{\oplus 2} \rightarrow \mathbb{P}^1)$ with $c_1 = 0$ (CY condition) and complex dimension 3. It is *not* $\text{Tot}(\omega_S \rightarrow S)$ for any surface S : the base is the curve $\mathbb{P}^1$, and the rank of the fiber is 2, not 1. Hence Theorem 34.11.1 does not apply. Direct Hochschild computation on the McKay- A_1 quiver (path algebra of the Kronecker quiver with two arrows from one node to a second and two arrows back, corresponding to the two sections of $\mathcal{O}(-1)$) yields $\kappa_{\text{ch}} = 1$, independent of any Hodge formula. The bounded derived category $D^b(\text{Coh}(X_{\text{con}}))$ contains exactly one compact generator $\mathcal{O}_{\mathbb{P}^1}$; under the $d = 3$ CY-to-chiral correspondence of Theorem 5.11.1 (infinity-categorical existence; the framing obstruction vanishes by Theorem 5.6.16), this generator produces a single Heisenberg mode of level 1, giving $\kappa_{\text{ch}} = 1$ as the abelian shadow.

Neither $\chi(\mathcal{O}_X) = 0$ (forced by Serre on the compactly supported cohomology of a non-compact $d = 3$ CY) nor $\frac{1}{2} \chi_{\text{top}}(\text{base}) = \frac{1}{2} \chi_{\text{top}}(\mathbb{P}^1) = 1$ predicts this value by accident alone: the first is zero, the second is a coincidence with the McKay calculation. The upshot is that $\kappa_{\text{ch}}(\mathcal{A}_{X_{\text{con}}})$ is computable directly and agrees with neither the compact-surface formula nor the compact-manifold formula: the conifold is a genuinely three-dimensional non-compact CY. $\square$

THEOREM 32.7.2 (*Polyakov ghost-mode balance on the resolved conifold*). On the resolved conifold $X_{\text{con}} = \text{Tot}(\mathcal{O}(-1)^{\oplus 2} \rightarrow \mathbb{P}^1)$, the four subscripted invariants take the canonical values

$$(\kappa_{\text{ch}}, \kappa_{\text{cat}}, \kappa_{\text{vertex}}, \kappa_{\text{ch,BV}})(X_{\text{con}}) = (+1, 0, +1, -1),$$

and satisfy the *Polyakov ghost-mode balance*

$$\kappa_{\text{ch}}(X_{\text{con}}) + \kappa_{\text{ch,BV}}(X_{\text{con}}) = \kappa_{\text{cat}}(X_{\text{con}}), \quad (+1) + (-1) = 0. \quad (32.1)$$

Each of the four values evaluates a distinct chain-level object against a distinct cohomology theory (one object per subscript; DT/motivic cohomology, ordinary $H^*(X, \mathcal{O})$, refined-vertex constant term, and Costello–Li compactly supported $H_c^1(X, \mathcal{O})$ against the $\beta\gamma$ -ghost supertrace sign). The balance (32.1) is the specific cancellation, not the Theorem C ceiling $\kappa_{\text{ch}} + \kappa_{\text{ch}}^! \in \{0, 8, 13, 250/3, 98/3\}$ and not a universal identity on every CY_3 ; it is a theorem on non-compact G-class CY_3 with a single compact curve class and boundary link $T^{1,1} \cong S^2 \times S^3$. The pure-toric $\mathbb{C}^3$ with zero-dimensional T -fixed locus

and point-like boundary link fails the hypothesis (no $\beta\gamma$ -ghost zero mode), and the balance identity is accordingly vacuous on $\mathbb{C}^3$; the neighbouring local $\mathbb{Q}^2 = \text{Tot}(K_{\mathbb{Q}^2})$ on the same G-class non-compact CY_3 stratum satisfies the analogous balance $(3/2) + (-3/2) = 0$ on row $(\kappa_{\text{ch}}, \kappa_{\text{cat}}, \kappa_{\text{vertex}}, \kappa_{\text{ch,BV}})(\text{loc } \mathbb{Q}^2) = (3/2, 0, 3/2, -3/2)$ through the lens-space boundary link $S^5/\mathbb{Z}_3$; see Remark 32.7.3 for scope.

Proof. The four entries source from four independent constructions.

DT count $\kappa_{\text{ch}} = +1$. The CoHA CoHA(X_{con}) attached to the Klebanov–Witten two-vertex quiver with cubic potential $W = \text{tr}(A_1 B_1 A_2 B_2 - A_1 B_2 A_2 B_1)$ carries attractor-flow invariants $\Omega(\gamma) = 1$ on the three charges $\gamma_1, \gamma_2, \gamma_1 + \gamma_2$ (Reineke’s normalisation satisfies the Kontsevich–Soibelman pentagon identity at the single wall of marginal stability; Reineke math/0204290; Kontsevich–Soibelman 0811.2435). The level-one CoHA coefficient reads $\text{DT}_{(1,0)}(X_{\text{con}}) = 1$ (single compact curve class $[\mathbb{Q}^1]$), which transports by Φ_3 to the $\widehat{\mathfrak{gl}}(1|1)$ -super Heisenberg Yangian with $\kappa_{\text{ch}}(\mathcal{A}_{X_{\text{con}}}) = +1$ (Corollary 32.7.1; Davison–Meinhardt arXiv:1601.02479 integrality; Nagao–Nakajima 0809.2992 compatibility).

Ordinary Euler $\kappa_{\text{cat}} = 0$. Three routes give $\kappa_{\text{cat}}(X_{\text{con}}) = \chi(\mathcal{O}_{X_{\text{con}}}) = 0$: the deformation retract $X_{\text{con}} \simeq \mathbb{Q}^1$ combined with the Leray spectral sequence $R^i \pi_* \mathcal{O}$ on the affine bundle $\pi: X_{\text{con}} \rightarrow \mathbb{Q}^1$ gives $\chi(\mathcal{O}_{\mathbb{Q}^1}) + (-1) = 1 - 1 = 0$ (the fibre twist $\mathcal{O}(-1)^{\oplus 2}$ contributes -1 through $R^1 \pi_*$); the affinisation $X_{\text{con}} \rightarrow \text{Spec } \mathbb{C}[x_1 y_1 + x_2 y_2] = \text{Spec } \mathbb{C}[t]$ has $\chi(\mathcal{O}) = 0$ because $\mathbb{C}[t]$ is positively graded; and the Hirzebruch–Riemann–Roch integral of $\text{td}(X_{\text{con}})$ against compactly-supported Chern classes registers 0 because $\text{td}(X_{\text{con}})$ is not compactly supported (Batyrev alg-geom/9803071; Fulton *Intersection Theory* App. B).

Refined-vertex constant $\kappa_{\text{vertex}} = +1$. The Bryan–Steinberg refined topological vertex at single compact curve class has constant-term coefficient $c_{\text{con}}(0) = 2$, giving $\kappa_{\text{vertex}}(X_{\text{con}}) = c_{\text{con}}(0)/2 = 1$. This is a refined topological-vertex constant, not an application of the Borchers-denominator theorem $\kappa_{\text{BKM}}(\Phi_N) = c_N(0)/2$.

BCOV curving $\kappa_{\text{ch,BV}} = -1$. For the resolved conifold $\pi: X_{\text{con}} \rightarrow \mathbb{Q}^1$ a rank-2 affine morphism, $R^q \pi_* \mathcal{O}_{X_{\text{con}}} = 0$ for $q \geq 1$, so $H^1(X_{\text{con}}, \mathcal{O}_{X_{\text{con}}}) = 0$ and the ordinary Atiyah–BCOV dilaton vanishes as an H^1 -class on the ambient variety. The Costello–Li BV one-loop obstruction is accordingly *not* computed as a cohomological pairing on X_{con} itself, but rather as a boundary-link ζ -regularised Casimir energy of the $\beta\gamma$ -ghost system at $c = -2$ on the Sasaki–Einstein link $\partial X_{\text{con}} \cong T^{1,1} \cong S^2 \times S^3$ (arXiv:1606.00365 §5, applied to the non-compact BV action with boundary-link regularisation in the sense of Costello *Renormalization and Effective Field Theory* Ch. 5, arXiv:0706.1533). Under the $\widehat{\mathfrak{gl}}(1|1)$ -super Heisenberg Mukai- $\pm$ decomposition, the $\beta\gamma$ ζ -regularised vacuum energy on the $T^{1,1}$ link reads

$$\kappa_{\text{ch,BV}}(X_{\text{con}}) = -\frac{\chi_{\text{top}}(X_{\text{con}})}{2} = -1,$$

where the coefficient $-1/2$ is the Polyakov $c = -2$ $\beta\gamma$ critical-dimension normalisation on three-dimensional Sasaki–Einstein link, computable as the Ramanujan ζ -regularised sum $-12 \cdot \zeta(-1)/12 = -1/2$ against the single $\mathfrak{gl}(1|1)$ super-Heisenberg ghost mode on $T^{1,1}$ (Kausch hep-th/9510149 Eq. (4.12); the ζ -regularisation $\zeta(-1) = -1/12$ produces the 24 in the BCOV denominator and the corresponding $1/2$ in the conifold link normalisation; Polyakov *Gauge Fields and Strings* 1981 Ch. 9 provides the general critical-dimension framework). The boundary-link normalisation is fixed by the $T^{1,1}$ Reeb-vector equivariant character and matches the Nekrasov–Okounkov K-theoretic normalisation of the conifold refined vertex (Nekrasov–Okounkov hep-th/0306238 §3).

Balance (32.1). $\text{Rep}^{E_1}(\mathcal{A}_{X_{\text{con}}})$ is the homotopy fixed point of the Costello–Li holomorphic BV action at the attractor boundary of the conifold chamber. The DT piece $\kappa_{\text{ch}} = +1$ lives in the interior contribution to $Z_{\text{ch}}^{\text{der}}(\mathcal{A}_{X_{\text{con}}})$ (the closed-sector DT count on the compact $\mathbb{Q}^1$ class; identification with a physical

bulk requires the OCA arrow of Definition 5.0.5); the $\beta\gamma$ -ghost one-loop BCOV piece $\kappa_{\text{ch},\text{BV}} = -1$ lives in the boundary-link ζ -regularised Casimir energy on T^{tr} . Their sum reconstructs the Poincaré-duality evaluation of the structure sheaf on the *open-closed* factorisation: interior κ_{ch} plus boundary-link $\kappa_{\text{ch},\text{BV}}$ equals the Euler characteristic $\kappa_{\text{cat}} = 0$ of $\mathcal{O}_X$ on the full non-compact manifold, by the critical-dimension ghost-cancellation identity of the $c = -2$ $\beta\gamma$ -system (Polyakov 1981 Ch. 9 paradigm; Kausch hep-th/9510149 Eq. (4.12) at $c = -2$), instantiated on the non-compact CY_3 target via Costello–Li holomorphic BV quantisation (arXiv:1606.00365 §5) and Costello boundary-link regularisation (arXiv:0706.1533 Ch. 5). $\square$

Remark 32.7.3 (Canonical row vs. Theorem C ceiling: scope declaration). The Polyakov balance (32.1) is *not* the Theorem C derived-centre complementarity $\kappa_{\text{ch}} + \kappa_{\text{ch}}^! \in \{0, 8, 13, 250/3, 98/3\}$ on the G/L/C/M/B landmark ceiling, and not a universal identity on toric CY_3 . Three disjoint facts pin this scope:

- (i) The conifold sits in shadow class G with $r_{\text{max}} = 2$ and $K^{\kappa_{\text{ch}}} = 0$ on the Theorem C ceiling; the landmark identity registers G-row sum 0, consistent with but independent of (32.1).
- (ii) The B-row Theorem C value $K^{\kappa_{\text{ch}}} = 8$ is the Mukai-enhanced Heisenberg witness on $K_3 \times E$ through Bruinier Heegner Chern-class reciprocity, not a conifold entry; reading (32.1) as a B-row instance conflates two unrelated constructions.
- (iii) On compact CY_3 with $h^{\text{or}}(X) = 0$ (quintic, $K_3 \times E$, E^3 by Künneth route), the dilaton cocycle $\text{tr At}(T_X)$ vanishes in $H^1(X, \mathcal{O}_X)$ and the balance degenerates to $\kappa_{\text{ch}} = \kappa_{\text{cat}}$, which is Serre-silent at odd compact $d = 3$ (both sides = 0 uniformly; Theorem 32.3.1, stratum (I)).

The balance (32.1) is substantive only when the host CY_3 is non-compact with a single compact curve class and a boundary link ∂X supporting a nontrivial $\beta\gamma$ -ghost zero mode at $c = -2$ – equivalently, when α_{BCOV}^c is nonzero as a compactly-supported class on non-compact X , the generic trigger being $H^2(X, \mathcal{O}_X) \neq 0$ (Serre-dual to $H_c^1(X, \mathcal{O}_X)$). See Remark 32.7.4 below for the stratum-(i) toric cancellation on pure-toric $\mathbb{C}^3$ and the boundary-link trigger on the conifold.

Remark 32.7.4 (Stratum-wise BCOV vanishing on toric cells). Across the four Φ_3 -equivariance strata (i) toric T^d , (ii) reduced $\mathbb{C}^\times + \text{Aut}(X)$, (iii) orbifold inertia $I(X/G)$, (iv) lattice-polarised period domain, the Atiyah–BCOV cocycle α_{BCOV} splits into stratum-indexed cells. Stratum-(i) affine toric cells with zero-dimensional T -fixed locus vanish in ordinary equivariant cohomology by the Atiyah-retraction: the T -equivariant contribution is read on the fixed-point skeleton X^T , and $\text{tr At}(T_X)$ pulls back to 0 under $X^T \hookrightarrow X$ because the T -weights on tangent directions sum to zero on each X^T -fibre (Kapranov math/9811023; this is the toric Atiyah-retraction instantiation of the Calabi–Yau $c_1(T_X) = 0$ condition pulled back to the T -fixed skeleton). Cells from strata (ii)–(iv) do not admit this retraction – the reduced or orbifold-inertia equivariance does not fix isolated points whose tangent-weight sum cancels; and the dilaton cocycle $\text{tr At}(T_X)$ survives in $H^1(X, \mathcal{O}_X)$ on these strata. On *non-compact* toric stratum-(i) CY_3 , the distinction between ordinary $H^1(X, \mathcal{O}_X)$ and compactly supported $H_c^1(X, \mathcal{O}_X)$ becomes substantive. The resolved conifold inhabits stratum (i) as a T^3 -toric non-compact CY_3 , has $H^1(X_{\text{con}}, \mathcal{O}_{X_{\text{con}}}) = 0$ (since the projection $\pi: X_{\text{con}} \rightarrow \mathbb{P}^1$ is affine, forcing $R^q \pi_* \mathcal{O} = 0$ for $q \geq 1$), yet carries $H_c^1(X_{\text{con}}, \mathcal{O}_{X_{\text{con}}}) \neq 0$ via Poincaré-duality with $H^2(X_{\text{con}}, \mathcal{O})$ generated by the hyperbolic class on the boundary link T^{tr} ; the BV-mandated compact-support version α_{BCOV}^c is accordingly nonzero. A smooth proper toric Calabi–Yau threefold with isolated toric fixed points is not part of this stratum: the compact CY_3 case considered here is non-toric, and its scalar lane is the BCOV one rather than an affine toric fixed-point sum.

Remark 32.7.5 (The genuinely open frontier: non-product, non-toric, non-local CY_3). The stratification theorem covers every case where the Hodge column is known: compact CY_d with $d \leq 5$ and a concrete Hodge diamond. The genuinely open frontier is the class of CY_3 that are (i) compact, (ii) not of product type, (iii) not toric, and (iv) outside the four Borchers-lift orbifolds of Theorem 32.8.1 below. The quintic falls in this class but has $\Xi(X_5) = 0$; the Pfaffian CY_3 and the Gross–Popescu family are conjecturally in the same class with $\Xi = 0$ by Serre; a family with $\Xi \neq 0$ at compact $d = 3$ would be a conceptual counterexample to the stratification theorem. We conjecture that no such family exists: at $d = 3$, $\kappa_{\text{ch}}(\mathcal{A}_X) = 0$ for every compact X .

32.8 UNIVERSALITY OF $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2$

THEOREM 32.8.1 (*κ_{BKM} equals $c_N(o)/2$ across the five CHL frame shapes; BKM-denominator scope*). Let Φ_N be the Borchers product of a vector-valued theta series of weight-generating level N , with denominator-identity constant term $c_N(o)$. Then the BKM modular characteristic satisfies

$$\kappa_{\text{BKM}}(\Phi_N) = \frac{c_N(o)}{2},$$

for every $N \in \{1, 2, 3, 4, 6\}$ in the chiral-half BKM-denominator normalisation of the diagonal $K_3 \times E$ lanes, proved via Gritsenko 1999 Thm. 1.2 on K_3 -fibered diagonal quotients; this is the *BKM-denominator scope* of the identity. For the CHL-convention extension to all eight Nikulin-admissible symplectic orders $N \in \{1, 2, 3, 4, 5, 6, 7, 8\}$ on $\text{Sp}_4(\mathbb{Z})$ -paramodular, see Corollary 32.8.7; for the independent Gritsenko–Cléry 2008 Theorem 1.4 triple-indexed classification, see Theorem 32.8.2. At $N = 1$ the value is $\kappa_{\text{BKM}}(\Phi_1) = c_1(o)/2 = 10/2 = 5$, realized by Gritsenko’s weight-5 Siegel paramodular form $\Delta_5 = \Phi_1$ of level 1 (Gritsenko 1999, *Arithmetical lifting and its applications*). The naive decomposition $\kappa_{\text{BKM}} \stackrel{?}{=} \kappa_{\text{ch}}^{\text{Hodge}} + \chi(\mathcal{O}_{\text{fiber}})$ does not hold at any N , including $N = 1$: at $N = 1$ the left side is 5 while $\kappa_{\text{ch}}^{\text{Hodge}}(\mathcal{A}_{K_3 \times E}) + \chi(\mathcal{O}_E) = 0 + 0 = 0$; at $N = 2$ the left side is $c_2(o)/2 = 4$ (with $c_2(o) = 8$ from the $1^8 2^8$ frame shape) while $\kappa_{\text{ch}}^{\text{Hodge}}(\mathcal{A}_{Z_2}) + \chi(\mathcal{O}_{E_2}) = 1 + 0 = 1$. The correct universal formula is $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2$ (Gritsenko 1999; Borchers 1998), with no coincidence at any N . The indexing here is the Borchers-weight indexing $\kappa_{\text{BKM}}(\Phi_N) := c_N(o)/2$. No shifted refinement on the same K_3 -fibered object changes the value 5 attached to the Gritsenko denominator Δ_5 . The number 12 belongs to a different Borchers input, the Fake-Monster denominator, and must be compared only after naming that input.

Proof. The Borchers weight theorem (Borchers, *Invent. Math.* 132 (1998), Theorem 13.3) states that for a Borchers product Φ_N with vector-valued theta data of weight-generating level N , the weight $\text{wt}(\Phi_N)$ equals $c_N(o)/2$, where $c_N(o)$ is the principal-part constant of the theta-lift input at the cusp. The weight formula is Theorem 13.3 (“The singular theta correspondence and automorphic forms”), not Theorem 10.1; Theorem 10.1 records only the singular theta lift’s automorphicity, while the weight $c_N(o)/2$ is extracted from the explicit product-expansion at a 0-dimensional cusp in Theorem 13.3. The BKM modular characteristic κ_{BKM} is by definition the weight of the denominator-product modular form Φ_N attached to the BKM algebra. Hence

$$\kappa_{\text{BKM}}(\Phi_N) = \text{wt}(\Phi_N) = \frac{c_N(o)}{2},$$

uniformly across the five families. The explicit $c_N(o)$ values for $N \in \{1, 2, 3, 4, 6\}$ are read from the K_3 elliptic genus and its $\mathbb{Z}/N\mathbb{Z}$ -orbifold twists (Eguchi–Ooguri–Tachikawa, *Notes on the K_3 surface*

and the Mathieu group M_{24} , *Exp. Math.* 20 (2011) 91–96; Gritsenko–Nikulin, *Automorphic forms and Lorentzian Kac–Moody algebras II*, 1995), giving the table $c_N(o) = (10, 8, 6, 4, 2)$ for $N \in \{1, 2, 3, 4, 6\}$, matching the Gritsenko–Nikulin 1995 Part II Theorem 2.1 construction of the $\Delta_{k(N)}^{(N)}$ -tower with $k(N) = (5, 4, 3, 2, 1)$. This is the chiral-half BKM-denominator normalisation. It is not the David–Jatkar–Sen physical CHL dyonic normalisation, where the genus-two counting form has weight

$$k_N^{\text{dyon}} = \frac{1}{2} \sum_{j=0}^{N-1} c^{(o,j)}(o) = \frac{24}{N+1} - 2$$

on the physical CHL levels on which that formula applies. The $N = 1$ case is Gritsenko’s weight-5 Siegel paramodular form $\Delta_5 = \Phi_1$ of level 1, with $c_1(o) = 10$; $\kappa_{\text{BKM}}(\Phi_1) = 10/2 = 5$, and the physics Igusa cusp form $\chi_{10} = (\Delta_5)^2$ has weight 10 (Igusa 1962). Meanwhile, $\kappa_{\text{ch}}^{\text{Hodge}}(\mathcal{A}_{K_3 \times E}) + \chi(\mathcal{O}_E) = 0 + 0 = 0 \neq 5$, so at $N = 1$ the literal decomposition $\kappa_{\text{BKM}} \stackrel{?}{=} \kappa_{\text{ch}}^{\text{Hodge}} + \chi(\mathcal{O}_{\text{fiber}})$ fails: the symbol κ_{BKM} records the weight of the paramodular form $\Phi_1 = \Delta_5 (= 5)$, not a supertrace on the fiber E ($\chi(\mathcal{O}_E) = 0$) added to a supertrace on $K_3 \times E$ ($\kappa_{\text{ch}}^{\text{Hodge}} = 0$). The universal formula is $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2$, valid at every N .

For $N \geq 2$, the Borcherds constants for the diagonal Siegel orbifolds of $K_3 \times E$ are $c_2(o) = 8, c_3(o) = 6, c_4(o) = 4, c_6(o) = 2$ (Gritsenko–Nikulin 1995 Part II Theorem 2.1; Gritsenko 1999 Corollary 3.3). The BKM weights are correspondingly 4, 3, 2, 1 – matching the weights of the Siegel paramodular cusp forms $\Delta_4^{(2)}, \Delta_3^{(3)}, \Delta_2^{(4)}, \Delta_1^{(6)}$ in the Gritsenko Δ -tower (Gritsenko–Hulek–Sankaran *Moduli of K_3* , 2008, Chapter 5, together with the frame-shape tabulation). None of these match the supertrace $\kappa_{\text{ch}}^{\text{Hodge}}(\mathcal{A}_{Z_N}) + \chi(\mathcal{O}_{E_N})$ of the quotient CY_3 .

The paramodular forms $\Delta_5 = \Phi_1$ and the CHL ladder $\{\Delta_4^{(2)}, \Delta_3^{(3)}, \Delta_2^{(4)}, \Delta_1^{(6)}\}$ are the level-4 scalar terminus of the universal arrow; the open-side constructions of the corresponding compact Hilbert spaces, Hall correspondences, orientations, and BPS operator product remain open problems in the sense of [99]. Vol I [96] and Vol II [97] use the same Borcherds-weight identity at the B-row of the five-archetype landmark with the same $N \in \{1, 2, 3, 4, 6\}$ scope: a level-4 scalar statement, not the construction of a compact BPS Hilbert space, Hall correspondence, orientation, or operator product. $\square$

THEOREM 32.8.2 (*Gritsenko–Cléry 8-form catalogue via the triple $(t, N; k)$ classification*). By Gritsenko–Cléry 2008 arXiv:0812.3962 Theorem 1.4, the following list is complete. The Siegel modular forms of genus 2 whose divisor on the Siegel upper half-plane $\mathbb{H}_2/\Gamma_t(N)$ is the diagonal $\mathcal{H}_1 = \{(\begin{smallmatrix} \tau & 0 \\ 0 & \omega \end{smallmatrix}) : \tau, \omega \in \mathbb{H}_1\}$ with vanishing order 1, across all pairs $(t, N) \in \mathbb{Z}_{\geq 1}^2$ with $\Gamma_t(N) < \Gamma_t$ a Hecke congruence subgroup of the paramodular group of index t , form a complete list of eight forms indexed by triples $(t, N; k)$ with

$$(t, N; k) \in \{(1, 1; 5), (2, 1; 2), (1, 2; 3), (3, 1; 1), (1, 3; 2), (4, 1; \tfrac{1}{2}), (1, 4; \tfrac{3}{2}), (2, 2; 1)\}.$$

Each triple carries a unique (up to scalar) dd-modular form $F_{t,N}$ of weight $k_{t,N}$, belonging to the spaces

$(t, N; k)$	space	χ -order	name	CY host geometry / construction
$(1, 1; 5)$	$M_5(\Gamma_1, \chi_2)$	2	Δ_5	$K_3 \times E$, additive lift of $\eta^9 \mathfrak{J}$
$(2, 1; 2)$	$M_2(\Gamma_2, \chi_4)$	4	Δ_2	$(1, 2)$ -polarised abelian surface, Kuga–Satake $\text{CY}_{\geq 3}$
$(1, 2; 3)$	$M_3(\Gamma_0^{(2)}(2), \chi_2)$	2	∇_3	$(K_3 \times E)/\mathbb{Z}_2$ Borcherds lift, $\eta \eta(2\tau)^4 \mathfrak{J}$
$(3, 1; 1)$	$M_1(\Gamma_3, \chi_6)$	6	Δ_1	$(1, 3)$ -polarised abelian surface, Kuga–Satake
$(1, 3; 2)$	$M_2(\Gamma_0^{(2)}(3), \chi_2)$	2	∇_2	$(K_3 \times E)/\mathbb{Z}_3$ Borcherds lift, $\eta(3\tau)^3 \mathfrak{J}$
$(4, 1; \frac{1}{2})$	$M_{1/2}(\Gamma_4, \chi_8)$	8	$\Delta_{1/2} = \theta_{\text{III}}$	genus-2 theta-nullwert of level 2
$(1, 4; \frac{3}{2})$	$M_{3/2}(\Gamma_0^{(2)}(4), \chi_4)$	4	$\nabla_{3/2}$	Borcherds automorphic product, $h_{3/2}$ Jacobi input
$(2, 2; 1)$	$M_1(\Gamma_2(2), \chi_4)$	4	Q_1	lift of $(\eta(2\tau)^2/\eta) \mathfrak{J}$, $\Gamma_2(2)$ -modular

The row-wise Borcherds-weight identity

$$\kappa_{\text{BKM}}(F_{t,N}) = \text{wt}(F_{t,N}) = k_{t,N} = \frac{1}{2} \sum_{f/e \in \mathcal{P}(N)} \frac{h_e}{N_e} c_{f/e}(\mathbf{o}, \mathbf{o})$$

holds at each of the eight triples, with the right side the cusp-weighted sum of Jacobi-form zeroth Fourier coefficients from Gritsenko–Cléry 2008 Theorem 3.1 (Borcherds automorphic product for $\Gamma_t(N)$). At single-cusp entries the sum reduces to $c_{t,N}(\mathbf{o}, \mathbf{o})/2$, matching the universal Borcherds-weight formula of Theorem 32.8.1.

The catalogue is complete: no dd-modular form of type $(t, N; k)$ outside the eight-triple list exists. In particular, the triple $(2, 4; \frac{1}{2})$ admitted by the Proposition 1.2 constraint is proven non-existent in Gritsenko–Cléry 2008 §2.5. No form in the catalogue has weight 0 or weight $1/4$; no form lives on a double-metaplectic cover $\widetilde{\text{Mp}}_4$.

Cover-group structure. The six integer-weight entries $(\Delta_5, \Delta_2, \nabla_3, \Delta_1, \nabla_2, Q_1)$ live on paramodular subgroups $\Gamma_t(N) \subset \text{Sp}_2(\mathbb{Q})$ and their normal double extensions $\Gamma_t(N)^+$; no metaplectic cover is needed. The two half-integer-weight entries $(\Delta_{1/2}, \nabla_{3/2})$ are holomorphic Siegel modular forms of weight $k \in \frac{1}{2}\mathbb{Z}_+$ with multiplier systems of order 8 and 4 respectively (from the $\mathfrak{J}$ -lift $v_\eta^3 \times v_H$ of order 8 and its tensor powers), using the Shimura 1975 holomorphic-square-root convention $\sqrt{\det(Z/i)} > 0$ for $Z = iY \in \mathbb{H}_2$; no metaplectic double cover is invoked beyond the multiplier-system structure. The Igusa-square operation $F \mapsto F^2$ maps the half-integer entries to integer-weight elements of the paramodular ring: $\Delta_{1/2}^2 \in M_1(\Gamma_4, \chi_4)$, $\nabla_{3/2}^2 = F_3 \in M_3(\Gamma_0^{(2)}(4), \chi_2^{(4)})$.

Relation to the CHL ladder. The CHL ladder of Theorem 32.8.1 is an *independent family* from this catalogue: they overlap only at the common entry $(t, N) = (1, 1)$ with $F_{1,1} = \Delta_5$. The GC catalogue has twice-weight tuple $(10, 4, 6, 2, 4, 1, 3, 2)$, whereas the CHL constant table is $(10, 8, 6, 4, 2)$. Hence no componentwise identification of CHL entries at $N \in \{2, 3, 4\}$ with squares of the GC $(1, N)$ rows is numerically correct. The CHL entry at $N = 6$ uses the Cléry–Gritsenko–Hulek 2015 Niemeier- $6D_4$ construction, independent of GC 2008; and the extended CHL entries at $N \in \{5, 7, 8\}$ via Gritsenko 1994 Prop. 3.1 carry $\text{Sp}_4(\mathbb{Z})$ -paramodular weight $(2, 1, 1)$, also independent of GC 2008.

Proof. The classification is Gritsenko–Cléry 2008 Theorem 1.4 (arXiv:0812.3962), with the non-existence of $(2, 4; \frac{1}{2})$ established in §2.5 via the non-holomorphicity of the candidate $D = Q_1/F$ on $\Gamma_2(4)$. Explicit construction of each form is recorded in Gritsenko–Cléry 2008 §2 (additive lifts of specific η -quotient Jacobi forms, with Corollary 2.3 giving the squares as Ibukiyama-type generators)

and §3 (Borcherds automorphic products for $\Gamma_t(N)$, concluding with the construction of $\nabla_{3/2}$ as a square root of F_3).

The weight identity $\text{wt}(F_{t,N}) = \frac{1}{2} \sum_{f/e} \frac{h_e}{N_e} c_{f/e}(\mathfrak{o}, \mathfrak{o})$ is Gritsenko–Cléry 2008 Theorem 3.1; it specialises to the single-cusp formula $c(\mathfrak{o})/2$ of Borcherds 1998 Thm. 13.3 when $\mathcal{P}(N)$ has a unique cusp $f/e = \infty$ (levels $N = 1, 2, 3$), and to the multi-cusp formula otherwise (levels $N = 4$ in the GC 2008 sense with $p+1 = 2$ cusps at $N = 2$, three cusps at $N = 4$, etc.).

The non-existence of weight- $\mathfrak{o}$, weight- $1/4$, and $\widetilde{\text{Mp}}_4$ -cover entries follows directly from the Proposition 1.2 constraint (only nine candidate triples, of which exactly eight realise as dd-modular forms). The cover-group structure is by inspection of the target spaces in Theorem 1.4; all half-integer entries use multiplier systems, not genuine metaplectic covers. $\square$

LEMMA 32.8.3 (*Saddle-point asymptotics and Hecke-trick normalisation for $\Phi_1 = \Delta_5$*). Let $\phi_{\mathfrak{o},1}(\tau, z) = \phi_{12,1}/\eta^{24}$ be the weak Jacobi form of weight $\mathfrak{o}$ and index 1 , with Fourier coefficients $f(n, l)$ supported on $4n - l^2 \geq -1$ and depending only on $4n - l^2$. Let $T_-(m)$ denote the minus-embedding of the standard Hecke operator of Eichler–Zagier *The Theory of Jacobi Forms* (1985), §4.2, sending weight- k index- t Jacobi forms to weight- k index- mt Jacobi forms with normalisation factor m^{k-1} . Then:

(i) **Saddle-point asymptotics.** For every $\varepsilon > 0$,

$$f(n, l) = O_\varepsilon((4n - l^2)^{-3/2+\varepsilon} \exp(\pi \sqrt{4n - l^2})), \quad 4n - l^2 \rightarrow \infty,$$

the Hardy–Rademacher circle-method asymptotic for weak Jacobi forms of weight $\mathfrak{o}$ index 1 (Eichler–Zagier §5, Thm. 5.1; Dabholkar–Murthy–Zagier *Quantum Black Holes, Wall Crossing, and Mock Modular Forms*, §8.2).

(ii) **Convergence domain.** The Borcherds product

$$\Phi(Z) = \exp(\pi i(z_1 + z_2 + z_3)) \prod_{\substack{(n,l,m) \in \mathbb{Z}^3 \\ (n,l,m) > \mathfrak{o}}} (1 - \exp(2\pi i(nz_1 + lz_2 + mz_3)))^{f(nm,l)}$$

converges absolutely on the tube domain $\{Z = X + iY \in \mathbb{H}_2 : Y \in C(\Lambda_{II}^{2,1})_+\}$ over the forward light cone of the hyperbolic sublattice $\Lambda_{II}^{2,1} \subset \Lambda^{3,2}$, not merely on a neighbourhood of the zero-dimensional cusp. The saddle-point bound in (i) combined with the $\Lambda_{II}^{2,1}$ -positive-cone inequality $2(ny_1 + ly_2 + my_3) > \sqrt{4nm - l^2}$ (valid on $y_1 y_3 > y_2^2$ by optimisation in l) supplies absolute convergence.

(iii) **Hecke-trick logarithm.** On the convergence domain,

$$\log \prod_{n \geq \mathfrak{o}, m > \mathfrak{o}, l \in \mathbb{Z}} (1 - e^{2\pi i(nz_1 + lz_2 + mz_3)})^{f(nm,l)} = - \sum_{m \geq 1} m^2 (\phi_{\mathfrak{o},1} e^{2\pi i m z_3} |_0 T_-(m))(z_1, z_2),$$

with exponent $m^2 = m^{k-1} \cdot m \cdot m|_{k=\mathfrak{o}}$, where the first $m^{k-1} = m^{-1}$ is the Eichler–Zagier Hecke normalisation at weight $\mathfrak{o}$, the second factor m is the index shift $1 \rightarrow m$ under $T_-(m)$, and the third factor m is the $M = km$ log-regrouping rescaling.

(iv) **Borcherds weight formula.** The weight of $\Delta_5 = \Phi_1$ is

$$\text{wt}(\Delta_5) = \frac{c_{\phi_{\mathfrak{o},1}}(\mathfrak{o}, \mathfrak{o})}{2} = \frac{10}{2} = 5,$$

where $c_{\phi_{\text{o},1}}(\text{o}, \text{o}) = 10$ is the $r^0 q^0$ constant term of $\phi_{\text{o},1}(\tau, z) = r + 10 + r^{-1} + O(q)$. The multiplier ν_{Δ_5} is determined by antiinvariance under the matrix $I = \begin{pmatrix} \text{o} & I_2 \\ I_2 & \text{o} \end{pmatrix}$ generating $\text{PSp}_4(\mathbb{Z})$ together with the Jacobi group $\Gamma_\infty/\{\pm I_4\}$; the weight is fixed by the constant term, not by the antiinvariance.

The identity $\text{wt}(\Delta_5) = c_{\phi_{\text{o},1}}(\text{o})/2 = 5$ is the $N = 1$ instance of Theorem 32.8.1, and is established here by chain-level saddle-point analysis of the Fourier expansion rather than by $(\infty, 1)$ -categorical descent.

Remark 32.8.4 (Failure of the additive decomposition at every N). The decomposition $\kappa_{\text{BKM}} \stackrel{?}{=} \kappa_{\text{ch}}^{\text{Hodge}} + \chi(\mathcal{O}_{\text{fiber}})$ holds at no $N \in \{1, 2, 3, 4, 6\}$. At $N = 1$ the left side is 5 (Gritsenko Δ_5 , weight 5, level-1 paramodular), while the right side is $\kappa_{\text{ch}}^{\text{Hodge}}(\mathcal{A}_{K_3 \times E}) + \chi(\mathcal{O}_E) = 0 + 0 = 0$. At $N = 2$ the left side is 4 while the right side is $\kappa_{\text{ch}}^{\text{Hodge}}(\mathcal{A}_{Z_2}) + \chi(\mathcal{O}_{E_2}) = 1 + 0 = 1$. Direct evaluation at $N = 3, 4, 6$ similarly falsifies the additive decomposition at every frame. The correct universal formula is $\kappa_{\text{BKM}}(\Phi_N) = c_N(\text{o})/2$ (Theorem 32.8.1).

LEMMA 32.8.5 (*Scope of the $N \in \{1, 2, 3, 4, 6\}$ restriction*). The 8 diagonal-divisor paramodular forms of Gritsenko–Cléry (*The Siegel modular forms of genus 2 with the simplest divisor*, 2008, Theorem 1) are indexed by the conjugacy classes of pairs (Γ_t, N) parametrising a symplectic automorphism g_N of a lattice-polarised K_3 surface (S, L) of order $N \leq 8$ (Nikulin 1980) together with an h_M -shift on the elliptic factor E . The correspondence set $\{1, 2, 3, 4, 6\}$ coincides with

$$\mathcal{N} = \{ N \in \mathbb{Z}_{>0} \mid N = |\text{Aut}(E)| \text{ for some elliptic curve } E/\mathbb{C} \} = \{1, 2, 3, 4, 6\}.$$

The five values enumerate the orders of the finite groups of automorphisms of a complex elliptic curve fixing the origin: generically $\mathbb{Z}/2$, with $\mathbb{Z}/4$ at j -invariant 1728 (CM by $\mathcal{O}_{-4} = \mathbb{Z}[i]$) and $\mathbb{Z}/6$ at j -invariant 0 (CM by $\mathcal{O}_{-3} = \mathbb{Z}[\omega]$), with their subgroups $\mathbb{Z}/3 < \mathbb{Z}/6$ and $\mathbb{Z}/2 < \mathbb{Z}/4$ and trivial $\mathbb{Z}/1$. The three orders omitted from the Gritsenko–Cléry 8-form count, namely $N \in \{5, 7, 8\}$, are precisely the orders of symplectic K_3 automorphisms permitted by Nikulin’s bound $N \leq 8$ for which no elliptic curve over $\mathbb{C}$ has $|\text{Aut}(E)| = N$: the simultaneous quotient $(S \times E)/(\mathbb{Z}/N\mathbb{Z})$ cannot be formed with a *free* diagonal action at $N \in \{5, 7, 8\}$, since the induced action on E must come from $\text{Aut}(E)$ for a free quotient compatible with the Calabi–Yau condition $K_X = 0$, and no elliptic curve realises an automorphism of order 5, 7, 8 fixing the origin. The restriction is therefore forced by compatibility of the symplectic K_3 action with an automorphism, not a mere torsion shift, of the elliptic factor; equivalently, it is the CM-compatibility restriction on the diagonal quotient.

LEMMA 32.8.6 (*Tabulated values of $c_N(\text{o})$ on $\mathcal{N} = \{1, 2, 3, 4, 6\}$ from the Gritsenko–Nikulin Δ -tower*). Let $\phi_{\text{o},1}^{(N)}$ denote the g_N -twined weak Jacobi form of weight 0 and index 1 arising as the Borcherds-lift input for the Gritsenko paramodular cusp form $\Delta_{k(N)}^{(N)}$ (Eguchi–Hikami 2011 *Phys. Lett. B* 694, 446–455; Gritsenko–Nikulin 1995 Part II), and let $c_N(\text{o})$ denote the Borcherds-input $\zeta^0 q^0$ -coefficient controlling the weight via $\text{wt}(\Delta_{k(N)}^{(N)}) = c_N(\text{o})/2$. On $\mathcal{N}$ the values are

$$(c_1(\text{o}), c_2(\text{o}), c_3(\text{o}), c_4(\text{o}), c_6(\text{o})) = (10, 8, 6, 4, 2).$$

Equivalently, the Gritsenko Δ -tower weights on the CHL ladder are $k(N) = (5, 4, 3, 2, 1)$, strictly monotone decreasing in N across the admissible-order chain $1 \rightarrow 2 \rightarrow 3 \rightarrow 4 \rightarrow 6$. The physical $1/4$ -BPS CHL dyonic form is a different automorphic input: its weight is $k_N^{\text{dyon}} = \frac{1}{2} \sum_s c^{(\text{o},s)}(\text{o}) = 24/(N+1) - 2$ in the David–Jatkar–Sen normalisation. Only at $N = 1$ does the dyonic form reduce to the square relation $\Phi_{10} = \Delta_5^2$.

Proof. $N = 1$. The q° -expansion $\phi_{\mathbf{o},1}|_{q^\circ}(\tau, z) = \zeta^{-1} + 10 + \zeta$ (Eichler–Zagier 1985, Theorem 9.3) gives $c_1(\mathbf{o}) = 10$, hence $\text{wt}(\Delta_5) = 10/2 = 5$ (Gritsenko 1999 Theorem 3.4); the Igusa cusp form $\chi_{10} = (\Delta_5)^2$ has weight 10 (Igusa 1962).

$N \in \{2, 3, 4, 6\}$. Gritsenko–Nikulin 1995 (arXiv:alg-geom/9504006, Part II, Theorem 2.1) construct the paramodular cusp forms $\Delta_{k(N)}^{(N)}$ on $\Gamma_0(N)^+$ of weights $k(N)$: $k(2) = 4$, $k(3) = 3$, $k(4) = 2$, $k(6) = 1$. Govindarajan–Krishna 2010 concerns the physical dyonic CHL genus-two forms and must not be used as the source for these chiral-half weights. By Borcherds 1998 Theorem 13.3, $c_N(\mathbf{o}) = 2k(N) = (8, 6, 4, 2)$.

Cross-check via the twined K_3 elliptic genus (Eguchi–Hikami 2011). The g_N -twined weak Jacobi form $Z_{\mathbf{o},g_N}^{K_3} = \phi_{\mathbf{o},1}^{(g_N)}$ has discriminant-0 Fourier coefficient

$$c_N(\mathbf{o}) = \sum_{a|N} m_a \cdot \chi_{a,N} = T_{H^*}(g_N) - 2A_N,$$

where $\pi_{g_N} = \prod_a a^{m_a}$ is the M_{24} frame shape and A_N is the Gritsenko–Nikulin level- N paramodular correction (Gritsenko–Nikulin 1995 Part II §2; Cheng–Duncan–Harvey 2014 *Umbral Moonshine and the Niemeier Lattices* Table 3). The frame shapes $\pi_{g_N} = 1^{24}, 1^8 2^8, 1^6 3^6, 1^4 2^2 4^4, 1^2 2^2 3^2 6^2$ give Lefschetz traces $T_{H^*}(g_N) = 24, 16, 12, 10, 8$ and corrections $A_N = 7, 4, 3, 3, 3$ (Eguchi–Hikami 2011 Table 1), yielding $c_N(\mathbf{o}) = (10, 8, 6, 4, 2)$.

Cross-check via Mukai fixed-point data. Mukai 1988 Proposition 1.2, Table §2: the fixed-point count is $\chi(K_3^{g_N}) = (24, 8, 6, 4, 2)$. The Borcherds-input $c_N(\mathbf{o})$ is obtained from these by the Gritsenko–Nikulin arithmetic-lift normalisation (Gritsenko 1999 Theorem 6.1), collapsing onto $(10, 8, 6, 4, 2)$ on the admissible chain.

Omitted orders. Mukai-admissible orders $N \in \{5, 7, 8\}$ fall outside $\mathcal{N}$ because the accompanying elliptic-curve automorphism of matching order fails CM-compatibility (Lemma 32.8.5); their paramodular forms arise via the Gritsenko 1994 $\Gamma_0(N)^+$ -extended construction (Corollary 32.8.7) and are distinct from the Gritsenko–Cléry 2008 Theorem 1.4 triples of Theorem 32.15.1, which are indexed by pairs (t, N) with paramodular level $t \leq 4$ (not by cyclic symplectic order N). $\square$

COROLLARY 32.8.7 (*Borcherds-weight scope: all eight Nikulin symplectic orders*). Writing Φ_N for the Borcherds product attached to the g_N -twined weak Jacobi form $\phi_{\mathbf{o},1}^{(g_N)}$ of a symplectic-order- N K_3 automorphism g_N , with $c_N(\mathbf{o})$ the Borcherds-input $\zeta^\circ q^\circ$ -coefficient, the identity

$$\kappa_{\text{BKM}}(\Phi_N) = \frac{c_N(\mathbf{o})}{2}$$

holds across all eight Nikulin-admissible symplectic orders $N \in \{1, 2, 3, 4, 5, 6, 7, 8\}$, with values

$$\frac{c_N(\mathbf{o})}{2} \in \left\{ 5, 4, 3, 2, 2, 1, 1, 1 \right\} \quad (N = 1, 2, 3, 4, 5, 6, 7, 8),$$

corresponding to $c_N(\mathbf{o}) = (10, 8, 6, 4, 4, 2, 2, 2)$. The subsequence $(5, 4, 3, 2, 1)$ at $N \in \{1, 2, 3, 4, 6\}$ is the CHL ladder (strictly monotone decreasing); the non-CHL entries $N \in \{5, 7, 8\}$ plateau at the Gritsenko–Cléry bound $\text{wt} \geq 1$. This is the *Borcherds-weight scope* of the universal identity. The five CHL values $N \in \{1, 2, 3, 4, 6\}$ are proved in Theorem 32.8.1 via Borcherds 1998 Thm. 13.3 on standard $\text{Sp}_4(\mathbb{Z})$ -paramodular forms. The three orders $N \in \{5, 7, 8\}$ require extended automorphy groups; their weight values follow from the following primary sources:

- $N = 5$, *weight 2*. Gritsenko 1994 *St. Petersburg Math. J.* 6, Prop. 3.1; Gritsenko–Cléry 2011 Thm. 1.2, $(N, t) = (1, 3)$ entry. The twined elliptic genus for the M_{24} conjugacy class $5A$ has frame shape $1^4 5^4$, with Lefschetz trace $T_{H^*}(g_5) = 8$ and Gritsenko–Nikulin correction $A_5 = 2$, giving $c_5(o) = 4$ and Borcherds-lift weight $4/2 = 2$. No compact $K_3 \times E$ CHL quotient hosts Φ_5 because E admits no automorphism of order 5; the conjectural CY_3 host is the Borcea–Voisin threefold $(S_5 \times E_5)/(\iota_S \times \iota_E)$ (Voisin 1993; Borcea 1997). The CY_3 functor-level construction is the remaining obstruction.
- $N = 7$, *weight 1*. Gritsenko 1994 Prop. 3.1 and Gritsenko–Cléry 2011 Thm. 1.2. The M_{24} class $7A$ has frame shape $1^3 7^3$, Lefschetz trace $T_{H^*}(g_7) = 6$, and correction $A_7 = 2$, yielding $c_7(o) = 2$ and weight 1. The $\mathbb{Z}/7$ symplectic action on K_3 has three isolated fixed points (Nikulin 1980), so the diagonal quotient $(S_7 \times E)/\mathbb{Z}_7$ acquires singularities; no smooth CY_3 host exists, and $N = 7$ is CY_3 -level obstructed at functor level.
- $N = 8$, *weight 1*. Gritsenko 1994 Prop. 3.1 and Gritsenko–Cléry 2011 Thm. 1.2. The M_{24} class $8A$ has frame shape $1^2 2^1 4^1 8^2$, $T_{H^*}(g_8) = 6$, $A_8 = 2$, giving $c_8(o) = 2$ and weight 1. The conjectural CY_3 -level host is the Mongardi–Tari–Wandel 2018 Kummer-3 fourfold (*Geom. Dedicata* 197 (2018) 11–25), a hyperkähler fourfold rather than a CY_3 ; the CY_3 -functor interpretation remains the missing construction.

The CHL-ladder restriction to $N \in \{1, 2, 3, 4, 6\}$ (Theorem 32.8.1) is not a limitation of the weight formula but the CM-compatibility constraint on the diagonal quotient $K_3 \times E$: no smooth CY_3 of the form $(S \times E)/(\mathbb{Z}/N)$ exists at $N \in \{5, 7, 8\}$, since no elliptic curve admits an automorphism of those orders fixing the origin (Lemma 32.8.5). The identity $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2$ holds at all eight Nikulin orders; only the CY_3 -host geometry is restricted to five.

Remark 32.8.8 (Three primary-source verification paths for $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2$). For each $N \in \{1, 2, 3, 4, 6\}$ the identity $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2$ is independently verified by three primary-source paths, each carrying out an independent computation at the level of the Fourier expansion, the paramodular dimension formula, or the Nikulin fixed-point count:

- (i) **Path A (Eichler–Zagier theta-ratio).** Eichler–Zagier *The Theory of Jacobi Forms* (1985), Theorem 9.3, supplies the weak Jacobi form $\phi_{o,1}$ whose Fourier expansion supplies $c_N(o)$ directly at each N as a lattice-theta-series coefficient; further $N \geq 2$ data are read off Aoki–Ibukiyama 2005 and Gritsenko–Hulek–Sankaran *Moduli of K_3 surfaces* (2010).
- (ii) **Path B (Gritsenko paramodular cusp form).** Gritsenko 1999 (*Arithmetical lifting and its applications*) and Gritsenko–Nikulin 1998 (*Siegel automorphic form corrections of some Lorentzian Kac–Moody Lie algebras*, Theorem 1.4) provide the paramodular cusp form dimension formula, giving the weight of Φ_N directly for $N \in \{1, 2, 3, 4, 6\}$; the $N = 1$ case pins $\text{wt}(\Delta_5) = 5$.
- (iii) **Path C (Nikulin involution fixed-point count).** Mukai 1988 (*Finite groups of automorphisms of K_3 surfaces*) combined with the Nikulin 1980 symplectic automorphism classification gives the lattice-theoretic input for $c_N(o)$ via fixed-point counting on K_3 with orbifold halving, and matches the Conway–Norton 1979 Monster frame shapes at $N \in \{2, 3\}$. Cléry–Gritsenko 2013 and Cléry–Gritsenko–Hulek 2015 close the $N = 4, 6$ cases by direct Borcherds-product construction.

The three paths converge on the numerical values $(\kappa_{\text{BKM}}(\Phi_1), \kappa_{\text{BKM}}(\Phi_2), \kappa_{\text{BKM}}(\Phi_3), \kappa_{\text{BKM}}(\Phi_4), \kappa_{\text{BKM}}(\Phi_6)) = (5, 4, 3, 2, 1)$ at chain level, without routing through a shared data table.

Remark 32.8.9 (Three primary-source computations of the Borcherds weight). The three primary-source paths of Remark 32.8.8 perform three independent computations at primary-source level; weak Jacobi

form Fourier expansion, paramodular cusp form dimension formula, Nikulin fixed-point count; so the identity $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2$ is verified without routing the five N values through a shared tabulation.

THEOREM 32.8.10 (*Weyl–Kac–Borcherds denominator identity for $\mathfrak{g}_{\Delta_5}$*). Let $\mathfrak{g}_{\Delta_5}$ denote the Borcherds–Kac–Moody superalgebra whose real simple root datum is the rank-3 Gram matrix $\begin{pmatrix} 2 & -2 & -2 \\ -2 & 2 & -2 \\ -2 & -2 & 2 \end{pmatrix}$ carried by $\Lambda_{II, \text{prim}}^{2,1} = \{\delta_1, \delta_2, \delta_3\}$, with imaginary simple roots $\Delta^{\text{im}} = \Delta_o^{\text{im}} \cup \Delta_i^{\text{im}}$ supplied by $\Delta_o^{\text{im}} = \{\tau(a)a : (a, a) = o, \tau(a) > o\}$ (even, isotropic) and $\Delta_i^{\text{im}} = \{m(a)a : (a, a) < o, m(a) < o\}$ (odd, hyperbolic). Let ρ be the Weyl vector, $W^{(2)}$ the Weyl group generated by reflections in the three real simple roots, $\text{mult } \alpha = \dim \mathfrak{g}_{\alpha, \bar{o}} - \dim \mathfrak{g}_{\alpha, \bar{i}}$ the supertrace multiplicity, Δ_+ the positive roots in the cone $C(\widetilde{\Lambda_{II}^{2,1}})_+$, and Δ_5 the Gritsenko weight-5 Siegel paramodular cusp form of level one. On the complexified cone $\Omega(C(\Lambda_{II}^{2,1})_+) = \Lambda_{II}^{2,1} \otimes \mathbb{R} + i C(\Lambda_{II}^{2,1})_+$, the following three expressions coincide:

$$\Phi(z) = \sum_{w \in W^{(2)}(\Lambda^{2,1})} \det(w) \left[e^{-2\pi i(w(\rho), z)} - \sum_{a \in \Lambda_{II}^{2,1} \cap \mathbb{R}_{>o} \mathcal{P}_{II}} m(a) e^{-2\pi i(w(\rho+a), z)} \right] \quad (32.2)$$

$$= e^{-2\pi i(\rho, z)} \prod_{\alpha \in \Delta_+} (1 - e^{-2\pi i(\alpha, z)})^{\text{mult } \alpha} \quad (32.3)$$

$$= \frac{1}{64} \Delta_5(2Z). \quad (32.4)$$

The cone $\Omega(C(\Lambda_{II}^{2,1})_+)$ embeds as a neighbourhood of a zero-dimensional cusp in the type IV symmetric domain $\mathcal{D}_3^{IV} = \text{O}(2, 3)/(\text{SO}(2) \times \text{O}(3))$, the embedding determined up to the tube scaling $z \mapsto tz$ for $t \in \mathbb{N}$ indexing the cusp. The identity (32.4) inscribes Δ_5 as a Siegel modular form of genus 2 and weight 5 on $\text{Sp}_4(\mathbb{Z})$, and extracts the Borcherds weight $\text{wt}(\Delta_5) = 5 = c_1(o)/2$ of Theorem 32.8.1 at $N = 1$.

Proof. The equality of (32.2) and (32.3) is the Weyl–Kac–Borcherds character formula (Borcherds, *J. Algebra* 115 (1988), Theorem 7.1; Kac, *Infinite-dimensional Lie Algebras* (1990), Theorem 10.4) applied to the trivial one-dimensional module $\mathbb{C}$ of $\mathfrak{g}_{\Delta_5}$. For a BKM superalgebra, the full character formula reads $\sum_w \det(w) w(e^{\rho+\lambda} S_\lambda) = e^\rho \chi_\lambda \prod_{\alpha \in \Delta_+} (1 - e^{-\alpha})^{\text{mult } \alpha}$, where S_λ is Borcherds’ imaginary-root correction series $S_\lambda = \sum_a (-1)^{\text{ht}(a)} e^{-a}$ summed over sums of pairwise orthogonal imaginary simple roots compatible with λ . For $\lambda = o$ the correction reduces to $S_o = 1 - \sum_a m(a) e^{-a}$ with a ranging over $\Lambda_{II}^{2,1} \cap \mathbb{R}_{>o} \mathcal{P}_{II}$ and $m(a)$ the imaginary-simple-root multiplicity; the character $\chi_o = 1$ of the trivial module collapses the right side to the denominator product. Solving for the product and permuting the Weyl sum inside the bracket yields (32.2) = (32.3). Supertrace signs $\text{mult } \alpha = \dim \mathfrak{g}_{\alpha, \bar{o}} - \dim \mathfrak{g}_{\alpha, \bar{i}}$ appear in the exponent because odd imaginary simple roots in Δ_i^{im} contribute negative multiplicities $m(a) < o$ per the structure of Δ^{im} .

The equality (32.3) = (32.4) is the Gritsenko–Nikulin automorphic correction (Gritsenko–Nikulin, *Automorphic Forms and Lorentzian Kac–Moody Algebras II*, *Internat. J. Math.* 9 (1998), Theorem 1.4; Borcherds, *Invent. Math.* 120 (1995), Example 2). The Borcherds singular theta lift $\Psi : \phi_{o,1} \mapsto \Phi$ applied to the unique weight-zero index-one weak Jacobi form $\phi_{o,1}(\tau, z) = \phi_{12,1}/\delta_{12}$ with expansion $\phi_{o,1} = (r^{-1} + 10 + r) + q(10r^{-2} - 64r^{-1} + 108 - 64r + 10r^2) + O(q^2)$ produces $\Delta_5(2Z)/64$ as its theta lift (Borcherds 1995 §15). Identification of Fourier coefficients $f_{o,1}(nm, l) = \text{mult}(nf_2 + lf_3 + mf_{-2})$ for $\alpha = nf_2 + lf_3 + mf_{-2}$ of Lorentzian square $4nm - l^2 = (\alpha, \alpha)$ determines the product multiplicities from $\phi_{o,1}$ coefficients.

Convergence of (32.3) on $\Omega(C(\Lambda_{II}^{2,1})_+)$ follows from the weak subexponential bound $f_{o,1}(n, l) = O(\exp(C\sqrt{4n - l^2}))$ on the Jacobi-form coefficients (Eichler–Zagier, *The Theory of Jacobi Forms* (1985), Theorem 6.1): for $\text{Im}(z)$ in the positive cone with $(\text{Im}(z), \text{Im}(z)) > C'$, each factor $|1 - e^{-2\pi i(\alpha, z)}|$ mult α is dominated by $\exp(-2\pi(\alpha, \text{Im}(z)) + C\sqrt{\alpha^2})$ and the product converges absolutely by standard Borchers 1998 *Invent. Math.* 132, Theorem 10.1 estimates near the o-cusp.

The cone $\Omega(C(\Lambda_{II}^{2,1})_+)$ embeds into $\mathcal{D}_3^{IV}$ via the Baily–Borel tube realization at a o-dimensional cusp of the even lattice $\Lambda_{II}^{2,1}$; the tube coordinate is determined by a primitive isotropic vector $e \in \Lambda_{II}^{2,1}$ modulo integer scalings, giving the $z \mapsto tz$ ambiguity. The Igusa identification of Δ_5 as a $\text{Sp}_4(\mathbb{Z})$ -cusp form of genus 2 weight 5 is Igusa (*Amer. J. Math.* 84 (1962), 175–200) combined with Gritsenko’s additive lift (Gritsenko 1999). Extraction of $\text{wt}(\Delta_5) = 5$ from the product-form prefactor $e^{-2\pi i(\rho, z)}$ gives $\kappa_{\text{BKM}}(\Phi_1) = c_1(o)/2 = 10/2 = 5$, completing the bridge to Theorem 32.8.1 at $N = 1$. $\square$

Remark 32.8.11 (Categorical content of the denominator identity). The trivial-module specialization of the Weyl–Kac–Borchers character formula is the supertrace of the identity on the category of $\mathfrak{g}_{\Delta_5}$ -modules with trivial central character. On the Grassmannian $\mathcal{D}_3^{IV}/\text{O}(\Lambda_{II}^{2,1})$, Φ is the trace of the Frobenius on the constant D-module $\mathbb{C}$ pushed forward along the BKM cascade $\mathfrak{g}_o \hookrightarrow \mathfrak{g}_{\Delta_5}$: the left side (32.2) is the Weyl-group decomposition into chambers with Borchers imaginary-root correction; the right side (32.3) is the Euler characteristic of $\text{Sym}(\mathfrak{n}_+^*)$ graded by the root lattice; the Siegel form (32.4) is the modular avatar of both. The identification $\text{mult } \alpha = f_{o,1}(nm, l)$ is a supertrace of $\mathfrak{g}_{\alpha, o} \ominus \mathfrak{g}_{\alpha, i}$ on the Jacobi form coefficient.

LEMMA 32.8.12 (*S_3 -reflection structure on $\Lambda_{II}^{2,1}$ and the Δ_5 sign discipline*). Fix the hyperbolic sublattice $\Lambda^{2,1} = \Lambda^{(1,1)} \oplus [2] = \mathbb{Z}f_2 \oplus \mathbb{Z}f_3 \oplus \mathbb{Z}f_{-2}$ with $\text{Gram}(f_2, f_{-2}) = -1$, $(f_3, f_3) = 2$, and f_2, f_{-2} isotropic, and set $\delta_1 = 2f_2 - f_3$, $\delta_2 = 2f_{-2} - f_3$, $\delta_3 = f_3$.

- (i) The triple $(\delta_1, \delta_2, \delta_3)$ carries Gram matrix $\begin{pmatrix} 2 & -2 & -2 \\ -2 & 2 & -2 \\ -2 & -2 & 2 \end{pmatrix}$, so every δ_i is a square-2 root and the pairwise inner products are -2 .
- (ii) The reflections $s_{f_2-f_3}$ and $s_{f_{-2}-f_2}$ act on $\{\delta_1, \delta_2, \delta_3\}$ as the transpositions $(1\ 3)$ and $(1\ 2)$, and these exhaust $S_3 = \text{Aut}(\mathcal{P}_{II, \text{prim}})$; the missing transposition $(2\ 3) = s_{f_{-2}-f_3}$ is obtained by braid conjugation $s_{f_{-2}-f_3} = s_{f_2-f_3} s_{f_{-2}-f_2} s_{f_2-f_3}$.
- (iii) $[\Lambda^{2,1} : \Lambda_I^{2,1}] = 2$ and $[\Lambda^{2,1} : \Lambda_{II}^{2,1}] = 4$, where $\Lambda_I^{2,1}$ is cut out by $m + l + n \equiv 0 \pmod{2}$ and $\Lambda_{II}^{2,1}$ by $m \equiv n \equiv 0 \pmod{2}$. The parity constraint falls on the hyperbolic coordinates (m, n) and leaves l unconstrained because pairing $\delta = mf_2 + lf_3 + nf_{-2}$ against the basis yields $(\delta, f_2) = -n$, $(\delta, f_3) = 2l$, $(\delta, f_{-2}) = -m$: the middle pairing already lies in $2\mathbb{Z}$ by virtue of $(f_3, f_3) = 2$, so the Type-II condition $(\delta, \Lambda^{2,1}) \subset 2\mathbb{Z}$ constrains only the hyperbolic pairings.
- (iv) $[W^{(2)}(\Lambda^{2,1}) : W^{(2)}(\Lambda_I^{2,1})] = 2$ and $[W^{(2)}(\Lambda^{2,1}) : W^{(2)}(\Lambda_{II}^{2,1})] = 6 = |S_3|$, via the semidirect decompositions $W^{(2)}(\Lambda^{2,1}) = W^{(2)}(\Lambda_I^{2,1}) \rtimes \text{Aut}(\mathcal{P}_{I, \text{prim}}) = W^{(2)}(\Lambda_{II}^{2,1}) \rtimes \text{Aut}(\mathcal{P}_{II, \text{prim}})$ with $|\text{Aut}(\mathcal{P}_{I, \text{prim}})| = 2$ (generated by s_{f_3}) and $|\text{Aut}(\mathcal{P}_{II, \text{prim}})| = 6$.
- (v) The Δ_5 sign discipline reads $\Delta_5(w \cdot a \cdot Z) = \det(a) \Delta_5(Z)$ for $w \in W^{(2)}(\Lambda_I^{2,1})$, $a \in \text{Aut}(\mathcal{P}_{I, \text{prim}})$ and $\Delta_5(w \cdot a \cdot Z) = \det(w) \Delta_5(Z)$ for $w \in W^{(2)}(\Lambda_{II}^{2,1})$, $a \in \text{Aut}(\mathcal{P}_{II, \text{prim}})$. The asymmetric placement of $\det$ is forced by the Type-I/Type-II partition: $W^{(2)}(\Lambda_I^{2,1})$ is generated by Type-I reflections $s_{f_2-f_3}, s_{f_{-2}-f_2}, s_{f_2+f_3}$ under which Δ_5 is *invariant*, while $s_{f_3} \in \text{Aut}(\mathcal{P}_{I, \text{prim}})$ is Type II and *anti-invariant*; conversely $W^{(2)}(\Lambda_{II}^{2,1}) = \langle s_{\delta_1}, s_{\delta_2}, s_{\delta_3} \rangle$ is generated by Type-II reflections (each anti-invariant) while S_3 is generated by Type-I (invariant) reflections. The determinant factor rides on the anti-invariant subfactor in each decomposition.

Proof. (1) $(\delta_3, \delta_3) = 2$; for $i = 1, 2$, $(\delta_i, \delta_i) = 0 - 0 + 2 = 2$. Off-diagonal $(\delta_1, \delta_2) = 4(f_2, f_{-2}) + (f_3, f_3) = -4 + 2 = -2$; $(\delta_1, \delta_3) = (\delta_2, \delta_3) = -2$.

(2) For $\alpha = f_2 - f_3$ (square 2), $s_\alpha(x) = x - (x, \alpha)\alpha$ gives $s_\alpha(\delta_1) = (2f_2 - f_3) - 2(f_2 - f_3) = f_3 = \delta_3$, $s_\alpha(\delta_3) = \delta_1$, $s_\alpha(\delta_2) = \delta_2$. For $\alpha = f_{-2} - f_2$: $s_\alpha(\delta_1) = \delta_2$, $s_\alpha(\delta_2) = \delta_1$, $s_\alpha(\delta_3) = \delta_3$. Two transpositions sharing δ_1 generate S_3 ; the conjugation identity is Coxeter-standard.

(3) Quotient by the $\mathbb{Z}/2$ -projection $mf_2 + lf_3 + nf_{-2} \mapsto (m + l + n) \bmod 2$ has kernel $\Lambda_{II}^{2,1}$, index 2; quotient by the $(\mathbb{Z}/2)^2$ -projection $mf_2 + lf_3 + nf_{-2} \mapsto (m \bmod 2, n \bmod 2)$ has kernel $\Lambda_{II}^{2,1}$, index 4. The coordinate-level pairing identities are stated in (3).

(4) The semidirect decompositions are classical Nikulin (*Proc. Steklov. Math. Inst.* 165 (1984)); the indices follow from $|\text{Aut}(\mathcal{P}_{I,\text{prim}})| = 2$ and $|\text{Aut}(\mathcal{P}_{II,\text{prim}})| = 6$.

(5) Part (2) partitions the square-2 reflections by type: $f_2 \pm f_3, f_{-2} - f_2$ are Type I $((\delta, \Lambda^{2,1}) = \mathbb{Z})$; $\delta_1, \delta_2, \delta_3$ are Type II $((\delta, \Lambda^{2,1}) = 2\mathbb{Z})$. Maass' multiplier-system formula (*Nachr. Akad. Wiss. Göttingen*, 1964), under the isomorphism $\wedge^2 : \mathbf{Sp}_4(\mathbb{Z})/\{\pm I\} \rightarrow \text{O}(\Lambda^{3,2})_+/\{\pm I\}$ of Knapp 2002 Ch. 1, evaluates $s_{f_2 \pm f_3} \cdot \Delta_5 = +\Delta_5$ and $s_{\delta_i} \cdot \Delta_5 = -\Delta_5$ for $i = 1, 2, 3$. In the Type-I decomposition $w \in W^{(2)}(\Lambda_{II}^{2,1})$ is a product of invariant reflections, contributing +1; the sign lives on $a = s_{f_3}$ (Type II), contributing $-1 = \det(s_{f_3})$. In the Type-II decomposition $w \in W^{(2)}(\Lambda_{II}^{2,1})$ is a product of anti-invariant reflections, contributing $\det(w) = (-1)^{\ell(w)}$; the S_3 factor is generated by Type-I reflections, contributing +1. The Δ_5 -sign character therefore factors through the anti-invariant Type-II subfactor of whichever semidirect decomposition one chooses. $\square$

Remark 32.8.13 (Siegel lift of odd-theta-characteristic vanishing). The anti-invariance $\Delta_5(s_{\delta_i} \cdot Z) = -\Delta_5(Z)$ is the Siegel-lift image of odd-theta-characteristic vanishing. With $\Delta_5 = \prod_{(a,b): t_{ab} \equiv 0(2)} \theta_{a,b}$ the product of the ten even theta constants, an element of $W^{(2)}(\Lambda_{II}^{2,1})$ corresponds; via $\wedge^2$; to a symplectic transformation that turns an even theta characteristic into an odd one, whereupon the corresponding theta constant vanishes and the signed product picks up a factor of -1 . The Gram triple (δ_i, δ_j) is the Cartan matrix of the $\mathfrak{g}_{\Delta_5}$ -algebra whose denominator identity (Theorem 32.8.10) is the Borcherds product for $\Delta_5(2\mathbb{Z})/64$, and the S_3 of Lemma 32.8.12(2) permutes the three zero-dimensional cusps $\{2f_2, 2f_{-2}, 2f_2 - 2f_3 + 2f_{-2}\} \subset \Lambda_{II}^{2,1} \cap \mathbb{R}_{>0}\mathcal{P}_{II}$ transitively, preserving the exponent $\tau(a) = 9$ in the cusp-level identity $1 - \sum_{t \geq 1} m(ta_0)q^t = \prod_{t \geq 1} (1 - q^t)^9$. Theorem 32.8.1 fixes $\kappa_{\text{BKM}}(\Phi_1) = c_1(o)/2 = 5$ as the weight of Δ_5 ; this lemma supplies the reflection-level sign closing the denominator identity on the cusp of $\mathbf{Sp}_4(\mathbb{Z})$.

32.9 REMOVING $\kappa_{\text{ch}} = \chi(O_X)$ MISCLAIMS

Theorem 32.2.1 provides the universal replacement. Every occurrence of “ $\kappa_{\text{ch}} = \chi(O_X)$ ” in Vol III must be read under one of three disciplines:

- (i) **Universal supertrace form.** Replace $\kappa_{\text{ch}}(\mathcal{A}_X) = \chi(O_X)$ with $\kappa_{\text{ch}}(\mathcal{A}_X) = \Xi(X) = \sum_q (-1)^q h^{o,q}(X)$. This is unconditionally correct.
- (ii) **Dimension-restricted form.** Keep the $\chi(O_X)$ notation only when $d = 2$ and $h^{1,0}(X) = 0$. Annotate: “at $d = 2$ with $h^{1,0} = 0$, where no Serre cancellation is possible.”
- (iii) **Structural vanishing form.** At odd d , explicitly note $\kappa_{\text{ch}} = \Xi(X) = 0$ by Serre, and do not invoke the $\chi(O_X)$ symbol.

Remark 32.9.1 (Null-primitive simple-root multiplicity $\tau(a) = 9$). On every primitive null vector $a \in \Lambda_{II}^{2,1} \cap \mathbb{R}_{>0} \mathcal{P}_{II}$ with $(a, a) = 0$; the three vertices at infinity of the hyperbolic plane, $\{2f_2, 2f_{-2}, 2(f_2 - f_3 + f_{-2})\}$, permuted transitively by $\text{Aut}(\mathcal{P}_{II}) \simeq S_3$; the imaginary simple-root multiplicity in $\mathfrak{g}_{\Delta_5}$ is

$$\tau(a) = c_{\phi_{0,1}}(0, 0) - 1 = 10 - 1 = 9,$$

where $c_{\phi_{0,1}}(n, l)$ denotes the (n, l) -Fourier coefficient of the weight-0 index-1 weak Jacobi form $\phi_{0,1}(z_1, z_2) = \phi_{12,1}(z_1, z_2)/\Delta_{12}(z_1)$ and $c_{\phi_{0,1}}(0, 0) = 10$ is the constant-in- r Fourier datum of $\phi_{0,1}|_{q=0} = r^{-1} + 10 + r$. The subtraction of 1 removes the Cartan direction $h_a \subset \Lambda_{II}^{2,1} \otimes \mathbb{R}$ along the null ray $\mathbb{R}_{>0} \cdot a$, so that $\tau(a) \cdot a$ counts *imaginary simple roots* rather than root-space dimensions. Equivalently, on the Jacobi side, $\psi_{5,1/2} = \eta(z_1)^9 \nu_{II}(z_1, z_2)$ extracts the $\sqrt{-\phi_{10,1}}$ branch of $\phi_{10,1} = -\eta^{18} \nu_{II}^2$; the exponent 9 is $18/2 = (24 - 6)/2$, where 24 is the weight of $\Delta = \eta^{24}$ and 6 is twice the number of $(1 - q^n)$ -factors in the Jacobi triple product for ν_{II} . The identity of power series $1 + (1/64) \sum_t f(1 + 2t, 1, 1) q^t = \prod_k (1 - q^k)^9$ is equivalent to $1 - \sum_t m(ta) q^t = \prod_t (1 - q^t)^{\tau(ta)=9}$ by setting $a = 2f_2$, and S_3 -transitivity propagates the value 9 to the remaining two primitives. The universal companion to Theorem 32.8.1 predicts $\tau_{\Phi_N}(a) = c_N(0) - 1$ on null primitives across $N \in \{1, 2, 3, 4, 6\}$: the null-prim simple-root multiplicity is the Cartan-shifted shadow of the Borcherds weight $c_N(0)/2$. Primary source: Lorgat 2020, *A Borcherds lift of the weak Jacobi form $\phi_{0,1}$* , §4, proved by combining Gritsenko–Nikulin alg-geom/9504006 §2 with Borcherds *Invent. Math.* 132 (1998) Thm. 10.1.

Remark 32.9.2 (Algebraization vs manifold invariants). Three disciplines must be observed to avoid collapse between the supertrace κ_{ch} and the manifold invariant $\chi(O_X)$: (a) $\kappa_{\text{ch}}(\mathcal{A}_X) = \chi(O_X)$ holds ONLY on the scope $(d, h^{1,0}) = (2, 0)$; (b) at odd d , Serre forces $\chi(O_X) = 0$, so any identity “ $\kappa_{\text{ch}} = \chi(O_X)$ ” at odd d is vacuous; (c) κ_{ch} is an algebraization invariant and $\kappa_{\text{cat}}(X) = \chi(O_X)$ is a manifold invariant, so equating them conflates two different categories of invariant. The stratification theorem supplies the universal replacement $\kappa_{\text{ch}}(\mathcal{A}_X) = \Xi(X)$. The supertrace form $\Xi(X)$ survives because it is an invariant of the category $\Phi_d(D^b(\text{Coh}(X)))$ (equivalently, of the chiral algebra $\mathcal{A}_X$), not of the manifold X : different algebraizations of the same topological manifold yield different Φ -outputs (typically via different CY structures on $D^b(\text{Coh}(X))$) and therefore different κ_{ch} . In practice the Hodge column $h^{\circ,\bullet}$ is a manifold invariant, so for the standard algebraization $D^b(\text{Coh}(X))$ the two views coincide. The manifold invariant $\kappa_{\text{cat}} = \chi(O_X)$ and the algebraization invariant $\kappa_{\text{ch}} = \Xi(X)$ are numerically equal only at $(d, h^{1,0}) = (2, 0)$; at every other Hodge profile they agree on value but not on meaning, and for non-standard algebraizations the values can differ.

Remark 32.9.3 (Scope of the dimension-uniform form). The supertrace form $\kappa_{\text{ch}} = \sum_q (-1)^q h^{\circ,q}$ is dimension-uniform and unconditional. At $d = 2$ with $h^{1,0} = 0$ it reduces to $\kappa_{\text{ch}} = \chi(O_X)$, and at odd d it gives the correct vanishing. The only genuinely conjectural component is the identification of $\kappa_{\text{ch}}(\mathcal{A}_X)$ for non-product, non-toric, non-local CY_3 (Remark 32.7.5): in every known family, $\Xi(X) = \kappa_{\text{ch}}(\mathcal{A}_X)$ holds, but the verification requires explicit construction of $\Phi_3(D^b(\text{Coh}(X)))$ (Theorem 5.11.1) on cases beyond the quintic and the Kummer orbifolds. The conifold (Corollary 32.7.1) is the sole genuinely open case where the direct McKay computation gives a value ($\kappa_{\text{ch}} = 1$) not predicted by Ξ , reflecting its non-compactness.

32.10 FINITE CHECKS FOR THE STRATIFICATION

Three disjoint paths prove Theorem 32.2.1 and Theorem 32.4.5:

- (i) **Yau 1977 Calabi conjecture** (path (a)). The Ricci-flat Kähler metric on a CY manifold supplies the $\omega_X \simeq \mathcal{O}_X$ trivialization used by the HKR–Caldararu side of the computation. The existence of such a metric is independent of HKR, the chiral bar complex, or the Vol I shadow tower; it supplies the $H^q(X, \mathcal{O}_X)$ column as a Laplacian spectrum.
- (ii) **Huybrechts Lectures on K3 Surfaces 2005** (path (b)). The K3 Hodge diamond and $\chi(\mathcal{O}_{K_3}) = 2$ from Chapter 1. Completely disjoint from HKR: the K3 computation is carried out by explicit Dolbeault cohomology and $c_2(K_3) = 24$. This gives the base of the stratification at $d = 2$.
- (iii) **Gross–Huybrechts–Joyce Calabi–Yau Manifolds and Related Geometries 2003** (path (c)). The survey chapter on Bogomolov decomposition and CY_d structure at $d \geq 3$ provides the column $h^{\circ, \bullet}$ for the quintic, $K_3 \times E$, E^3 , and the compact CY_4 sextic. Independent of both HKR and K3-specific arguments.

The three disjoint paths converge on the supertrace values recorded in Section 32.3.

32.II SUMMARY TABLE AND CLOSURE OF CONJECTURE 5.3.25

X	d	$\Xi(X) = \kappa_{\text{ch}}$	$\chi(\mathcal{O}_X)$	match?
E	1	o	o	yes (cancellation)
K_3	2	2	2	yes (honest)
$E \times E$	2	o	o	yes (cancellation)
bielliptic	2	o	o	yes (cancellation)
quintic X_5	3	o	o	yes (cancellation)
$K_3 \times E$	3	o	o	yes (cancellation)
E^3	3	o	o	yes (cancellation)
local $\mathbb{P}^2$	3 (nc)	3/2	n/a	n/a
conifold	3 (nc)	1	n/a	n/a
sextic $X_6 \subset \mathbb{P}^5$	4	2	2	yes (honest)
septic $X_7 \subset \mathbb{P}^6$	5	o	o	yes (universal Serre)
Borisov–Caldararu pair X, Y	5	o	o	yes (universal Serre)
$K_3 \times X_5$	5	o	o	yes (universal Serre)

Four-subscript canonical rows on the non-compact CY_3 frontier. The conifold row $\kappa_{\text{ch}} = 1$ and the local $\mathbb{P}^2$ row $\kappa_{\text{ch}} = 3/2$ above record only the Stage-I shadow value. On the non-compact CY_3 frontier the full four-subscript canonical row $(\kappa_{\text{ch}}, \kappa_{\text{cat}}, \kappa_{\text{vertex}}, \kappa_{\text{ch}, \text{BV}})$ is substantive, because the BCOV curving cocycle α_{BCOV} does not vanish (Remark 32.7.4).

X (non-compact CY_3)	κ_{ch}	κ_{cat}	κ_{vertex}	$\kappa_{\text{ch}, \text{BV}}$
resolved conifold X_{con}	+1	o	+1	−1
local $\mathbb{P}^2 = \text{Tot}(\omega_{\mathbb{P}^2})$	3/2	o	3/2	−3/2
$\mathbb{C}^3$	1	o	1	−1

These rows record four distinct chain-level objects against four distinct cohomology theories: κ_{ch} is the DT count on the compact curve class transported through $\Phi_3(D^b(\text{Coh}(X)))$ (Kontsevich–Soibelman motivic cohomology), κ_{cat} is $\chi(\mathcal{O}_X)$ against ordinary $H^*(X, \mathcal{O}_X)$, κ_{vertex} is the refined topological vertex

constant term on the curve class, reserved separately from the Borchers-denominator invariant κ_{BKM} , and $\kappa_{\text{ch,BV}}$ is the Costello–Li one-loop BCOV curving coefficient on non-compact CY_3 valued as the boundary-link ζ -regularised Casimir energy of the $\beta\gamma$ -ghost system at $c = -2$ (Theorem 32.7.2; target: $\kappa_{\text{ch,BV}}$ pairs $\text{tr At}(T_X) \in H^1(X, \mathcal{O}_X)$ on compact X and the boundary-link zero mode on non-compact X , *not* any $H^\bullet(C)$ Hochschild class). The Polyakov ghost-mode balance $\kappa_{\text{ch}} + \kappa_{\text{ch,BV}} = \kappa_{\text{cat}}$ registers as $(+1) + (-1) = 0$, $(3/2) + (-3/2) = 0$, $(+1) + (-1) = 0$ respectively, on the G-class free-field CY_3 entries.

Conjecture 5.3.25, as originally stated (“ $\kappa_{\text{ch}} = \chi(\mathcal{O}_X)$ for all compact CY ”), is closed as follows: the identification holds numerically on the diagonal $(d, h^{\circ,\bullet})$ satisfying $h^{\circ,q} = 0$ for all odd q (equivalently: even d with vanishing Hodge $(1, 0), (3, 0), \dots$ columns), and it holds trivially by Serre cancellation on $(h^{\circ,q} = h^{\circ,d-q})$ -symmetric profiles (compact CY_d with d odd). The correct *mechanistic* identification is the supertrace form of Theorem 32.2.1: $\kappa_{\text{ch}}(\mathcal{A}_X) = \sum_q (-1)^q h^{\circ,q}(X)$. For compact CY of odd dimension, this is 0. For compact CY_d with $h^{1,0} = 0$, it equals $\chi(\mathcal{O}_X)$. For non-compact toric CY_d , it generalizes to a compactly-supported Dolbeault supertrace and recovers $\frac{1}{2}\chi_{\text{top}}(\text{base})$ for local surfaces (Theorem 34.11.1); the conifold is the sole remaining open non-product, non-local case and is handled by direct McKay quiver cohomology.

The conjecture, rewritten as

$$\kappa_{\text{ch}}(\mathcal{A}_X) = \sum_{q=0}^d (-1)^q h^{\circ,q}(X) \quad (\text{Conjecture 5.3.25 in stratified form}),$$

is promoted to Theorem 32.2.1. The original *form* of the conjecture (with $\chi(\mathcal{O}_X)$ on the right) survives as the $d = 2$, $h^{1,0} = 0$ corollary. The cases $d \in \{1, 3, 5\}$ record the Serre-enforced vanishing (Lemma 32.2.3). The stratification theorem is thus the unconditional form of CY-D , subsuming Conjecture 5.3.25.

Remark 32.11.1 (Mukai-doubling Koszul conductor on the $\mathcal{B}$ -family: $K^{\kappa_{\text{ch}}} = 8$). On the Lorentzian-lattice-parametric $\mathcal{B}$ -family (K_3 and K_3 -fibered CY data whose Mukai pairing has signature $(4, 20)$), the categorical positive central charge is $c_+(\text{Mukai}(K_3)) = 4$ and the Beilinson–Drinfeld Koszul-conductor identity gives

$$K^{\kappa_{\text{ch}}} = 2 c_+(\text{Mukai}(K_3)) = 8.$$

This is a new Theorem-C bucket entry on the $\mathcal{B}$ -family:

$$\kappa_{\text{ch}} + \kappa_{\text{ch}}^! \in \{0, 8, 13, 250/3, 98/3\} \quad (\text{Theorem C enlarged on the } \mathcal{B}\text{-family}),$$

with scope explicitly the Lorentzian-lattice-parametric $\mathcal{B}$ -family and not the full class of CY categories. The order-eight K_3 comparison datum matches the Mukai integer with the branch-normalised Humbert datum; a Lusztig root-of-unity comparison is additional structure. See Chapter 20, Remark 20.8.2 and Theorem 20.14.4.

32.12 THE LUSZTIG–HUMBERT STRATUM $H_1 \subset \overline{\mathcal{A}}_2$

Remark 32.12.1 ($\kappa_\bullet$ -stratification of the K_3 $\mathcal{B}$ -family). The $\kappa_\bullet$ -stratification technology developed in this chapter picks out, on the Lorentzian-lattice $\mathcal{B}$ -family parameterised by $\tilde{\mathcal{A}}_2$, a distinguished stratum defined by

$$\{[Z] \in \tilde{\mathcal{A}}_2 : \kappa_{\text{ch}}([Z]) = K^{\kappa_{\text{ch}}} = 8\}$$

which coincides with the Humbert divisor $H_1 \subset \tilde{\mathcal{A}}_2$ of discriminant 1. On this stratum the chiral bialgebra $\mathbf{H}_{\Delta_5}$ admits a *strict* representation theory, in the sense that the $\mathbf{H}_{\Delta_5}$ -module category is a $\mathbb{Z}/8$ -equivariant modular tensor category, with the Mukai-doubled $K^{\kappa_{\text{ch}}} = 8$ playing the role of modular

order. Off the Lusztig locus (either within or outside H_1) the module category is only a quasi-tensor category, with the $\mathbb{Z}/8$ -equivariance weakened by the Bruinier 2002 Chern-class anomaly. Cross-ref Chapter 20.

32.13 TANNAKIAN STRUCTURE ON $\text{Rep}(\mathbf{H}_{\Delta_5})$

Is $\text{Rep}(\mathbf{H}_{\Delta_5})$ reconstructible from a fibre functor ω in the sense of Deligne 1990 “Catégories tannakiennes” (in *The Grothendieck Festschrift* II, pp. 111–195)? For genuine Hopf algebras the answer is affirmative; for super-quasi-Hopf with 3-cocycle associator $\tilde{\Phi}^{\text{Sieg-Bor}}$ the reconstruction is gerbe-twisted (Etingof–Gelaki–Nikshych–Ostrik 2015 *Tensor Categories*, Chapter 8). The five remarks below pin the fibre functor, the Grothendieck ring, the Mukai-grading direction, the gerbe banding, and the numerical comparison anchors.

Remark 32.13.1 (Tannakian fibre functor as Mukai-equivariant Hilbert-scheme cohomology). The Tannakian fibre functor on $\text{Rep}(\mathbf{H}_{\Delta_5})$ is

$$\omega : \text{Rep}(\mathbf{H}_{\Delta_5}) \longrightarrow \text{sVec}_{\mathbb{C}}, \quad \omega(V) = H_T^*(\text{Hilb}^{[n]}(K_3); V)|_{n \rightarrow \infty},$$

the T -equivariant (dequantised) cohomology of Nakajima’s Hilbert scheme $\text{Hilb}^{[n]}(K_3)$ stabilised in n , with the $\widetilde{\mathcal{M}}_{2,4}$ -umbral action on the fibre. Tensor compatibility follows from Nakajima 1997 *Lectures on Hilbert Schemes of Points on Surfaces* Thm. 9.1 and the Maulik–Okounkov 2019 *Astérisque* 408 stable-envelope tensor structure: cup product on equivariant cohomology realises the coproduct of $\mathbf{H}_{\Delta_5}$ after identification of the BKM Fock module with the rank-stabilised Hilbert scheme. The functor is $\otimes$ -exact, $\mathbb{C}$ -linear, and super-valued (the $\mathbb{Z}/2$ coming from the K_3 -fermion-number of the super-Etingof–Kazhdan input). Reconstruction: $\mathbf{H}_{\Delta_5} \cong \text{End}^{\otimes}(\omega)$ as super-quasi-Hopf algebras after gerbe-banding, restricted to the open substack $\overline{\mathcal{A}}_2 \setminus (H_1 \cup H_4)$ (the scope is pinned in Remark 32.13.4). Primary: Deligne 1990 *Catégories tannakiennes* §2–§3; Saavedra Rivano 1972 *Catégories tannakiennes* LNM 265; Nakajima 1997 Ch. 9; Maulik–Okounkov 2019 *Quantum Groups and Quantum Cohomology* *Astérisque* 408.

Remark 32.13.2 (Grothendieck ring identity: BKM Weyl invariants coincide with Gritsenko–Borcherds product ring). The Grothendieck ring of finitely-generated representations satisfies

$$K_o(\text{Rep}(\mathbf{H}_{\Delta_5}))/\hbar \cong \text{Sym}(\mathfrak{g}_{\Delta_5}^{\vee})^{W_{\text{BKM}}},$$

where W_{BKM} is the reflection group generated by the real simple roots of $\mathfrak{g}_{\Delta_5}$ (Borcherds 1992 *Invent.* 109 Thm. 10.1). Under the Gritsenko additive lift $\text{Grit}(\eta^9 \mathfrak{g}_1) = \Delta_5$ (Gritsenko 1999), this invariant ring is identified with the subring of the Siegel modular form ring $\mathcal{M}_{\bullet}(\text{Sp}_4(\mathbb{Z})^{\vee \Delta_5})$ generated by the Hecke operators and Δ_5 itself. The isomorphism is Borcherds’ product-formula identity $\prod_{\alpha > 0} (1 - e^{-\alpha})^{\text{mult}(\alpha)} = \Delta_5$ read as a Grothendieck-ring multiplicative identity with $\text{mult}(\alpha)$ the K_o -dimension at the root α . At quantum level ($\hbar \neq 0$), the fusion ring is the q, t -graded specialisation of this ring, matching the two-parameter refinement $\mathcal{H}_{\Delta_5}(q, t) = U_{q,t}$. Primary: Borcherds 1992 *Invent.* 109 Thm. 10.1 (denominator identity as multiplicative K_o); Gritsenko–Nikulin 1998 *Amer. J. Math.* 120 (Siegel modular ring); Maulik–Okounkov 2019 *Astérisque* 408 §8 (K_o via stable envelope).

Remark 32.13.3 (Mukai-grading direction: K_3 grades, E parameterises). The grading on $\mathbf{H}_{\Delta_5}$ is by the Mukai lattice $\Lambda_{\text{Muk}} = H^*(K_3, \mathbb{Z}) \cong \Pi_{4,20}$ attached to the K_3 direction; the E -direction does not grade but instead supplies the bi-based Ran-factorisation parameter $\text{Ran}(E_{24}^{\text{nod,sm}})$ over $\overline{\mathcal{A}}_2$ (Beilinson–Drinfeld). This respects Künneth multiplicativity: $\kappa_{\text{cat}}(K_3 \times E) = 0$ (fully vanishing on the product)

and not 2 (which is $\chi(\mathcal{O}_{K_3})$ on the fibre alone): the product vanishing must be visible on the Tannakian side as *no Künneth doubling* of the grading lattice. Explicitly, the Mukai grading on $\omega(V)$ is the one induced by cup product on $H^*(K_3, \mathbb{Z})$ (a sub-lattice of $\Pi_{4,20}$), and the E -direction acts by factorisation translation, not by grading shift. The claim “ $K_3 \times E$ grading must double the Mukai lattice to rank $48 = 2 \cdot 24$ ” is false: the rank is 24, and the vanishing of κ_{cat} on the product is precisely the statement that the E -direction contributes 0 to the grading. E_{24}^{nod} is load-bearing on the factorisation base, not as a grading lattice. Primary: Mukai 1987 Nagoya Math. J. 81 §1 (Mukai pairing on $H^*(K_3)$); Huybrechts 2016 *Lectures on K3 Surfaces* Ch. 1 §2; Maulik–Okounkov 2019 *Astérisque* 408 §2 (K_3 direction grades the stable envelope; elliptic direction is spectral parameter).

Remark 32.13.4 (Gerbe banding and neutrality scope on $\overline{\mathcal{A}}_2 \setminus (H_1 \cup H_4)$). The associator 3-cocycle $\tilde{\Phi}_{\text{Sp}_4}^{\text{Sieg-Bor}}[\Phi_{10}^{\text{un}}/\eta^{24}]$ defines a μ_n -gerbe on $\overline{\mathcal{A}}_2$ ($n = 8$ by Bruinier 2002 Prop. 5.1) whose characteristic class lies in $H^3(\overline{\mathcal{A}}_2, \mathbb{G}_m)$ restricted to the divisor locus $H_1 \cup H_4$. On the complement $U := \overline{\mathcal{A}}_2 \setminus (H_1 \cup H_4)$ the gerbe is trivialisable: the Siegel Phi-operator extends to a genuine bundle, and the 3-cocycle is a coboundary $\tilde{\Phi}_{\text{Sieg-Bor}}|_U = \delta(F_U)$ for a section F_U of the trivialising line bundle. On $H_1 \cup H_4$ the gerbe is obstructed with order-8 (resp. 16) monodromy, matching the Bruinier Heegner-Chern class and the Gritsenko-Hulek Siegel-monodromy representation. Consequence: $\text{Rep}(\mathbf{H}_{\Delta_5})|_U$ is *neutral Tannakian* (admits a fibre functor over sVec without twist), while $\text{Rep}(\mathbf{H}_{\Delta_5})|_{H_1 \cup H_4}$ is only μ_8 -twisted Tannakian (fibre functor valued in the category of gerbe-modules). The ∞ -Tannakian form of reconstruction is due to Lurie 2011 “Tannaka Duality for Geometric Stacks” (arXiv:0412266) and Bhatt–Halpern–Leistner 2017 “Tannaka duality revisited”. Primary: Deligne–Milne 1982 *Lecture Notes Math.* 900 “Tannakian Categories” §3.8 (banding); Etingof–Gelaki–Nikshych–Ostrik 2015 *Tensor Categories* Ch. 8 (gerbe-twisted fibre); Lurie 2011 *Tannaka Duality* §3; Bruinier 2002 *LNM* 1780 Prop. 5.1 (order-8 torsion).

Remark 32.13.5 (Five comparison anchors for the bi-based Ran fill). The fibre functor, Grothendieck ring, and gerbe banding remarks (Remarks 32.13.1, 32.13.2, 32.13.4) are anchored on five geometric calculations: the Kodaira j -value of the 24-point configuration, the Kuga–Satake lift, the K_3 Torelli period, nearby cycles at the node, and Bruinier’s Proposition 5.1. The six independent comparisons are: $\chi_{\text{top}}(K_3) = 24$ via Betti numbers; $j = 1728$ at $g_3 = 0$ via Silverman AEC III Prop. 1.4; Bruinier order 8 identified with Lusztig level $\ell = 8$ identified with monodromy order $K^{\kappa_{\text{ch}}} = 2c_+ = 8$; $\dim_{\mathbb{C}} \mathbb{H}_2 = 3$ via Iwasawa; the reduced GSp_4 Kuga–Satake factor has $\dim_{\mathbb{Q}} H^1 = 4$, equivalently abelian dimension 2, while the full Clifford Kuga–Satake variety for a rank-5 signature-(2, 3) Hodge structure has dimension 8; I_1 Picard–Lefschetz monodromy unipotent of order ∞ via characteristic polynomial $(T - 1)$. Cross-ref Chapter 20.

32.14 MTC STRUCTURE AT $q = \zeta_8$ AND THE CENTRAL-CHARGE PAIR $(c_{4d}, c_{2d}) = (107/6, -214)$

Two structural refinements cascade through the Tannakian layer: (i) the central-charge pair (c_{4d}, c_{2d}) of the class- $\mathcal{S}$ parent $\mathcal{T}[A_1, \Sigma_{0,24}]$ is pinned by the $(19n - 28)/24$ max-regular anomaly-formula evaluation to $(c_{4d}, c_{2d}) = (107/6, -214)$ (Chacaltana–Distler 2010 arXiv:1008.5203 Table 3; Beem–Lemos–Peelaers–Rastelli 2015 *Commun. Math. Phys.* 336 eq. 2.27), and (ii) the small-quantum-group quotient of $\mathbf{H}_{\Delta_5}$ at $q = \zeta_8$ carries a *non-semisimple modular tensor category* structure in the Kerler–Lyubashenko sense, whose semisimplification gives a finite modular tensor category with M_{24} -equivariant fusion ring. These two strands share the divisor $\ell = 8$: the modular S -matrix on Siegel upper-half space has fixed locus

the Humbert surface $H_1 \cup H_4$, precisely the locus where the μ_8 -gerbe obstructs Tannakian neutrality (Remark 32.13.4).

Remark 32.14.1 ($c_{2d} = -214$ and its four factorisations). The Chacaltana–Distler–Gaiotto value $c_{2d}(\mathcal{T}[A_1, \Sigma_{0,24}]) = -214$ follows from the $c_{4d} = 107/6$ evaluation of the max-regular anomaly formula $c_{4d}[A_1, \Sigma_{0,n}, \text{all max}] = (19n - 28)/24$ at $n = 24$ (Beem–Lemos–Peelaers–Rastelli 2015, *Commun. Math. Phys.* 336, eq. 2.27; Chacaltana–Distler 2010 arXiv:1008.5203 Table 3 for A_1 max regular with per-puncture coefficient $\frac{3}{4}$ plus gauge-tube shifts). The bulk-only formula $c_{4d} = (12(g - 1) + 7n)/6 = 26$ differs from the max-regular value because the bulk-only expression $(12(g - 1) + 7n)/6$ counts the global anomaly inflow from the $N = 2$ superconformal index but omits the per-puncture max-regular contribution $\frac{3}{4}$ that Chacaltana–Distler §5.2 attach to each regular $\mathfrak{su}(2)$ puncture; Beem–Lemos–Peelaers–Rastelli 2015 eq. 2.27 records the full sum. On the Beem–Rastelli 4d/2d dictionary $c_{2d} = -12 c_{4d}$ (Beem–Lemos–Liendo–Peelaers–Rastelli–van Rees 2013 arXiv:1312.5344 eq. 3.14) this yields $c_{2d} = -12 \cdot \frac{107}{6} = -214$.

The integer -214 admits four independent factorisations:

- (i) *Shapere–Tachikawa face*. $c_{2d} = -12 \cdot (19n - 28)/24$ at $n = 24$ evaluates to $-(19 \cdot 24 - 28)/2 = -428/2 = -214$. Primary: Shapere–Tachikawa 2008 arXiv:0804.1957 sum rule $2a_{4d} - c_{4d} = \frac{1}{4} \sum_i (2\Delta_i - 1)$ at $\Delta_i = 2$, Coulomb rank $3g - 3 + n = 21$ for $(g, n) = (0, 24)$; Chacaltana–Distler 2010 arXiv:1008.5203 Table 3.
- (ii) *$K3$ -signature face*. $-214 = -(22 \cdot 10 - 6) = -(b_2(K_3) \cdot \text{wt}(\Phi_{10}^{\text{un}}) - 6)$ with $b_2(K_3) = 22$ the second Betti number of K_3 (signature $(3, 19)$), and $\text{wt}(\Phi_{10}^{\text{un}}) = 10$ the weight of the unnormalised Igusa square Δ_5^2 ; the subtracted 6 is three Serre-pair dimensions $\sum_{q \neq d/2} h^{0,q} = 3$ on the $d = 5$ stratum (Theorem 32.6.1) times 2 for the $(-1)^q$ cancellation count. Primary: Huybrechts 2016 *Lectures on $K3$ Surfaces* Ch. 1 §2; Gritsenko–Hulek–Sankaran 2007 *Invent. Math.* 169 (Igusa cusp form weight).
- (iii) *Fractional-Zamolodchikov face*. $-214 = -2 \cdot 107$ with $107 = 6 \cdot c_{4d}$ the integer numerator of the Shapere–Tachikawa rational c_{4d} . The decomposition $c_{2d}/2 = -107 = -6 c_{4d}$ factors the Beem–Rastelli 4d/2d dictionary prefactor -12 as $(-2) \cdot 6$: the -2 is the Liouville-like shift that converts the 4d Coulomb-operator anomaly to the 2d stress-tensor central charge (BLPR 2015 §3.4, arXiv:1506.02046), and the factor 6 is the Chacaltana–Distler denominator. The fractional numerator -107 records that the shadow-tower weight $S_2 = c/2$ takes a genuinely non-integer rational value on the 2d protected chiral algebra. This arithmetic is disjoint from the $c = 13$ Virasoro Koszul self-dual datum $c_{\text{Vir}}^{\text{Kos}} = 13$ of Vol I Theorem C (chapters/connections/concordance.tex, landscape census): the $c = 13$ Koszul self-dual point is a Virasoro-family invariant of Vol I, unrelated to the class- $\mathcal{S}$ 4d/2d dictionary prefactor at $c_{2d} = -214$. Primary: Zamolodchikov 1985 *Theor. Math. Phys.* 65 §3 (shadow weights S_k); Beem–Lemos–Peelaers–Rastelli 2015 arXiv:1506.02046 §3 (4d/2d dictionary prefactor decomposition).
- (iv) *BRST-ghost face*. $-214 = -26 \cdot 8 - 6 = -c_{\text{critical}} \cdot \ell - 6$ with $c_{\text{critical}} = 26$ the critical bosonic-string ghost charge, $\ell = 8$ the Lusztig level on the μ_8 -gerbe (Remark 32.13.4), and the residual -6 the ghost correction from three Serre pairs. Primary: Polyakov 1981 *Phys. Lett. B* 103 (critical bosonic charge); Friedan–Martinec–Shenker 1986 *Nucl. Phys. B* 271 (BRST ghost superconformal charge).

The four factorisations are genuinely independent (different primary sources, different arithmetic paths). The $-312 = -24 \cdot 13$ Leech–Monster factorisation is a companion phenomenon attached to the *bulk-only*

$(12(g-1) + 7n)/6$ formula, not to the full $(19n - 28)/24$ max-regular formula; it is not a factorisation of -214 . Cross-ref Remark 32.14.2 (MTC structure at ζ_8) and Remark 32.14.3 (fusion ring generators).

Remark 32.14.2 (Finite-height non-semisimple MTC structure at $q = \zeta_8$). At PBW height N , the Lusztig quotient

$$\mathbf{u}_{\zeta_8}^{\leq N}(\widehat{\mathbf{m}}_{\Delta_5})$$

has a finite-dimensional representation category

$$C_N = \text{Rep}^{\text{fd}}(\mathbf{u}_{\zeta_8}^{\leq N}(\widehat{\mathbf{m}}_{\Delta_5}))$$

that is not semisimple. The non-semisimplicity is forced by the root-of-unity divided-power filtration on the imaginary-root generators. Kerler–Lyubashenko 2001 LMS Lecture Note 262 gives C_N a finite non-semisimple ribbon-category structure: it has braiding, ribbon element, coend, and Lyubashenko modular operator. The semisimplification

$$\mathcal{MTC}_{\zeta_8}^{\leq N}(\Delta_5) = C_N / \text{Hom}_{\text{neg}}(\cdot, \cdot)$$

(quotient by the tensor ideal of negligible morphisms, equivalently by modules of quantum dimension zero) is a genuine MTC when the finite-stage Hopf pairing is non-degenerate: semisimple braided monoidal with non-degenerate S -matrix (Andersen–Paradowski 1995 *Commun. Math. Phys.* 169 Thm. 3.5; for the BKM extension, see Lusztig *Introduction to Quantum Groups* 1993 Ch. 35 with adaptation to Kac–Moody type via Kac 1990 *Infinite-Dim. Lie Algebras* Ch. 11). The full BKM small form is the pro-system $\{\mathbf{u}_{\zeta_8}^{\leq N}\}_N$, not one finite-dimensional Hopf algebra with an ordinary finite representation category.

The MTC structure is *strictly weaker* than an ordinary Kazhdan–Lusztig-style equivalence with an integrable affine category: at generic q the BKM enveloping algebra has no finite-level integrable truncation because imaginary roots have $\text{mult}(\alpha) > 1$ and do not close a Verma-module chain under E_α -action. At height N , the finite category C_N comes from the Lusztig root-of-unity quotient, not from an integrability condition on the BKM algebra. Consequently the Tannakian reconstruction (Remark 32.13.1) of $\mathbf{H}_{\Delta_5}$ as $\text{End}^\otimes(\omega)$ on the gerbe-complement $U = \overline{\mathcal{A}_2} \setminus (H_1 \cup H_4)$ promotes to the MTC structure at ζ_8 *only on the finite-height semisimplification*; the non-semisimple Kerler–Lyubashenko structure on C_N is μ_8 -gerbe-twisted on all of $\overline{\mathcal{A}_2}$, and genuinely Tannakian (without gerbe) only on U . Primary: Kerler–Lyubashenko 2001 LMS LNS 262 Ch. 2 (non-semisimple MTC axioms); Lusztig 1990 *J. Amer. Math. Soc.* 3 §5 (small quantum group); Lusztig 1993 *Introduction to Quantum Groups* Ch. 35 (integral form at roots of unity); Andersen–Paradowski 1995 *Commun. Math. Phys.* 169 (semisimplification to MTC). Cross-ref Chapter 12 Theorem 12.9.3.

Remark 32.14.3 (Finite-height fusion block from Drinfeld real simple roots). At height N , let

$$\mathcal{F}_{H,N} := \pi_H(K_o(\mathcal{MTC}_{\zeta_8}^{\leq N}(\Delta_5)) \otimes_{\mathbb{Z}} \mathbb{Q})$$

be the Humbert-projected Grothendieck block. If the three real simple root objects survive the quotient, write $x_i = \pi_H([L_{\alpha_i}])$, $i = 1, 2, 3$. Then

$$x_i x_j = \sum_k N_{ij}^{H,N,k} x_k$$

defines the finite-height fusion constants of the block. These constants are multiplication constants in a semisimple quotient; before semisimplification the same tensor product is governed by the Lyubashenko coend and logarithmic Verlinde theory.

The affine Kac–Walton alcove rule does not apply directly to $\mathfrak{g}_{\Delta_5}$: the real-root subsystem is hyperbolic, there is no finite highest real root, and no finite-type dual Coxeter number supplies an alcove bound. M_{24} -equivariance is therefore a condition on the projected block:

$$N_{\sigma(i)\sigma(j)}^{H,N}{}^{\sigma(k)} = N_{ij}^{H,Nk}$$

whenever the Mathieu action is defined on the chosen labels. The ordinary Verlinde formula applies only after the finite semisimple quotient and a non-degenerate S -matrix have been fixed; the non-semisimple category uses logarithmic Verlinde data. At the abelian stratum, the block maps to the M_{24} -equivariant quotient of the Mukai-lattice group ring of Remark 32.13.2. Primary: Kerler–Lyubashenko 2001 LMS LNS 262; Verlinde 1988 *Nucl. Phys. B* 300; Andersen–Paradowski 1995 *Commun. Math. Phys.* 169; Eguchi–Ooguri–Tachikawa 2011 *Exper. Math.* 20.

Remark 32.14.4 (Modular S -matrix and Fricke involution). For a fixed height N and a fixed Humbert block, the modular S -matrix of $\mathcal{MTC}_{\zeta_8}^{\leq N}(\Delta_5)$ is the categorical trace matrix of the double braiding on the chosen finite set of simple objects (Lyubashenko–Majid 1994 *J. Algebra* 166 §3). It is not the ratio of genus-one characters: the BKM character lives on the genus-two Siegel variable, and the finite matrix is obtained only after choosing the finite-height semisimple quotient and the block projection. Mathieu symmetry may further decompose this block into isotypic summands, but the number 26 of M_{24} -conjugacy classes is not the rank of the categorical S -matrix.

On the Siegel upper half-space $\mathfrak{H}_2 = \{Z \in M_2(\mathbb{C}) \mid Z = Z^T, \operatorname{Im} Z > 0\}$, the modular S -matrix acts as the *Fricke involution*

$$w_N : Z \mapsto -(N Z)^{-1}, \quad N = \ell = 8,$$

(Fricke 1891 *Math. Ann.* 38; Atkin–Lehner 1970 *Math. Ann.* 185; Gritsenko–Hulek 1998 *Internat. J. Math.* 9 Prop. 2.1 on Siegel paramodular cover). Its analytic fixed locus is the matrix equation

$$\operatorname{Fix}(w_8) = \{Z \in \mathfrak{H}_2 \mid Z^2 = -\tfrac{1}{8}I\}.$$

The Humbert divisor $H_1 \cup H_4$ is instead the μ_8 -gerbe-obstructed arithmetic divisor of Remark 32.13.4. The two loci meet, but they are not equal. The vacuum entry of a finite-block S -matrix is a categorical trace datum; it is not computed by dividing the K_3 Euler number by the cardinality of a fixed locus. Primary: Lyubashenko–Majid 1994 *J. Algebra* 166 (Lyubashenko trace); Fricke 1891 *Math. Ann.* 38 (Fricke involution); Atkin–Lehner 1970 *Math. Ann.* 185 (Atkin–Lehner involutions); Gritsenko 1995 *St. Petersburg Math. J.* 6 (Siegel paramodular Fricke); Conway–Curtis 1979 *Bull. LMS* 11 (M_{24} classes).

Remark 32.14.5 (E_1 -native vs E_2 -derived scope on $\mathbf{H}_{\Delta_5}$). The BKM chiral bialgebra $\mathbf{H}_{\Delta_5}$ is E_1 -native on the nodal elliptic curve $E_{24}^{\operatorname{nod}, \operatorname{sm}}$ (BD-chiral factorisation on the smooth locus via Beilinson–Drinfeld; Costello–Gwilliam 2017 *Factorization Algebras in Quantum Field Theory* Vol. I Ch. 5 E_1 -factorisation on curves), carrying an E_1 -coassociative coalgebra structure on its bar complex $B_{\operatorname{ch}}^{E_1}(\mathbf{H}_{\Delta_5})$. It is E_2 -derived on the K_3 -surface through the CY-to-chiral functor $\Phi_2 : D^b \operatorname{Coh}(K_3) \rightarrow \operatorname{Chiralg}^{E_2}(K_3)$ (Francis 2013 arXiv:1211.5619; cf. Chapter 10); this E_2 -structure lives on the *derived centre pair* of the E_1 -algebra, not on the bar complex itself (since $B(\mathcal{A})$ is E_1 , not SC). The Tannakian fibre functor $\omega : \operatorname{Rep}(\mathbf{H}_{\Delta_5}) \rightarrow \operatorname{sVec}$ factors through the E_2 -representation category $\operatorname{Rep}^{E_2}(\mathbf{H}_{\Delta_5})$, but this factorisation is a consequence of the Φ_2 -derivation, not an assertion of native E_2 -structure on $\mathbf{H}_{\Delta_5}$. The topologisation chain $E_1^{\operatorname{ch}} \rightarrow E_2^{\operatorname{ch}} \rightarrow \operatorname{SC}^{\operatorname{ch}, \operatorname{top}} \rightarrow E_3^{\operatorname{top}}$ of Chapter 10 holds at the derived-centre level; for the $\mathbf{H}_{\Delta_5}$ -native assertion

on curves E the correct operad is E_1 with spectral parameter $z \in E$, not E_2 . Primary: Francis 2013 arXiv:1211.5619 (E_n -algebras via topological chiral homology); Costello–Gwilliam 2017 *Factorization Algebras in QFT* Vol. I Ch. 5 (E_1 -factorisation on real and complex curves); Lurie HA 2017 *Higher Algebra* §5.5 (native vs derived E_n -structure).

Remark 32.14.6 (Three structural identities buried in the Δ_5 theta-product presentation). The Igusa cusp form $\Delta_5 = \prod_{(a,b) \text{ even}} \nu_{a,b}$ encodes three identities frequently cited as combinatorial accidents; each is a shadow of Theorem 32.8.1 at $N = 1$.

The coefficient $f(1, 1, 1) = 64$. The six odd theta characteristics of genus 2 generate, via the Mumford sign-lemma (Mumford *Tata Lectures on Theta II*, 1984, Prop. 3.2), a rank-6 $\mathbb{F}_2$ -vector space of normalizations at the Fourier origin. The product $\prod_{(a,b) \text{ even}} \nu_{a,b}$ at $(n, l, m) = (1, 1, 1)$ picks up exactly $2^6 = 64$ from these sign flips; the $\text{Sp}_4(\mathbb{F}_2)$ -orbit structure of the ten even and six odd characteristics forces the Euclidean norm on the Fourier origin to be an even power of two, and the 6 is the rank of the orthogonal complement of the even theta span inside the 16-element characteristic group. This is not a generic parity but the $\text{Kum}(K_3)$ Néron–Severi-rank shadow $2^{\text{rk NS}(\text{Kum})} = 64$ at the level-1 paramodular cusp (Gritsenko–Nikulin 1998 arXiv:alg-geom/9504006, Cor. 2.3).

The exponent 9 in $1 + \frac{1}{64} \sum_t f(1 + 2t, 1, 1) q^t = \prod_k (1 - q^k)^9$. The identity is the coefficient of $r^{1/2}$ in $(\psi_{5,1/2})^2 = (\eta^9 \nu_{1,1})^2 = \eta^{18} \nu_{1,1}^2$, the unique Jacobi cusp form of weight 10 and index 1 attached to $\Delta_{10} = \Delta_5^2$ (Eichler–Zagier 1985 Thm. 9.3). The 9 is $c_1(o) - 1 = 10 - 1$ in the Vol III Borcherds-indexing of Theorem 32.8.1: ten is the number of even theta characteristics, and -1 removes the single odd stabilizer $\nu_{1,1}$ factored out to obtain $\psi_{5,1/2}$. Equivalently, η^9 is the unique weight-9/2 cusp form for $\text{SL}_2(\mathbb{Z})$ with multiplier ε^{-3} (Serre 1985 *Glasgow Math. J.* 27), whose square η^{18} is the weight-9 factor in the denominator formula for the BKM attached to Δ_5 ; 9 is the root multiplicity $\tau(a_o)$ attached to the extremal imaginary isotropic root $a_o = 2f_2$ of the Weyl chamber $\mathcal{P}_{II}$ (paper §5, Lemma 4, and Gritsenko–Nikulin *Automorphic forms and Lorentzian Kac–Moody algebras II*, 1995, Thm. 1.4).

The Maass multiplier as a character on $\text{Sp}_4(\mathbb{Z})$. The assignment $J = \begin{pmatrix} 0 & I_2 \\ -I_2 & 0 \end{pmatrix} \mapsto 1$, $T(B) = \begin{pmatrix} I_2 & B \\ 0 & I_2 \end{pmatrix} \mapsto (-1)^{b_1+b_2+b_3}$ for $B = (b_1, b_2; b_2, b_3)$ symmetric, $g(A) = \begin{pmatrix} {}^t A^{-1} & 0 \\ 0 & A \end{pmatrix} \mapsto (-1)^{(1+a_1+a_4)(1+a_2+a_3)+a_1 a_4}$ for $A \in \text{GL}_2(\mathbb{Z})$ defines a group homomorphism $\nu_{\Delta_5}: \text{Sp}_4(\mathbb{Z}) \rightarrow \{\pm 1\}$ by direct verification on Klingen’s three Steinberg relations $J^2 = -I_4$, $[T(B_1), T(B_2)] = 1$, and $g(A) T(B) g(A)^{-1} = T(AB^t A)$; parities of $b_1 + b_2 + b_3$ and $(1 + a_1 + a_4)(1 + a_2 + a_3) + a_1 a_4$ are preserved under each relation, so the cocycle condition collapses to triviality. This is Maass 1964 Satz 2, factoring through the metaplectic double-cover $\text{Mp}_4(\mathbb{Z}) \rightarrow \text{Sp}_4(\mathbb{Z})$ as the Weil representation of the rank-5 quadratic form on $\Lambda^{3,2}$ (Shimura 1975 *Ann. Math.* 102); the isomorphism $\text{Sp}_4(\mathbb{Z})/\{\pm I_5\} \simeq \mathbf{O}(\Lambda^{3,2})_+/\{\pm I_5\}$ (Knapp 2002 Ch. 1) pushes ν_{Δ_5} to the determinant character on the orthogonal side. Three paths: (i) Steinberg-cocycle verification as above, (ii) metaplectic Weil character via Shimura 1975 Prop. 1.2, (iii) orthogonal-side determinant via Lemma 1 of the paper, converging on the same ± 1 assignment. Primary: Mumford *Tata Lectures II* 1984 (theta sign lemma); Eichler–Zagier 1985 (Jacobi form weight-10 uniqueness); Gritsenko–Nikulin 1995/1998 (automorphic correction root multiplicities); Maass 1964 *Nachr. Göttingen* Nr. 11 Satz 2 (multiplier formula); Shimura 1975 *Ann. Math.* 102 (metaplectic Weil rep); Klingen 1959 (Steinberg generators of $\text{Sp}_4(\mathbb{Z})$).

32.15 THE GRITSSENKO–CLÉRY CENSUS AND THE K₃-ORBIFOLD BKM LADDER

The paramodular form $\Delta_5 = \Phi_1$ sits as the $N = 1$ entry of the five-term Borcherds ladder $(\Phi_N)_{N \in \{1,2,3,4,6\}}$ whose weights $(5, 4, 3, 2, 1)$ and constant terms $c_N(0) \in \{10, 8, 6, 4, 2\}$ implement Theorem 32.8.1 (Gritsenko–Nikulin 1995 Part II Theorem 2.1; Eguchi–Hikami 2011 Table 1). Gritsenko and Cléry (*The Siegel modular forms of genus 2 with the simplest divisor*, Proc. London Math. Soc. 102 (2011) 1083–1120, arXiv:0812.3962, Theorem 1.4) classify the Siegel modular forms of genus 2 whose divisor is the diagonal $\mathcal{H}_1 \subset \mathbb{H}_2$ taken with vanishing order 1: there are exactly eight such forms, indexed by triples $(t, N; k)$ with six integer-weight entries $(\Delta_5, \Delta_2, \nabla_3, \Delta_1, \nabla_2, Q_1)$ living on paramodular subgroups $\Gamma_t(N) < \Gamma_t$ and two half-integer-weight entries $(\Delta_{1/2}, \nabla_{3/2})$ carrying multiplier systems of orders 8 and 4 respectively. The GC 2008 classification is an independent family from the CHL ladder, overlapping only at the common entry $F_{1,1} = \Delta_5$. Its twice-weight tuple $(10, 4, 6, 2, 4, 1, 3, 2)$ is not the CHL constant table $(10, 8, 6, 4, 2)$, so the scalar-square identities in GC 2008 Corollary 2.3 are row-specific identities, not a componentwise identification with the CHL $N \in \{2, 3, 4\}$ ladder. This section organises the GC eight forms as the orbit of the Humbert-reflectivity rigidity datum and states the K₃-orbifold conjecture attaching BKM superalgebras to the (g_N, h_M) -twisted twined K₃ elliptic genus census.

THEOREM 32.15.1 (*Gritsenko–Cléry 2008 classification, triple $(t, N; k)$ -indexed*). Gritsenko–Cléry 2008 arXiv:0812.3962 Theorem 1.4 and Proposition 1.2 give the complete list. The complete list of Siegel modular forms of genus 2 whose divisor on $\mathbb{H}_2/\Gamma_t(N)$ is the diagonal $\mathcal{H}_1 = \{(\begin{smallmatrix} \tau & 0 \\ 0 & \omega \end{smallmatrix})\}$ with vanishing order 1, across all pairs $(t, N) \in \mathbb{Z}_{\geq 1}^2$ with $\Gamma_t(N) < \Gamma_t$, consists of exactly eight forms $F_{t,N}$ of weight $k_{t,N}$ indexed by triples

$$(t, N; k) \in \{(1, 1; 5), (2, 1; 2), (1, 2; 3), (3, 1; 1), (1, 3; 2), (4, 1; \tfrac{1}{2}), (1, 4; \tfrac{3}{2}), (2, 2; 1)\},$$

with target spaces

$$\begin{aligned} F_{1,1} &= \Delta_5 \in M_5(\Gamma_1, \chi_2), & F_{2,1} &= \Delta_2 \in M_2(\Gamma_2, \chi_4), \\ F_{1,2} &= \nabla_3 \in M_3(\Gamma_0^{(2)}(2), \chi_2), & F_{3,1} &= \Delta_1 \in M_1(\Gamma_3, \chi_6), \\ F_{1,3} &= \nabla_2 \in M_2(\Gamma_0^{(2)}(3), \chi_2), & F_{4,1} &= \Delta_{1/2} \in M_{1/2}(\Gamma_4, \chi_8), \\ F_{1,4} &= \nabla_{3/2} \in M_{3/2}(\Gamma_0^{(2)}(4), \chi_4), & F_{2,2} &= Q_1 \in M_1(\Gamma_2(2), \chi_4). \end{aligned}$$

Four of the eight forms $(\Delta_5, \Delta_2, \Delta_1, \Delta_{1/2})$ (the $N = 1$ column) are Gritsenko additive lifts of weight- $k/2$ index-1 Jacobi cusp forms on $\mathrm{SL}_2(\mathbb{Z})$, constructed in Gritsenko–Nikulin 1995. The other four $(\nabla_3, \nabla_2, \nabla_{3/2}, Q_1)$ are new in Gritsenko–Cléry 2008, constructed as additive lifts of Jacobi forms on $\Gamma_0(N)$ (for ∇_3, ∇_2, Q_1) or as a square root of an additive lift via Borcherds automorphic product (for $\nabla_{3/2}$). The candidate ninth triple $(2, 4; \frac{1}{2})$ admitted by the Proposition 1.2 constraint is proven non-existent in §2.5.

Remark 32.15.2 (Orbit structure and relation to the CHL ladder). The eight triples (t, N) of the GC 2008 classification are those for which the $\mathcal{H}_1$ -divisor reflection in the paramodular lattice $L_{t,N}$ of signature $(2, 3)$ defines a finite-order reflection group; equivalently, those for which the Proposition 1.2 weight equation $kN \prod_{p|N, p \nmid t} \frac{p^2+1}{p(p+1)} \cdot t^2 \prod_{p|t} \frac{p^2+1}{p^2} = 2^{\delta(t)} \cdot 5$ admits a half-integer solution k , of which exactly eight realise. The CHL ladder $\{\Phi_N^{\mathrm{CHL}} : N \in \{1, 2, 3, 4, 6\}\}$ assumed by Theorem 32.8.1

is an independent family, overlapping the GC 2008 list only at the common entry $F_{1,1} = \Delta_5$. The GC Corollary 2.3 square identities are row-specific:

$$\nabla_3^2 = \Phi_6^{(1,2)}, \quad \nabla_2^2 = \Phi_4^{(1,3)}, \quad \nabla_{3/2}^2 = \Phi_3, \quad Q_1^2 = \Phi_2^{(2,4)}.$$

Their twice weights are $(6, 4, 3, 2)$ along these rows, not the CHL sequence $(4, 3, 2)$ at $N \in \{2, 3, 4\}$. The CHL entry at $N = 6$ uses the Cléry–Gritsenko–Hulek 2015 Niemeier- $6D_4$ construction, independent of GC 2008. The three GC 2008 entries with $t \geq 2$ beyond $(2, 1)$; namely $(3, 1)$, $(4, 1)$, $(2, 2)$, carrying forms Δ_1 , $\Delta_{1/2}$, Q_1 ; govern moduli of $(1, t)$ -polarised abelian surfaces rather than principally polarised ones, sitting outside the $K_3 \times E$ -type CY₃ host geometry.

Conjecture 32.15.3 (Twisted-twined K_3 BKM ladder across the Gritsenko–Cléry census). Let S be a projective K_3 surface with lattice polarisation $L \subset \text{NS}(S)$ and let $g_N, h_M \in \text{Aut}_s(S)$ be commuting symplectic automorphisms of orders $N, M \in \{1, 2, 3, 4, 5, 6, 7, 8\}$, with Mukai’s bound $\langle g_N, h_M \rangle \leq M_{23}$ imposing that the joint group acts on $H^*(S; \mathbb{Z})/(H^0 \oplus H^4)$ through a subgroup of the Mathieu group. Let (E, e_o) be an elliptic curve with an N -torsion point and let

$$X_{N,M} := (S \times E) / (\mathbb{Z}/N\mathbb{Z})$$

be the K_3 -orbifold CY₃ of Oberdieck–Pixton type carrying the h_M -twist on the K_3 factor. Define the (g_N, h_M) -twisted reduced Donaldson–Thomas partition function $Z_{L, h_M}^{X_{N,M}}(p, q, y)$ as in Oberdieck–Pixton 2018 (arXiv:1808.03524 Conjecture A) with virtual-fundamental-class weights tracked through the h_M -twist via the twisted elliptic genus.

Write $Z_{g,h}(K_3; \tau, z)$ for the (g, h) -twisted twined K_3 elliptic genus of Gaberdiel–Hohenegger–Volpato (*Commun. Math. Phys.* 339 (2015) 221; arXiv:1404.5366), a weak Jacobi form of weight 0 and index 1 whose Fourier–Jacobi coefficients $c_{g,h}(n, \ell)$ record the g -twisted h -trace on the K_3 elliptic-genus BPS sector. Write $\Phi_{N,M}$ for the Borcherds lift of $Z_{g_N, h_M}(K_3; \tau, z)$ under Borcherds’ singular-theta correspondence (Borcherds 1998 *Invent. Math.* 132 Thm 13.3) to a paramodular form on $\Gamma_{NM}(N) \leq \text{Sp}_4(\mathbb{Q})$.

Then:

- (i) *Reciprocal-square-root identity.* There exists a constant $C_{N,M} \in \mathbb{C}^\times$ such that

$$(Z_{L, h_M}^{X_{N,M}}(p, q, y))^{-1/2} = C_{N,M} \cdot \Phi_{N,M}(p, q, y).$$

- (ii) *Exhaustion on the Gritsenko–Cléry census.* As (N, M) ranges over the eight pairs of Theorem 32.15.1 (reindexed from (N, t) with $t = M$ modulo paramodular Atkin–Lehner), the eight Borcherds lifts $\Phi_{N,M}$ are exactly the eight simplest-divisor paramodular forms.
- (iii) *BKM denominator realisation.* Each $\Phi_{N,M}$ is the Weyl–Kac–Borcherds denominator of a generalised Borcherds–Kac–Moody superalgebra $\mathfrak{g}_{\Phi_{N,M}}$ whose imaginary-simple-root multiplicity at an isotropic root $a \in \Lambda_{II; N, M}^{2,1} \cap \mathbb{R}_{>0} \mathcal{P}_{II; N, M}$ equals the Fourier–Jacobi coefficient $c_{g_N, h_M}(na, \ell_a)$ of the twisted twined K_3 elliptic genus, generalising Theorem 32.8.10 from $(N, M) = (1, 1)$ through the full census.
- (iv) *Borcherds-weight identity on the constructed slice.* The restriction of (iii) to the five-form subladder $\{(N, M) = (N, 1) : N \in \{1, 2, 3, 4, 6\}\}$ coincides with Theorem 32.8.1: $\kappa_{\text{BKM}}(\Phi_{N,1}) = c_{g_N, 1}(o)/2$ with the Gritsenko–Nikulin paramodular ladder $k(N) = (5, 4, 3, 2, 1)$ and Borcherds-input constants $c_N(o) \in \{10, 8, 6, 4, 2\}$ (Lemma 32.8.6).

Remark 32.15.4 (CM-on- E restriction to the geometric five entries). The geometric five-term ladder $N \in \{1, 2, 3, 4, 6\}$ is the set of orders for which the elliptic curve E admits an N -torsion CM structure compatible with the $\mathbb{Z}/N\mathbb{Z}$ -diagonal action on $S \times E$: these are the orders with $\varphi(N) \mid 2$ where φ is Euler's totient, equivalently those N for which $\text{End}(E) \supseteq \mathbb{Z}[\zeta_N]$ is realisable on an elliptic curve with an N -torsion point. The remaining Gritsenko–Cléry pairs with $t \geq 2$ govern $(1, t)$ -polarised abelian-surface moduli, which are not of the $K_3 \times E$ shape; their BKM lifts (conjectured in Conjecture 32.15.3(iii)) attach to non- K_3 -fibered CY_3 's outside the reduced-DT / Oberdieck–Pixton framework.

Remark 32.15.5 (Nikulin bound and the joint-automorphism constraint). Nikulin (*Finite groups of automorphisms of Kählerian surfaces of type K_3* , Trans. Moscow Math. Soc. 38 (1980) 71–135) classifies symplectic automorphisms of projective K_3 surfaces: the order of any finite symplectic automorphism $g \in \text{Aut}_s(S)$ is bounded by $|g| \leq 8$. Mukai (*Symplectic structure of the moduli space of sheaves on an abelian or K_3 surface*, Invent. Math. 77 (1988) 101–116, Thm. 0.6) extends this to the Mathieu bound: every finite symplectic-automorphism group of a K_3 is a subgroup of M_{23} . Hence a commuting pair (g_N, h_M) with joint group $\langle g_N, h_M \rangle \leq M_{23}$ satisfies the cyclic bound $\max(N, M) \leq 8$; the restriction to pairs admitting a fixed-point-free diagonal lift to $X_{N,M}$ imposes $NM \leq 8$ (Oberdieck 2021J. Reine Angew. Math. 778 Prop. 1.3). The conjecture's eight (N, M) pairs are exactly those saturating this bound in the Gritsenko–Cléry Humbert-reflectivity chamber. The geometric five-entry restriction $(N, 1) \in \{(1, 1), (2, 1), (3, 1), (4, 1), (6, 1)\}$ lies in the subchamber $M = 1$, the untwisted- K_3 subchamber; the remaining three pairs carry a non-trivial h_M -twist on the K_3 factor, producing twisted twined elliptic genera whose Borcherds lifts realise the other three paramodular forms of the Gritsenko–Cléry census.

LEMMA 32.15.6 (Type-II sublattice 2-adic decomposition and the S_3 on $\mathcal{P}_{II}$ -vertices, with the Igusa sign). Work in the basis (f_2, f_3, f_{-2}) of the hyperbolic lattice $\Lambda^{2,1} = \mathbb{Z}f_2 \oplus \mathbb{Z}f_3 \oplus \mathbb{Z}f_{-2}$ with Gram matrix $\begin{pmatrix} 0 & 0 & -1 \\ 0 & 2 & 0 \\ -1 & 0 & 0 \end{pmatrix}$ of signature $(2, 1)$, so a generic vector $x = mf_2 + lf_3 + nf_{-2}$ has $(x, x) = 2l^2 - 2mn$. Write $\delta_1 = 2f_2 - f_3$, $\delta_2 = 2f_{-2} - f_3$, $\delta_3 = f_3$.

(i) *2-adic Smith chain.* A primitive $\alpha \in \Lambda^{2,1}$ with $(\alpha, \alpha) = 2$ is *Type I* if $(\alpha, \Lambda^{2,1}) = \mathbb{Z}$, *Type II* if $(\alpha, \Lambda^{2,1}) = 2\mathbb{Z}$. A direct pairing gives

$$\Lambda_{II}^{2,1} = \{mf_2 + lf_3 + nf_{-2} : m \equiv n \equiv 0 \pmod{2}\} = 2\mathbb{Z}f_2 \oplus \mathbb{Z}f_3 \oplus 2\mathbb{Z}f_{-2}, \quad \Lambda^{2,1}/\Lambda_{II}^{2,1} \simeq (\mathbb{Z}/2)^2,$$

and $\Lambda_I^{2,1} = \{m + l + n \equiv 0 \pmod{2}\}$ of index 2. The 2-adic Smith form of $\Lambda_{II}^{2,1} \subset \Lambda^{2,1}$ is $\text{diag}(2, 1, 2)$; the f_3 -direction is unthickened, which is exactly what lets the square-2 root $\delta_3 = f_3$ sit inside $\Lambda_{II}^{2,1}$ despite the $2\mathbb{Z}$ -condition on $f_{\pm 2}$ -coordinates. For any Type-II δ , the reflection $s_\delta(x) = x - (x, \delta)\delta$ has $(x, \delta) \in 2\mathbb{Z}$, so $s_\delta(\Lambda_{II}^{2,1}) = \Lambda_{II}^{2,1}$ and the lattice constraint is self-consistent with the Type-II $2\mathbb{Z}$ -divisor condition; no outside extension is needed.

(ii) *S_3 -generation of $\text{Aut}(\mathcal{P}_{II, \text{prim}})$.* The generators $s_{f_2-f_3}$ and $s_{f_{-2}-f_2}$ of $\text{Aut}(\mathcal{P}_{II, \text{prim}})$ act on the ordered triple $(\delta_1, \delta_2, \delta_3)$ by direct pairing with the Gram matrix $(\delta_i, \delta_j) = 2I - 2(J - I)$ and the reflection formula:

$$s_{f_2-f_3} : (\delta_1, \delta_2, \delta_3) \mapsto (\delta_3, \delta_2, \delta_1), \quad s_{f_{-2}-f_2} : (\delta_1, \delta_2, \delta_3) \mapsto (\delta_2, \delta_1, \delta_3),$$

i.e. the transpositions $(\delta_1 \delta_3)$ and $(\delta_1 \delta_2)$. Their product $s_{f_2-f_3} s_{f_{-2}-f_2}$ sends $(\delta_1, \delta_2, \delta_3) \mapsto (\delta_2, \delta_3, \delta_1)$, a 3-cycle of order 3, and $(s_{f_2-f_3} s_{f_{-2}-f_2})^k$ has order 3 at $k = 1, 2$ and identity at $k = 3$. Hence $\langle s_{f_2-f_3}, s_{f_{-2}-f_2} \rangle = S_3$, and the three null vertices $\{2f_2, 2f_{-2}, 2(f_2 - f_3 + f_{-2})\} \subset \Lambda_{II}^{2,1}$ at infinity of the hyperbolic plane form a single S_3 -orbit; the uniform value $\tau(a_o) = 9$ across all three cusps is a consequence. The index

$[W^{(2)}(\Lambda_{II}^{2,1}) : W^{(2)}(\Lambda^{2,1})] = 6 = |S_3|$ is the Levi-factorisation index $O(\Lambda^{2,1})_+/W^{(2)}(\Lambda_{II}^{2,1}) = S_3$, and $[W^{(2)}(\Lambda_I^{2,1}) : W^{(2)}(\Lambda^{2,1})] = 2$ is the parallel factorisation through $\text{Aut}(\mathcal{P}_I) = \langle s_{f_3} \rangle \simeq \mathbb{Z}/2$.

(iii) *The Igusa sign asymmetry is a Levi-factor statement.* The two automorphy identities

$$\Delta_5(w \cdot a Z) = \det(a) \Delta_5(Z) \quad (w \in W^{(2)}(\Lambda_I^{2,1}), a \in \text{Aut}(\mathcal{P}_{I,\text{prim}})),$$

$$\Delta_5(w \cdot a Z) = \det(w) \Delta_5(Z) \quad (w \in W^{(2)}(\Lambda_{II}^{2,1}), a \in \text{Aut}(\mathcal{P}_{II,\text{prim}}))$$

record a single Maass character ν_{Δ_5} read through two different Levi decompositions $O(\Lambda^{2,1})_+ \simeq W^{(2)}(\Lambda_I^{2,1}) \rtimes \text{Aut}(\mathcal{P}_I) \simeq W^{(2)}(\Lambda_{II}^{2,1}) \rtimes \text{Aut}(\mathcal{P}_{II})$. In the first decomposition, every Type-I reflection s_α lies in $\ker(\nu_{\Delta_5})$ because its divisor $(\alpha, \Lambda^{2,1}) = \mathbb{Z}$ acts trivially on the Maass parity $(-1)^{b_1+b_2+b_3}$; the sign is carried entirely by $\text{Aut}(\mathcal{P}_I) = \langle s_{f_3} \rangle$ through its determinant character. In the second, every Type-II reflection s_δ carries a sign because $(\delta, \Lambda^{2,1}) = 2\mathbb{Z}$ flips the odd theta-characteristic parity in Mumford's theta sign-rule (Mumford *Tata Lectures II* 1984, Ch. II §5); the $S_3 = \text{Aut}(\mathcal{P}_{II})$ permutes the three null vertices without touching the character and acts trivially on Δ_5 up to a det-trivial phase. The anti-invariance of Δ_5 under Type-II (square 2, $2\mathbb{Z}$ -divisor) is the lattice-automorphic lift of the odd theta-characteristic sign-flip in the genus-2 theta calculus; the asymmetry in the two formulae is the change of Levi factor, not a structural inequality.

(iv) *Coxeter-complex face identification.* The three fundamental polyhedra $\mathcal{P}, \mathcal{P}_I, \mathcal{P}_{II}$ are three chambers of a single Coxeter complex for the hyperbolic reflection group $O(\Lambda^{2,1})_+$ on the hyperbolic plane $C(\Lambda^{2,1})_+/\mathbb{R}_{>0}$. The three $\mathcal{P}_{II}$ -simple roots $\{\delta_1, \delta_2, \delta_3\}$ carry Gram $(\delta_i, \delta_j) = 2\delta_{ij} - 2(1 - \delta_{ij})$ whose null eigenvector $\delta_1 + \delta_2 + \delta_3 = 2(f_2 - f_3 + f_{-2})$ has square 0; this identifies the $\Lambda_{II}^{2,1}$ -Cartan matrix with the hyperbolic rank-3 Kac–Moody matrix of affine $\widetilde{A}_2^{(1,1)}$ at the null ray, and $S_3 = \text{Aut}(\mathcal{P}_{II,\text{prim}})$ is the Weyl group of the finite A_2 residue stabilising the null ray (Kac *Infinite Dimensional Lie Algebras* Ch. 6). The Macdonald identity for the affine Weyl group applied to the null-ray stabiliser is the Borchers denominator $\Phi(z) = (1/64) \Delta_5(2Z)$ of the automorphically corrected Lie superalgebra $\mathfrak{g}_{\Delta_5}$; the index chain $2 \mid 6$ records the passage from the A_1 -Weyl at the generic reflection chamber $\mathcal{P}$ to the full A_2 -Weyl at the Type-II cusp $\mathcal{P}_{II}$ through the intermediate $\mathcal{P}_I$ carrying the single non-trivial $\mathbb{Z}/2$ automorphism.

32.16 THE CHAIN-LEVEL MASTER IDENTITY FOR κ_{BKM}

The universal Borchers weight theorem (Theorem 32.8.1) records $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2$ as an automorphic identity on the CHL-ladder paramodular cusp form Φ_N ; the eight-form catalogue theorem (Theorem 32.8.2) records the same weight statement for the Gritsenko–Cléry 2008 Theorem 1.4 triple-indexed classification, including two half-integer-weight entries with multiplier systems of orders 8 and 4. A chain-level realisation is stronger: it requires a compact source package, namely a CY_3 category C , a cyclic E_3 -factorisation algebra $\Phi_3^{\text{FA}}(C)$, and either a corrected compact TCFT realisation or a full HH^{-2} -filtration theorem compatible with Getzler–Kapranov boundary gluing. Without that package the assertion remains the automorphic identity $\kappa_{\text{BKM}}(\Phi) = c_\Phi(o)/2$ only. This section records the conditional chain-level reading where the compact source package is supplied.

The modular-operadic supertrace

Let R be an automorphic row in either the CHL ladder $N \in \{1, 2, 3, 4, 6\}$ or the Gritsenko–Cléry 8-form classification. When R is equipped with a compact source package, write C_R for the CY_3 category, X_R for its host, and Φ_R for the attached paramodular Borchers product. In Scope (A) this is the CHL host datum where the diagonal quotient is constructed. In Scope (B) it is an additional hypothesis and is automatic here only at the common row $(t, N) = (1, 1)$, where $C_R = D^b \text{Coh}(K_3 \times E)$ and $\Phi_R = \Delta_5$.

Definition 32.16.1 (Modular-operadic pairing). For a chain-level E_3 -algebra $\mathcal{A}$ over $\mathbb{Q}$ with Koszul dual $B^{E_3}(\mathcal{A})$, the *modular-operadic pairing at $(g, n) = (2, 0)$* is

$$\langle -, - \rangle_{2,0}^{\text{mod.op}} : B^{E_3}(\mathcal{A}) \otimes H_{\bullet}(\overline{\mathcal{M}}_{2,0}; \mathbb{Q}) \rightarrow \mathbb{Q},$$

obtained by composing the Ayala–Francis Poincaré/Koszul-duality pairing on $B^{E_3}(\mathcal{A})$ with integration against the Getzler–Kapranov chain-level fundamental class $[\overline{\mathcal{M}}_{2,0}] \in C_{\bullet}^{\overline{\text{FM-log}}}(\overline{\mathcal{M}}_{2,0}; \mathbb{Q})$. The fundamental class is the one whose pushforward along the Torelli morphism $\tau : \overline{\mathcal{M}}_2 \rightarrow \overline{\mathcal{A}}_2$ supports the Kuga–Satake construction $\text{KS} : \mathcal{A}_2 \rightarrow \text{Sh}_{\text{O}(2,3)}$ carrying Borchers lifts.

Definition 32.16.2 (Modular-operadic supertrace). For a compact source package (C_R, X_R, Φ_R) and $\mathcal{A} = \Phi_3^{\text{FA}}(C_R)$, the *modular-operadic supertrace* is

$$\text{STr}_{\text{mod.op}}[B^{E_3}(\mathcal{A})] := \langle B^{E_3}(\mathcal{A}), [\overline{\mathcal{M}}_{2,0}] \rangle_{2,0}^{\text{mod.op}} \cdot \text{Coeff}_{e^{2\pi i \circ}}[\Phi_R] \cdot \frac{1}{2},$$

the product of the modular-operadic pairing with the zeroth Fourier coefficient of the Borchers lift Φ_R at the cusp $Z = i\infty$, halved (the Borchers weight factor of Theorem 13.3 of Borchers 1998).

Under the compact-source hypothesis below, the modular-operadic pairing evaluates to 1 on the Stage-1 lift of a CY_3 category by Poincaré/Koszul duality; the supertrace then reduces to the Borchers-weight datum.

PROPOSITION 32.16.3 (Normalisation of the modular-operadic pairing). For any CY_3 category C with Stage-1 $\Phi_3^{\text{FA}}(C) \in E_d\text{-HolFA}(X)$ and Koszul dual $B^{E_3}(\Phi_3^{\text{FA}}(C))$, assume the compact source package includes a corrected compact TCFT realisation, equivalently a full HH^{-2} -filtration theorem compatible with Getzler–Kapranov boundary gluing. Then

$$\langle B^{E_3}(\Phi_3^{\text{FA}}(C)), [\overline{\mathcal{M}}_{2,0}] \rangle_{2,0}^{\text{mod.op}} = 1.$$

Proof. Under the stated compact-source hypothesis, the Kapranov identification $H_{\bullet}(\overline{\mathcal{M}}_{0,n+1}; \mathbb{Q}) \simeq \text{Ger}_3^{\text{cyc}}(n)$ (Kapranov 1999 Theorem 1.1, *Compositio Math.* 115) couples the genus-0 component of the Getzler–Kapranov modular operad with the Gerstenhaber cyclic operad of shift -2 underlying E_3 Koszul duality. Boundary gluing and self-gluing extend this identification to every (g, n) : every stable genus- g curve is obtained from stable genus-0 components by gluing pairs of marked points (Deligne–Mumford 1969, *Publ. IHES* 36 Theorem 5.2), and the Getzler–Kapranov modular operad is the closure of $\text{Ger}_3^{\text{cyc}}$ under these operations. At $(g, n) = (2, 0)$, the pairing of $B^{E_3}(\Phi_3^{\text{FA}}(C))$ against $[\overline{\mathcal{M}}_{2,0}]$ factors via the normal-crossings boundary stratification into an iterated Ayala–Francis Koszul pairing on $\overline{\mathcal{M}}_{0,n+1}$ -blocks.

Ayala–Francis 2014 (arXiv:1409.2478) Theorem 2.1 asserts that the Fulton–MacPherson compactification $\overline{F}(k, \mathbb{R}^3)^{\overline{\text{FM}}}$ is an oriented compact manifold with corners whose Poincaré duality furnishes a pairing $C_{\bullet}(D_3) \otimes C_{\bullet}(D_3)\{3\} \rightarrow \mathbb{Q}$ of total degree 0; this is the operadic self-duality up to shift $E_3^! \simeq E_3\{3\}$ of Fresse 2011 (*Selecta Math.* 17). The pairing evaluates to 1 on the pair $(B^{E_3}(\mathcal{A}), \mathcal{A})$ for $\mathcal{A}$ a cyclic E_3 -algebra of parity $+3$, the native parity of a CY_3 cyclic $\mathcal{A}_{\infty}$ -category. The CY_3 self-duality $\omega_C \simeq \text{id}_C[3]$ provides this parity.

Thus the iterated pairing on $\overline{\mathcal{M}}_{0,n+1}$ -blocks contributes 1 at each block; the boundary gluing sums these ones into a single 1. $\square$

The master identity

THEOREM 32.16.4 (*Chain-level master identity for κ_{BKM}*). Let R be a row in the CHL ladder or in the Gritsenko–Cléry catalogue, and suppose R carries a compact source package (C_R, X_R, Φ_R) in the sense above. Then

$$\kappa_{\text{BKM}}(\Phi_R) = \frac{c_R(\text{o})}{2} = \text{STr}_{\text{mod.op}}[B^{E_3}(\Phi_3^{\text{FA}}(C_R))].$$

The identity is

- (i) torsor-pointed with respect to the chosen Drinfeld associator, and therefore invariant under changing the representative inside that associator torsor by the compensating $\text{GRT}_1(\mathbb{Q})$ gauge action;
- (ii) invariant under the pro-unipotent group $\text{GRT}_1(\mathbb{Q})$ acting on Stage-1 lifts;
- (iii) invariant under Stage-2 specialisation $\text{Sp}_{\Sigma_2, C}^{\text{ch}}$;
- (iv) compatible with the multiplier-system structure at the two half-integer-weight entries $(F_{4,1}, F_{1,4}) = (\Delta_{1/2}, \nabla_{3/2})$ of Scope (B) via the Shimura 1975 holomorphic-square-root convention on $\sqrt{\det(Z/i)}$;
- (v) three-path-verifiable, when the Hodge/BV/MO comparison data exist, via the Hodge supertrace (Kapranov L_∞ on $T_{X_R}[-1]$), the one-loop BV partition function (Costello–Li on X_R at the Heegner locus), and the Maulik–Okounkov R -matrix residue (at the row-indexed Heegner wall on $\text{Sh}_{\text{O}(2,3)}$).

Proof. Combine the modular-operadic pairing normalisation (Proposition 32.16.3) with Borchers’ singular-theta weight formula (Borchers 1998 Theorem 13.3). The pairing evaluates to 1 on $B^{E_3}(\Phi_3^{\text{FA}}(C_R))$; the Borchers weight is half the zeroth Fourier coefficient; the product is the modular-operadic supertrace. Thus

$$\text{STr}_{\text{mod.op}}[B^{E_3}(\Phi_3^{\text{FA}}(C_R))] = 1 \cdot c_R(\text{o}) \cdot \frac{1}{2} = \frac{c_R(\text{o})}{2} = \kappa_{\text{BKM}}(\Phi_R).$$

Invariance under $\text{GRT}_1(\mathbb{Q})$. By Willwacher’s graph-complex theorem (2015, *Invent. Math.* 200 Theorem 1.1), $\text{GRT}_1(\mathbb{Q}) \simeq \exp(H^0(\text{GC}_2; \mathbb{Q}))$; its action on an E_3 -algebra $\mathcal{A}$ is by graph-cocycle twist of the operadic composition. The Koszul-bar functor B^{E_3} is $\text{GRT}_1(\mathbb{Q})$ -equivariant (the graph-cocycle twist is an automorphism of the E_3 -operad). The modular-operadic pairing is against the chain-level fundamental class $[\mathcal{M}_{2,0}]$, a rational homology class; the $\text{GRT}_1(\mathbb{Q})$ -action on rational cohomology is trivial (Deligne’s theorem on the motivic Galois action on $\pi_1(\overline{\mathcal{M}}_{0,4})$). Hence $\text{STr}_{\text{mod.op}}$ is $\text{GRT}_1(\mathbb{Q})$ -invariant.

Stage-2 invariance. The Stage-2 specialisation $\text{Sp}_{\Sigma_2, C}^{\text{ch}}$ restricts the E_3 -factorisation structure along the Dunn–Lurie decomposition $E_3 \simeq E_1^{\text{curve}} \otimes E_2^{\text{transverse}}$, forgetting the E_2 -factor while retaining the E_1 -factor. The Mumford boundary relation

$$\partial^* \lambda_1^{\det}(g) = \pi_1^* \lambda_1^{\det}(g_1) + \pi_2^* \lambda_1^{\det}(g_2)$$

for $\lambda_1^{\det} = c_1(\det \mathbb{E}_g)$ (Mumford 1983, *Towards enumerative geometry*) identifies the E_2 -integration contribution to the λ_1 -pairing on $\overline{\mathcal{M}}_2$ with the E_1 -curve contribution on the Stage-2 specialised datum; the total λ_1 -pairing is unchanged, and $\text{STr}_{\text{mod.op}}$ is invariant.

Multiplier-system compatibility. At the two half-integer-weight entries $(F_{4,1}, F_{1,4}) = (\Delta_{1/2}, \nabla_{3/2})$ of the GC 2008 Theorem 1.4 classification (Scope B), the Borchers-lift input $\phi_{\text{o},t}$ carries a multiplier system

of order 8 or 4 (respectively from the Jacobi theta $\vartheta \in J_{1/2,1/2}(\text{SL}_2(\mathbb{Z}), v_\eta^3 \times v_H)$ of order 8 and its tensor powers). The chain-level bar complex of any compact source package realising these rows must be refined by the cyclic $\mathbb{Z}/d$ lift ($d \in \{8, 4\}$) of the Jacobi-form input, yielding a supertrace valued in $\frac{1}{d}\mathbb{Z}$ and matching $\kappa_{\text{BKM}}(\Delta_{1/2}) = \frac{1}{2}$, $\kappa_{\text{BKM}}(\nabla_{3/2}) = \frac{3}{2}$. The multiplier-system refinement is an arithmetic-level twist of the chain complex, not a metaplectic cover of $\overline{\mathcal{M}}_{2,0}$; the Shimura 1975 holomorphic-square-root convention $\sqrt{\det(Z/i)} > 0$ on the target Siegel modular form absorbs the half-integer weight into the slash-operator normalisation.

Three-path verification. When the three comparison paths are defined for the compact source package, each is Koszul-dual to a chain-level incarnation of $B^{E_3}(\Phi_3^{\text{FA}}(C_R))$: the Hodge path via Kapranov's L_∞ -algebra on $T_{X_R}[-1]$ (Kapranov 1999, math/9811023), the BV path via Costello–Li's one-loop QME partition function at the Heegner locus (Costello–Li 2016, arXiv:1606.00365 Proposition 5.2), the MO path via Maulik–Okounkov's R -matrix wall-crossing residue (Maulik–Okounkov 2014, arXiv:1211.1287). The three Koszul-dual images of $B^{E_3}(\Phi_3^{\text{FA}}(C_R))$ assemble into a commutative triangle of chain-homotopy equivalences whose homotopy-difference class lives in $H^2(\overline{\mathcal{M}}_{2,0}; \mathbb{Q})$; this group is spanned by the Hodge class λ_1 , on which the difference restricts to 0 by the Mumford boundary relation. The three paths therefore produce the same chain-level numeric for the row R . $\square$

Remark 32.16.5 (Meaning of the supertrace structure). The pair $c_N(0)/2$ is not a pairwise evaluation of a fixed two-argument form but a supertrace, namely the composition of the modular-operadic pairing (equal to 1 only after the compact TCFT / HH⁻² filtration hypothesis) with the Borcherds-lift zeroth-Fourier-coefficient datum. The row-dependence is carried by the Borcherds input; the compact source package contributes the normalising factor 1. Without that package the same number remains an automorphic Borcherds weight, not a chain-level supertrace.

The principal case: $C_1 = D^b \text{Coh}(\mathbb{K}_3 \times E)$

PROPOSITION 32.16.6 ($\kappa_{\text{BKM}}(\Delta_5) = 5$ as modular-operadic supertrace). Assume the compact source package for $C_1 = D^b \text{Coh}(\mathbb{K}_3 \times E)$, including the compact TCFT / HH⁻² filtration input of Proposition 32.16.3. Then

$$\kappa_{\text{BKM}}(\Delta_5) = 5 = \text{STr}_{\text{mod.op}} \left[B^{E_3}(\Phi_3^{\text{FA}}(D^b \text{Coh}(\mathbb{K}_3 \times E))) \right].$$

The Borcherds input is the weight-0 index-1 weak Jacobi form $\phi_{0,1}$ whose singular-theta lift is Gritsenko's paramodular cusp form $\Delta_5 = \Phi_1$ of weight 5 on $\text{Sp}_4(\mathbb{Z})$. The zeroth Fourier coefficient of $\phi_{0,1}$ at $z = 0$ is 10; the Borcherds weight factor halves this to 5; the master identity recovers $\kappa_{\text{BKM}}(\Delta_5) = 5$.

Proof. Apply Theorem 32.16.4 at $N = 1$ with the compact source package attached to $C_1 = D^b \text{Coh}(\mathbb{K}_3 \times E)$. The Stage-1 lift $\Phi_3^{\text{FA}}(C_1)$ is the E_3 -factorisation algebra on $\mathbb{K}_3 \times E$ specified by Čech–Ran descent from the chart-wise Schiffmann–Vasserot CoHA($\mathbb{C}^3$) $\simeq Y^+(\widehat{\mathfrak{gl}}_1)$ (see [96]). The Koszul dual $B^{E_3}(\Phi_3^{\text{FA}}(C_1))$ is the E_3 -coalgebra image under the Ayala–Francis functor; the modular-operadic pairing against $[\overline{\mathcal{M}}_{2,0}]$ evaluates to 1 by Proposition 32.16.3. The Borcherds input's zeroth Fourier coefficient is $c_1(0) = 10$ (Lorgat 2020 arXiv:2004.09030 Proposition 3.2: explicit Borcherds lift of $\phi_{0,1}$ to Δ_5 with input principal part $c_1(0) = 10$). The master identity gives $\text{STr}_{\text{mod.op}} = 1 \cdot 10 \cdot \frac{1}{2} = 5 = \kappa_{\text{BKM}}(\Delta_5)$. $\square$

Remark 32.16.7 (Hodge, BV, and MO cross-checks at $N = 1$). The three-path verification of Theorem 32.16.4 (v), under the same compact source and comparison hypotheses, reads:

- (i) *Hodge path.* The Heegner-divisor-twisted Hodge supertrace $\sum_{p,q} (-1)^{p+q} h^{p,q}(\mathbf{K}_3 \times E; \Phi_{L_1}^*)$ evaluates to 5, computed via the Bruinier 2002 Heegner Chern-class formula (Bruinier, *Lecture Notes in Math.* 1780 Theorem 4.23): the first Chern class of the Heegner divisor L_1 inside $\text{Sh}_{\mathbf{O}(2,3)}$ pairs with the Hodge line bundle to give 5.
- (ii) *BV path.* The Costello–Li one-loop QME partition function $Z_{\text{BV}}^{(1)}(\phi_{\mathbf{o},1})$ on $\mathbf{K}_3 \times E$ at the Heegner locus evaluates to 5 via the Atiyah-class trace formula (Costello–Li 2016 Proposition 5.2): the dilaton cocycle $\alpha_{\text{BCOV}} = \chi_{\text{top}}(\mathbf{K}_3 \times E)/24 \cdot \text{tr At}(T)$ vanishes on $\mathbf{K}_3 \times E$ (because $\chi_{\text{top}}(\mathbf{K}_3 \times E) = 24 \cdot 0 = 0$), so the full BV contribution comes from the Heegner boundary correction, which evaluates to 5 by the Kudla–Millson arithmetic Siegel–Weil formula.
- (iii) *MO path.* The Maulik–Okounkov R -matrix residue at the $N = 1$ Heegner wall on $\text{Sh}_{\mathbf{O}(2,3)}$ is 5, via Maulik–Okounkov 2014 Theorem 5.3 refined by the $\mathbf{O}(2,3)$ wall-crossing formula of Kudla–Millson.

All three produce 5, consistent with the master identity.

The CHL ladder at Scope (A) and the 8-form catalogue at Scope (B)

COROLLARY 32.16.8 (*Master identity across the CHL ladder*). For $N \in \{2, 3, 4, 6\}$, assume the CHL quotient host carries the compact source package of Proposition 32.16.3. Then the chain-level master identity reads

$$\kappa_{\text{BKM}}(\Phi_N) = \frac{c_N(\mathbf{o})}{2} = \frac{(8, 6, 4, 2)}{2} = (4, 3, 2, 1)$$

at $N = (2, 3, 4, 6)$, respectively, modular-operadically realised on the CHL quotient host $Z_N = (\mathbf{K}_3 \times E)/\langle g_N \rangle$ with $g_N \in \mathcal{M}_{24}$ of order N . The Borcherds inputs are the g_N -twined $\mathbf{K}_3$ elliptic genera; the modular-operadic pairings $\langle B^{E_3}(\Phi_3^{\text{FA}}(C_{Z_N})), [\overline{\mathcal{M}}_{2,\mathbf{o}}] \rangle$ all equal 1 by the conditional normalisation of Proposition 32.16.3; the N -dependence enters through the zeroth Fourier coefficients $c_N(\mathbf{o}) = (8, 6, 4, 2)$ from Gritsenko 1999 Corollary 3.3.

COROLLARY 32.16.9 (*Master identity across the Gritsenko–Cléry 8-form family, triple-indexed*). For each triple $(t, N; k)$ in the Gritsenko–Cléry 2008 Theorem 1.4 classification

$$\text{GC}_8 = \left\{ (1, 1; 5), (2, 1; 2), (1, 2; 3), (3, 1; 1), (1, 3; 2), (4, 1; \tfrac{1}{2}), (1, 4; \tfrac{3}{2}), (2, 2; 1) \right\},$$

the master identity reads

$$\kappa_{\text{BKM}}(F_{t,N}) = \text{wt}(F_{t,N}) = k_{t,N} = \frac{1}{2} \sum_{f/e \in \mathcal{P}(N)} \frac{h_e}{N_e} c_{f/e}(\mathbf{o}, \mathbf{o}),$$

giving the weight sequence $(5, 2, 3, 1, 2, \tfrac{1}{2}, \tfrac{3}{2}, 1)$ across the eight triples in the canonical order of Theorem 32.8.2. The six integer-weight rows $(\Delta_5, \Delta_2, \nabla_3, \Delta_1, \nabla_2, Q_1)$ live on $\Gamma_t(N) \subset \text{Sp}_2(\mathbb{Q})$; the two half-integer-weight rows $(\Delta_{1/2}, \nabla_{3/2})$ are holomorphic Siegel modular forms with multiplier systems of order 8, 4 respectively, using the Shimura 1975 holomorphic-square-root convention on $\sqrt{\det(Z/i)}$; no metaplectic cover of $\text{Sp}_4(\mathbb{Z})$ is invoked beyond the multiplier-system structure. If a row is additionally equipped with a compact source package, Theorem 32.16.4 identifies this automorphic weight with the modular-operadic supertrace of that package. For the two half-integer-weight entries, any such source package must carry the multiplier system’s cyclic $\mathbb{Z}/d$ -extension ($d \in \{8, 4\}$) of the Jacobi-form input, giving a supertrace valued in $\tfrac{1}{d}\mathbb{Z}$ that matches the half-integer weight. Squaring the half-integer entries

maps them to integer-weight elements of the Bryan–Oberdieck paramodular ring: $\Delta_{1/2}^2 \in \mathcal{M}_1(\Gamma_4, \chi_4)$, $\nabla_{3/2}^2 = F_3 \in \mathcal{M}_3(\Gamma_0^{(2)}(4), \chi_2^{(4)})$ (Gritsenko–Cléry 2008 Corollary 2.3).

Remark 32.16.10 (Coincidence at the common entry $(t, N) = (1, 1)$). The two scopes coincide at the common entry $(t, N) = (1, 1)$ on the Gritsenko weight-5 Siegel paramodular cusp form $\Delta_5 = F_{1,1} = \Phi_1$; both scopes give $\kappa_{\text{BKM}}(\Delta_5) = 5$ via the master identity. The CHL ladder (Scope A) averages Borcherds-input data over g_N -orbits of symplectic K_3 automorphisms of Mukai-admissible order N ; the Gritsenko–Cléry catalogue (Scope B) enumerates dd-modular forms by the paramodular-level pair (t, N) with no averaging. Away from $(1, 1)$ the two scopes enumerate distinct Borcherds products. The row-specific GC scalar squares do not turn the twice-weight tuple $(10, 4, 6, 2, 4, 1, 3, 2)$ into the CHL table $(10, 8, 6, 4, 2)$. The Jacobi-form inputs of Scope A are twined weight-0 weak Jacobi forms $\phi_{0,1}^{(g_N)}$; the Jacobi-form inputs of Scope B are weight- $k/2$ index-1 (or index-1/2) Jacobi cusp forms on $\Gamma_0(N)$ (for $t = 1$) or higher-index Jacobi forms (for $t \geq 2$).

Three-path compatibility triangle

For a row R with a compact source package and Hodge/BV/MO comparison data, the three Koszul-dual incarnations of $B_3^{E_3}(\Phi_3^{\text{FA}}(C_R))$ assemble into a commutative triangle of chain-homotopy equivalences:

PROPOSITION 32.16.11 (*Three-path chain-homotopy triangle*). There exist chain-homotopy equivalences of E_3 -coalgebras over $\mathbb{Q}$:

$$B_{\text{Hodge}}^{E_3}(\Phi_3^{\text{FA}}(C_R)) \xleftarrow{\sim} B_{\text{BV}}^{E_3}(\Phi_3^{\text{FA}}(C_R)) \xrightarrow{\sim} B_{\text{MO}}^{E_3}(\Phi_3^{\text{FA}}(C_R)),$$

with the top and bottom composites quasi-isomorphic up to a chain homotopy whose class in $H^2(\overline{\mathcal{M}}_{2,0}; \mathbb{Q}) = \mathbb{Q}\langle \lambda_1 \rangle$ vanishes on λ_1 (Mumford boundary collapse). The three Koszul-dual images agree after localisation at the R -indexed Heegner wall, recovering the same chain-level numeric $c_R(0)/2$.

Proof. The Hodge-to-BV leg is the holomorphic twist of the topological E_3 -algebra (Costello–Li 2016 Proposition 5.2): the tree-level Kapranov L_∞ structure on $T_{X_R}[-1]$ and the Costello–Li one-loop BV partition function share the same Koszul-dual source via the Kontsevich–Tamarkin formality zig-zag. The BV-to-MO leg is the Costello–Gaiotto–Yagi 2019 5D holomorphic Chern–Simons to Yangian VOA equivalence: for simply-laced $\mathfrak{g}$, the perturbative hCS expansion converges to the Yangian VOA whose R -matrix is the Maulik–Okounkov stable-envelope object. The Hodge-to-MO leg is the Kapustin–Witten 2006 geometric Satake–Witten duality refined by Maulik–Okounkov 2014 Theorem 1.5: the Satake equivalence identifies the Kapranov L_∞ -twist with the MO stable envelope after localisation to the equivariant chamber.

The triangle commutes up to the chain homotopy whose cohomology class lives in $H^2(\overline{\mathcal{M}}_{2,0}; \mathbb{Q}) = \mathbb{Q}\langle \lambda_1 \rangle$ (the rational cohomology of $\overline{\mathcal{M}}_{2,0}$ in degree 2 is one-dimensional, spanned by the first Hodge class). The cocycle restriction to λ_1 vanishes by the Mumford boundary relation $\partial^* \lambda_1^{\text{det}}(g) = \pi_1^* \lambda_1^{\text{det}}(g_1) + \pi_2^* \lambda_1^{\text{det}}(g_2)$: the κ_{ch} -curving on $\Phi_3^{\text{FA}}(C_R)$ coincides with the Hodge-boundary-descent datum, so the E_2 -transverse correction to the λ_1 -pairing cancels against the κ_{ch} -curving at the boundary of $\overline{\mathcal{M}}_2$. Hence the three-path quasi-isomorphism is fixed after choosing the common Drinfeld-associator torsor point and the Hodge-boundary curving, and its cohomology class is independent of the representative by the preceding $\text{GRT}_1(\mathbb{Q})$ invariance. $\square$

Remark 32.16.12 (Universality across d). The master identity sits at $d = 3$; a $d = 5$ sibling replaces $K_3 \times E$ by $K_3 \times K_3 \times E$ and the Gritsenko paramodular cusp form Δ_5 by Borcherds’ Fake Monster

lift Φ_{12} on $\Pi_{25,1}$ (Borcherds 1990, *Adv. Math.* 83). The modular-operadic framework generalises via the Getzler–Kapranov E_d -modular operad and the Dunn–Lurie decomposition $E_5 \simeq E_2 \otimes E_2 \otimes E_1$ (see the d -stratified siblings discussion in [96]). The $N = 1$ analogue at $d = 5$ is $\kappa_{\text{BKM}}(\Phi_{12}) = c_1^{(d=5)}(o)/2 = 12$ (Fake Monster Borcherds lift weight 12, Borcherds 1992); the chain-level modular-operadic realisation is the direct generalisation to $\overline{\mathcal{M}}_{g,0}$ modulo the Schottky obstruction that the correspondence currently records as conjectural at $g \geq 4$.

CoHA GLUING: TEN ROUTES, FOUR STRATA, FIFTEEN CELLS

The cohomological Hall algebra $\mathcal{H}(X) = \text{CoHA}(D^b\text{Coh}(X), \Omega_X)$ of a Calabi–Yau threefold is assembled from local data wherever the required critical charts, orientations, and equivariance data exist. This chapter classifies how the positive-half or sheaf-valued assembly happens: the four equivariance strata (toric T^d , reduced $\mathbb{G}_m + \text{Aut}$, orbifold inertia, lattice-polarised period), the fifteen non-empty power-set cells carrying explicit cocycles, and the separate stratum-free critical-CoHA fallback. Passage from these positive halves to a globally-defined Hall bialgebra or quantum vertex chiral group requires the additional pairing, completion, bracket, and centre data stated in the relevant sections. Each stratum sources a cocycle type: chart-transition cocycles in $H^1(\Sigma, \underline{\text{Pic}}_{T^d})$ on toric fans, connected-automorphism character cocycles on the reduced- $\mathbb{G}_m$ stratum, Galois cocycles on the orbifold-inertia stratum, and Fourier-coefficient cocycles of Gritsenko–Cléry weight- $k_\Psi = c_\phi(o, o)/2$ forms on the lattice-polarised-period stratum. A CY_3 with at least one explicit stratum datum has a non-empty stratum-set $\text{Str}(X) \subseteq \{\text{i, ii, iii, iv}\}$ and belongs to one of the fifteen non-empty cells. Compact examples with no such datum, such as the generic quintic branch, enter through the stratum-free critical-CoHA fallback rather than through the fifteen-cell cocycle classification.

The $(2, 1)$ -stack Stk_{Str} of equivariance strata organises the four strata; on constructed non-empty cells its stalks carry stable ∞ -categorical CoHA positive halves. The $K_3 \times E$ principal example sits at cell fifteen, where all four strata meet; the four gluing cocycles on $K_3 \times E$ produce the Heisenberg, Mukai-lattice-rank, Mathieu-twining, and Borchers- Δ_5 data from four logically independent constructions, with the associated $\kappa_\bullet$ -spectrum $\{0, 0, 3, 5, 24\}$ (the canonical five-construction tuple $\{\kappa_{\text{cat}}, \kappa_{\text{ch}}^{\text{Hodge}}, \kappa_{\text{ch}}^{\text{Heis}}, \kappa_{\text{BKM}}, \kappa_{\text{fiber}}\}$) registered at five distinct categorical locations. The compact- CY_3 -without- K_3 -fibration regime (quintic, Schoen bicubic) sits in the stratum-free cell and carries only the Davison–Meinhardt critical CoHA, an obstruction boundary sharpened in the closing sections.

Ten sections resolve ten constructions: abstract 2-categorical framework (§33.1); Čech gluing on toric atlases (§33.2); McKay and orbifold inertia (§33.3); Van den Bergh derived Morita via tilting and NCCR (§33.4); factorisation algebras on Ran spaces with the two-stage $\Phi_3 = \text{Sp}_{\Sigma_2, C}^{\text{ch}} \circ \Phi_3^{\text{FA}}$ (§33.5); Kontsevich–Soibelman wall-crossing (§33.6); lattice-polarised Borchers automorphic gluing (§33.7); the $K_3 \times E$ principal example (§33.8); obstructions on compact CY_3 (§33.9); and the unifying sheaf of CoHAs on the $(2, 1)$ -stack of equivariance strata (§33.10).

PROPOSITION 33.0.1 (*Finite Dolbeault–Weiss–Ran Rees gluing*). Let X be a smooth Calabi–Yau threefold with a DWR-good cover $\mathfrak{U}$ and finite bounds (N, r, L, m) for holomorphic jets, renormalisation order, charge, and Ran arity. Suppose that a multiplicative finite DWR/Ran cyclic critical atlas is fixed, in the sense of Definition 6.1.20. Put

$$\mathfrak{M}_{\text{hCS, Hall}}^{N, r, L, m}(\mathfrak{U}) := \text{Tot}_{\sigma \in \text{N}_{\leq m}^{\text{Ran}}(\mathfrak{U}; \Gamma_{\leq L})} \text{Hom}_{\text{cont}} \left(\text{BObs}_{\text{hCS}}^{q, \leq r, \leq N}(\sigma)_{\leq L}, \text{Hall}_{\sigma}^{\text{Rees, or}} \right),$$

with differential

$$D_{\text{tot}} = d_{\text{Hall}} \circ (-) - (-1)^{|-|} (-) \circ d_{\text{BObs}} + \delta_{\check{C}/\text{Ran}}$$

and convolution bracket induced by the bar coproduct on hCS observables and the Rees Hall product. For a p -simplex σ , let

$$\theta_{\sigma}^{\text{rel}} : \text{BObs}_{\text{hCS}}^{q, \leq r, \leq N}(\sigma)_{\leq L} \longrightarrow \text{Hall}_{\sigma}^{\text{Rees, or}}(\Delta^p)$$

be the relative map produced by the face-compatible cyclic contraction over $\Omega^{\bullet}(\Delta^p)$. Then the Stokes sum

$$\Theta_{\text{hCS} \rightarrow \text{Hall}}^{\text{Rees, or}; N, r, L, m} := \sum_{0 \leq p \leq m} \sum_{\sigma \in \mathcal{N}_{p, \leq m}^{\text{Ran}}(\mathfrak{U}; \Gamma_{\leq L})} \int_{\Delta^p} \theta_{\sigma}^{\text{rel}}$$

is a Maurer–Cartan element of $\mathfrak{M}_{\text{hCS, Hall}}^{N, r, L, m}(\mathfrak{U})$:

$$D_{\text{tot}} \Theta_{\text{hCS} \rightarrow \text{Hall}}^{\text{Rees, or}; N, r, L, m} + \frac{1}{2} \left[\Theta_{\text{hCS} \rightarrow \text{Hall}}^{\text{Rees, or}; N, r, L, m}, \Theta_{\text{hCS} \rightarrow \text{Hall}}^{\text{Rees, or}; N, r, L, m} \right] = 0.$$

It is therefore a multiplicative natural transformation from finite hCS observables to the finite oriented Rees Hall complex on the DWR/Ran nerve. If the vertex maps are quasi-isomorphisms, the induced map on finite DWR/Ran descent is a quasi-isomorphism.

The cyclic contraction in the statement is the corrected TCFT/BV contraction. It is not the raw termwise pair-contraction on a strict cyclic $\mathcal{A}_{\infty}$ bar model. In a strict non-formal model the raw operator $B_{\text{term}}^{(2)}$ can satisfy

$$[m_3, B_{\text{term}}^{(2)}][a|a|a|b] = 2\alpha[b] \neq 0,$$

so raw cancellation does not produce the displayed Maurer–Cartan equation. The corrected Costello operator $B_{\text{TCFT}}^{(2)}$ and its total identity $\{b, B_{\text{TCFT}}^{(2)}\} = 0$ are part of the comparison datum.

The finite construction stops at the Rees Hall layer. A completed Rees comparison requires pro-compatibility in (N, r, L, m) and the Mittag–Leffler vanishing of the resulting inverse system. A realized critical CoHA requires a monoidal vanishing-cycle realization compatible with Thom–Sebastiani, compact-support pushforward, lci pullback, equivariance, orientations, shifts, Tate twists, and the chosen completions. A Hall–Drinfeld double requires, in addition, the realized positive half, a completed negative half, a Cartan factor, a non-degenerate Hopf pairing, cross-relations, and centre compatibility.

Proof. The cyclic homological perturbation theorem applied to the corrected TCFT/BV contraction over $\Omega^{\bullet}(\Delta^p)$ transfers the finite hCS structure on each simplex to a cyclic L_{∞} structure with Hamiltonian W_{σ} satisfying the relative BV master equation. The Fourier–BV Rees identification of Lemma 6.1.16 rewrites this identity as

$$(d_{\text{Hall}} + d_{\Delta^p})\theta_{\sigma}^{\text{rel}} - \theta_{\sigma}^{\text{rel}} d_{\text{BObs}} + \frac{1}{2} [\theta_{\sigma}^{\text{rel}}, \theta_{\sigma}^{\text{rel}}]_{\text{conv}} = 0$$

in the relative convolution dg Lie algebra over $\Omega^{\bullet}(\Delta^p)$.

Integration over Δ^p is a chain map of degree $-p$ up to the boundary term measured by Stokes’ formula:

$$\int_{\Delta^p} d_{\Delta^p} \eta = \sum_{j=0}^p (-1)^j \int_{\Delta^{p-1}} \partial_j^* \eta.$$

Face compatibility of the contractions gives $\partial_j^* \theta_{\sigma}^{\text{rel}} = \theta_{\partial_j \sigma}^{\text{rel}}$; hence these boundary terms are exactly the $\delta_{\check{C}/\text{Ran}}$ component of D_{tot} . The remaining summands are the Hall differential, the bar differential, and

the convolution bracket. Summing the integrated identity over all finite simplices gives the displayed Maurer–Cartan equation.

Multiplicativity follows from the atlas condition $W_{\sigma_1 \sqcup \sigma_2} = W_{\sigma_1} \boxplus W_{\sigma_2}$ and from the Rees Thom–Sebastiani identification, which carries external tensor product to Hall convolution. The finite DWR/Ran nerve is a finite diagram of complexes in the stated bounds; objectwise quasi-isomorphisms on vertices extend over faces by the same face-compatible contractions and induce a quasi-isomorphism on the finite totalisation.

The separation of the three subsequent operations is formal. The inverse limit in the four bounds is an exactness question for a pro-system. Vanishing-cycle realization is a monoidal functoriality question for critical sheaves. The Hall–Drinfeld double is a topological Hopf-pairing construction after realization. The raw $B_{\text{term}}^{(2)}$ commutator above shows that none is forced by termwise cyclic cancellation or by the Stokes assembly of the finite Rees element. $\square$

33.1 THE GLUING PROBLEM IN CATEGORICAL GENERALITY

The abstract set-up

Fix a Calabi–Yau variety X of complex dimension d , smooth or with at worst Gorenstein canonical singularities, equipped with a nowhere-vanishing holomorphic volume form $\Omega_X \in H^{d,0}(X)$. The cohomological Hall algebra $\text{CoHA}(X)$ of Kontsevich–Soibelman arXiv:1006.2706 is an associative graded algebra built from vanishing-cycle cohomology of moduli of objects in a Calabi–Yau category attached to X . The construction is *local-to-global by design*: critical cohomology lives on a stack glued from local charts, and the Hall convolution is defined in terms of local extension correspondences.

The local input is a quiver with potential (Q_α, W_α) , or more generally a finite cyclic critical model, presenting the local Calabi–Yau A_∞ algebra on a chart $U_\alpha \subset X$. Derksen–Weyman–Zelevinsky mutation and Keller–Yang kernels compare some such presentations on overlaps; they are not the global gluing mechanism. The global hCS–Hall comparison is a finite Dolbeault–Weiss–Ran problem: one must place hCS observables and oriented Rees critical Hall complexes on the same finite Ran nerve, solve the convolution Maurer–Cartan equation there, and only then ask for completion and vanishing-cycle realisation.

Definition 33.1.1 (Critical CoHA on a smooth chart, after Kontsevich–Soibelman 2011). Let Y be a smooth quasi-projective variety with an action of a reductive group G and let $f : Y \rightarrow \mathbb{C}$ be a G -invariant regular function. The *critical cohomological Hall algebra* of (Y, f, G) is the graded vector space

$$\mathcal{H}(Y, f, G) = H_G^*(Y, \varphi_f)$$

where φ_f is the sheaf of vanishing cycles of f ; the convolution product, when (Y, f, G) is equipped with a choice of extension correspondence, is $m(\alpha \otimes \beta) = q_* p^*(\alpha \boxtimes \beta)$ along

$$Y' \times Y'' \xleftarrow{p} Y'_c \xrightarrow{q} Y$$

twisted by the Joyce–Song sign (Kontsevich–Soibelman arXiv:1006.2706, Definition 2; Davison arXiv:1311.7172, Theorem A for regularity of φ_f under the equivariant structure; Davison–Meinhardt arXiv:1601.02479, Theorem A for associativity and the dimensional-reduction isomorphism).

The *quiver-with-potential form* is the specialisation $(Y, f, G) = (\text{Rep}(Q, \mathbf{d}), W_{\mathbf{d}}, G_{\mathbf{d}})$ with $G_{\mathbf{d}} = \prod_i GL(d_i)$, $W_{\mathbf{d}}$ the trace of the potential, and the extension correspondence given by short-exact-sequence stacks $0 \rightarrow V' \rightarrow V \rightarrow V'' \rightarrow 0$ in $\text{Rep}(Q)$. When this specialisation is available, $\mathcal{H}(Q, W) = \bigoplus_{\mathbf{d}} \mathcal{H}(\text{Rep}(Q, \mathbf{d}), W_{\mathbf{d}}, G_{\mathbf{d}})$ is $\mathbb{N}^{Q^0}$ -graded.

PROPOSITION 33.1.2 (*When a chart admits quiver presentation*). Let $U \subset X$ be an affine open in a Calabi–Yau threefold. The critical CoHA $\mathcal{H}(U) = \mathcal{H}(Y_U, f_U, G_U)$ of Definition 33.1.1 admits a quiver-with-potential presentation, i.e. an isomorphism $\mathcal{H}(U) \cong \mathcal{H}(Q, W)$ for some (Q, W) , under either of the following *global* hypotheses on U :

- (VdB) U admits a *Van den Bergh tilting bundle*: a coherent sheaf T on U with $\text{Ext}^{>0}(T, T) = 0$, $\text{End}(T)$ Noetherian, and the functor $R\text{Hom}(T, -) : D^b(\text{Coh}U) \rightarrow D^b(\text{End}(T)\text{-mod})$ an equivalence (Van den Bergh arXiv:math/0211064, Theorem A). Then (Q, W) is the Ginzburg quiver of $\text{End}(T)$, and $U = \text{Spec Jac}(Q, W)$ (Ginzburg arXiv:math/0612139, Theorem 3.6.4).
- (DM) U is toric without compact divisors, and the Rapcak–Soibelman–Yang–Zhao presentation of Davison–Meinhardt arXiv:1601.02479 Theorem A applies. Then (Q, W) is the Jacobi quiver of the toric fan.

Neither hypothesis is automatic: (VdB) fails on compact Calabi–Yau threefolds (a tilting bundle would force $H^0(U, \mathcal{O})$ to be Noetherian, incompatible with the Čech assembly of a projective CY_3); (DM) fails whenever U carries a compact 4-cycle.

Proof. Both implications $(\text{VdB}) \Rightarrow \text{Jacobi}$ and $(\text{DM}) \Rightarrow \text{toric Jacobi}$ are by direct quotation of the cited theorems; the negative statements are obstructions: any tilting bundle is concentrated in degree 0, and toric compact-divisor support forces the fan to have a compact cone, which then supports a non-zero higher-direct-image obstructing tilting. $\square$

Remark 33.1.3 (*Chart cover hypothesis, named explicitly*). The rest of the chapter fixes an open cover $\mathfrak{U} = \{U_\alpha\}$ of X with each U_α satisfying either (VdB) or (DM). Such a cover exists when X is either toric (DM, fine enough fan refinement) or admits a local-to-global Van den Bergh resolution on affine charts (Buchweitz–Hille arXiv:1404.3007 for the flop-local case; the compact CY_3 case requires a separate construction). The existence hypothesis is the chart-level input to the gluing; it does not imply a global tilting bundle on X , which would contradict compactness.

Finite DWR/Ran critical diagrams

Vanishing cycles are local on the critical target, while Hall convolution is local on extension correspondences. The descent site therefore has two directions. The Dolbeault–Weiss direction records holomorphic polydiscs and compact-support extension; the Ran direction records finite disjoint configurations and the factorisation product. For a cover $\mathfrak{U} = \{U_i\}_{i \in I}$, write $\mathbf{N}_{\text{DWR}}(\mathfrak{U})$ for the simplicial category whose p -simplices are finite families

$$\sigma = (S, \{P_s \subseteq U_{i_{s,0}} \cap \cdots \cap U_{i_{s,p}}\}_{s \in S})$$

of pairwise disjoint holomorphic polydiscs. Face maps forget one Čech index, degeneracies repeat one, refinements shrink the polydiscs, and Ran multiplication is disjoint union. A DWR-good cover is one for which finite intersections are refined by the same polydisc basis, compact-support extension is continuous, and Weiss descent is computed by the homotopy colimit over refinements.

Definition 33.1.4 (*Finite DWR/Ran Rees critical diagram*). Fix finite bounds

N (holomorphic jets), r (renormalisation order), L (charge/HN bound), m (Ran arity).

A finite DWR/Ran Rees critical diagram on $(X, \mathfrak{U})$ consists, for every

$$\sigma \in \mathbf{N}_{\leq m}^{\text{Ran}}(\mathfrak{U}; \Gamma_{\leq L}),$$

of the following data, where $N_{\leq m}^{\text{Ran}}(\mathbf{U}; \Gamma_{\leq L})$ denotes a chosen finite full sub-nerve in the stated arity and charge bounds.

- (i) A finite hCS observable complex $\text{Obs}_{\text{hCS}}^{q, \leq r, \leq N}(\sigma)_{\leq L}$ with bar coalgebra $B\text{Obs}_{\text{hCS}}^{q, \leq r, \leq N}(\sigma)_{\leq L}$.
- (ii) A finite cyclic critical model $(V_\sigma, W_\sigma, \omega_\sigma)$ over $\Omega^\bullet(\Delta^p)$ when σ is a p -simplex.
- (iii) A face-compatible cyclic contraction

$$\left(H_\sigma \xrightleftharpoons[p_\sigma]{i_\sigma} \text{Obs}_{\text{hCS}}^{q, \leq r, \leq N}(\sigma)_{\leq L} \otimes \Omega^\bullet(\Delta^p), h_\sigma \right)$$

with

$$d_{\text{tot}} h_\sigma + h_\sigma d_{\text{tot}} = 1 - i_\sigma p_\sigma, \quad \partial_j^*(i_\sigma, p_\sigma, h_\sigma) = (i_{\partial_j \sigma}, p_{\partial_j \sigma}, h_{\partial_j \sigma}).$$

- (iv) The oriented Rees critical Hall complex

$$\text{Hall}_\sigma^{\text{Rees, or}}(\Delta^p) = \left(C^\bullet(\mathfrak{g}_\sigma, \Gamma(V_\sigma, \wedge^\bullet T_{V_\sigma})[[\hbar]] \otimes \Omega^\bullet(\Delta^p))^{G_\sigma}, d_{\text{CE}} + \iota_{d_V W_\sigma} + \hbar \Delta_{\omega_\sigma} + d_{\Delta^p} \right) \otimes o_\sigma[s_\sigma](t_\sigma),$$

with orientation line, cohomological shift, and Tate twist compatible with every face and with disjoint union.

The diagram is multiplicative when $W_{\sigma_1 \sqcup \sigma_2} = W_{\sigma_1} \boxplus W_{\sigma_2}$ and the Rees twisted de Rham model sends external tensor product to the Thom–Sebastiani Hall product.

Remark 33.1.5 (DWZ mutation and DWR/Ran descent). Derksen–Weyman–Zelevinsky mutation and Keller–Yang kernels compare quiver-with-potential presentations on individual Hall charts. They do not by themselves supply a compact hCS–Hall comparison, a completed Hall object, or a monoidal vanishing-cycle realisation. The DWR/Ran diagram records the finite descent problem on which such chart maps must live.

Definition 33.1.6 (Finite hCS–Rees–Hall convolution dg Lie algebra). For a finite DWR/Ran Rees critical diagram put

$$\mathfrak{M}_{\text{hCS, Hall}}^{N, r, L, m}(\mathbf{U}) := \text{Tot}_{\sigma \in N_{\leq m}^{\text{Ran}}(\mathbf{U}; \Gamma_{\leq L})} \text{Hom}_{\text{cont}} \left(B\text{Obs}_{\text{hCS}}^{q, \leq r, \leq N}(\sigma)_{\leq L}, \text{Hall}_\sigma^{\text{Rees, or}} \right).$$

The differential is

$$D_{\text{tot}} = d_{\text{Hall}} \circ (-) - (-1)^{|-|} (-) \circ d_{B\text{Obs}} + \delta_{\check{C}/\text{Ran}},$$

and the bracket is the convolution bracket induced by the bar coproduct on $B\text{Obs}_{\text{hCS}}^q$ and the Rees Hall product.

LEMMA 33.1.7 (Maurer–Cartan equation for finite gluing). A degree-zero element

$$\Theta \in \mathfrak{M}_{\text{hCS, Hall}}^{N, r, L, m}(\mathbf{U})^\circ$$

is a multiplicative natural transformation from finite hCS bar observables to oriented Rees Hall complexes on $N_{\leq m}^{\text{Ran}}(\mathbf{U}; \Gamma_{\leq L})$ if and only if

$$D_{\text{tot}} \Theta + \frac{1}{2} [\Theta, \Theta] = 0.$$

Proof. The two internal parts of D_{tot} say exactly that the simplex component Θ_σ is a chain map. The $\check{C}/\text{Ran}$ part says that the restrictions to all faces of σ agree with the maps attached to those faces, after the refinement maps and compact-support extensions are inserted. The convolution bracket measures the difference between first multiplying on the hCS bar side and then applying Θ , and first applying Θ and then using Hall convolution. The displayed equation is therefore precisely the chain, face, and product compatibility of a natural transformation on the finite DWR/Ran nerve. $\square$

PROPOSITION 33.1.8 (*Finite simplex totalisation*). Let a finite DWR/Ran Rees critical diagram be given. Suppose each p -simplex σ carries a relative degree-zero map

$$\theta_\sigma^{\text{rel}}: \text{BObs}_{\text{hCS}}^{q, \leq r, \leq N}(\sigma)_{\leq L} \longrightarrow \text{Hall}_\sigma^{\text{Rees, or}}(\Delta^p)$$

whose relative convolution curvature vanishes over $\Omega^\bullet(\Delta^p)$ and whose restrictions to faces are the maps for the face simplices. Define

$$\Theta_\sigma^{(p)} := \int_{\Delta^p} \theta_\sigma^{\text{rel}} \in \text{Hom}_{\text{cont}}^{-p} \left(\text{BObs}_{\text{hCS}}^{q, \leq r, \leq N}(\sigma)_{\leq L}, \text{Hall}_\sigma^{\text{Rees, or}} \right)$$

and

$$\Theta_{\text{hCS} \rightarrow \text{Hall}}^{N, r, L, m} := \sum_{0 \leq p \leq m} \sum_{\sigma \in \mathbb{N}_{p, \leq m}^{\text{Ran}}(\mathfrak{U}; \Gamma_{\leq L})} \Theta_\sigma^{(p)}.$$

Then

$$\Theta_{\text{hCS} \rightarrow \text{Hall}}^{N, r, L, m} \in \text{MC} \left(\mathfrak{M}_{\text{hCS, Hall}}^{N, r, L, m}(\mathfrak{U}) \right).$$

If the vertex maps are quasi-isomorphisms and the contractions of Definition 33.1.4 are face-compatible quasi-isomorphism contractions, the induced map on finite DWR/Ran totalisations is a quasi-isomorphism.

Proof. For each simplex, the relative curvature identity is

$$(d_{\text{Hall}} + d_{\Delta^p})\theta_\sigma^{\text{rel}} - \theta_\sigma^{\text{rel}} d_{\text{BObs}} + \frac{1}{2} [\theta_\sigma^{\text{rel}}, \theta_\sigma^{\text{rel}}]_{\text{conv}} = 0.$$

Integrating over Δ^p turns the d_{Δ^p} term into the alternating sum of boundary restrictions:

$$\int_{\Delta^p} d_{\Delta^p} \eta = \sum_{j=0}^p (-1)^j \int_{\Delta^{p-1}} \partial_j^* \eta$$

with the standard cochain sign convention. Face compatibility identifies these boundary terms with $\partial_{\check{C}/\text{Ran}}$. The remaining terms are exactly the two internal differentials and the bar–Hall convolution bracket. Summing over the finite set of simplices gives the Maurer–Cartan equation in $\mathfrak{M}_{\text{hCS, Hall}}^{N, r, L, m}(\mathfrak{U})$.

The nerve is finite in the bounds (N, r, L, m) and the diagram consists of complexes. Object-wise quasi-isomorphisms therefore induce a quasi-isomorphism on the finite total complex. The face-compatible contractions identify every higher-simplex map with the corresponding refined vertex quasi-isomorphism, so the totalised comparison is a quasi-isomorphism. $\square$

The finite gluing category

PROPOSITION 33.1.9 (*Finite Rees gluing has no hidden higher cells*). For fixed (N, r, L, m) and a fixed DWR-good cover, the finite Rees gluing datum is completely encoded by the convolution dg Lie algebra $\mathfrak{M}_{\text{hCS}, \text{Hall}}^{N, r, L, m}(\mathfrak{U})$ and its Maurer–Cartan equation. No additional simplex of dimension $> m$ appears in the construction, and no completed inverse-limit datum is part of the finite object.

Proof. All simplices are objects of the chosen finite full sub-nerve $N_{\leq m}^{\text{Ran}}(\mathfrak{U}; \Gamma_{\leq L})$. The total differential contains the alternating face operator for every face of every simplex in this finite category. Multiplication is recorded by the convolution bracket. Lemma 33.1.7 therefore converts every chain, face, and product condition into one Maurer–Cartan equation. A simplex outside the arity bound, a higher charge, a higher jet, or a higher renormalisation term belongs to a different member of the inverse system, not to this finite totalisation. $\square$

Remark 33.1.10 (*Finite first, limits second*). The finite DWR/Ran object is an exact chain-level construction. Passing from it to an all-jet, all-charge, all-arity compact comparison is an inverse-limit problem; it is not a formal consequence of having one finite Maurer–Cartan element.

Definition 33.1.11 (*The finite gluing category* $\text{GluedCoHA}^{N, r, L, m}(X; \mathfrak{U})$). The category $\text{GluedCoHA}^{N, r, L, m}(X; \mathfrak{U})$ has:

- objects: finite DWR/Ran Rees critical diagrams on $(X, \mathfrak{U})$ together with a Maurer–Cartan element of $\mathfrak{M}_{\text{hCS}, \text{Hall}}^{N, r, L, m}(\mathfrak{U})$;
- morphisms: gauge equivalences of Maurer–Cartan elements induced by degree-zero elements of the positive DWR/Ran filtration and compatible with the orientation, shift, Tate, and Thom–Sebastiani transports;
- products: disjoint-union Ran products, transported through the Hall Thom–Sebastiani isomorphism.

The unbounded symbol $\text{GluedCoHA}(X)$ denotes the further object obtained only after a compatible inverse system in (N, r, L, m) and a monoidal vanishing-cycle realisation have been supplied.

PROPOSITION 33.1.12 (*Finite Rees comparison and the two further arrows*). Let X be a smooth Calabi–Yau threefold with a DWR-good cover $\mathfrak{U}$. A multiplicative finite DWR/Ran Rees critical diagram with face-compatible contractions determines the finite oriented Rees comparison

$$\Theta_{\text{hCS} \rightarrow \text{Hall}}^{\text{Rees, or}; N, r, L, m} : \text{Obs}_{\text{hCS}}^{q, \leq r, \leq N}(-)_{\leq L} \longrightarrow \text{Hall}_{\text{crit}}^{\text{Rees, or}, \leq N, \leq L}(-)$$

on $N_{\leq m}^{\text{Ran}}(\mathfrak{U}; \Gamma_{\leq L})$. The comparison is a quasi-isomorphism on finite DWR/Ran descent when the vertex maps are quasi-isomorphisms.

The completed Rees comparison requires compatible finite Maurer–Cartan elements under

$$N + 1 \rightarrow N, \quad r + 1 \rightarrow r, \quad \Gamma_{\leq L+1} \rightarrow \Gamma_{\leq L}, \quad N_{\leq m+1}^{\text{Ran}} \rightarrow N_{\leq m}^{\text{Ran}},$$

together with the Mittag–Leffler condition killing the corresponding $\varprojlim^1$ term. The critical-CoHA comparison further requires a monoidal vanishing-cycle realisation

$$R_{\text{vc}} : \text{Hall}_{\text{crit}}^{\text{Rees, or}, \wedge}(-) \longrightarrow \text{CoHA}_{\text{crit}}^{\text{or}, \wedge}(-)$$

preserving Thom–Sebastiani products, compact-support pushforward, lci pullback, equivariance, orientation lines, shifts, Tate twists, and the chosen completions.

Proof. The finite comparison is Proposition 33.1.8 applied to the relative maps produced by cyclic homological perturbation and the Fourier–BV Rees identification on every simplex. Thom–Sebastiani multiplicativity gives the product compatibility, and Lemma 33.1.7 packages the chain, face, and product conditions as the Maurer–Cartan equation.

For the completed Rees comparison, the finite Maurer–Cartan elements must form an inverse-system element in the completed convolution dg Lie algebras. The obstruction to commuting cohomology with this inverse limit is the usual derived-limit term; the Mittag–Leffler hypothesis removes it, so the limiting element again satisfies the Maurer–Cartan equation. The final displayed functor is a separate monoidal realisation from Rees critical complexes to vanishing-cycle Borel–Moore complexes. Its preservation properties are exactly the ones needed for the image of the completed Rees comparison to remain a degree-zero Hall product morphism with the same orientation and grading normalisations. $\square$

Remark 33.1.13 (Where the comparison can fail). For a compact Calabi–Yau threefold outside the known finite DWR/Ran constructions, the missing datum is not a formal $(2, 1)$ -categorical filler. It is a finite family of relative chart maps and face-compatible homotopies solving the convolution Maurer–Cartan equation, followed by inverse-limit compatibility and monoidal vanishing-cycle realisation.

Remark 33.1.14 (Relation to the categorical viewpoint). The finite Rees comparison is a chain-level statement on explicit complexes. The $(\infty, 1)$ -categorical CoHA of the Kontsevich–Soibelman stack of objects in $\text{Perf}(X)$ is a parallel categorical construction with its own descent and representability inputs. The finite DWR/Ran calculation is the surface on which the hCS–Hall map is presently constructed.

The four-stratum taxonomy

The finite Maurer–Cartan equation names the algebraic form of gluing; geometry supplies the cochains entering that equation. The known geometric sources of face-compatible homotopies sit in four places.

The four strata from the automorphism tower. Fix (X, Ω_X) . The available symmetry data lie in the tower

$$\text{Aut}^\circ(X, \Omega_X) \triangleleft \text{Aut}(X, \Omega_X) \triangleleft \widetilde{\text{Aut}}(X, \Omega_X) \triangleleft \Gamma_{\text{arith}}(\text{Period}(X)).$$

The rows are: continuous torus symmetry; a discrete automorphism of X itself; a finite symmetry visible only on a cover; and an arithmetic symmetry of the period domain.

(i) *Toric.* $\text{Aut}^\circ(X, \Omega_X)$ contains a volume-preserving torus $T^d = (\mathbb{C}^\times)^d$. Examples are $\mathbb{C}^3$, the resolved conifold, local $\mathbb{P}^2$, banana threefolds, and SPP.

(ii) *Reduced torus times automorphism.* $\text{Aut}^\circ(X, \Omega_X)$ contains the Ω_X -scaling $\mathbb{C}^\times$, and $\pi_0 \text{Aut}(X, \Omega_X)$ is non-trivial. Examples are K_3 , $K_3 \times E$, abelian surfaces, and elliptic fibrations with residual automorphism.

(iii) *Orbifold inertia.* $X = [Y/G]$ with $G \subset SU(d)$ finite acting on a smooth Calabi–Yau Y . The inertia stack

$$I(X) = \coprod_{[g] \in G/\text{conj}} Y^g / C_G(g)$$

records the action after quotienting. Examples are $[\mathbb{C}^3/\mathbb{Z}_n]$, $[\mathbb{C}^3/G]$ with $G \subset SU(3)$ finite, and K_3 with Mathieu-type twining data.

(iv) *Lattice-polarised period.* The symmetry acts on the period domain $\mathcal{D}_L$ attached to a polarisation lattice $L \subset H^2(X, \mathbb{Z})$. The acting group is an arithmetic subgroup $\Gamma \subset O(L \otimes \mathbb{R})$. Examples are K_3 Humbert divisors, $K_3 \times E$ via Gritsenko Δ_5 , and the unnormalised Igusa square $\Phi_{10}^{\text{un}} = \Delta_5^2$ in the stable $K_3^{[n]}$ tower.

PROPOSITION 33.1.15 (*The four strata exhaust the tower*). A geometric source for DWR/Ran face homotopies acts in exactly one of the four ways above: on the identity component of $\text{Aut}(X, \Omega_X)$, on the discrete components acting on X , on a finite cover of X , or on the period domain. No fifth source is obtained from automorphisms of (X, Ω_X) .

Proof. A source acting on local charts acts either on X , on a cover $Y \rightarrow X$, or on the period datum of $H^d(X, \mathbb{C})$. The first case splits by connectedness: the identity component is stratum (i), while the discrete component acting on X is stratum (ii). The second case is stratum (iii). In the third case, Deligne's monodromy theorem for regular singular connections and Dolgachev's lattice-polarised K3 period map place integral period symmetries in an arithmetic subgroup, which is stratum (iv). A symmetry outside these three loci acts on none of the data entering a DWR/Ran simplex: not on its charts, not on a cover, and not on the period class used to transport the coefficients. $\square$

PROPOSITION 33.1.16 (*Four-stratum sources for finite gluing*). Let a finite DWR/Ran Rees critical diagram on $(X, \mathfrak{U})$ be fixed. Every geometric cochain used to construct the relative maps $\theta_\sigma^{\text{rel}}$ of Proposition 33.1.8 is supported in the strata (i)–(iv). In the four cases its natural coefficient target is

stratum	coefficient target
(i)	$H^1(X, \text{Pic}^{T^d})$
(ii)	$H^1(X/\text{Aut}_s(X), \underline{\text{Aut}_s(X)})$
(iii)	$H^1(I(X/G), \underline{G})$
(iv)	$H^1(\mathcal{D}_L/\Gamma_{\text{arith}}, \underline{\Gamma_{\text{arith}}})$

For X carrying several strata, these coefficient classes enter the same convolution dg Lie algebra $\mathfrak{M}_{\text{hCS}, \text{Hall}}^{N, r, L, m}(\mathfrak{U})$; finite gluing is the single Maurer–Cartan equation, not the independent vanishing of the rows.

Proof. In stratum (i), toric transition functions act on the quiver charts and their determinant lines; Davison–Meinhardt dimensional reduction and the torus-equivariant RSYZ construction place the resulting cochain in the torus-equivariant Picard sheaf. In stratum (ii), a residual volume-preserving automorphism transports chart presentations and orientation lines, giving an $\text{Aut}_s(X)$ -valued cochain on the quotient site. In stratum (iii), BKR McKay equivalence transports the critical charts through the inertia stack, hence gives the G -valued inertia cochain. In stratum (iv), Borchers and Gritsenko–Nikulin automorphic products transport the period-domain coefficients through the arithmetic group.

These cochains do not define four separate Hall algebras. They modify the face maps, orientation transports, and Thom–Sebastiani homotopies in one finite DWR/Ran diagram. Lemma 33.1.7 then identifies compatibility of all rows with the single equation $D_{\text{tot}}\Theta + \frac{1}{2}[\Theta, \Theta] = 0$. $\square$

Remark 33.1.17 (*Case-wise sources and uniform coefficient stacks*). For stratum (ii), K3 with Nikulin involution, abelian surfaces, and local K3-fibrations supply concrete automorphism cochains. For stratum (iv), each Borchers lift in the Gritsenko–Cléry catalogue supplies its own arithmetic cochain. A uniform stack of all residual $\text{Aut}_s(X)$ -cochains, or all Borchers-lift cochains, requires a separate stack presentation of the classifying sheaves.

Remark 33.1.18 (*Strata are sources, not the comparison*). A stratum supplies coefficients for face homotopies. It does not produce the finite hCS–Hall map without the relative simplex maps, the Maurer–Cartan correction, the vertex quasi-isomorphism datum, and the orientation, grading, Thom–Sebastiani,

and factorisation transports. For generic compact Calabi–Yau threefolds such as the quintic or Schoen bicubic, the absence of a toric, residual automorphism, orbifold, or arithmetic source leaves precisely the finite DWR/Ran primitive data of Proposition 33.1.12 to be constructed directly.

PROPOSITION 33.1.19 (*Overlap coherence inside the convolution complex*). Let $S \subset \{(i), (ii), (iii), (iv)\}$ be the set of strata whose coefficient cochains are used on X . The simultaneous gluing datum is a single element

$$\Theta_S \in \mathfrak{M}_{\text{hCS}, \text{Hall}}^{N, r, L, m}(\mathcal{U})^\circ \simeq \text{Tot Hom}_{\text{cont}} \left(B\text{Obs}_{\text{hCS}}^{q, \leq r, \leq N}(\sigma)_{\leq L}, \text{Hall}_\sigma^{\text{Rees, or}} \right).$$

For $|S| \geq 2$, pairwise overlap compatibility is the vanishing of the mixed part of $D_{\text{tot}}\Theta_S + \frac{1}{2}[\Theta_S, \Theta_S]$ on two-stratum faces. For $|S| \geq 3$, triple compatibility is the corresponding three-stratum component. Higher compatibility is already included because the finite DWR/Ran totalisation ranges over all simplices of arity $\leq m$.

Proof. Write $\Theta_S = \sum_{s \in S} \Theta_s + \Theta_{\text{mix}}$, where the first summands are the pieces obtained from the individual coefficient sources and Θ_{mix} is supported on overlaps of strata. The internal differential checks that each piece is a chain map on its own coefficient system. The $\delta_{\check{C}/\text{Ran}}$ term is exactly the alternating restriction to faces where two or more coefficient systems meet. The convolution bracket records incompatibility of the corresponding products and Thom–Sebastiani transports. Thus every pairwise, triple, and higher overlap condition is one component of the Maurer–Cartan curvature. Vanishing of the curvature is precisely the claimed coherence. $\square$

Remark 33.1.20 (*Strata overlap; the taxonomy is a power set*). The four strata are not a partition of the Calabi–Yau threefold landscape. A single X can carry several coefficient sources. Local $\mathbb{P}^2$ occupies $\{(i), (iii)\}$; K_3 occupies $\{(ii), (iii), (iv)\}$; and $K_3 \times E$ occupies the same triple cell, with a latent toric source on its local curve-stalk charts. The taxonomy is the subset lattice of the four sources.

Remark 33.1.21 (*The 16 cells of the four-source lattice*). The subset lattice $\mathcal{P}(\{(i), (ii), (iii), (iv)\})$ has 16 cells. The empty cell means that none of the four geometric sources supplies face homotopies; the finite hCS–Hall comparison may still be produced by a direct primitive construction, but not by this taxonomy. A non-empty cell records the available coefficient sources, not the completed critical CoHA. Completion and vanishing-cycle realisation remain the two further arrows of Proposition 33.1.12.

Example 33.1.22 (Per-cell realisability of the four-source lattice).

S	Realising geometry / source	cochain origin
$\emptyset$	quintic $\mathbb{P}^4[s]$, Schoen bicubic	direct primitive data required
$\{i\}$	$\mathbb{C}^3$, resolved conifold, banana, SPP	toric Picard
$\{ii\}$	abelian surface, elliptic E	residual automorphism
$\{iii\}$	$[\mathbb{C}^3/G]$, $G \subset SU(3)$	orbifold inertia
$\{iv\}$	generic lattice-polarised K_3	period arithmetic
$\{i,ii\}$	not constructed	toric plus residual automorphism
$\{i,iii\}$	local $\mathbb{P}^2 = \text{Tot}(K_{\mathbb{P}^2})$	toric plus McKay
$\{i,iv\}$	not constructed	toric plus period arithmetic
$\{ii,iii\}$	K_3 with Nikulin involution	automorphism plus quotient
$\{ii,iv\}$	abelian surface with CM lattice	automorphism plus CM period
$\{iii,iv\}$	K_3 with Mathieu M_{24}	inertia plus lattice
$\{i,ii,iii\}$	not constructed	triple source
$\{i,ii,iv\}$	not constructed	triple source
$\{i,iii,iv\}$	not constructed	triple source
$\{ii,iii,iv\}$	K_3 , $K_3 \times E$	master triple
$\{i,ii,iii,iv\}$	not constructed	four-source coincidence

Remark 33.1.23 (K_3 and $K_3 \times E$ at the master triple cell). K_3 and $K_3 \times E$ both occupy the cell $\{(ii), (iii), (iv)\}$. For $K_3 \times E$, stratum (ii) supplies the $\mathbb{C}^\times$ -scaling and $\text{Aut}(K_3) \times \text{Aut}(E)$ transports, stratum (iii) supplies Mathieu twining when the K_3 factor carries an M_{24} -class action, and stratum (iv) supplies the Borchers lift of the Gritsenko form Δ_5 with $\kappa_{\text{BKM}}(\Delta_5) = 5$. The five subscripted invariants $\kappa_{\text{cat}}(K_3 \times E) = o(\text{K\"unneth})$, $\kappa_{\text{ch}}^{\text{Hodge}}(K_3 \times E) = o(\text{Hodge supertrace at } d=3)$, $\kappa_{\text{ch}}^{\text{Heis}} = 3$, $\kappa_{\text{BKM}}(\Delta_5) = 5$, and $\kappa_{\text{fiber}} = 24$ come from five distinct constructions. The $K_3 \times E$ section constructs the curve-stalk positive-half surface and records the further hCS–Hall, completion, pairing, and Hall–Borchers requirements.

Abstract framework in one paragraph

The finite gluing object is the total complex over the bounded DWR/Ran nerve $N_{\leq m}^{\text{Ran}}(\mathfrak{U}; \Gamma_{\leq L})$. A comparison map is a degree-zero element of the convolution dg Lie algebra $\mathfrak{M}_{\text{hCS, Hall}}^{N, r, L, m}(\mathfrak{U})$ satisfying

$$D_{\text{tot}}\Theta + \frac{1}{2}[\Theta, \Theta] = o.$$

Face-compatible cyclic contractions over $\Omega^\bullet(\Delta^p)$ produce the simplex maps; Stokes' formula turns their boundary terms into the Čech/Ran differential. The four strata supply known geometric coefficient sources for those face homotopies. They do not replace the Maurer–Cartan solution, the inverse-limit completion, or the monoidal vanishing-cycle realisation.

§33.2 realises the finite framework on the toric source, beginning with the two-chart conifold.

33.2 CHART-WISE GLUING ON TORIC CY_3 (STRATUM I)

Stratum i is the toric regime: every top-dimensional cone of the fan contributes a $\mathbb{C}^3$ -chart whose local critical Hall algebra is the Schiffmann–Vasserot positive half $Y^+(\widehat{\mathfrak{gl}}_1)$. The gluing object in this section

is finite: after a DWR/Ran refinement of the toric atlas and finite bounds (N, r, L, m) , the chart data form an oriented Rees Hall coefficient system on the finite Čech/Ran nerve. The output is the Maurer–Cartan element in the total convolution dg Lie algebra; completion, vanishing-cycle realisation, Drinfeld doubling, and vertex-algebra evaluation are separate operations. Thus a $\mathbb{C}^3$ chart contributes $Y^+(\widehat{\mathfrak{gl}}_1)$, not $\mathcal{W}_{1+\infty}$, and the finite assembly below is not a compact CoHA. The simplest non-trivial instance is the resolved conifold $\mathbf{Y} = \text{Tot}(\mathcal{O}_{\mathbb{P}^1}(-1) \oplus \mathcal{O}_{\mathbb{P}^1}(-1))$ with its two-chart atlas $\mathbf{Y} = U_+ \cup U_-$. The multi-chart generalisation indexes over a toric fan; the compact-4-cycle obstruction separates zero-interior-point diagrams from diagrams requiring McKay resolution; the zero-interior case isolates the finite Rees layer available before realisation.

Čech gluing of two charts: the conifold paradigm

The obstruction resolved by a two-chart atlas is the absence of a global $\mathbb{C}^3$ -parametrisation: the resolved conifold $\mathbf{Y}$ is a rank-2 vector bundle over $\mathbb{P}^1$, not an affine variety. Any chart-wise Schiffmann–Vasserot construction must name the transition datum that turns two copies of $\mathbb{C}^3$ into $\mathbf{Y}$, then transport that datum through every intermediate step; the $(3, 0)$ -form, the polyvector fields, the Hall product, and the orientation line.

THE TWO-CHART ATLAS

Let $z \in \mathbb{P}^1$ be the standard affine coordinate on the base, with $\tilde{z} = z^{-1}$ on the complementary chart. On the total space $\mathbf{Y} = \text{Tot}(\mathcal{O}_{\mathbb{P}^1}(-1) \oplus \mathcal{O}_{\mathbb{P}^1}(-1))$ introduce fibre coordinates u_+, v_+ in the trivialisation over the z -chart and u_-, v_- in the trivialisation over the $\tilde{z}$ -chart. The cover

$$U_+ = \{z \neq \infty\} \times \mathbb{C}^2 \cong \mathbb{C}^3, \quad U_- = \{\tilde{z} \neq \infty\} \times \mathbb{C}^2 \cong \mathbb{C}^3,$$

has overlap $U_+ \cap U_- = (\mathbb{P}^1 \setminus \{0, \infty\}) \times \mathbb{C}^2 \cong \mathbb{C}^\times \times \mathbb{C}^2$. A section of $\mathcal{O}_{\mathbb{P}^1}(-1)$ is a function $f(z)$ on U_+ that transforms to $\tilde{z}f(\tilde{z}^{-1}) = z^{-1}f(z)$ on U_- . Writing $u_\pm, v_\pm$ as the fibre coordinates of the two $\mathcal{O}(-1)$ summands one finds the transition

$$\tilde{z} = z^{-1}, \quad u_- = z u_+, \quad v_- = z v_+, \quad (33.1)$$

as the natural datum forced by the $\mathcal{O}(-1) \oplus \mathcal{O}(-1)$ twist. The standard atlas of $\mathbb{P}^1$ carries an orientation flip across $z \leftrightarrow \tilde{z}$: the holomorphic 1-form $dz = -\tilde{z}^{-2} d\tilde{z}$ reverses sign through the change of chart, and this sign propagates to the $(3, 0)$ -form computation of the next subsection.

JACOBIAN OF THE TRANSITION ON THE $(3, 0)$ -FORM

The Calabi–Yau $(3, 0)$ -form $\Omega_{\mathbf{Y}}$ is specified on U_+ by the requirement that it trivialise the canonical bundle of $U_+ \cong \mathbb{C}^3$:

$$\Omega_{\mathbf{Y}}|_{U_+} = dz \wedge du_+ \wedge dv_+.$$

To transport $\Omega_{\mathbf{Y}}$ to U_- one computes the Jacobian of the transition (33.1) explicitly. The exterior derivatives are

$$dz = -\tilde{z}^{-2} d\tilde{z}, \quad du_+ = d(z^{-1}u_-) = -z^{-2}u_- dz + z^{-1}du_-, \quad dv_+ = -z^{-2}v_- dz + z^{-1}dv_-,$$

so that

$$dz \wedge du_+ = dz \wedge z^{-1}du_-, \quad dz \wedge du_+ \wedge dv_+ = dz \wedge z^{-1}du_- \wedge z^{-1}dv_- = z^{-2}dz \wedge du_- \wedge dv_-.$$

Substituting $dz = -\tilde{z}^{-2} d\tilde{z}$ and the fibre Jacobian $z^{-2} = \tilde{z}^2$:

$$\Omega_{\mathbf{Y}}|_{U_+} = dz \wedge du_+ \wedge dv_+ = \underbrace{z^{-2}}_{\text{fibre twist}} \underbrace{dz}_{-\tilde{z}^{-2} d\tilde{z}} \wedge du_- \wedge dv_- = \underbrace{\tilde{z}^2 \cdot (-\tilde{z}^{-2})}_{=-1} d\tilde{z} \wedge du_- \wedge dv_- = -d\tilde{z} \wedge du_- \wedge dv_- . \quad (33.2)$$

The two factors $\tilde{z}^2$ (fibre twist, one $\tilde{z}$ per $\mathcal{O}(-1)$ summand) and $-\tilde{z}^{-2}$ (cotangent coefficient from dz) cancel exactly, leaving no residual $\tilde{z}^\pm$ and only the base-orientation sign -1 of $\mathbb{P}^1$. This is the statement that $K_{\mathbf{Y}}$ is trivial; the transition cocycle on $U_+ \cap U_-$ collapses to a constant -1 , with no $\tilde{z}$ -dependence; and is precisely the cancellation required by the Calabi–Yau condition $c_1(\mathcal{O}(-1) \oplus \mathcal{O}(-1)) = -2H = -c_1(T_{\mathbb{P}^1})$ (degrees of the two $\mathcal{O}(-1)$ -summands sum to $-\deg K_{\mathbb{P}^1} = -2$).

RESOLVED-CONIFOLD hCS DESCENT BEFORE THE HALL COMPARISON

Let $U_{+-} = U_+ \cap U_-$. For an admissible open $V \subset \mathbf{Y}$, put

$$\mathcal{E}_{\text{hCS},c}(V, \mathfrak{g}) := \Omega_c^{\circ, \bullet}(V, \mathfrak{g})[1], \quad Q_{\text{hCS}} = \bar{\partial},$$

where $\mathfrak{g}$ is a finite-dimensional metric Lie algebra. The classical hCS action on V is

$$I_V(\alpha) = \int_V \Omega_{\mathbf{Y}} \wedge \left(\frac{1}{2} \langle \alpha, \bar{\partial} \alpha \rangle + \frac{1}{6} \langle \alpha, [\alpha, \alpha] \rangle \right),$$

with the $(0, 3)$ -part taken before integration. The corresponding classical observable complex is

$$\text{Obs}_{\text{hCS}}^{\text{cl}}(V, \mathfrak{g}) := \left(\widehat{\text{Sym}}(\mathcal{E}_{\text{hCS},c}(V, \mathfrak{g})^\vee[-1]), d_{\bar{\partial}} + \{I_V, -\}_{\text{BV}} \right),$$

completed by polynomial degree in the continuous dual topology. For disjoint opens $V_1, \dots, V_k \subset V$, the factorisation product is the usual product of functionals after restriction of fields from V to the V_i .

THEOREM 33.2.1 (*Resolved-conifold hCS factorisation descent*). Let

$$\mathbf{Y} = \text{Tot}_{\mathbb{P}^1}(\mathcal{O}_{\mathbb{P}^1}(-1) \oplus \mathcal{O}_{\mathbb{P}^1}(-1)) = U_+ \cup U_-$$

with transition (33.1), and orient $\mathbf{Y}$ by the holomorphic volume form whose U_+ -expression is $dz \wedge du_+ \wedge dv_+$. Then the local E_3 -holomorphic hCS factorisation algebra on $U_+ \simeq \mathbb{C}^3$ and $U_- \simeq \mathbb{C}^3$ descends to a global classical BV factorisation algebra

$$\text{Obs}_{\text{hCS}}^{\text{cl}}(-, \mathfrak{g})$$

on $\mathbf{Y}$. More precisely:

(i) on U_{+-} the pullback

$$T_{+-}^{\text{BV}} : \Omega_c^{\circ, \bullet}(U_{+-}, \mathfrak{g})[1]_- \longrightarrow \Omega_c^{\circ, \bullet}(U_{+-}, \mathfrak{g})[1]_+, \quad \alpha \longmapsto (\tilde{z} = z^{-1}, u_- = zu_+, v_- = zv_+)^* \alpha,$$

is an isomorphism of cyclic BV L_∞ -algebras;

(ii) the compactly supported hCS fields satisfy the Mayer–Vietoris descent sequence of complexes

$$0 \longrightarrow \mathcal{E}_{\text{hCS},c}(U_{+-}, \mathfrak{g}) \xrightarrow{(j_{+*}, -j_{-*})} \mathcal{E}_{\text{hCS},c}(U_+, \mathfrak{g}) \oplus \mathcal{E}_{\text{hCS},c}(U_-, \mathfrak{g}) \xrightarrow{j_{+*} + j_{-*}} \mathcal{E}_{\text{hCS},c}(\mathbf{Y}, \mathfrak{g}) \longrightarrow 0,$$

where equality on the overlap is read through T_{+-}^{BV} ;

(iii) if $\mathbf{U}_Y = \{U_+, U_-\}$ and $\text{DWR}(\mathbf{U}_Y)$ is the Ran–Weiss category of finite disjoint unions of holomorphic polydiscs, each polydisc lying in one of U_+ , U_- , or U_{+-} , then the canonical descent map

$$\text{hocolim}_{P \in \text{DWR}(\mathbf{U}_Y)/V} \text{Obs}_{\text{hCS}}^{\text{cl}}(P, \mathfrak{g}) \xrightarrow{\sim} \text{Obs}_{\text{hCS}}^{\text{cl}}(V, \mathfrak{g})$$

is a quasi-isomorphism of prefactorisation algebras for every admissible open $V \subset \mathbf{Y}$. In particular, taking $V = \mathbf{Y}$ gives a genuine non-affine global hCS E_3 -factorisation algebra obtained by gluing two standard $\mathbb{C}^3$ charts.

The construction is the resolved-conifold descent case. It uses the exceptional zero-section $\mathbb{P}^1 \subset \mathbf{Y}$ and is therefore not the single affine $\mathbb{C}^3$ calculation. It also makes no compact-CoHA or Hall–Drinfeld-double assertion.

Proof. First, the transition is cyclic. Since the map $(z, u_+, v_+) \mapsto (\tilde{z}, u_-, v_-) = (z^{-1}, zu_+, zv_+)$ is holomorphic, its pullback commutes with $\bar{\partial}$ and with the pointwise Lie bracket on $\mathfrak{g}$ -valued Dolbeault forms. The Jacobian calculation (33.2) says exactly that the holomorphic volume form changes by the constant orientation sign forced by the base coordinate and by no residual power of z . Absorbing that sign into the U_- -trivialisation of Ω_Y , the change-of-variables formula gives

$$\int_{U_{+-}} \Omega_Y \wedge \langle T_{+-}^{\text{BV}} \alpha, T_{+-}^{\text{BV}} \beta \rangle = \int_{U_{+-}} \Omega_Y \wedge \langle \alpha, \beta \rangle,$$

and the same equality for the quadratic and cubic terms in I . Thus T_{+-}^{BV} preserves the BV pairing, bracket, action, and classical master equation.

Second, compactly supported Dolbeault fields are a cosheaf for ordinary open covers. For the two-chart cover this is the displayed exact Mayer–Vietoris sequence. Injectivity is clear because a compactly supported field on U_{+-} has a smooth extension by zero to both charts. If two chart fields have the same extension to $\mathbf{Y}$, their difference is supported on the overlap and comes from the first term. Surjectivity follows by choosing a smooth partition of unity ρ_+, ρ_- subordinate to U_+, U_- and writing a compactly supported field α on $\mathbf{Y}$ as $\rho_+ \alpha + \rho_- \alpha$. All arrows commute with $\bar{\partial}$, hence the sequence is exact as a sequence of complexes.

Third, the preceding two paragraphs give a global elliptic local L_∞ -algebra on $\mathbf{Y}$, namely $\Omega_c^{\circ, \bullet}(-, \mathfrak{g})[1]$ with Dolbeault differential, pointwise bracket, cyclic pairing, and cubic hCS local functional. The Costello–Gwilliam factorisation-envelope construction applied to this global local L_∞ -algebra is exactly the displayed completed classical BV observable complex, with differential $d_{\bar{\partial}} + \{I, -\}_{\text{BV}}$. Its structure maps are induced by restriction of fields and multiplication of polynomial functionals, so they are compatible with the Mayer–Vietoris differential and with the transition T_{+-}^{BV} .

Finally, refine the two-chart cover by the Ran–Weiss category $\text{DWR}(\mathbf{U}_Y)$. Every finite subset of an admissible open $V \subset \mathbf{Y}$ is contained in a finite disjoint union of holomorphic polydiscs adapted to U_+ , U_- , and U_{+-} , and the transition on a component lying in U_{+-} is the already constructed T_{+-}^{BV} . On each polydisc the observable complex is the standard $\mathbb{C}^3$ hCS E_3 -algebra; for disjoint unions the structure map is multiplication after restriction of fields. These maps commute with the Čech differential and with T_{+-}^{BV} , so the Ran–Weiss homotopy colimit identifies with $\text{Obs}_{\text{hCS}}^{\text{cl}}(V, \mathfrak{g})$. This proves descent as a holomorphic E_3 -factorisation algebra. $\square$

Definition 33.2.2 (Anomaly-free hCS gauge datum). For a finite-dimensional metric Lie superalgebra $\mathfrak{g}$, let

$$\mathfrak{a}_{\mathfrak{g}} \in H_{\text{loc}}^1(\mathbb{C}^3, \text{Dens}_{\mathbb{C}^3}) \otimes (\text{Sym}^4 \mathfrak{g}^\vee)^{\mathfrak{g}}$$

be the Costello one-loop holomorphic-Chern–Simons anomaly, represented on a polydisc by the wheel graph with four external hCS fields. Its Lie-theoretic coefficient is the cyclic symmetrisation of

$$(x_1, x_2, x_3, x_4) \mapsto \text{Str}_{\mathfrak{g}}(\text{ad}_{x_1} \text{ad}_{x_2} \text{ad}_{x_3} \text{ad}_{x_4}).$$

The datum $(\mathfrak{g}, \langle -, - \rangle)$ is *bCS-anomaly-free in complex dimension 3* when this local cohomology class vanishes. Abelian metric Lie algebras and matrix Lie superalgebras whose fourth adjoint supertrace is zero satisfy the condition.

THEOREM 33.2.3 (*Resolved-conifold quantum bCS descent*). Let $\mathfrak{g}$ be an anomaly-free hCS gauge datum in the sense of Definition 33.2.2. The resolved conifold $\mathbf{Y}$ carries a renormalised quantum hCS factorisation algebra

$$\text{Obs}_{\text{hCS}}^q(-, \mathfrak{g}) = \left(\mathcal{O}_{\text{ren,loc/multiloc}}(\Omega_c^{\circ,\bullet}(-, \mathfrak{g})[1])[[\hbar]], \bar{\partial} + \{I[\ell], -\}_{\text{BV}} + \hbar \Delta_\ell \right)$$

whose restriction to U_+ and U_- is the standard Costello–Gwilliam hCS quantisation on $\mathbb{C}^3$, and whose overlap transition is T_{+-}^{BV} . For every pair of scales $0 < \epsilon < \ell < \infty$, the propagator is

$$P_{\epsilon, \ell} = \int_{\epsilon}^{\ell} (\bar{\partial}_h^* \otimes 1) K_t dt,$$

where h is any complete Kähler metric of bounded geometry on $\mathbf{Y}$, K_t is the heat kernel of $\Delta_{\bar{\partial}, h} = [\bar{\partial}, \bar{\partial}_h^*]$, and $\bar{\partial}_h^*$ is the adjoint determined by h and $\Omega_{\mathbf{Y}}$. The effective interaction is the renormalised formal graph sum

$$I[\ell] = \lim_{\epsilon \rightarrow 0} \left(\sum_{\Gamma} \frac{\hbar^{b_1(\Gamma)}}{|\text{Aut } \Gamma|} \mathcal{W}_{\Gamma}(P_{\epsilon, \ell}, I_{\text{hCS}}) + I_{\epsilon}^{\text{CT}} \right),$$

with local counterterm I_{ϵ}^{CT} , and it satisfies the quantum master equation

$$(\bar{\partial} + \hbar \Delta_\ell) e^{I[\ell]/\hbar} = 0.$$

The resulting quantum observables satisfy the same DWR/Ran descent as Theorem 33.2.1.

Proof. The total space of $\mathcal{O}_{\mathbb{P}^1}(-1) \oplus \mathcal{O}_{\mathbb{P}^1}(-1)$ admits a complete Kähler metric of bounded geometry: take the Fubini–Study metric on $\mathbb{P}^1$, Hermitian metrics on the two $\mathcal{O}(-1)$ -summands, and replace the fibre metric outside a compact set by a cylindrical radial metric. The associated Dolbeault Laplacian has a smooth heat kernel with the small-time asymptotic expansion required by Costello’s renormalisation theorem. The propagator $P_{\epsilon, \ell}$ is therefore a well-defined smooth kernel away from the diagonal and has the standard local singularity on every holomorphic polydisc.

The counterterms are local functionals depending only on the finite jet of the metric, the holomorphic volume form, and the hCS interaction at the diagonal. On U_{+-} the transition (33.1) is holomorphic and (33.2) preserves the CY density up to the constant orientation sign already absorbed in the cyclic trivialisation. Hence T_{+-}^{BV} conjugates $\bar{\partial}$, the BV pairing, the heat-kernel parametrix, and the local counterterm density. If two gauge fixings are used, their propagators differ by the Costello renormalisation-group homotopy; the corresponding effective interactions are canonically equivalent.

The obstruction to solving the quantum master equation is the local one-loop class $\mathfrak{a}_{\mathfrak{g}}$. It is local on $\mathbb{C}^3$, natural under holomorphic volume-preserving coordinate changes, and has no additional global component on the resolved conifold because the two-chart Čech cocycle for $\Omega_{\mathbf{Y}}$ is constant. The vanishing

hypothesis on $\mathfrak{g}$ kills the obstruction. Costello's recursive construction then supplies local counterterms I_ϵ^{CT} and effective interactions $I[\ell]$ solving the displayed QME at every order in $\hbar$. The solution is unique up to contractible renormalisation-group equivalence.

For disjoint opens the factorisation product is multiplication of renormalised multilocal functionals after restriction of fields. These maps commute with T_{+-}^{BV} and with compact-support Mayer–Vietoris. The DWR/Ran descent argument of Theorem 33.2.1 therefore applies to the renormalised quantum complexes. $\square$

THE CHART-WISE SCHIFFMANN–VASSEROT CoHA

Each chart $U_\pm \cong \mathbb{C}^3$ carries the Jordan-triple quiver with potential

$$Q_{\text{Jor}} : \underbrace{\bullet}_{\circ} \text{ with three loops } x_\pm, y_\pm, z_\pm, \quad W_\pm = \text{tr}(x_\pm[y_\pm, z_\pm]).$$

The critical CoHA of $(Q_{\text{Jor}}, W_\pm)$ is the positive half of the affine Yangian of $\widehat{\mathfrak{gl}}_1$ (Schiffmann–Vasserot 2012 arXiv:1202.2756; Tsymbaliuk 2014 arXiv:1404.5240),

$$\text{CoHA}(U_\pm, W_\pm) \cong Y^+(\widehat{\mathfrak{gl}}_1),$$

with generators $\ell_r^{(\pm)}, f_r^{(\pm)}, h_r^{(\pm)}$ indexed by $r \in \mathbb{Z}_{\geq 0}$ and structure functions given by the RSYZ shuffle kernel (Rapcak–Soibelman–Yang–Zhao 2020 arXiv:1810.10402 §5, equation (5.3), specialised to the single-vertex Jordan-triple case). At weight $(1, 1)$ the shuffle kernel evaluates to

$$\varphi_{\text{II}}(u_1; u_2) = \frac{1}{(u_1 - u_2 - \varepsilon_1)(u_1 - u_2 - \varepsilon_2)} \xrightarrow{u_2 \rightarrow u_1} \frac{1}{\varepsilon_1 \varepsilon_2}, \quad (33.3)$$

the structure constant that every downstream computation must reproduce.

FOURIER–MUKAI TRANSITION KERNEL

On the overlap $U_+ \cap U_- = \mathbb{C}^\times \times \mathbb{C}^2$ the derived category $D^b(\text{Coh}(U_+ \cap U_-))$ carries the autoequivalence implementing the transition (33.1) at the level of sheaves. Its integral kernel is

$$K_{+-} = \mathcal{O}_\Delta \otimes \pi_1^* \mathcal{O}_{\mathbb{P}^1}(-1) \in D^b(\text{Coh}(U_+ \cap U_-) \times (U_+ \cap U_-)), \quad (33.4)$$

with Δ the diagonal and π_1 the projection onto the first factor. The transform $T_{+-}(\mathcal{F}) := \pi_{2,*}(\pi_1^* \mathcal{F} \otimes K_{+-})$ acts on polyvector fields $\text{PV}^\bullet(U_\pm) = \bigoplus_p \wedge^p T_{U_\pm}$ through the chain rule applied to (33.1) combined with the $\mathcal{O}_{\mathbb{P}^1}(-1)$ -twist.

Chain rule on the cotangent basis. Differentiate (33.1) to obtain

$$du_+ = d(z^{-1}u_-) = -z^{-2}u_- dz + z^{-1}du_-, \quad dv_+ = -z^{-2}v_- dz + z^{-1}dv_-.$$

On the vertical (fibre-degree) sector; the sector entering the Schiffmann–Vasserot Hall product; only the $z^{-1}du_-$ and $z^{-1}dv_-$ terms survive (the dz -terms drop under pairing with the Jordan-triple fibre polyvectors by (33.3)). The cotangent multiplier is therefore z^{-1} per fibre slot, giving $z^{-(a+b)}$ on a fibre-form $du_+^a \wedge dv_+^b$.

Polyvector transport via Ω_Y -duality. The critical CoHA identifies polyvectors with differential forms via Serre duality against the $(3, 0)$ -form Ω_Y :

$$\Lambda^p T_Y \cong \Omega_Y^{3-p} \otimes K_Y^{-1} \cong \Omega_Y^{3-p}$$

using triviality of K_Y (equation (33.2)). Under this identification the fibre-polyvector $\partial_{u_+}^a \partial_{v_+}^b$ corresponds (up to sign) to the fibre-form $du_+^a \wedge dv_+^b$ contracted against the base dz -direction of Ω_Y . Its transport under T_{+-} is the cotangent transformation $du_+^a \wedge dv_+^b = z^{-(a+b)} du_-^a \wedge dv_-^b$.

$\mathcal{O}(-1)$ -kernel twist. The factor $\pi_1^* \mathcal{O}_{\mathbb{P}^1}(-1)$ in K_{+-} contributes a further multiplier z^{-1} tracking the base- $\mathbb{P}^1$ line-bundle weight carried by CoHA sections (the critical CoHA acts on φ_W -twisted sheaves that inherit the $\mathcal{O}(-1)$ -weight of the superpotential $W_{\pm} = \text{tr}(x_{\pm}[\gamma_{\pm}, z_{\pm}])$ along the compact base): a section g of $\mathcal{O}_{\mathbb{P}^1}(-1)$ expressed as $g(z)$ on U_+ reads $\tilde{z} g(\tilde{z}^{-1}) = z^{-1} g(z)$ on U_- .

Net multiplier on polyvector sections. The CoHA-relevant sections are polyvector densities $f \cdot \partial^a \partial^b$ with f a section of $\mathcal{O}(-1)$ (the superpotential line bundle restricted to the overlap), not a scalar function. Combining the cotangent chain rule (fibre-form multiplier $z^{-(a+b)}$) and the $\mathcal{O}(-1)$ -kernel twist (scalar-section multiplier z^{-1}),

$$\underbrace{\left[z^{-(a+b)} \right]}_{\text{cotangent chain rule, fibre slots}} \cdot \underbrace{\left[z^{-1} \right]}_{\mathcal{O}(-1)\text{-kernel twist, base weight}} = z^{-(1+a+b)}.$$

The Fourier–Mukai transport of a Jordan-triple fibre polyvector density therefore reads

$$T_{+-}^* : f(z, u_+, v_+) \partial_{u_+}^a \partial_{v_+}^b \longmapsto f(\tilde{z}^{-1}, \tilde{z} u_-, \tilde{z} v_-) z^{-(1+a+b)} \partial_{u_-}^a \partial_{v_-}^b, \quad (33.5)$$

with f understood as a section of $\mathcal{O}(-1)$ on the base. The base-polyvector sector (powers of ∂_z) picks up the base-orientation multiplier $(-\tilde{z}^2)$ per ∂_z -slot; the Jordan-triple selection rule (33.3) restricts the Hall product to the fibre sector $\alpha = 0$ on which the base orientation enters only through the global sign of (33.2).

FINITE ČECH/RAN REES GLUING

The pair (U_+, U_-) with overlap $U_+ \cap U_-$ is an ordinary Čech spine, not a Weiss cover. Factorisation locality enters only after a DWR/Ran refinement. Fix finite bounds

$$N \quad (\text{holomorphic jets}), \quad r \quad (\text{renormalisation order}), \quad L \quad (\text{charge}), \quad m \quad (\text{Ran arity}).$$

Let $\mathfrak{U}_Y$ be a DWR-good refinement of the two toric charts by polydiscs subordinate to U_+ , U_- , and $U_+ \cap U_-$. A p -simplex of the finite Ran nerve has the form

$$\sigma = (S, \{P_s \in U_{\epsilon_{s,0}} \cap \cdots \cap U_{\epsilon_{s,p}}\}_{s \in S}), \quad \epsilon_{s,j} \in \{+, -\},$$

with $|S| \leq m$ and charge bounded by $\Gamma_{\leq L}$. On a vertex lying in $U_{\pm}$ the finite cyclic critical model is the Jordan triple $(Q_{\text{Jor}}, W_{\pm})$ truncated at (N, r, L) ; on an edge lying in $U_+ \cap U_-$ it is transported by the Fourier–Mukai kernel K_{+-} and the multiplier (33.5).

LEMMA 33.2.4 (*Conifold Čech/Ran cyclic atlas*). For every finite bound (N, r, L, m) the data above form a multiplicative finite DWR/Ran cyclic critical atlas on $\mathfrak{U}_Y$. Its 0-simplex Hall cohomology is the local positive half

$$H^0(\text{Hall}_{U_{\pm}}^{\text{Rees, or}}/\hbar) \cong Y^+(\widehat{\mathfrak{gl}}_1),$$

and the edge restriction is the same positive half transported by K_{+-} ; no vertex of the atlas is a $\mathcal{W}_{1+\infty}$ -module.

Proof. The Jacobian calculation (33.2) gives a constant transition for the holomorphic volume form, hence transports the cyclic pairing without a residual Laurent monomial. The chain rule and the $\mathcal{O}(-1)$ kernel give exactly the fibre multiplier of (33.5); face restriction of a polydisc in $U_+ \cap U_-$ is therefore the pullback of the vertex cyclic model by the same Fourier–Mukai transition. On the triple faces of the refined nerve the two possible restrictions are equal because the line-bundle transition cocycle of $\mathcal{O}(-1)$ is multiplicative and the diagonal kernels compose by convolution.

For a disjoint Ran family $\sigma_1 \sqcup \sigma_2$ the finite potential is $\mathcal{W}_{\sigma_1} \boxplus \mathcal{W}_{\sigma_2}$ and the cyclic form is the external orthogonal sum. Thom–Sebastiani identifies the corresponding Rees Hall complex with the completed tensor product of the two Rees Hall complexes. The vertex computation is the Schiffmann–Vasserot $\mathbb{C}^3$ theorem applied to the Jordan triple, so the local cohomology is $Y^+(\widehat{\mathfrak{gl}}_1)$. The construction has used only critical Hall polyvectors and Rees deformation; no vertex-algebra representation or Drinfeld double has been supplied. $\square$

Let

$$\mathfrak{M}_{\text{hCS, Hall}}^{N, r, L, m}(\mathfrak{U}_Y) = \text{Tot}_{\sigma \in \mathbb{N}_{\leq m}^{\text{Ran}}(\mathfrak{U}_Y; \Gamma_{\leq L})} \text{Hom}_{\text{cont}}(B\text{Obs}_{\text{hCS}}^{q, \leq r, \leq N}(\sigma)_{\leq L}, \text{Hall}_{\sigma}^{\text{Rees, or}})$$

with differential $D_{\text{tot}} = d_{\text{Hall}} \circ (-) - (-1)^{|-|}(-) \circ d_{B\text{Obs}} + \delta_{\check{C}/\text{Ran}}$ and convolution bracket induced by the bar coproduct and the Rees Hall product.

Construction 33.2.5 (*The finite hCS–Rees–Hall chart map*). Let $P \Subset U_{\epsilon}$, $\epsilon \in \{+, -, +-\}$, be a holomorphic polydisc with coordinates w_1, w_2, w_3 . Fix finite bounds (N, r, L) . The Dolbeault–Taylor projection

$$\pi_{P, N} : \Omega_c^{\circ, \bullet}(P, \mathfrak{gl}_{\leq L})[1] \longrightarrow \mathfrak{gl}_{\leq L} \otimes \mathbb{C}[w_1, w_2, w_3]/(w_1, w_2, w_3)^{N+1}[1]$$

is the Dolbeault contraction of P onto holomorphic functions followed by Taylor truncation at the centre of P . Choose the Bochner–Martinelli homotopy h_P and a compactly supported inclusion $i_{P, N}$ of truncated jets. The triple $(i_{P, N}, \pi_{P, N}, h_P)$ is cyclic for the residue pairing induced by Ω_Y .

The cyclic homological perturbation lemma transfers the cubic hCS Hamiltonian to the finite jet space by the tree formula

$$W_{P, N}^{\text{tr}} = \sum_{T \text{ rooted}} \frac{1}{|\text{Aut } T|} \pi_{P, N} I_{\text{hCS}}(h_P I_{\text{hCS}})^T i_{P, N}^{\otimes \text{leaves}(T)}.$$

For the constant $\mathfrak{gl}_{\leq L}$ -framing this transferred Hamiltonian is the Jordan-triple potential

$$W_{P, N}^{\text{tr}} = \text{tr}(X[Y, Z]) \quad \text{modulo } (w_1, w_2, w_3)^{N+1}$$

on the finite representation space of triples $(X, Y, Z) \in \text{End}(\mathbb{C}^d)^3$, $d \leq L$. Let

$$\mathfrak{F}_{\omega_P} : B\text{Obs}_{\text{hCS}}^{q, \leq r, \leq N}(P)_{\leq L} \longrightarrow \text{Hall}_P^{\text{Rees, or}}$$

be the BV Fourier transform determined by the finite cyclic volume $\omega_P = \Omega_Y|_P$: a polynomial functional is contracted with ω_P , and the differential becomes $\iota_{dW_{P,N}^{\text{tr}}} + \hbar \Delta_{\omega_P}$. The chart map is

$$\theta_P^{N,r,L} := \mathfrak{F}_{\omega_P} \circ B(\pi_{P,N}) \circ \text{HPL}_{P,N,r,L}.$$

Here $\text{HPL}_{P,N,r,L}$ is the filtered homological perturbation quasi-isomorphism from the scale- ℓ , loop-order $\leq r$, charge- $\leq L$ bar observable complex to the transferred finite jet BV complex determined by $(i_{P,N}, \pi_{P,N}, h_P)$. Its Taylor coefficients are the rooted-tree operators displayed in the formula for $W_{P,N}^{\text{tr}}$, with internal edges labelled by h_P and vertices by the cubic hCS bracket. For a Ran simplex $\sigma = (S, \{P_s\})$, put $\theta_\sigma^{\text{rel}} = \widehat{\otimes}_{s \in S} \theta_{P_s}^{N,r,L}$ and extend over $\Omega^\bullet(\Delta^p)$ by the relative cyclic contraction.

LEMMA 33.2.6 (*Overlap conjugacy of the conifold chart map*). On U_{+-} , the maps of Construction 33.2.5 satisfy

$$\theta_+^{N,r,L} B(T_{+-}^{\text{BV}}) = T_{+-}^{\text{PV}} \theta_-^{N,r,L},$$

where T_{+-}^{PV} is the Fourier–Mukai/Rees polyvector transport with multiplier (33.5). The same identity holds on every face of the finite DWR/Ran nerve.

Proof. The Dolbeault–Taylor projection is natural under holomorphic coordinate change: Taylor monomials transform by the Jacobian of (33.1), and the Bochner–Martinelli homotopy changes by a $\bar{\partial}$ -exact homotopy. The cyclic residue pairing is preserved by (33.2). Cyclic HPL therefore transfers the hCS Hamiltonian to the same Jordan potential on the overlap, written in the two coordinate systems. The BV Fourier transform is natural for cyclic linear isomorphisms; after Ω_Y -duality the coordinate change is precisely the polyvector transport computed in (33.5). Tensoring over a disjoint Ran family and restricting to faces preserves the equality. $\square$

PROPOSITION 33.2.7 (*Conifold Čech/Ran Maurer–Cartan equation*). The relative chart maps of Construction 33.2.5, with the overlap conjugacy of Lemma 33.2.6, assemble to

$$\Theta_Y^{\text{Rees}, N, r, L, m} := \sum_{0 \leq p \leq m} \sum_{\sigma \in \mathcal{N}_{p, \leq m}^{\text{Ran}}(\mathcal{U}_Y; \Gamma \leq L)} \int_{\Delta^p} \theta_\sigma^{\text{rel}} \in \mathfrak{M}_{\text{hCS}, \text{Hall}}^{N, r, L, m}(\mathcal{U}_Y),$$

and this element satisfies

$$D_{\text{tot}} \Theta_Y^{\text{Rees}, N, r, L, m} + \frac{1}{2} [\Theta_Y^{\text{Rees}, N, r, L, m}, \Theta_Y^{\text{Rees}, N, r, L, m}] = 0.$$

Thus the conifold atlas gives a finite oriented hCS-to-Rees-Hall comparison on the Čech/Ran nerve. It does not identify the conifold with $\mathcal{W}_{1+\infty}$, with a compact CoHA, or with a Hall–Drinfeld double.

Proof. On every simplex the cyclic homological perturbation transfer gives a relative Hamiltonian W_σ over $\Omega^\bullet(\Delta^p)$ satisfying the BV master equation. The relative Fourier–BV identification rewrites this equation as

$$(d_{\text{Hall}} + d_{\Delta^p}) \theta_\sigma^{\text{rel}} - \theta_\sigma^{\text{rel}} d_{B\text{Obs}} + \frac{1}{2} [\theta_\sigma^{\text{rel}}, \theta_\sigma^{\text{rel}}]_{\text{conv}} = 0.$$

Integration over Δ^p converts the d_{Δ^p} term into the alternating sum over faces by Stokes’ formula. Face compatibility in Lemma 33.2.4 identifies that boundary sum with $\delta_{\check{C}/\text{Ran}}$ in D_{tot} . Summing over the finite nerve gives the displayed Maurer–Cartan equation. The last non-identification follows because the finite Rees Hall complex precedes vanishing-cycle realisation, Hopf pairing, completion, and vertex-algebra evaluation. $\square$

Orientation sign in the finite Rees product. The base-orientation flip in $\Omega_Y|_{U_-} = -d\tilde{z} \wedge du_- \wedge dv_-$ enters the orientation line o_σ of the edge Rees Hall complex. On cross-chart Hall products the sign is the Koszul sign in the Thom–Sebastiani transport, hence a coefficient of the Maurer–Cartan element above. A super-Yangian presentation may be recovered only after the separate realised quiver–Hall identification with the Klebanov–Witten conifold quiver; it is not the output of the finite Čech/Ran equation.

Coefficient check for the $(1, 1)$ term. The $(1, 1)$ structure constant in the finite Rees Hall product equals $(\varepsilon_1 \varepsilon_2)^{-1}$ through three independent computations:

- (i) *Čech two-chart gluing:* the limit $u_2 \rightarrow u_1$ of the chart-wise Jordan shuffle (33.3).
- (ii) *Van den Bergh tilting:* the integral of the φ_W -twisted Euler class over $\text{Ext}^1(S_o, S_1) = \mathbb{C}^2$, the rank-2 Ext-space between the simple modules of the Klebanov–Witten quiver.
- (iii) *Klebanov–Witten super-shuffle:* the Jordan kernel residue at $z_1 = z_2$ of the direct super-shuffle algebra.

Agreement across these computations pins $(\varepsilon_1 \varepsilon_2)^{-1}$ as the local coefficient carried by the finite Rees Hall comparison.

Multi-chart toric fan generalisation

The two-chart finite Rees assembly generalises to any local toric CY_3 . The obstruction resolved is the absence of a global affine chart: a toric variety is covered by affine opens U_σ indexed by the maximal cones σ of the fan, and the finite Rees Hall coefficient system is assembled by running the Čech/Ran machinery along the face lattice of the fan.

TORIC FAN AND CHART DECOMPOSITION

Let $X = X_\Sigma$ be a smooth toric CY_3 with fan Σ in the lattice $N \cong \mathbb{Z}^3$. The Calabi–Yau condition is that the primitive generators of all rays of Σ lie in a common affine hyperplane, equivalently that there exists a lattice vector $m \in M = N^\vee$ such that $\langle m, v_\rho \rangle = 1$ for every ray generator v_ρ . A natural choice places all ray generators at height 1 along the last coordinate; the toric diagram is then the 2-dimensional polytope obtained by projecting the rays to the plane $\{x_3 = 1\}$.

Chart structure at top cones. Each maximal (top-dimensional) cone $\sigma \in \Sigma(3)$ of a smooth toric CY_3 is generated by exactly three rays ρ_1, ρ_2, ρ_3 forming a $\mathbb{Z}$ -basis of N , and determines an affine chart

$$U_\sigma = \text{Spec } \mathbb{C}[\sigma^\vee \cap M] \cong \mathbb{C}^3.$$

Coordinates $(x_1^\sigma, x_2^\sigma, x_3^\sigma)$ on U_σ are the characters of the dual basis of $\sigma^\vee$. The Jordan-triple potential on each chart is

$$W_\sigma = \text{tr}(x_1^\sigma [x_2^\sigma, x_3^\sigma]),$$

and the chart-wise CoHA is $\text{CoHA}(U_\sigma, W_\sigma) \cong Y^+(\widehat{\mathfrak{gl}}_1)$ by the Schiffmann–Vasserot theorem applied to each $\mathbb{C}^3$ with the standard Jordan-triple.

Equivariant weights and the CY condition. The three-torus $T^3 = (\mathbb{C}^\times)^3$ acts on each $U_\sigma \cong \mathbb{C}^3$ with equivariant weights $(\varepsilon_1^\sigma, \varepsilon_2^\sigma, \varepsilon_3^\sigma)$. The Calabi–Yau constraint on W_σ to be a tri-vector of vanishing weight is

$$\varepsilon_1^\sigma + \varepsilon_2^\sigma + \varepsilon_3^\sigma = 0,$$

which specialises the chart-wise weights to those of a local CY_3 . Along a compact direction (a ray ρ in $\Sigma(1)$ whose dual edge in the toric diagram is an internal edge) the equivariant parameter vanishes: the two fixed points of the compact $\mathbb{P}^1$ -base on that edge would carry opposite weights, obstructing global regularity of sections. This is the mechanism that set $\varepsilon_3 = 0$ for the conifold base in §33.2.

PROPOSITION 33.2.8 (*Affine hCS BV chart and CY transition law*). Let $U_\sigma \simeq \mathbb{C}^3$ be a maximal-cone chart of a smooth toric CY_3 , with coordinates $x_1^\sigma, x_2^\sigma, x_3^\sigma$, and write

$$\Omega_X|_{U_\sigma} = \lambda_\sigma dx_1^\sigma \wedge dx_2^\sigma \wedge dx_3^\sigma, \quad \lambda_\sigma \in \mathcal{O}(U_\sigma)^\times.$$

For a metric Lie algebra $\mathfrak{g}$, the affine-chart hCS BV complex is

$$\mathcal{E}_{\text{hCS},c}(U_\sigma, \mathfrak{g}) = \Omega_c^{\circ, \bullet}(U_\sigma, \mathfrak{g})[1], \quad Q_{\text{hCS}} = \bar{\partial},$$

with pairing and classical action

$$(\alpha, \beta)_\sigma = \int_{U_\sigma} \Omega_X \wedge \langle \alpha, \beta \rangle, \quad I_\sigma(\alpha) = \int_{U_\sigma} \Omega_X \wedge \left(\frac{1}{2} \langle \alpha, \bar{\partial} \alpha \rangle + \frac{1}{6} \langle \alpha, [\alpha, \alpha] \rangle \right).$$

An element of Dolbeault degree q has BV cohomological degree $q - 1$. The pairing is non-zero only on components with $q_1 + q_2 = 3$, hence has degree -1 on $\Omega_c^{\circ, \bullet}[1]$; the displayed superfield action means taking the $(0, 3)$ -component before integrating. On non-compact charts the compact-support convention is understood after restriction to the overlap on which the transition map is applied. If $U_\sigma \cap U_{\sigma'} \neq \emptyset$ and $\phi_{\sigma\sigma'}$ is the holomorphic transition map from σ -coordinates to σ' -coordinates, then

$$\lambda_\sigma = (\lambda_{\sigma'} \circ \phi_{\sigma\sigma'}) \det \left(\frac{\partial x_a^{\sigma'}}{\partial x_b^\sigma} \right)_{a,b=1}^3.$$

The transition map

$$T_{\sigma\sigma'}^{\text{BV}}: \mathcal{E}_{\text{hCS},c}(U_{\sigma'}, \mathfrak{g})|_{U_\sigma \cap U_{\sigma'}} \longrightarrow \mathcal{E}_{\text{hCS},c}(U_\sigma, \mathfrak{g})|_{U_\sigma \cap U_{\sigma'}}, \quad \alpha \longmapsto \phi_{\sigma\sigma'}^* \alpha,$$

commutes with $\bar{\partial}$, preserves the BV pairing and action, and satisfies the Čech cocycle identity on triple overlaps. The same Jacobian identity transports the finite Rees Hall divergence by conjugacy:

$$T_{\sigma\sigma'}^{\text{PV}} \Delta_{\omega_{\sigma'}} = \Delta_{\omega_\sigma} T_{\sigma\sigma'}^{\text{PV}}, \quad T_{\sigma\sigma'}^{\text{PV}} \iota_{dW_{\sigma'}} = \iota_{dW_\sigma} T_{\sigma\sigma'}^{\text{PV}},$$

whenever $W_\sigma = \phi_{\sigma\sigma'}^* W_{\sigma'}$. Equivalently $T_{\sigma\sigma'}^{\text{PV}}$ conjugates the finite Rees differential $\iota_{dW} + \hbar \Delta_\omega$. Here $\omega_\sigma = \Omega_X|_{U_\sigma}$ is the finite cyclic volume form.

Proof. The formula for λ_σ is the equality $\Omega_X|_{U_\sigma} = \phi_{\sigma\sigma'}^*(\Omega_X|_{U_{\sigma'}})$ written in coordinates. Since $\phi_{\sigma\sigma'}$ is holomorphic, $\phi_{\sigma\sigma'}^* \bar{\partial} = \bar{\partial} \phi_{\sigma\sigma'}^*$. The change of variables formula and the displayed Jacobian identity give

$$\int_{U_{\sigma'}} \Omega_X \wedge \langle \alpha, \beta \rangle = \int_{U_\sigma} \Omega_X \wedge \langle \phi_{\sigma\sigma'}^* \alpha, \phi_{\sigma\sigma'}^* \beta \rangle,$$

and the same calculation applies to the quadratic and cubic terms of I_σ , using invariance of $\langle -, - \rangle$. Thus the degree- (-1) BV pairing, bracket, and master equation are transported without an extra density. On triple overlaps the coordinate transitions compose, and the determinants multiply; hence the transition maps form a Čech cocycle. The divergence operator Δ_ω is characterised on polyvectors by $\mathfrak{F}_\omega(\Delta_\omega \xi) = d \mathfrak{F}_\omega(\xi)$, equivalently by $L_\xi \omega = (\Delta_\omega \xi) \omega$ for vector fields. Since $\mathfrak{F}_{\omega_\sigma} T_{\sigma\sigma'}^{\text{PV}} = \phi_{\sigma\sigma'}^* \mathfrak{F}_{\omega_{\sigma'}}$, the same Jacobian conjugates Δ_ω ; the equality $W_\sigma = \phi_{\sigma\sigma'}^* W_{\sigma'}$ gives the contraction term. This is precisely the finite Rees compatibility used by Lemma 6.1.16. $\square$

THEOREM 33.2.9 (*Smooth toric CY_3 hCS factorisation descent*). Let Σ be a finite smooth three-dimensional fan in $N \simeq \mathbb{Z}^3$, let $X = X_\Sigma$, and assume the toric Calabi–Yau condition: there is $m_o \in M = N^\vee$ with $\langle m_o, v_\rho \rangle = 1$ for every ray generator v_ρ . Let Ω_X be the corresponding toric holomorphic volume form. For every finite-dimensional metric Lie algebra $\mathfrak{g}$, the affine hCS BV factorisation algebras on the maximal-cone charts $U_\sigma \simeq \mathbb{C}^3$ glue over the face lattice to a global classical BV holomorphic E_3 -factorisation algebra

$$\text{Obs}_{\text{hCS}}^{\text{cl}}(-, \mathfrak{g}) = \left(\widehat{\text{Sym}} \left(\Omega_c^{\circ, \bullet}(-, \mathfrak{g})[1]^\vee[-1] \right), d_{\bar{\partial}} + \{I_X, -\}_{\text{BV}} \right),$$

where

$$I_X(\alpha) = \int_X \Omega_X \wedge \left(\frac{1}{2} \langle \alpha, \bar{\partial} \alpha \rangle + \frac{1}{6} \langle \alpha, [\alpha, \alpha] \rangle \right).$$

If $\mathfrak{U}_\Sigma$ is the toric affine cover and $\text{DWR}(\mathfrak{U}_\Sigma)$ is any Ran–Weiss refinement by holomorphic polydiscs, then for every admissible open $V \subset X$ the canonical descent morphism

$$\text{hocolim}_{P \in \text{DWR}(\mathfrak{U}_\Sigma)/V} \text{Obs}_{\text{hCS}}^{\text{cl}}(P, \mathfrak{g}) \xrightarrow{\sim} \text{Obs}_{\text{hCS}}^{\text{cl}}(V, \mathfrak{g})$$

is a quasi-isomorphism of prefactorisation algebras. If, in addition, X is equipped with a complete bounded-geometry Kähler metric and $\mathfrak{g}$ is anomaly-free in the sense of Definition 33.2.2, the same statement holds for the renormalised quantum hCS factorisation algebra.

Proof. For a maximal cone $\sigma = \langle v_1, v_2, v_3 \rangle$, smoothness makes v_1, v_2, v_3 a $\mathbb{Z}$ -basis of N , hence $U_\sigma = \text{Spec } \mathbb{C}[\sigma^\vee \cap M] \simeq \mathbb{C}^3$. Let $m_1^\sigma, m_2^\sigma, m_3^\sigma$ be the dual basis and $x_i^\sigma = \chi^{m_i^\sigma}$. The Calabi–Yau condition gives $m_o = m_1^\sigma + m_2^\sigma + m_3^\sigma$, so on U_σ

$$\Omega_X = \lambda_\sigma dx_1^\sigma \wedge dx_2^\sigma \wedge dx_3^\sigma$$

with λ_σ an invertible monomial. If σ, σ' share a face, the transition is monomial:

$$x_a^{\sigma'} = \prod_b (x_b^\sigma)^{A_{ab}}, \quad A \in GL_3(\mathbb{Z}).$$

The equality of the two expressions for m_o forces the CY Jacobian identity for Ω_X ; the determinant contributes only the orientation sign of the lattice basis. Proposition 33.2.8 therefore supplies cyclic BV isomorphisms $T_{\sigma\sigma'}^{\text{BV}}$ on every overlap.

Finite intersections of affine toric charts are face charts

$$U_{\sigma_0} \cap \cdots \cap U_{\sigma_p} = U_\tau, \quad \tau = \sigma_0 \cap \cdots \cap \sigma_p,$$

with $U_\tau \simeq \mathbb{C}^{\dim \tau} \times (\mathbb{C}^\times)^{3-\dim \tau}$. On triple overlaps the monomial matrices multiply, determinants multiply, and pullbacks compose; hence the $T_{\sigma\sigma'}^{\text{BV}}$ form a strict Čech cocycle on the face lattice.

Compactly supported Dolbeault fields are a cosheaf. Since the fan is finite, the augmented Čech complex

$$\cdots \rightarrow \bigoplus_{\sigma_0 < \cdots < \sigma_p} \Omega_c^{\circ, \bullet}(U_{\sigma_0} \cap \cdots \cap U_{\sigma_p}, \mathfrak{g})[1] \rightarrow \cdots \rightarrow \bigoplus_{\sigma} \Omega_c^{\circ, \bullet}(U_\sigma, \mathfrak{g})[1] \rightarrow \Omega_c^{\circ, \bullet}(X, \mathfrak{g})[1] \rightarrow 0$$

is exact, with equality on overlaps read through the cyclic transition maps. The proof is the smooth partition-of-unity argument; compact support makes extension by zero smooth and produces no boundary term at infinity.

The preceding paragraph constructs the global elliptic local L_∞ -algebra $\Omega_c^{\bullet,*}(-, \mathfrak{g})[1]$ with its cyclic pairing and hCS Hamiltonian. The Costello–Gwilliam classical observable envelope gives the displayed factorisation algebra. A toric affine cover is not itself Weiss-local, so it is refined by holomorphic polydiscs and closed under finite disjoint unions. Every finite point configuration in V lies in such a disjoint union, and the Ran–Weiss homotopy colimit computes the factorisation algebra on V .

For the quantum statement, the heat-kernel construction of Theorem 33.2.3 is local on the diagonal and natural under the same CY transition maps. The anomaly class is the universal local class $\mathfrak{a}_{\mathfrak{g}}$, so its vanishing kills every chart obstruction and the Čech cocycle introduces no new one. $\square$

GLUING COCYCLE ON THE FACE LATTICE

Two top cones σ, σ' of $\Sigma(3)$ sharing a common face $\tau = \sigma \cap \sigma' \in \Sigma(2)$ of codimension one define an overlap $U_\sigma \cap U_{\sigma'} = U_\tau$. The face τ is a two-dimensional cone, generated by two rays; the corresponding overlap is

$$U_\tau \cong \mathbb{C}^\times \times \mathbb{C}^2,$$

with the $\mathbb{C}^\times$ -factor encoding the direction transverse to τ within the full three-dimensional lattice. The transition between the chart coordinates $(x_1^\sigma, x_2^\sigma, x_3^\sigma)$ and $(x_1^{\sigma'}, x_2^{\sigma'}, x_3^{\sigma'})$ follows the lattice change of basis between $\sigma^\vee$ and $(\sigma')^\vee$: when σ' differs from σ by a toric flop sending ray ρ_1 to ρ'_1 across the shared face τ (generated by ρ_2, ρ_3), the conifold-type transition is

$$x_1^{\sigma'} = (x_1^\sigma)^{-1}, \quad x_i^{\sigma'} = x_1^\sigma \cdot x_i^\sigma \quad \text{for } i = 2, 3,$$

in direct analogy with the conifold transition (33.1). More generally, if the toric flop twists the fibre ρ_1 -direction with multiplicity (k_2, k_3) along ρ_2, ρ_3 (equivalently, the fibre bundle over the shared $\mathbb{P}^1_\tau$ is $\mathcal{O}(-k_2) \oplus \mathcal{O}(-k_3)$), the transition reads $x_i^{\sigma'} = (x_1^\sigma)^{k_i} x_i^\sigma$ on the i -th fibre coordinate. The Fourier–Mukai kernel on the overlap is

$$K_{\sigma\sigma'} = \mathcal{O}_\Delta \otimes \pi_1^* \mathcal{O}_{\mathbb{P}^1_\tau}(-1),$$

the $\mathcal{O}(-1)$ -twist sourced by the compact $\mathbb{P}^1_\tau$ -base transverse to τ ; the polyvector multiplier $(x_1^\sigma)^{-(1+k_2, a+k_3, b)}$ generalises (33.5) with a, b the fibre polyvector indices. The Jacobian argument of §33.2 carries over with z replaced by x_1^σ on each codimension-one face, and with the fibre twist exponents (k_2, k_3) replacing the conifold's $(1, 1)$; the Calabi–Yau condition $k_2 + k_3 = 2$ (sum of $\mathcal{O}(-k_i)$ -degrees equals $-\deg K_{\mathbb{P}^1_\tau} = -2$) enforces triviality of $K_X|_{\mathbb{P}^1_\tau}$.

The face lattice cocycle. The collection $\{K_{\sigma\sigma'}\}_{\sigma, \sigma' \text{ adjacent}}$ forms a cocycle on the face lattice of Σ : at any triple overlap $U_\sigma \cap U_{\sigma'} \cap U_{\sigma''}$ (corresponding to a codimension-two face $\tau = \sigma \cap \sigma' \cap \sigma''$), the compatibility

$$K_{\sigma\sigma''} = K_{\sigma'\sigma''} \circ K_{\sigma\sigma'}$$

holds up to canonical isomorphism, because each kernel is the pullback of $\mathcal{O}_{\mathbb{P}^1}(-1)$ along a $\mathbb{P}^1$ -fibre direction and the fibre directions compose additively in the toric fan. The cocycle class is the derivative of the data on the fan's 1-skeleton and is classified by the sheaf cohomology group $H^1(\Sigma, \underline{\text{Pic}}(\mathbb{P}^1))$ on the fan viewed as a CW complex.

GALAKHOV–LI–YAMAZAKI BOND FACTORS

Galakhov–Li–Yamazaki (2021 arXiv:2106.01230; Li–Yamazaki 2020 arXiv:2003.08909 eq (8.125)) present the multi-chart gluing data via *bond factors* $\varphi^{a \Rightarrow b}(u)$ indexed by ordered pairs (a, b) of vertices in the toric quiver. The convention is:

$$\varphi^{a \Rightarrow b}(u) = \frac{\prod_{I \in \text{Arr}(a \rightarrow b)} (u + h_I^{a \rightarrow b})}{\prod_{J \in \text{Rel}(a \rightarrow b)} (u + h_J^{a \rightarrow b})}, \quad (33.6)$$

with $h_I^{a \rightarrow b}$ the equivariant weight of the I -th arrow from vertex a to vertex b , and $h_J^{a \rightarrow b}$ the equivariant weight of the J -th Jacobi relation $(\partial W / \partial(\text{arrow}))$ tying arrows from a into and out of a trip through b . The *numerator is arrow weights; the denominator is Jacobi-relation weights*; the $(u + h)$ -convention signs track the Drinfeld shifted- R -matrix normalisation (Neguț 2015 arXiv:1512.06473 eq (1.6); Tsymbaliuk 2014 arXiv:1404.5240).

Conifold bond factor from first principles. The conifold quiver (Klebanov–Witten 1998 hep-th/9807080) has two vertices $\{0, 1\}$, two arrows $a_1, a_2 : 0 \rightarrow 1$ with equivariant weights h_1, h_2 , two arrows $b_1, b_2 : 1 \rightarrow 0$ with weights $-h_1, -h_2$, and the Klebanov–Witten superpotential $W_{\text{con}} = \text{tr}(a_1 b_1 a_2 b_2 - a_1 b_2 a_2 b_1)$ of T_{CY}^2 -weight zero. For the bond $0 \Rightarrow 1$, the numerator of (33.6) enumerates the two $0 \rightarrow 1$ arrows with weights h_1, h_2 , giving $(u + h_1)(u + h_2)$. The denominator enumerates the two Jacobi relations tied to $0 \Rightarrow 1$, namely the F-term ideal generators $\partial W / \partial b_1, \partial W / \partial b_2$ read as elements of the weight-graded path algebra at vertex 0: the KW ideal admits a canonical generating pair $(\mathbf{r}_{\text{sym}}, \mathbf{r}_{\text{asym}}) = (a_1 b_1 + a_2 b_2, a_1 b_2 a_2 b_1 - a_1 b_1 a_2 b_2)$ of T_{CY}^2 -weights 0 (symmetric moment-map trace) and $h_1 + h_2$ (Hessian-quadratic deformation direction) respectively, matching the Neguț–Tsymbaliuk rank-2 shuffle presentation (arXiv:1404.5240 §4). Substituting into the GLY formula (33.6):

$$\varphi_{\text{con}}^{0 \Rightarrow 1}(u) = \frac{(u + h_1)(u + h_2)}{u \cdot (u + h_1 + h_2)}, \quad (33.7)$$

matching Neguț’s conifold shuffle kernel (Neguț 2015 arXiv:1512.06473 eq (1.6)) and Li–Yamazaki’s BPS-quiver-algebra master formula (arXiv:2003.08909 eq (8.125)). At the Calabi–Yau torus-equivariant slice $\varepsilon_1 + \varepsilon_2 + \varepsilon_3 = 0$, the conifold weights are $h_1 = \varepsilon_1, h_2 = \varepsilon_2$, and $h_1 + h_2 = \varepsilon_1 + \varepsilon_2 = -\varepsilon_3$; substituting into (33.7):

$$\varphi_{\text{con}}^{0 \Rightarrow 1}(u) = \frac{(u + \varepsilon_1)(u + \varepsilon_2)}{u(u + \varepsilon_1 + \varepsilon_2)} = \frac{(u + \varepsilon_1)(u + \varepsilon_2)}{u(u - \varepsilon_3)}.$$

Both presentations are equivalent through the Calabi–Yau constraint $\varepsilon_3 = -\varepsilon_1 - \varepsilon_2$.

Arrow-weight / relation-weight trace on the toric diagram. The arrow count $|\text{Arr}(a \rightarrow b)|$ matches the number of toric diagram edges joining the dual vertices of a and b ; the Jacobi-relation count $|\text{Rel}(a \rightarrow b)|$ matches the number of toric triangles sharing the edge. For the conifold (2 arrows, 2 relations per direction) the $2 + 2$ tally reflects the two-edge, two-triangle diagram. For local $\mathbb{P}^2$ the bond factors are labelled by the three $\mathbb{Z}_3$ -characters of the McKay quiver (Beilinson nine-arrow structure, §33.2); for the banana threefold, by the three edges of the banana diagram; for the suspended pinch point, by the pinch-point bond structure.

EXAMPLES

$\mathbb{C}^3/\mathbb{Z}_n$ (*linear toric*). The fan has n maximal cones arrayed along the toric diagram edge, each $\mathbb{C}^3$; the face lattice is a linear chain with $n - 1$ codimension-one faces; the gluing cocycle is a chain of $n - 1$ FM kernels, each a $O(-1)$ -twist. The finite Rees atlas carries the $\mathcal{A}_{n-1}$ -type McKay quiver-Hall coefficient system, matching the Beasley–Plesser antisymmetric quiver on $\mathbb{C}^3/\mathbb{Z}_n$ after the orbifold realisation.

Banana threefold. Three ray clusters meeting at a common vertex produce a fan with three maximal cones and three codimension-one faces. The finite Čech/Ran atlas requires three FM kernels on a triangular face lattice; the finite Rees coefficient system is a triangular gluing of three Schiffmann–Vasserot $Y^+(\widehat{\mathfrak{gl}}_1)$ copies, governed by the three-arrow banana quiver with cubic potential after quiver-Hall realisation.

Suspended pinch point. The SPP singularity $\{xy = zw^2\} \subset \mathbb{C}^4$ has toric diagram the trapezoid $\{(0, 0), (2, 0), (1, 1), (0, 1)\}$ with minimal triangulation into three triangles sharing a common internal edge (the “pinch”). The fan has three maximal cones and three codimension-one faces; the Čech/Ran cocycle is defined on this triangulated trapezoid; the finite Rees coefficient system carries the SPP quiver of Uranga (1999 hep-th/9811004) and Aganagic–Karch–Lüst–Miemiec (1999 hep-th/9903093) after the realised quiver-Hall step.

The compact 4-cycle obstruction

The obstruction resolved here is subtle: a local toric CY_3 with a compact divisor; a maximal cone whose dual vertex lies in the *interior* of the toric diagram; admits a chart-wise $\mathbb{C}^3$ cover, but the boundary Čech/Ran Rees atlas of §33.2 misses the wheel term of the compact divisor.

INTERIOR LATTICE POINTS AND COMPACT DIVISORS

Let X_Σ be a local toric CY_3 with toric diagram Δ_Σ a lattice polygon in the plane $\{x_3 = 1\}$. The duality between toric fans and toric diagrams identifies:

$$\text{rays of } \Sigma \longleftrightarrow \text{vertices of } \Delta_\Sigma, \quad \text{maximal cones} \longleftrightarrow \text{internal triangulation triangles},$$

and one distinguishes:

- *boundary rays*: rays whose dual vertex lies on the boundary of Δ_Σ ; these correspond to non-compact divisors in X ;
- *interior rays*: rays whose dual vertex lies in the interior of Δ_Σ ; these correspond to compact divisors, i.e. compact 4-cycles in X .

The resolved conifold has no interior lattice point: its toric diagram is a unit square with vertices $(0, 0), (1, 0), (0, 1), (1, 1)$ and no interior lattice point, consistent with $\chi(\mathbf{Y}) = 2$ and no compact 4-cycle. Local $\mathbb{P}^2 = \text{Tot}(K_{\mathbb{P}^2})$ has exactly one interior lattice point: its toric diagram is the triangle with vertices $(1, 0), (0, 1), (-1, -1)$ (the three non-compact divisor rays at height 1) and the interior lattice point $(0, 0)$ at the origin; the ray $(0, 0, 1)$ attached to this interior point generates the zero-section $\mathbb{P}^2 \subset K_{\mathbb{P}^2}$, a compact 4-cycle.

WHY CHART-WISE GLUING MISSES THE COMPACT DIVISOR

The boundary Čech/Ran Rees atlas of §33.2 has three ingredients on each chart: the Schiffmann–Vasserot $Y^+(\widehat{\mathfrak{gl}}_1)$, the equivariant torus action, and the FM kernel on codimension-one overlaps. None of these detect the cohomology of a compact divisor:

- The chart-wise polyvector complex $PV^\bullet(U_\sigma)$ is concentrated in $(0, *)$ -degree (holomorphic polyvector fields on $\mathbb{C}^3$), and has no contribution from the class of a compact surface.
- The FM kernels $K_{\sigma\sigma'}$ transport polyvectors across codimension-one faces but do not generate new cohomology classes: they are sheaves of derived Morita data, not cycle classes.
- The T^3 -equivariant localisation concentrates all integrals at the fixed points of the torus action, i.e. the maximal cones; the contribution of a compact divisor is the *sum over the fixed points contained in the divisor*, which must be computed by a separate procedure.

The Neguț wheel-condition corrections; the shuffle-algebra relations forced by the presence of an interior lattice point; are missed by the boundary Čech/Ran Rees atlas. For local $\mathbb{P}^2$ with single interior point at the origin of the triangulation, the correct shuffle algebra is the $\mathbb{Z}_3$ -McKay variant of $Y^+(\widehat{\mathfrak{gl}}_1)$ whose kernel carries an additional wheel-condition multiplier tracking the $\mathbb{Z}_3$ -orbit of the interior lattice point (Neguț 2015 arXiv:1512.06473; Rapcak–Soibelman–Yang–Zhao 2020 arXiv:2001.10549). The direct multi-chart Čech/Ran Rees atlas of §33.2 picks up only the boundary contributions to $\varphi_{a \Rightarrow b}$ and misses this wheel-condition multiplier.

RESOLUTION VIA MCKAY/ORBIFOLD ROUTE

The standard resolution of the obstruction is to pass to the orbifold quotient: local $\mathbb{P}^2 = [\mathbb{C}^3/\mathbb{Z}_3]^{\text{res}}$ (the crepant resolution of the McKay orbifold), and apply the Bridgeland–King–Reid equivalence

$$D^b(\text{Coh}(K_{\mathbb{P}^2})) \simeq D^b(\text{Coh}^{\mathbb{Z}_3}(\mathbb{C}^3))$$

(Bridgeland–King–Reid 2001 arXiv:math/9908027 Thm. 1.2). The right-hand category is a single $\mathbb{C}^3$ -chart with $\mathbb{Z}_3$ -equivariance; the finite Hall model of this orbifold chart carries the Neguț wheel-condition multipliers automatically, since the $\mathbb{Z}_3$ -action on $\mathbb{C}^3$ produces exactly the interior-point shifts at each orbit element. The compact 4-cycle cohomology is recovered as the $\mathbb{Z}_3$ -fixed part of the $\mathbb{C}^3/\mathbb{Z}_3$ inertia stack.

Alternatively, one may keep the multi-chart cover and enrich each chart-wise shuffle kernel with a higher-rank Neguț correction: replace $\varphi_{a \Rightarrow b}(u)$ by the shuffle kernel $\varphi_{a \Rightarrow b}^{\text{rank}-r}(u)$ of the rank- r shuffle algebra, with r the number of interior lattice points of the toric diagram. The two resolutions; McKay/orbifold route (§33.3) and higher-rank shuffle correction; are Morita-equivalent under the Rapcak–Soibelman–Yang–Zhao toric theorem (2020 arXiv:2001.10549 Thm. B), but differ in their chart-wise presentations.

PROPOSITION 33.2.10 (Compact-4-cycle obstruction). Let X_Σ be a local toric CY_3 with toric diagram Δ_Σ carrying $r \geq 1$ interior lattice points. The direct multi-chart Čech/Ran Rees atlas of §33.2, built only from chart-wise single-vertex Jordan triples, presents the boundary positive halves and misses the interior-lattice wheel terms. A finite Rees atlas for the full toric quiver Hall layer must replace the local chart data by either:

- (a) the G -equivariant Schiffmann–Vasserot data on $[\mathbb{C}^3/G]$, where $G \subset \text{SU}(3)$ is the McKay group whose crepant resolution $\widetilde{\mathbb{C}^3/G}$ recovers X_Σ (McKay/orbifold route; applies when Δ_Σ is a McKay triangle, including $X_\Sigma = K_{\mathbb{P}^2}$ with $G = \mathbb{Z}_3$);
- (b) the multi-vertex Neguț shuffle algebra $Y^+(Q_X, W_X)$ whose vertex set matches the full toric quiver of X_Σ (interior and boundary lattice points together) and whose bond factors carry the wheel-condition multipliers tracking the interior-point positions (higher-rank shuffle route).

The boundary multi-chart Rees atlas with only the chart-wise $Y^+(\widehat{\mathfrak{gl}}_1)$ data therefore stops at the boundary Rees Hall coefficient system.

Proof. The chart-wise single-vertex polyvectors generate only the boundary-vertex portion of the full toric quiver shuffle algebra; the interior-vertex portion is generated by compositions extending into the G -McKay inertia (Bridgeland–King–Reid 2001 arXiv:math/9908027 Thm. 1.2). In the McKay route the finite critical chart is $[C^3/G]$, so the twisted sectors of the inertia stack supply exactly the missing interior weights. In the higher-rank shuffle route the finite critical chart is the full toric quiver (Q_X, W_X) ; the Neguţ wheel factors are relations in the Rees Hall product and are visible before any completion. Rapcak–Soibelman–Yang–Zhao (2020 arXiv:2001.10549 Thm. B) identifies these two presentations of the same toric quiver shuffle data. The single-vertex atlas lacks both the twisted sectors and the wheel relations, hence cannot produce the interior-lattice terms. $\square$

Finite zero-interior Rees assembly

The combination of §§33.2–33.2 has a sharp zero-interior consequence. Boundary cones and codimension-one faces supply all Rees Hall coefficients; no compact-divisor wheel term remains to be added.

PROPOSITION 33.2.11 (*Finite zero-interior toric Rees assembly*). Let X_Σ be a smooth local toric Calabi–Yau threefold whose toric diagram Δ_Σ has zero interior lattice points. Choose a DWR-good refinement $\mathfrak{U}_\Sigma$ of its finite toric C^3 -atlas and finite bounds (N, r, L, m) . Then:

- (1) the chart Jordan triples $(Q_{\text{Jor}}, W_\sigma)$ on maximal cones, together with the Fourier–Mukai transitions on common faces, form a multiplicative finite DWR/Ran cyclic critical atlas on $\mathfrak{U}_\Sigma$;
- (2) the Stokes sum

$$\Theta_{X_\Sigma}^{\text{Rees}, N, r, L, m} = \sum_{0 \leq p \leq m} \sum_{\sigma \in \mathcal{N}_{p, \leq m}^{\text{Ran}}(\mathfrak{U}_\Sigma; \Gamma_{\leq L})} \int_{\Delta^p} \theta_\sigma^{\text{rel}}$$

satisfies the Čech/Ran Maurer–Cartan equation in the finite convolution dg Lie algebra $\mathfrak{M}_{\text{hCS, Hall}}^{N, r, L, m}(\mathfrak{U}_\Sigma)$;

- (3) every 0-simplex lying in a toric chart has local Hall cohomology $Y^+(\widehat{\mathfrak{gl}}_1)$, and the positive-half quiver presentation attached to the toric diagram is obtained only after the separate realised quiver-Hall identification.

This constructs the finite oriented Rees Hall comparison on the Čech/Ran nerve. It does not construct $\mathcal{W}_{1+\infty}$, a compact CoHA, a completed critical CoHA, or a Hall–Drinfeld double.

Proof. The fan has finitely many maximal cones and codimension-one faces. On each maximal cone the local model is the Jordan triple on C^3 , whose critical Hall cohomology is $Y^+(\widehat{\mathfrak{gl}}_1)$ by Schiffmann–Vasserot. On a shared face the transition is the toric lattice change of basis; its Fourier–Mukai kernel is the same line-bundle transport as in (33.4), with multiplier computed by (33.5) after replacing the conifold exponents by the face exponents (k_2, k_3) . The Calabi–Yau condition makes the holomorphic-volume Jacobian constant on the face, so the cyclic pairing restricts compatibly.

On codimension-two intersections the toric line-bundle cocycle condition makes the two composites of Fourier–Mukai kernels canonically isomorphic. On disjoint Ran configurations the potentials add by $W_{\sigma_1 \sqcup \sigma_2} = W_{\sigma_1} \boxplus W_{\sigma_2}$, and Thom–Sebastiani gives the Rees Hall product. These two compatibilities are precisely the face and multiplicative axioms of a finite DWR/Ran cyclic critical atlas.

The relative BV master equation on every simplex becomes, after the relative Fourier–BV Rees identification,

$$(d_{\text{Hall}} + d_{\Delta^p})\theta_{\sigma}^{\text{rel}} - \theta_{\sigma}^{\text{rel}} d_{B\text{Obs}} + \frac{1}{2}[\theta_{\sigma}^{\text{rel}}, \theta_{\sigma}^{\text{rel}}]_{\text{conv}} = 0.$$

Integrating over Δ^p and summing over the finite nerve converts the simplex boundary term to $\delta_{\check{C}/\text{Ran}}$, hence gives the Maurer–Cartan equation for $\Theta_{X_{\Sigma}}^{\text{Rees}, N, r, L, m}$. Zero interior lattice points remove the Negut wheel corrections described in Proposition 33.2.10; the atlas therefore contains exactly the boundary face coefficients and no compact-divisor term. Rapcak–Soibelman–Yang–Zhao identify the realised toric quiver shuffle algebra after the quiver–Hall realisation is supplied; that identification is not part of the finite Rees construction proved here. $\square$

The class of local toric CY_3 covered by Proposition 33.2.11 (zero interior lattice points in Δ_{Σ}) includes:

- $\mathbb{C}^3$ (one chart, no overlaps, local positive half $Y^+(\widehat{\mathfrak{gl}}_1)$); toric diagram = triangle $\{(0, 0), (1, 0), (0, 1)\}$, 0 interior points;
- the resolved conifold (two charts, one overlap, finite Rees comparison with Klebanov–Witten quiver–Hall realisation available after the separate realisation step); toric diagram = unit square $\{(0, 0), (1, 0), (0, 1), (1, 1)\}$, 0 interior points;
- the banana threefold (local model: three $\mathbb{P}^1$'s meeting at two common nodes; three maximal cones, three overlaps, three-loop fan); local toric diagram with no interior lattice points;
- the suspended pinch point $\text{SPP} = \{x y = z w^2\} \subset \mathbb{C}^4$ (three maximal cones, three overlaps); toric diagram the trapezoid $\{(0, 0), (2, 0), (1, 1), (0, 1)\}$, 0 interior lattice points;
- generalised conifolds $X_{n,m} = \text{Tot}(\mathcal{O}(-n) \oplus \mathcal{O}(-m) \rightarrow \mathbb{P}^1)$ with $n + m = 2$ (two charts, one overlap with $\mathcal{O}(-n) \oplus \mathcal{O}(-m)$ -twist); toric diagram an elongated quadrilateral with no interior lattice points.

The class outside the proposition comprises exactly those local toric CY_3 with one or more interior lattice points. Among toric smooth surfaces giving local CY_3 , these are: local $\mathbb{P}^2 = K_{\mathbb{P}^2}$ (one interior point $(0, 0)$), local $\mathbb{P}^1 \times \mathbb{P}^1 = K_{\mathbb{P}^1 \times \mathbb{P}^1}$ (one interior point), local Hirzebruch $\mathbb{F}_n$ for $n \geq 1$ (one interior point), and local toric del Pezzo $dP_k = \text{Bl}_k \mathbb{P}^2$ for $k = 1, 2, 3$ (the only toric del Pezzos beyond $\mathbb{P}^2$; each with one interior point in its toric diagram). Non-toric del Pezzos dP_k for $k \geq 4$ fall outside the toric framework entirely. These all carry compact 4-cycles and must pass through Proposition 33.2.10's McKay/orbifold or higher-rank shuffle resolutions. §33.3 takes up this resolution, replacing the boundary chart-wise Čech/Ran atlas by the BKR equivalence and the inertia-stack decomposition of the orbifold route; in particular, the nine-arrow Beilinson quiver of local $\mathbb{P}^2$ enters through the $[\mathbb{C}^3/\mathbb{Z}_3]$ chart and its $\mathbb{Z}_3$ skew-group algebra, not through the boundary $\mathbb{C}^3$ -chart atlas alone.

The finite Rees assembly of Stratum i is determined by three data: the face-lattice cocycle with values in $H^1(\Sigma, \text{Pic})$; the bond-factor presentation of Galakhov–Li–Yamazaki on the toric diagram edges; the zero-interior-point criterion that separates the boundary-chart diagrams from those requiring McKay resolution. §33.3 addresses the McKay route for diagrams with one or more interior points, and §33.4 takes up derived Morita gluing for the Van den Bergh tilting presentation common to both. The master instance $K_3 \times E$, which combines Stratum i with Strata ii–iv, is resolved in §33.8 via the full four-stratum decomposition.

33.3 MCKAY AND ORBIFOLD GLUING

An orbifold $[X/G]$ with $G \subset \mathrm{SU}(d)$ finite is a CY_d category whose atlas is not a union of Čech charts but a single chart bearing the G -action. The gluing cocycle is not valued in H^1 of the overlap nerve; it is valued in the representation category $\mathrm{Rep}(G)$ attached to each conjugacy class of G , assembled over the inertia stack. The categorical content is the Bridgeland–King–Reid equivalence

$$D^b([X/G]) \simeq D_G^b(X),$$

and its CoHA-level incarnation: every local CoHA on $[X/G]$ pulls back to a G -equivariant CoHA on X , and the global Hall product is the G -invariant part after the inertia decomposition is unpacked.

Two examples organise the material. Local $\mathbb{P}^2 = [\mathbb{C}^3/\mathbb{Z}_3]^{\mathrm{res}}$ admits two compatible presentations: a single-chart skew-group presentation via the nine-arrow Beilinson quiver, and a three-chart Čech presentation on its crepant resolution $\mathrm{Tot}(K_{\mathbb{P}^2})$. The orbifold CoHA matches the chart-wise CoHA exactly when a compact-4-cycle Neğüt wheel-correction is installed. Mathieu $\mathcal{M}_{24}$ on K_3 occupies the intersection of Stratum (iii) with Stratum (iv): the orbifold gluing against a sporadic simple group is realised by twined elliptic genera whose weight- $1/2$ mock modular coefficients are the CoHA characters in each twisted sector.

Orbifold inertia and the Bridgeland–King–Reid equivalence

THE INERTIA STACK, ELEMENTARILY

Let $G \subset \mathrm{SU}(3)$ be finite, acting on $\mathbb{C}^3 = \mathrm{Spec} \mathbb{C}[x, y, z]$ preserving the holomorphic volume form $dx \wedge dy \wedge dz$. The quotient stack $[\mathbb{C}^3/G]$ has coherent sheaves presented as G -equivariant sheaves on $\mathbb{C}^3$:

$$\mathrm{Coh}([\mathbb{C}^3/G]) \simeq \mathrm{Coh}_G(\mathbb{C}^3).$$

This identification is elementary: a coherent sheaf on the stack $[\mathbb{C}^3/G]$ pulls back to a coherent sheaf on the atlas $\mathbb{C}^3$, equipped with descent data for the groupoid $G \times \mathbb{C}^3 \rightrightarrows \mathbb{C}^3$, and descent data for a groupoid whose unit arrows are group elements is precisely G -equivariant structure.

The *inertia stack* $I([\mathbb{C}^3/G])$ is the stack of pairs (p, g) with $p \in [\mathbb{C}^3/G]$ a point and $g \in \mathrm{Aut}(p)$ an automorphism. For an orbifold point p represented by $x \in \mathbb{C}^3$, the automorphism group $\mathrm{Aut}(p)$ is the stabiliser $G_x \subset G$, and an inertia datum is an element $g \in G_x$; equivalently, a pair (x, g) with $g \cdot x = x$. The inertia stack is the fibre product $[\mathbb{C}^3/G] \times_{[\mathbb{C}^3/G] \times [\mathbb{C}^3/G]} [\mathbb{C}^3/G]$ along the diagonal, which rewrites as the quotient $[\{(x, g) : g \cdot x = x\}/G]$ with G acting by simultaneous conjugation $h \cdot (x, g) = (h \cdot x, hgh^{-1})$.

Slicing this groupoid by G -conjugacy on the second factor: pick a representative g_o of each conjugacy class $[g] \in \mathrm{Conj}(G)$, and restrict to the slice $\{(x, g_o) : g_o \cdot x = x\} = \mathbb{C}^{3, g_o}$ (the fixed locus of g_o). The residual G -action on this slice is by the centraliser $C_G(g_o) \subset G$ (elements commuting with g_o). Summing over conjugacy classes,

$$I([\mathbb{C}^3/G]) = \bigsqcup_{[g] \in \mathrm{Conj}(G)} [\mathbb{C}^{3, g}/C_G(g)].$$

The identity class $[e]$ yields $[\mathbb{C}^{3, e}/G] = [\mathbb{C}^3/G]$, the *untwisted sector*. Each non-identity class $[g] \neq [e]$ yields a *twisted sector* indexed by g . For G abelian, every element is its own conjugacy class, $C_G(g) = G$, and the decomposition becomes $\bigsqcup_{g \in G} [\mathbb{C}^{3, g}/G]$.

The physics content is Dixon–Harvey–Vafa–Witten (*Nucl. Phys. B* 261, 1985; 274, 1986), the mathematical age-grading is Chen–Ruan (math/0004129): the orbifold cohomology of $[\mathbb{C}^3/G]$ is

$$H_{\text{orb}}^\bullet([\mathbb{C}^3/G]) = \bigoplus_{[g]} H^{\bullet-2 \operatorname{age}(g)}(\mathbb{C}^{3,g}/C_G(g)),$$

with $\operatorname{age}(g) = \sum_i a_i$ for g acting on a tangent frame by $\operatorname{diag}(e^{2\pi i a_1}, e^{2\pi i a_2}, e^{2\pi i a_3})$ with $a_i \in [0, 1)$. The $\mathrm{SU}(3)$ -condition $\det g = 1$ forces $\sum_i a_i \in \mathbb{Z}$; combined with the range constraint $\sum_i a_i \in [0, 3)$, the age lies in $\{0, 1, 2\}$.

SKEW-GROUP ALGEBRA AND MORITA EQUIVALENCE

The skew-group algebra $R\#G$ with $R = \mathbb{C}[x, y, z]$ is

$$R\#G = R \otimes \mathbb{C}[G] \quad \text{with multiplication} \quad (r \otimes g)(r' \otimes g') = r \cdot g(r') \otimes gg'.$$

Equivalently: $R\#G$ is the free R -module with basis G , and multiplication records the twist of the action. This is not an arbitrary algebra; it is the arrow algebra of the action groupoid $G \times \mathbb{C}^3 \rightrightarrows \mathbb{C}^3$, and its representation category is exactly G -equivariant sheaves:

$$(R\#G)\text{-mod} \simeq \operatorname{Coh}_G(\mathbb{C}^3) \simeq \operatorname{Coh}([\mathbb{C}^3/G]).$$

The first equivalence is the passage from arrow-algebra modules to equivariant modules; the second is the atlas identification from Section 33.3. Morita equivalence of $R\#G$ with its basic algebra (the endomorphism ring of a minimal projective generator) is the passage from infinite-dimensional to quiver-presented form.

BRIDGELAND–KING–REID, FIRST-PRINCIPLES SKETCH

The Bridgeland–King–Reid theorem (math/9908027) asserts: for $G \subset \mathrm{SL}(n, \mathbb{C})$ finite, $n \leq 3$, with $Y := G\text{-Hilb}(\mathbb{C}^n)$ the equivariant Hilbert scheme of G -clusters, the Fourier–Mukai transform with kernel the universal G -cluster $\mathcal{Z} \subset Y \times \mathbb{C}^n$ is an equivalence

$$\Phi_{\mathcal{Z}}: D^b(Y) \xrightarrow{\sim} D_G^b(\mathbb{C}^n) \simeq D^b([\mathbb{C}^n/G]).$$

The first-principles content:

- *Crepancy*: For $G \subset \mathrm{SL}(n)$ with $n \leq 3$, Y is smooth and the canonical class $K_Y = 0$; equivalently, the resolution $Y \rightarrow \mathbb{C}^n/G$ is crepant. The CY structure on $[\mathbb{C}^n/G]$ transports to a CY structure on Y .
- *Equivariant Hilbert scheme*: A G -cluster is a G -invariant 0-dimensional subscheme $Z \subset \mathbb{C}^n$ with $H^0(\mathcal{O}_Z) \cong \mathbb{C}[G]$ as G -representation. The moduli $G\text{-Hilb}(\mathbb{C}^n)$ parametrising these is the natural candidate resolution.
- *Universal kernel*: The universal family $\mathcal{Z} \subset Y \times \mathbb{C}^n$ is the incidence locus. Its structure sheaf, equipped with its G -equivariant structure via the second projection, is an object of $D^b(Y \times_G \mathbb{C}^n) \simeq D_G^b(Y \times \mathbb{C}^n)$.
- *Bridgeland–King–Reid criterion* (math/9908027 *Thm. 1.1*): The Fourier–Mukai transform $\Phi_{\mathcal{Z}}$ is an equivalence when the fibre-dimension bound

$$\dim(Y \times_{X_0} Y) \leq n + 1, \quad X_0 := \mathbb{C}^n/G,$$

holds, with Bondal–Kapranov spanning sufficing to upgrade fully-faithful to equivalence (BKR Lemma 3.1). For $G \subset \mathrm{SL}(n, \mathbb{C})$ with $n \leq 3$, crepancy of $Y = G\text{-Hilb}(\mathbb{C}^n) \rightarrow X_o$ (Nakamura [math/0003023](#) at $n = 3$) forces this bound; the authors verify $n \leq 3$ by explicit fibrewise analysis. The complementary Bondal–Orlov spanning-class criterion ([math/9712029](#)) applies to smooth projective varieties and is logically distinct: it supplies sufficient conditions via ample generation, whereas BKR exploits the specific crepant-resolution geometry.

- *CoHA transport*: The Hall product on $D^b(Y)$ pulls back along Φ_Z to a Hall product on $D_G^b(\mathbb{C}^n)$, which in turn decomposes via the inertia splitting into a conjugacy-class-indexed direct sum of twisted-sector CoHAs. This is the CoHA shadow of Chen–Ruan orbifold cohomology.

The BKR equivalence is thus the gluing cocycle for Stratum (iii): it assembles the G -equivariant critical CoHA on $\mathbb{C}^n$ with the $\mathbb{C}^3$ -Jordan-triple potential $W = \mathrm{tr}(x[y, z])$ into the CoHA of the crepant resolution Y , with the inertia decomposition recording the conjugacy-class-graded structure. On the resolution side, Y is a smooth toric CY_3 when G is abelian, and the chart-wise Stratum-(i) machinery applies; on the orbifold side, the skew-group presentation $R\#G$ provides a single global datum. The BKR kernel is the gluing cocycle reconciling the two.

Class-group obstruction to McKay presentation. The applicability of BKR is governed by an arithmetic invariant of the singular base $X_o = \mathbb{C}^n/G$: its divisor class group $\mathrm{Cl}(X_o)$. Watanabe’s theorem (1974, *Osaka J. Math.* 11) identifies

$$\mathrm{Cl}(\mathbb{C}^n/G) \cong G^{\mathrm{ab}} = G/[G, G]$$

for $G \subset \mathrm{SL}(n, \mathbb{C})$ acting without pseudo-reflections (the SL-condition suffices), so the class group is finite of order dividing $|G|$. Any Gorenstein CY singularity whose class group is *infinite* cannot be of the form $\mathbb{C}^n/G$ and lies outside BKR’s scope. The conifold $X_o^{\mathrm{con}} = \{xy - zw = 0\} \subset \mathbb{C}^4$ is the canonical outlier: $\mathrm{Cl}(X_o^{\mathrm{con}}) = \mathbb{Z}$, generated by the Weil divisor $\{x = z = 0\}$ (its pair $\{y = w = 0\}$ differs by the Cartier class of a hyperplane section; their difference is the class of the $\mathbb{P}^1$ exceptional of either small resolution). The infinite class group excludes any McKay presentation. The conifold’s NCCR is the Klebanov–Witten two-node Kronecker quiver with quartic potential $W_{\mathrm{con}} = \mathrm{tr}(a_1 b_1 a_2 b_2 - a_1 b_2 a_2 b_1)$ (Szendrői [arXiv:0705.3419](#)), contrasting with the Beilinson nine-arrow quiver’s cubic potential. The degree is forced by the quiver type: the McKay quiver for $\mathbb{C}^3/G$ is G -partite with coordinate-graded arrows, so cycles close at length three (Bocklandt [math/0603558](#)); the conifold’s two-node Kronecker quiver has four arrows closing at length four (Hanany–Kennaway [hep-th/0503149](#); Franco–Hanany–Kennaway–Vegh–Wecht [hep-th/0511063](#) brane-tiling dictionary).

Local $\mathbb{P}^2$ as $[\mathbb{C}^3/\mathbb{Z}_3]$ and the nine-arrow quiver

Local $\mathbb{P}^2$ is $\mathrm{Tot}(\mathcal{O}_{\mathbb{P}^2}(-3))$, the total space of the canonical bundle on $\mathbb{P}^2$. As a toric CY_3 , it has a compact 4-cycle (the zero-section $\mathbb{P}^2$ itself) and is not a union of $\mathbb{C}^3$ -charts without corrections. The orbifold route produces it as a crepant resolution $\mathrm{Tot}(K_{\mathbb{P}^2}) = [\mathbb{C}^3/\mathbb{Z}_3]^{\mathrm{res}}$, and the CoHA story becomes transparent through the Beilinson nine-arrow quiver.

THE $\mathbb{Z}_3$ ACTION AND ITS AGE DATA

Let $\zeta = e^{2\pi i/3}$. The group $\mathbb{Z}_3 = \langle \sigma \rangle$ acts on $\mathbb{C}^3$ by

$$\sigma \cdot (x, y, z) = (\zeta x, \zeta y, \zeta z).$$

The weights of σ on the tangent frame are $(1/3, 1/3, 1/3)$, with age

$$\text{age}(\sigma) = 1/3 + 1/3 + 1/3 = 1 \in \mathbb{Z},$$

confirming $\sigma \in \text{SU}(3)$ and the CY orbifold condition. The three conjugacy classes $\{e, \sigma, \sigma^2\}$ (abelian, every element its own class) give ages 0, 1, 2 respectively. The fixed loci are $\mathbb{C}^{3,e} = \mathbb{C}^3$, $\mathbb{C}^{3,\sigma} = \{0\}$, $\mathbb{C}^{3,\sigma^2} = \{0\}$, and the inertia decomposition is

$$I([\mathbb{C}^3/\mathbb{Z}_3]) = [\mathbb{C}^3/\mathbb{Z}_3] \sqcup B\mathbb{Z}_3 \sqcup B\mathbb{Z}_3.$$

The untwisted sector carries the ambient CY_3 structure; the two twisted sectors are point classes at the origin with age-shifts 1 and 2. McKay identifies them with the cohomology of the exceptional divisor $\mathbb{P}_{\text{exc}}^2 = \pi^{-1}(0)$ on the crepant resolution $\pi : \text{Tot}(K_{\mathbb{P}^2}) \rightarrow \mathbb{C}^3/\mathbb{Z}_3$: the age-1 twisted-sector point class maps to the hyperplane class $H \in H^2(\mathbb{P}_{\text{exc}}^2, \mathbb{C})$; the age-2 point class maps to $H^2 \in H^4(\mathbb{P}_{\text{exc}}^2, \mathbb{C})$; and the untwisted-sector class 1 maps to the fundamental class $1 \in H^0(\mathbb{P}_{\text{exc}}^2, \mathbb{C})$ (equivalently, to the $\text{Tot}(K_{\mathbb{P}^2})$ -unit, via the zero-section embedding). Batyrev–Denef–Loeser stringy cohomology confirms: $\chi_{\text{stringy}}([\mathbb{C}^3/\mathbb{Z}_3]) = 3 = \chi(\text{Tot}(K_{\mathbb{P}^2}))$, the ranks $(1, 1, 1)$ at degrees $(0, 2, 4)$ matching on both sides.

THE BEILINSON NINE-ARROW QUIVER

The skew-group algebra $\mathbb{C}[x, y, z] \# \mathbb{Z}_3$ has three indecomposable projectives corresponding to the three irreducible representations ρ_0, ρ_1, ρ_2 of $\mathbb{Z}_3$ (characters $1, \zeta, \zeta^2$). Its basic algebra is the path algebra of the quiver Q with three vertices $\{0, 1, 2\}$ (one for each character) and nine arrows

$$X_i, Y_i, Z_i : i \longrightarrow i + 1 \pmod{3}, \quad i \in \mathbb{Z}/3,$$

one triple (X_i, Y_i, Z_i) for each vertex, corresponding to the three coordinates (x, y, z) of $\mathbb{C}^3$. Because σ acts on each coordinate by the same weight ζ , each coordinate raises the ρ -degree by $+1 \pmod{3}$, producing the cyclic $0 \rightarrow 1 \rightarrow 2 \rightarrow 0$ arrow pattern with three arrows per step.

The Jacobi potential is the cubic

$$W = \sum_{i \in \mathbb{Z}/3} \text{tr}(X_i Y_{i+1} Z_{i+2} - X_i Z_{i+1} Y_{i+2}),$$

the cyclic unfolding of $\text{tr}(x[y, z]) = \text{tr}(xyz - xzy)$ across the three vertex-types, with each monomial a closed length-three cycle $i \rightarrow i + 1 \rightarrow i + 2 \rightarrow i$ of the quiver. The Jacobi relations $\partial W / \partial X_i = Y_{i+1} Z_{i+2} - Z_{i+1} Y_{i+2}$ (and cyclic permutations in X, Y, Z) encode the commutativity $[x, y] = [y, z] = [x, z] = 0$ unfolded across the three vertex-types. The pair (Q, W) is the *nine-arrow Beilinson quiver with cubic potential*, and Bocklandt (math/0603558, Thm. 3.2) proved $\text{Jac}(Q, W) \cong \mathbb{C}[x, y, z] \# \mathbb{Z}_3$, a Ginzburg CY_3 algebra (math/0612139, §4.3). The potential degree is three because the $\mathbb{Z}_3$ -character grading cycles in three components: each coordinate raises the ρ -grading by $+1 \pmod{3}$, and three coordinates suffice to close the cycle. The conifold's quartic potential $W_{\text{con}} = \text{tr}(a_1 b_1 a_2 b_2 - a_1 b_2 a_2 b_1)$ arises instead on a two-node Kronecker quiver with four arrows, where cycles must traverse $0 \rightarrow 1 \rightarrow 0 \rightarrow 1$ at length four. This cubic is the Hall-side McKay/Beilinson potential. It is not to be replaced by a higher transferred hCS potential unless a separate cyclic HPT calculation identifies that transfer with the same Jacobi algebra and then proves orientation, Thom–Sebastiani, Hall-product, and DWR/Ran coherence.

The equivalence with Beilinson's derived description of $\mathbb{P}^2$:

$$D^b(\mathbb{P}^2) \simeq D^b(\text{End}(O \oplus O(1) \oplus O(2))\text{-mod}),$$

is the classical Beilinson resolution. The three line bundles $\mathcal{O}, \mathcal{O}(1), \mathcal{O}(2)$ are the three indecomposable summands of the tilting bundle; the nine arrows are global sections $H^0(\mathbb{P}^2, \mathcal{O}(1)) = \langle x, y, z \rangle$ between consecutive summands. Under BKR, the Beilinson tilting bundle on $\mathbb{P}^2$ pulls up along the projection $\text{Tot}(K_{\mathbb{P}^2}) \rightarrow \mathbb{P}^2$ to a tilting bundle on local $\mathbb{P}^2$ whose endomorphism ring is precisely the Jacobi algebra $\text{Jac}(Q, W)$.

THE COHA VIA SCHIFFMANN–VASSEROT EQUIVARIANTISED

The Schiffmann–Vasserot theorem constructs the CoHA of $\mathbb{C}^3$ (with the Jordan-triple potential $W_{\mathbb{C}^3} = \text{tr}(x[y, z])$) as the positive half $Y^+(\widehat{\mathfrak{gl}}_1)$ of the affine Yangian of $\mathfrak{gl}_1$:

$$\mathcal{H}_{\mathbb{C}^3} = \bigoplus_n H_{\bullet}^{T^3}(\text{crit}(W)|_{\mathcal{M}_n^{\mathbb{C}^3}}) \cong Y^+(\widehat{\mathfrak{gl}}_1).$$

Equivariantising by the $\mathbb{Z}_3$ -action gives the CoHA of $[\mathbb{C}^3/\mathbb{Z}_3]$:

$$\mathcal{H}_{[\mathbb{C}^3/\mathbb{Z}_3]} = (\mathcal{H}_{\mathbb{C}^3})^{\mathbb{Z}_3} \oplus \mathcal{H}_{\mathbb{C}^3}^{\text{tw}, \sigma} \oplus \mathcal{H}_{\mathbb{C}^3}^{\text{tw}, \sigma^2},$$

where the second and third summands are the twisted-sector contributions indexed by the non-trivial conjugacy classes. The twisted sectors are modules over the untwisted invariant ring $Y^+(\widehat{\mathfrak{gl}}_1)^{\mathbb{Z}_3}$, in a manner that matches the age-graded decomposition. Explicitly: the equivariant parameters $(\epsilon_1, \epsilon_2, \epsilon_3)$ of T^3 pick up a $\mathbb{Z}_3$ -equivariant refinement; the $\mathbb{Z}_3$ -invariant combination $\epsilon_1 + \epsilon_2 + \epsilon_3 = 0$ (the CY relation) survives, and the twisted-sector generators carry additional ζ -charge compatible with age.

THE CHART-WISE COVER OF THE CREPANT RESOLUTION

Local $\mathbb{P}^2$ as a toric variety has fan Σ with three top-dimensional cones, corresponding to the three torus-fixed points of $\mathbb{P}^2$, each carrying a local $\mathbb{C}^3$ -chart (the affine toric patch trivialising $K_{\mathbb{P}^2}$ over that chart). Label the charts U_o, U_1, U_2 ; each is $\cong \mathbb{C}^3$ with local coordinates (u, v, w) such that the Jordan-triple potential $\text{tr}(u[v, w])$ holds on the chart.

The atlas reconciles with the orbifold presentation as follows: on the singular base $\mathbb{C}^3/\mathbb{Z}_3$ the resolution $\pi : \text{Tot}(K_{\mathbb{P}^2}) \rightarrow \mathbb{C}^3/\mathbb{Z}_3$ is an isomorphism away from the unique singular point $o \in \mathbb{C}^3/\mathbb{Z}_3$, and the preimage $\pi^{-1}(o) = \mathbb{P}^2$ is the exceptional divisor. The three toric charts U_o, U_1, U_2 cover $\text{Tot}(K_{\mathbb{P}^2})$ with pairwise overlaps $U_i \cap U_j \cong \mathbb{G}_m \times \mathbb{C}^2$ (one inverted ratio between adjacent $\mathbb{P}^2$ -charts, times the $K_{\mathbb{P}^2}$ -fibre $\mathbb{C}$) and triple overlap $U_o \cap U_1 \cap U_2 \cong (\mathbb{G}_m)^2 \times \mathbb{C}$ (the open torus orbit of $\mathbb{P}^2$ times the canonical-bundle fibre). Each chart U_i intersects the exceptional $\mathbb{P}^2$ in an $\mathbb{A}^2$ -patch centred at a torus-fixed point of $\mathbb{P}^2$, and the three patches assemble to the standard toric $\mathbb{A}^2$ -atlas of $\mathbb{P}^2$. On the resolution side the three smooth toric $\mathbb{C}^3$ -patches fully cover $\text{Tot}(K_{\mathbb{P}^2})$; on the orbifold side the single $[\mathbb{C}^3/\mathbb{Z}_3]$ -stacky chart at the origin is what BKR intertwines with the three-chart toric cover.

The gluing cocycle on the overlaps $U_i \cap U_j$ is the toric transition; the Schiffmann–Vasserot CoHA lives on each chart as $Y^+(\widehat{\mathfrak{gl}}_1)$, and the multi-chart CoHA is the homotopy limit over the Čech nerve. Because of the compact $\mathbb{P}^2$ -divisor, this limit picks up *internal-lattice contributions*: the Negeu wheel-condition corrections. Concretely, the Do-brane moduli on local $\mathbb{P}^2$ contain the torus-fixed points U_o, U_1, U_2 together with 1-parameter families of brane configurations *inside* the compact $\mathbb{P}^2$ -divisor, whose cohomological contribution is non-trivial and must be integrated separately.

RECONCILING THE TWO ROUTES

The orbifold CoHA via Schiffmann–Vasserot equivariantised on $[\mathbb{C}^3/\mathbb{Z}_3]$, and the chart-wise CoHA on the three-chart atlas of local $\mathbb{P}^2$, agree under the BKR-transport. The reconciliation proceeds through:

- (i) BKR gives $D^b(\text{local } \mathbb{P}^2) \simeq D_{\mathbb{Z}_3}^b(\mathbb{C}^3)$ as triangulated categories.
- (ii) The CoHA Hall product is preserved, because Hall multiplication is defined from the extension stack $\text{Ext}(\mathcal{E}, \mathcal{F})$, and extensions are preserved by BKR as an equivalence of derived categories.
- (iii) The orbifold side's inertia-graded decomposition $\mathcal{H}_{\text{orb}} = \mathcal{H}_{\text{untw}} \oplus \mathcal{H}_{\sigma} \oplus \mathcal{H}_{\sigma^2}$ matches the chart-wise side's cohomology-grading via the toric fan's three top-cones: each cone contributes one summand, with the Neğüt wheel-condition corrections encoding exactly the age-shifted contributions of the twisted sectors.
- (iv) Explicitly: the age-1 twisted sector on the orbifold side corresponds to the contribution from the exceptional $\mathbb{P}^2$ of the resolution in the chart-wise route; age-2 corresponds to the Poincaré-dual class of $\mathbb{P}^2$.

This is the first worked example of stratum overlap (i) $\cap$ (iii): local $\mathbb{P}^2$ is simultaneously toric (stratum i) and orbifold (stratum iii), and the two gluing cocycles agree through BKR. The skew-group presentation via the nine-arrow quiver is the most economical form; the chart-wise Čech presentation with Neğüt corrections is the most geometric form. Both compute the same CoHA, equal to the module-theoretic Jacobi-algebra CoHA of (Q, W) .

Mathieu M_{24} on K_3

The Mathieu moonshine of Eguchi–Ooguri–Tachikawa arXiv:1004.0956 is an orbifold gluing not against a geometric group action on K_3 , but against a sporadic simple group M_{24} acting by derived symmetries of the elliptic genus of a K_3 surface. This sits at the intersection of Stratum (iii) orbifold and Stratum (iv) lattice-polarised. The geometric-symmetry layer is Mukai's theorem (Mukai 1988, *Invent. Math.* 94): every finite group of symplectic automorphisms of a K_3 surface embeds in $M_{23} \subset M_{24}$ with orbit-count ≥ 5 on $\{1, \dots, 24\}$; the full Mathieu group M_{24} is *not* realised as automorphisms of any single K_3 . The stringy-symmetry layer is Gaberdiel–Hohenegger–Volpato arXiv:1008.0725: symmetries of any consistent K_3 $\mathcal{N} = (4, 4)$ sigma model embed in the Conway group Co_0 , giving a larger family than Mukai's geometric classification but still strictly smaller than M_{24} . The M_{24} of EOT emerges only at the level of the *BPS Hilbert space*; the graded Fourier coefficients of the $\mathcal{N} = 4$ -decomposed elliptic genus ϕ_{K_3} ; where all 26 conjugacy classes of M_{24} act, even though no single sigma model hosts the full action. The assembly of twined elliptic genera is therefore indexed by M_{24} -conjugacy classes with each ϕ_g a weak Jacobi form on $\mathbb{H} \times \mathbb{C}$ whose mock modular $\mathcal{N} = 4$ -massive component is a weight-1/2 mock form on $\mathbb{H}$.

THE EGUCHI–OOGURI–TACHIKAWA OBSERVATION

The K_3 elliptic genus is the weight-0 index-1 weak Jacobi form

$$\phi_{K_3}(\tau, z) = 2\phi_{0,1}(\tau, z) = 8 \sum_{\alpha=2,3,4} \left(\frac{\theta_{\alpha}(\tau, z)}{\theta_{\alpha}(\tau, 0)} \right)^2,$$

with $\phi_{0,1}$ the generator of $J_{0,1}$ normalised by Eichler–Zagier, and the factor of two encoding the Euler characteristic $\chi(K_3) = 24 = \phi_{K_3}(\tau, 0)$ (Eguchi–Ooguri–Taormina–Yang 1989, *Nucl. Phys. B* 315). The $\mathcal{N} = 4$ superconformal character-decomposition of ϕ_{K_3} reads

$$\phi_{K_3}(\tau, z) = 24 \cdot \chi_{1/4,0}(\tau, z) + \Sigma(\tau) \cdot \chi_{1/4,1/2}(\tau, z),$$

where $\chi_{1/4,h}$ are the $\mathcal{N} = 4$ Ramond characters at central charge $c = 6$ and conformal weight h , and

$$\Sigma(\tau) = 2q^{-1/8}(-1 + 45q + 231q^2 + 770q^3 + 2277q^4 + \dots).$$

The numerical observation of Eguchi–Ooguri–Tachikawa: the Fourier coefficients $\{45, 231, 770, 2277, \dots\}$ are dimensions of irreducible representations of M_{24} .

TWINED ELLIPTIC GENERA AND MOCK MODULARITY

For each $g \in M_{24}$, define the *twined elliptic genus*

$$\phi_g(\tau, z) = \text{tr}_{\mathcal{H}_{K_3}}(g \cdot (-1)^{F_L+F_R} q^{L_0-\bar{c}/24} \bar{q}^{\bar{L}_0-\bar{c}/24} y^{J_0}),$$

with $\mathcal{H}_{K_3}$ the Hilbert space of the K_3 sigma model, $F_{L/R}$ left/right fermion numbers, J_0 the $U(1)$ current of the $\mathcal{N} = 4$ superconformal algebra. The $g = e$ case recovers ϕ_{K_3} . For general g , the $\mathcal{N} = 4$ decomposition gives

$$\phi_g(\tau, z) = \chi_g \cdot \chi_{1/4,0}(\tau, z) + \Sigma_g(\tau) \cdot \chi_{1/4,1/2}(\tau, z),$$

with χ_g the character of g acting on $H^\bullet(K_3)$ (a finite integer depending only on the M_{24} -conjugacy class) and Σ_g a weight-1/2 *mock modular form* of a specified shadow and multiplier system.

Cheng arXiv:1005.5415 exhibited the twined Σ_g and their $\Gamma_0(|g|)$ transformation laws; Cheng–Duncan–Harvey (*Res. Math. Sci.* 1, arXiv:1204.2779) packaged the result into the umbral moonshine, assigning each conjugacy class of M_{24} a weight-1/2 mock modular form with specified shadow and multiplier. Gannon (*Commun. Number Theory Phys.* 10, arXiv:1211.5531) proved positivity and uniqueness of the M_{24} -representation decomposition of the Fourier coefficients. Gaberdiel–Hohenegger–Volpato arXiv:1008.0725 classified the symmetry groups of consistent $\mathcal{N} = (4, 4)$ K_3 sigma models as subgroups of the Conway group Co_0 acting on $\text{II}_{4,20}$ with rank- ≥ 4 fixed lattice; strictly enlarging Mukai’s geometric classification yet not exhausting M_{24} ; consequently no single K_3 sigma model realises the full M_{24} -action, which lives only at the level of the graded $\Sigma(\tau)$ -Fourier coefficients.

COHA TWISTED BY AN M_{24} -CONJUGACY CLASS

For each conjugacy class $[g] \in M_{24}$, there is a twisted CoHA $\mathcal{H}_{K_3}^g$ whose graded character is the twined elliptic genus ϕ_g after $\mathcal{N} = 4$ -decomposition. The twist-structure:

- The untwisted CoHA $\mathcal{H}_{K_3}^e$ has graded character ϕ_{K_3} , with BPS multiplicity $\phi_{K_3}(\tau, 0) = \chi(K_3) = 24$ in the massless $\mathcal{N} = 4$ sector and non-BPS multiplicities $2 \cdot \{45, 231, 770, 2277, \dots\}$ in the massive sector (from $\Sigma(\tau)$), both encoding Hall-positive-half BPS multiplicities. The Yangian or vertex-algebra structure enters only after the specified double/VOA construction.
- A twisted CoHA $\mathcal{H}_{K_3}^g$ has graded character ϕ_g and interprets the g -fixed BPS states: for $g \in M_{24}$ of cycle shape $\prod_i k_i^{n_i}$, the character $\chi_g(K_3) = \phi_g(\tau, 0) \in \mathbb{Z}$ is the Frame-shape-graded Euler characteristic, and the mock modular discrepancy Σ_g encodes the twisted-sector shadow.
- The full orbifold CoHA on $[K_3/M_{24}]$ assembles as

$$\mathcal{H}_{K_3}^{M_{24}\text{-orb}} = \bigoplus_{[g] \in \text{Conj}(M_{24})} (\mathcal{H}_{K_3}^g)^{C_{M_{24}}(g)},$$

with $C_{M_{24}}(g)$ the centraliser of g in M_{24} , acting on the twisted sector to extract the invariant piece. The cardinality of $\text{Conj}(M_{24})$ is 26, matching the table of M_{24} -conjugacy classes.

STRATUM (III) $\cap$ (IV) AND AUTOMORPHIC ASSEMBLY

Mathieu M_{24} on K_3 sits in stratum (iii) because K_3 has no global M_{24} -action on the variety itself but carries a derived M_{24} -symmetry of its $\mathcal{N} = 4$ chiral algebra; the symmetry acts on the BPS Hilbert space

(equivalently, on the CoHA). It sits in stratum (iv) because the twined elliptic genera ϕ_g are weak Jacobi forms on the K_3 lattice $\Pi_{4,20}$, and their assembly into a consistent system is an automorphic datum.

The two strata mesh through the Gritsenko lift. The half K_3 weak Jacobi form $\phi_{o,1}$ lifts via Borchers–Gritsenko to the paramodular form $\Delta_5 \in \mathcal{M}_5(\mathrm{Sp}_4(\mathbb{Z}))$ on the Siegel upper half-space, while the full elliptic genus $2\phi_{o,1}$ gives the Igusa-square scalar Δ_5^2 ; this is the stratum-(iv) face. Each normalised twined form ϕ_g lifts analogously to a Borchers–Gritsenko product $\Delta_g \in \mathcal{M}_{k_g}(\Gamma_g)$ on a congruence Siegel modular group, and these $\{\Delta_g\}_{[g] \in \mathrm{Conj}(\mathcal{M}_{24})}$ span the gluing cocycle for the $\mathcal{M}_{24}$ -orbifold CoHA. On the CHL sub-sequence $N \in \{1, 2, 3, 4, 6\}$ the weights are $k_N = c_N(o)/2 \in \{5, 4, 3, 2, 1\}$ (Gritsenko 1999, *Abh. Math. Sem. Hamburg* 69, Thm. 6.1; Borchers 1998, *Invent. Math.* 132 Thm. 10.1), so $\kappa_{\mathrm{BKM}}(\Phi_N) = c_N(o)/2$ across the ladder, with $N = 1$ recovering $\Delta_e = \Delta_5$ at cycle shape 1^{24} . The full Gritsenko–Cléry 8-form atlas carries weights $(5, 2, 3, 1, 2, 1/2, 3/2, 1)$ with Fourier seed values $c_N(o) \in \{10, 4, 6, 2, 4, 1, 3, 2\}$, so $\kappa_{\mathrm{BKM}}(\Phi_N) = c_N(o)/2$ for each form (Gritsenko–Cléry 2013, *J. Reine Angew. Math.* 678, §3); half-integral entries are lifted under double-cover paramodular groups via multiplier systems $v_\eta^3 \times v_H$, not via metaplectic.

The stratum overlap is therefore concrete: the orbifold side is the assembly

$$\mathcal{H}_{K_3}^{\mathcal{M}_{24}\text{-orb}} = \bigoplus_{[g]} \mathcal{H}_{K_3}^g,$$

and the lattice-polarised side is the assembly

$$\{\Delta_g\}_{[g]} \subset \bigoplus_{[g]} \mathcal{M}_{k_g}(\Gamma_g),$$

and the *twining consistency* between the two sides is the assertion that the Fourier-coefficient matrix of $\{\Delta_g\}$ matches the $\mathcal{M}_{24}$ -character table evaluated on the BPS-spectrum graded dimensions. This is the content of Mathieu moonshine at the level of Vol III CoHA theory.

WEIGHT-1/2 MOCK MODULAR SHADOW AND THE $\mathcal{M}_{24}$ -TWINING COCYCLE

The shadow S_g of Σ_g is a weight-3/2 holomorphic cusp form on $\Gamma_o(|g|)$ fixed by Zwegers’ completion: $\widehat{\Sigma}_g(\tau, \bar{\tau}) = \Sigma_g(\tau) + R_g(\tau, \bar{\tau})$ with R_g the non-holomorphic Eichler-integral completion whose $\bar{\partial}$ -derivative recovers $S_g(\tau)$ through the standard shadow-pairing $\bar{\partial}_{\bar{\tau}} R_g = (2i)^{1/2} \overline{S_g(\tau)} (\tau - \bar{\tau})^{-3/2}$. For $g = e$, $S_e(\tau) \propto \eta(\tau)^3$ (the weight-3/2 generator of the shadow space; Eguchi–Hikami 2009, *J. Phys. A* 42). For general g , S_g is a specific linear combination of η -quotients and Jacobi theta series indexed by the centraliser structure of g (Cheng–Duncan–Harvey 2014).

The shadow encodes the failure of Σ_g to be modular: Σ_g transforms under $\Gamma_o(|g|)$ modulo the lift of S_g across $\mathbb{H}$. In CoHA terms, the shadow records the deviation from a holomorphic global assembly: the $\mathcal{M}_{24}$ -twined CoHA is only mock-modularly consistent, with a precise shadow controlling the obstruction.

The twining cocycle is the assignment $g \mapsto (\phi_g, \Sigma_g, S_g)$ compatible with $\mathcal{M}_{24}$ -conjugation: $\phi_{hgh^{-1}} = \phi_g$, $\Sigma_{hgh^{-1}} = \Sigma_g$, etc. This cocycle is the orbifold-gluing datum of Stratum (iii) refined by the mock-modular Stratum (iv) data.

K_3 CoHA AS ORTHOGONAL YANGIAN $Y_{\hbar}(\mathfrak{so}(4, 20))$

The K_3 CoHA is conjecturally the orthogonal Yangian $Y_{\hbar}(\mathfrak{so}(4, 20))$ of Molev–Ragoucy [68] (or its Hodge-parity $\mathbb{Z}/2$ -super-extension $Y_{\hbar}(\mathfrak{so}(4 | 20))$, non-Kac and non-Kac), with $(4, 20)$ the signature of the Mukai lattice’s Hodge-polarised decomposition: a positive four-plane V_+ contains the Hodge

two-plane and the chosen positive hyperbolic/Kähler directions, and $V_- = V_+^\perp$ has signature $(0, 20)$. On both graded parts the Mukai pairing is symmetric; this excludes $\text{Kac } \mathfrak{osp}(4 | 20)$, whose defining form is symplectic on the 20-dimensional odd part. The orthogonal Yangian carries the Zamolodchikov rational R -matrix on $V = \mathbb{C}^{24}$, satisfying Yang–Baxter; its positive half is the K_3 -CoHA. See Chapter 18 for the $\mathfrak{so}(4, 20)$ versus $\text{Kac-}\mathfrak{osp}(4 | 20)$ trichotomy discussion.

The M_{24} -twining is compatible with this envelope: conjugation by $g \in M_{24}$ preserves the $(4, 20)$ -split (because M_{24} acts by symplectic automorphisms of K_3 , preserving the Hodge involution), and the twisted sector $\mathcal{H}_{K_3}^g$ is a $Y_h(\mathfrak{so}(4, 20))^{\langle g \rangle}$ -module, with the centraliser $C_{M_{24}}(g)$ -invariant part giving the global twisted CoHA.

Summary: orbifold gluing in the four-stratum taxonomy

The orbifold stratum (iii) provides three distinct gluing modes, each illustrated in this part:

- (i) *Global abelian orbifold action*, e.g., $[\mathbb{C}^3/\mathbb{Z}_3]$ for local $\mathbb{P}^2$. Gluing cocycle: BKR equivalence with kernel the universal G -cluster on $G\text{-Hilb}(\mathbb{C}^3)$. CoHA construction: either skew-group Schiffmann–Vasserot equivariantised, or chart-wise on the crepant resolution with Neguţ wheel-corrections. The two agree as derived Hall structures.
- (ii) *Finite non-abelian orbifold*, e.g., $[\mathbb{C}^3/G]$ for $G = \mathbb{Z}_n \times \mathbb{Z}_n$ or G the binary tetrahedral / octahedral / icosahedral group. Gluing cocycle: BKR extended to non-abelian case; the inertia decomposition becomes non-trivial with twisted sectors indexed by conjugacy classes rather than individual elements.
- (iii) *Sporadic / chiral orbifold symmetry*, e.g., Mathieu M_{24} on K_3 . Gluing cocycle: weight-1/2 mock modular forms Σ_g with shadow S_g , assembled into a twining system compatible with M_{24} -conjugation. This sits in Stratum (iii) $\cap$ (iv): the orbifold group M_{24} acts on the chiral-algebra side of Φ , and the Borchers–Gritsenko lifts $\{\Delta_g\}$ provide the automorphic gluing.

Each example passes through the same categorical pattern: a single G -equivariant chart X (or chiral-algebra action of G) carrying a CoHA structure, with the inertia-stack decomposition $I([X/G]) = \sqcup_{[g]} [X^g/C_G(g)]$ stratifying the global assembly into untwisted and twisted sectors. The global CoHA is the direct sum over conjugacy classes, each summand weighted by the age-shift and twisted-sector character. On the derived-category side, BKR (or its chiral generalisation for Mathieu) is the universal cocycle intertwining the orbifold presentation with the resolution presentation.

The K_3 -CoHA / $Y_h(\mathfrak{so}(4, 20))$ conjecture carries three coupled data: the orthogonal Yangian’s positive half as the K_3 -CoHA, the Mathieu M_{24} -action as its sporadic symmetry, and the Borchers lift $\Delta_5 \in \mathcal{M}_5(\text{Sp}_4(\mathbb{Z}))$ as the resulting Siegel modular form with $\kappa_{\text{BKM}}(\Delta_5) = 5$ the Gritsenko weight. The three are three faces of a single gluing cocycle straddling Strata (ii), (iii), (iv).

The compact CY₃ manifold $K_3 \times E$ inherits all three faces and adds a fourth through the E -factor’s translation equivariance; its treatment in §33.8 uses the orbifold tools of this section together with the other strata.

Transition to §33.4. The orbifold stratum admits a refinement: the gluing cocycle can also be presented as a *derived Morita equivalence* by a tilting object whose endomorphism algebra is the skew-group algebra. §33.4 develops this Van den Bergh tilting-bundle viewpoint, with local $\mathbb{P}^2$ reappearing there as the three-line-bundle tilting example, and the Serre-equivariant quasi-NCCR of $K_3 \times E$ emerging as the Morita-gluing obstruction that §33.3’s orbifold methods alone cannot resolve.

33.4 VAN DEN BERGH DERIVED MORITA GLUING

Parts I–III assembled global CoHAs from Čech, toric, and McKay atlases: each overlap carried a geometric transition; a Fourier–Mukai kernel, a toric cocycle, a BKR equivalence. §33.4 replaces the atlas by a single object. A *tilting bundle* T on a projective CY_3 (or a local CY_3) collapses the derived category of coherent sheaves onto the derived category of modules over a finite-dimensional algebra $\mathcal{A} = \mathrm{End}(T)$: all gluing information on X is encoded in the multiplicative structure of $\mathcal{A}$. The Hall product on critical cohomology transports along this collapse. Mutations of T act as the chamber-changing automorphisms of the associated CoHA.

Van den Bergh tilting bundles

THE OBSTRUCTION: $D^b(\mathrm{Coh}X)$ IS NOT COMPACTLY GENERATED FROM BELOW

For X a smooth projective variety, $D^b(\mathrm{Coh}X)$ admits no canonical generator. Locally one trivialises $\mathrm{Coh}X$ by $\mathrm{Coh}U \simeq \text{mod } R_U$ with $R_U = \Gamma(U, \mathcal{O}_X)$ a commutative affine ring, but the local presentations are incompatible: R_U is Morita-trivial (its module category is generated by the regular module R_U itself), whereas $D^b(\mathrm{Coh}X)$ globally admits no such single-generator description. A tilting bundle is the object that repairs this failure *globally*.

Definition 33.4.1 (Tilting bundle; Bondal–Kapranov 1990). Let X be a smooth variety. A coherent sheaf $T \in \mathrm{Coh}(X)$ is a *tilting bundle* if

- (T1) T is locally free of finite rank;
- (T2) $\mathrm{Ext}_{\mathcal{O}_X}^i(T, T) = 0$ for all $i \geq 1$ (“vanishing higher self-Ext”);
- (T3) T generates $D^b(\mathrm{Coh}X)$ as a triangulated category: the smallest full triangulated subcategory of $D^b(\mathrm{Coh}X)$ closed under shifts, cones, and direct summands and containing T is $D^b(\mathrm{Coh}X)$ itself.

The algebra $\mathcal{A} = \mathrm{End}_{\mathcal{O}_X}(T)^{\mathrm{op}}$ is called the *tilting algebra*.

Conditions (T1)–(T2) force $\mathrm{RHom}(T, T) = \mathrm{End}(T) = \mathcal{A}$ concentrated in degree zero; condition (T3) is the generation property. The reason for passing to the opposite algebra is that $\mathrm{RHom}(T, -)$ produces a *right* $\mathrm{End}(T)$ -module and, by convention, one wishes to write these as left $\mathcal{A}$ -modules.

THEOREM 33.4.2 (Derived Morita via tilting; Bondal 1989; Rickard 1989 for algebras; Bondal–Van den Bergh 2003, *arXiv:math/0204218* Thm. 3.1.1). Let T be a tilting bundle on X and $\mathcal{A} = \mathrm{End}(T)^{\mathrm{op}}$. The pair

$$L = T \otimes_{\mathcal{A}}^L (-) : D(\mathcal{A}\text{-mod}) \longrightarrow D_{\mathrm{qc}}(X), \quad R = \mathrm{RHom}_{\mathcal{O}_X}(T, -) : D_{\mathrm{qc}}(X) \longrightarrow D(\mathcal{A}\text{-mod})$$

is an adjoint pair $L \dashv R$. Two hypotheses make it an equivalence after restriction to the compact part:

- (H1) (*Compact generation*) T is a compact generator of $D_{\mathrm{qc}}(X)$: the smallest localising subcategory of $D_{\mathrm{qc}}(X)$ closed under arbitrary coproducts and containing T is all of $D_{\mathrm{qc}}(X)$, and T is compact (Bondal–Van den Bergh *loc. cit.*, Thm. 3.1.1);
- (H2) (*Higher Ext vanishing*) $\mathrm{Ext}_{\mathcal{O}_X}^{>0}(T, T) = 0$, so that the unit $\mathcal{A} \rightarrow R(L(\mathcal{A})) = \mathrm{RHom}(T, T \otimes_{\mathcal{A}}^L \mathcal{A}) = \mathrm{RHom}(T, T)$ is an isomorphism in $D(\mathcal{A}\text{-mod})$ concentrated in degree zero.

Under (H1)–(H2), $L \dashv R$ is a pair of mutually quasi-inverse equivalences

$$D_{\mathrm{qc}}(X) \simeq D(\mathcal{A}\text{-mod}), \quad \mathrm{Perf}(X) \simeq \mathrm{Perf}(\mathcal{A}) = D^{\mathrm{perf}}(\mathcal{A}\text{-mod}).$$

Restricting to bounded coherent objects on the left and finitely presented modules on the right yields the classical equivalence $D^b(\text{Coh} X) \simeq D^b(A\text{-mod})$.

Proof. The adjunction $L \dashv R$ is the standard tensor–Hom adjunction for the $A\text{-}\mathcal{O}_X$ bi-module T : for $M \in D(A\text{-mod})$ and $\mathcal{F} \in D_{\text{qc}}(X)$, $\text{Hom}_{D_{\text{qc}}(X)}(T \otimes_A^L M, \mathcal{F}) = \text{Hom}_{D(A)}(M, \text{RHom}_{\mathcal{O}_X}(T, \mathcal{F}))$ functorially. The unit $\eta_A: A \rightarrow R(L(A)) = \text{RHom}(T, T)$ is an isomorphism by (H2), which forces $\text{Ext}^{>0}(T, T) = 0$ and identifies $\text{RHom}(T, T) \simeq \text{End}(T) = A^{\text{op}}$ concentrated in degree zero; since A generates $D(A\text{-mod})$, this upgrades to $\eta_M: M \xrightarrow{\sim} R(L(M))$ for all $M \in D(A\text{-mod})$. The counit $\varepsilon_{\mathcal{F}}: L(R(\mathcal{F})) \rightarrow \mathcal{F}$ is an isomorphism on the compact generator T by the same computation, and T compactly generates $D_{\text{qc}}(X)$ by (H1), so ε is an isomorphism on all of $D_{\text{qc}}(X)$ (Bondal–Van den Bergh arXiv:math/0204218, Thm. 3.1.1: a compact generator with bounded Ext produces an equivalence with modules over its endomorphism dg-algebra, here concentrated in degree zero by (H2)). $\square$

NON-COMMUTATIVE CREPANT RESOLUTIONS

The obstruction on singular X is sharper: X admits no smooth model within its birational class without blowing up, but one may ask for a *non-commutative* smooth substitute.

Definition 33.4.3 (NCCR; Van den Bergh 2004, arXiv:math/0211064). Let R be a commutative Noetherian normal Gorenstein domain. A *non-commutative crepant resolution* of R is an R -algebra $A = \text{End}_R(M)$, for some reflexive R -module M , such that

- (N1) A is *homologically homogeneous*: all simple A -modules have the same projective dimension, equal to $\dim R$;
- (N2) A is a *maximal Cohen–Macaulay* R -module;
- (N3) A is generically Azumaya and M is a reflexive generator.

“Crepant” means $\omega_A \cong A$ as A -bimodules: the canonical class is trivial, matching the CY condition on $\text{Spec } R$.

THEOREM 33.4.4 (*Van den Bergh equivalence, arXiv:math/0211064 Thm. 6.6.1 and §8*). Let $Y \rightarrow X = \text{Spec } R$ be a crepant resolution (in the commutative sense) with R as in Definition 33.4.3, and suppose $\dim R \leq 3$. Then there exists a tilting bundle T_Y on Y with $\text{End}(T_Y)^{\text{op}} = A$ an NCCR of R in the sense of Definition 33.4.3, and the adjoint pair $L \dashv R$ of Theorem 33.4.2 is an equivalence

$$D^b(\text{Coh} Y) \simeq D^b(A\text{-mod}).$$

Both sides realise the same abstract triangulated category; when R is Gorenstein of dimension three with trivial dualising module, the *Ginzburg dg-lift* $\Gamma = \Gamma(Q, W)$ of A (Ginzburg 2006, arXiv:math/0612139 Thm. 5.3.1) carries a CY_3 structure: Γ is exact 3-Calabi–Yau as a dg-algebra, meaning the inverse dualising complex satisfies bimodule self-duality $\text{RHom}_{\Gamma^e}(\Gamma, \Gamma \otimes \Gamma)[3] \simeq \Gamma$ in the derived category of Γ -bimodules; the $[3]$ -shift is the bimodule incarnation of the PTVV shift $(d, \text{shift}, E_n^{\text{cl}}) = (3, -1, E_1)$ on CY_3 geometry. The Jacobi algebra $J = \text{Jac}(Q, W) = H^0(\Gamma)$ is not itself a CY_3 algebra; the self-duality is a property of the dg-lift, and descent to J requires the quasi-isomorphism $\Gamma \simeq J$ in Proposition 33.4.6(c).

Scope of existence. The hypothesis $\dim R \leq 3$ is sharp. Beyond dimension three, the existence of an NCCR is not guaranteed and *fails* in the cases most of interest: projective K_3 surfaces with generic polarisation (where $H^{0,2}(X) \neq 0$ obstructs higher Ext-vanishing), the quintic and other generic projective CY_3 without toric or orbifold presentation, and compact hyperkähler manifolds of dimension ≥ 4 . The

Van den Bergh existence theorem covers precisely the local three-dimensional crepant setting: toric CY_3 , orbifolds $\mathbb{C}^n/G$ with $G \subset \text{SU}(n)$ of dimension $n \leq 3$, (-3) -curve contractions, and their relatives.

On the conifold $R = \mathbb{C}[x, y, z, w]/(xw - yz)$ the NCCR is the *Klebanov–Witten quiver algebra* with tilting bundle $T = \mathcal{O} \oplus \mathcal{O}(1)$ on the resolved conifold $\tilde{Y} = \mathcal{O}_{\mathbb{P}^1}(-1) \oplus \mathcal{O}_{\mathbb{P}^1}(-1)$. On local $\mathbb{P}^2 = \text{Tot}(\mathcal{O}_{\mathbb{P}^2}(-3))$ the NCCR is the nine-arrow Beilinson algebra, with $T = \mathcal{O} \oplus \mathcal{O}(1) \oplus \mathcal{O}(2)$. On (-3) -curve contractions $\tilde{Y} \rightarrow X$ with $\tilde{Y}$ containing a $\mathbb{P}^1$ of self-intersection $(-1, -1, -1, -1)$ on its normal bundle, Craw’s tilting bundles (Craw 2008, building on Craw–Ishii 2004) play the same role. In each case, an explicit tilting object T reduces all geometric CoHA questions on X to finite-dimensional Hall-algebra questions on $\mathcal{A} = \text{End}(T)^{\text{op}}$; the superpotential $\mathcal{W}$ reconstructing $\mathcal{A}$ as a Jacobi algebra is uniquely determined (up to right-equivalence) from the cyclic $\mathcal{A}_\infty$ -structure on the tilting algebra (Bocklandt 2008, arXiv:math/0603558 Thm. 3.1).

EXISTENCE AND FAILURE

The Van den Bergh theorem (Theorem 33.4.4) guarantees the existence of a tilting bundle in precisely the *local three-dimensional* crepant setting: X obtained as a crepant resolution of an affine Gorenstein singularity $\text{Spec } R$ with $\dim R \leq 3$. This covers toric CY_3 , orbifolds $\mathbb{C}^n/G$ with $G \subset \text{SU}(n)$ of dimension $n \leq 3$, (-3) -curve contractions, and their relatives. Beyond this scope, global tilting *fails*. Three cases are central:

- (a) *Projective K3 surface S with generic polarisation.* The obstruction is $\text{Ext}_{\mathcal{O}_S}^2(\mathcal{F}, \mathcal{F}) \neq 0$ for any locally-free $\mathcal{F}$: Serre duality on a CY_2 identifies $\text{Ext}^2(\mathcal{F}, \mathcal{F}) \cong \text{Hom}(\mathcal{F}, \mathcal{F})^\vee \neq 0$. The higher-Ext vanishing hypothesis (H2) of Theorem 33.4.2 cannot hold. The K3 category admits compact generation (by Bondal–Van den Bergh, Thm. 3.1.1) but no tilting generator.
- (b) *Quintic threefold $X \subset \mathbb{P}^4$.* The obstruction is the non-triviality of $H^{\circ,3}(X) = \mathbb{C}$ (the holomorphic volume form), which combined with Serre duality forces $\text{Ext}_{\mathcal{O}_X}^3(\mathcal{F}, \mathcal{F}) \neq 0$ for non-zero $\mathcal{F}$. No $\text{Ext}^{>0}$ -vanishing tilting generator exists globally.
- (c) *Compact hyperkähler manifold of dimension ≥ 4 .* Hyperkähler symmetry forces $h^{\circ,p}(X) = 1$ for all p even, $0 \leq p \leq \dim X$; the higher Ext-vanishing hypothesis is obstructed at every even degree $\leq \dim X$.

The general pattern: at $d \geq 3$, if $H^{\circ,q}(X) \neq 0$ for some $1 \leq q \leq d$, then $\text{Ext}^q(T, T) \supseteq H^{\circ,q}(X) \neq 0$ for any locally-free T with $\mathcal{O}_X$ as a summand; the hypothesis (H2) of Theorem 33.4.2 fails. In such cases, no global tilting exists; only local tilting on Zariski patches, and the gluing of Parts I–III (or §33.5 via factorisation algebras) applies.

Tilting as gluing presentation

The tilting bundle is a *presentation* of X by a single quiver-with-potential: the quiver vertices are the summands of $T = \bigoplus_i T_i$, the arrows are extensions among them, and the potential encodes the exact 3-Calabi–Yau constraint on the Ginzburg dg-lift $\Gamma(Q, \mathcal{W})$.

THE DECOMPOSITION $T = \bigoplus_i T_i$

Write $T = \bigoplus_{i \in I} T_i$ as a finite direct sum of indecomposable summands. This decomposition is canonical up to isomorphism of summands (Krull–Schmidt on the additive category generated by T). Then

$$\mathcal{A} = \text{End}(T)^{\text{op}} = \bigoplus_{i,j \in I} \text{Hom}_{\mathcal{O}_X}(T_i, T_j)^{\text{op}}$$

is a matrix algebra over the “diagonal” algebras $\text{End}(T_i)$, indexed by pairs (i, j) . The off-diagonal block $\text{Hom}_{\mathcal{O}_X}(T_i, T_j)$ is the *arrow space* from i to j : its basis is the space of morphisms $T_i \rightarrow T_j$ in $\text{Coh}(X)$ modulo scaling.

In the conifold example $T = \mathcal{O} \oplus \mathcal{O}(-1)$:

$$\text{Hom}(\mathcal{O}, \mathcal{O}(-1)) = H^0(\mathbb{P}^1, \mathcal{O}(-1)) \oplus H^0(\mathbb{P}^1, \mathcal{O}(-1)) = \mathbb{C}^2 \oplus 0 = \mathbb{C}a_1 \oplus \mathbb{C}a_2,$$

and $\text{Hom}(\mathcal{O}(-1), \mathcal{O}) = H^0(\mathcal{O}(-1)) \oplus H^0(\mathcal{O}(-1)) = 0 \oplus \mathbb{C}^2 = \mathbb{C}b_1 \oplus \mathbb{C}b_2$ (the second term arises via the $\mathcal{O}(-1) \oplus \mathcal{O}(-1)$ fibre direction). Similarly $\text{End}(\mathcal{O}) = \text{End}(\mathcal{O}(-1)) = \mathbb{C}$. The Klebanov–Witten quiver with vertices $\{\circ, \bullet\}$, arrows $a_1, a_2: \circ \rightarrow \bullet$ and $b_1, b_2: \bullet \rightarrow \circ$, and superpotential $W = a_1b_1a_2b_2 - a_1b_2a_2b_1$ emerges *directly* from the cohomology count.

THE JACOBI ALGEBRA, THE POTENTIAL, AND THE GINZBURG DG-LIFT

The endomorphism algebra of a tilting bundle on a smooth local CY_3 carries a cyclic derivation structure: there exists a superpotential $W \in \mathbb{C}Q_{\text{cyc}} = \mathbb{C}Q/[CQ, CQ]$ in the cyclic quotient of the path algebra such that the relations among the arrows are precisely the cyclic derivatives $\partial_a W = 0$. The pair (Q, W) is the quiver with potential; the *Jacobi algebra* is

$$J = \text{Jac}(Q, W) = \mathbb{C}Q / \langle \partial_a W : a \in Q_1 \rangle.$$

The CY_3 property is carried not by J but by its *Ginzburg dg-lift*.

Definition 33.4.5 (Ginzburg dg-algebra; Ginzburg 2006, arXiv:math/0612139 §5). Given a quiver with potential (Q, W) , the *Ginzburg dg-algebra* $\Gamma(Q, W)$ is the tensor algebra on the graded quiver

- arrows of Q in degree 0;
- one reverse arrow $a^*: j \rightarrow i$ in degree -1 for each $a: i \rightarrow j$ in Q_1 ;
- one loop $t_i: i \rightarrow i$ in degree -2 at each vertex $i \in I$,

equipped with the differential $da = 0$, $da^* = \partial_a W$, and $dt_i = \sum_{a \in Q_1} [a, a^*] \cdot e_i$ (the total commutator at vertex i).

PROPOSITION 33.4.6 (*CY₃ property lives on Γ , not on J ; Ginzburg 2006, arXiv:math/0612139 Thm. 5.3.1 for the exact CY property of $\Gamma(Q, W)$; Keller 2011 arXiv:1102.4148 §6 for the descent of the CY_3 class to derived Morita*). For (Q, W) a quiver-with-potential arising from a local CY_3 :

- The dg-algebra $\Gamma(Q, W)$ is *exact 3-Calabi–Yau*: its inverse dualising complex satisfies $\text{RHom}_{\Gamma^e}(\Gamma, \Gamma \otimes \Gamma)[3] \simeq \Gamma$ as Γ -bimodules, with the CY_3 shift degree $+3$ matching the PTVV shift $(d, \text{shift}, E_n^{\text{cl}}) = (3, -1, E_1)$ under dg-Hochschild Serre duality.
- The Jacobi algebra $J = H^0(\Gamma(Q, W))$ is the degree-zero cohomology of Γ ; it is *not* by itself a CY_3 algebra. Calling J “ CY_3 ” conflates two distinct structures (J has no intrinsic shift structure). The three-dimensional duality is an assertion about Γ -bimodules.
- For Q connected and W suitably non-degenerate, $H^{<0}(\Gamma(Q, W)) = 0$, so $\Gamma \simeq J$ in the derived category of Γ (hence derived Morita between Γ and J), and only via this quasi-isomorphism does the CY_3 structure on Γ descend to the derived categorical structure $D^b(J\text{-mod})$.

THEOREM 33.4.7 (*Tilting-via-quiver presentation; Ginzburg 2006, Keller 2011 arXiv:1102.4148*). Let $T = \bigoplus_{i \in I} T_i$ be a tilting bundle on a smooth local CY_3 X . Let Q be the quiver with vertex set

I and arrow spaces $Q_i(i, j) = \text{Ext}_{\mathcal{O}_X}^1(T_i, T_j)^*$. There exists a quasi-homogeneous superpotential $W \in \mathbb{C}Q_{\text{cyc}}$, unique up to gauge, such that

$$\text{Jac}(Q, W) = \text{End}_{\mathcal{O}_X}(T)^{\text{op}}, \quad \Gamma(Q, W) \simeq \text{RHom}_{\mathcal{O}_X}(T, T) \text{ as dg-algebras,}$$

and the CY_3 structure on $\text{Perf}(X)$ transports (via Theorem 33.4.2 applied to Γ) to the exact CY_3 structure on Γ of Proposition 33.4.6(a).

Proof. The arrow spaces are Ext-spaces: under (H2) the underived and derived $\text{Hom}(T_i, T_j)$ agree in degree zero, so the first non-trivial term for $i \neq j$ is $\text{Ext}^1(T_i, T_j)$, which Serre-dualises to $\text{Ext}^2(T_j, T_i)$ on the CY_3 ; the potential encodes the m_3 Massey product. The construction of W is the Kontsevich–Costello reconstruction of a cyclic A_∞ -algebra from its degree-zero piece plus Serre duality: the m_3 on Ext^1 evaluated against Serre duality reproduces the degree-3 piece of W , higher m_k give higher-degree corrections, and quasi-homogeneity follows from the internal CY_3 grading on Γ . The quasi-isomorphism $\text{RHom}(T, T) \simeq \Gamma(Q, W)$ is Keller’s derived-equivalence theorem (Keller 2011 §A.15). The CY_3 property, as Proposition 33.4.6 records, is a property of Γ as a dg-algebra; the statement “ J is CY_3 ” is shorthand for “ Γ is CY_3 and $J = H^0(\Gamma)$ ”. $\square$

CANONICAL EXAMPLES

Conifold $\tilde{Y} = \mathcal{O}_{\mathbb{P}^1}(-1)^{\oplus 2}$. Tilting $T = \mathcal{O} \oplus \mathcal{O}(1)$. Quiver: two vertices, two arrows each way. Potential $W = a_1 b_1 a_2 b_2 - a_1 b_2 a_2 b_1$ (Klebanov–Witten, Szendrői 2008).

Local $\mathbb{P}^2 = \text{Tot}(\mathcal{O}_{\mathbb{P}^2}(-3))$. Tilting $T = \mathcal{O} \oplus \mathcal{O}(1) \oplus \mathcal{O}(2)$ (Beilinson 1978). Quiver: three vertices, $3 \times 3 = 9$ arrows grouped as three Koszul strands (Beilinson triple $\mathcal{O}, \mathcal{O}(1), \mathcal{O}(2)$). Potential $W_{\mathbb{P}^2} = \sum_{\sigma \in S_3} \text{sgn}(\sigma) x_{\sigma(1)} y_{\sigma(2)} z_{\sigma(3)}$: the antisymmetric McKay cubic (Beasley–Plesser 2001).

(−3)-curves. Let $\tilde{Y}$ contain a rational curve $C \cong \mathbb{P}^1$ with normal bundle $N_{C/\tilde{Y}} = \mathcal{O}(-1) \oplus \mathcal{O}(-1)$ that can be contracted to a singular point of X . Craw 2008 (building on the Craw–Ishii 2004 analysis of $\mathbb{C}^3/G$ -Hilb schemes) constructs tilting $T_C = \mathcal{O}_{\tilde{Y}} \oplus \mathcal{O}_{\tilde{Y}}(C)$ (or an explicit line-bundle refinement with intersection numbers read off from $N_{C/\tilde{Y}}$). The associated tilting algebra is derived-equivalent to the quiver from the contracted singularity; tilting automorphisms realise the flop $\tilde{Y} \dashrightarrow \tilde{Y}^+$ as derived Morita on the same CY_3 category.

$\mathbb{C}^3/\mathbb{Z}_n$ orbifolds. Tilting $T = \bigoplus_{k=0}^{n-1} \mathcal{O} \otimes \chi_k$ on the resolved orbifold, where χ_k are the characters of $\mathbb{Z}_n$. Quiver: n vertices arranged on a cycle; arrows per McKay graph; potential cubic (type A McKay).

QUIVER-WITH-POTENTIAL AS UNIVERSAL GLUING DATA

The force of Theorem 33.4.7 is that for every tilting presentation, a single pair (Q, W) plays the role of the entire Čech atlas plus all its transition functors. One algebra $\mathcal{A} = \text{Jac}(Q, W)$ encodes everything. In particular:

- The Čech nerve $\{U_\alpha\} \cup \{U_\alpha \cap U_\beta\} \cup \dots$ on X collapses to the vertex set I and the arrow set Q ;
- The transition functors between charts collapse to the relations $\partial_a W = 0$;
- The higher cocycle data on triple overlaps collapses to the higher A_∞ structure on $\Gamma(Q, W)$.

The tilting presentation is therefore the *economy* of the gluing: one single finite-dimensional algebra replaces the infinite-dimensional Čech diagram.

Transport of Hall product along derived Morita

The CoHA on X is defined via the moduli stack of coherent sheaves $\mathcal{M}(X)$ with its critical cohomology ring structure (Kontsevich–Soibelman 2008, Davison–Meinhardt 2020 arXiv:1601.02479). On the NCCR side, the same construction yields the CoHA on the moduli stack $\mathcal{M}(A)$ of finite-dimensional A -modules. The derived Morita equivalence lifts to these moduli stacks, and Davison–Hennecart–Schlegel Mejia (DHSM) 2023 arXiv:2303.12592 prove that the Hall product transports. The assertion of this section is the precise form of that transport and its first-principles derivation.

MODULI-STACK LIFT OF DERIVED MORITA

THEOREM 33.4.8 (*Moduli-stack Morita; Davison–Hennecart–Schlegel Mejia 2023, arXiv:2303.12592 Thm. A*). Let X be a smooth local CY_3 admitting a tilting bundle T satisfying hypotheses (H1)–(H2) of Theorem 33.4.2, and let $A = \mathrm{End}(T)^{\mathrm{op}} = \mathrm{Jac}(Q, W)$ be the associated Jacobi algebra. Then the adjoint pair $L \dashv R$ descends to an equivalence of (derived) moduli stacks of semistable objects

$$\mathcal{M}^{\mathrm{ss}}(X) \simeq \mathcal{M}^{\mathrm{ss}}(A)$$

under the class-level identification

$$\mathrm{cl}_T : K_0(\mathrm{Coh} X) \xrightarrow{\sim} \mathbb{Z}^I, \quad [\mathcal{F}] \mapsto (\dim \mathrm{RHom}(T_i, \mathcal{F}))_{i \in I}.$$

The lift intertwines the universal family $\mathcal{E}_X$ on $\mathcal{M}(X)$ with the universal representation V_A on $\mathcal{M}(A)$: $\mathrm{RHom}(T, \mathcal{E}_X) = V_A$ as coherent sheaves on the common moduli stack.

Sketch. Derived Morita transports the abelian heart (a t -structure on $D^b(\mathrm{Coh} X)$ whose heart is the image of $A\text{-mod}$) to the standard heart on $A\text{-mod}$. Bridgeland’s identification of stability conditions preserves semistability under this t -structure alignment. The resulting map on moduli is an equivalence of stacks because the universal family $\mathcal{E}_X$ on $\mathcal{M}(X)$ maps to the universal representation V_A on $\mathcal{M}(A)$, and conversely, via the inverse functor $T \otimes_A^L -$. $\square$

CRITICAL COHOMOLOGY TRANSPORTS

The CoHA on either side is

$$\mathcal{H}(X) = H_{T_{\mathrm{C}^\times}}^{\bullet, \mathrm{BM}}(\mathcal{M}(X), \varphi_{\mathrm{tr} W_X}),$$

where φ is the vanishing-cycle functor and W_X is the canonical CY_3 superpotential (pulled back from the framing). On the NCCR side, the superpotential is precisely $W = W_{Q, W}$; the potential of the quiver-with-potential; and $\varphi_{\mathrm{tr} W}$ is the vanishing-cycle sheaf on the representation variety $\mathrm{Rep}(Q, \underline{d})$.

THEOREM 33.4.9 (*Vanishing-cycle transport; DHSM 2023, extending Davison 2017*). Under the moduli equivalence of Theorem 33.4.8, the vanishing-cycle sheaf $\varphi_{\mathrm{tr} W_X}$ on $\mathcal{M}(X)$ is canonically isomorphic to $\varphi_{\mathrm{tr} W_Q}$ on $\mathcal{M}(A)$, compatibly with the T -equivariant structure. Consequently:

$$\mathcal{H}(X) \simeq \mathcal{H}(A) \quad \text{as equivariant Borel–Moore cohomology modules over the respective moduli stacks.}$$

First-principles derivation. A coherent sheaf $\mathcal{F}$ on X corresponds, under Φ_T , to an A -module $M = \mathrm{RHom}(T, \mathcal{F})$. Both $\mathcal{F}$ and M admit the same deformation theory: the obstruction space is $\mathrm{Ext}^2(\mathcal{F}, \mathcal{F}) \cong \mathrm{Ext}_A^2(M, M)$ (Serre duality on X matches the cyclic duality on A). The superpotential W_X on the deformation space matches $\mathrm{tr} W_Q$ pulled back along the tilting isomorphism, because

$$W_X|_{T_{[\mathcal{F}]}^* \mathcal{M}(X)} = \text{degree-3 part of the } A_\infty \text{ structure on } \mathrm{Ext}^\bullet(\mathcal{F}, \mathcal{F}),$$

and Theorem 33.4.7 identifies precisely this degree-3 piece with the Jacobi potential W . The vanishing-cycle sheaf is therefore an invariant of the pair (deformation space, superpotential), transporting identically along the moduli equivalence. $\square$

EXTENSION STACKS AND HALL PRODUCT TRANSPORT

The Hall product on $\mathcal{H}(X)$ is built from the *extension stack* $\text{Ext}(\mathcal{M} \times \mathcal{M}, \mathcal{M})$: for charge classes $\gamma_1, \gamma_2 \in K_0(\text{Coh} X)$, the extension stack parametrises short exact sequences $0 \rightarrow \mathcal{F}_1 \rightarrow \mathcal{F} \rightarrow \mathcal{F}_2 \rightarrow 0$ with $[\mathcal{F}_i] = \gamma_i$ and $[\mathcal{F}] = \gamma_1 + \gamma_2$. The Hall product is convolution along the push/pull diagram

$$\mathcal{M}_{\gamma_1} \times \mathcal{M}_{\gamma_2} \xleftarrow{\text{ends}} \text{Ext}_{\gamma_1, \gamma_2} \xrightarrow{\text{middle}} \mathcal{M}_{\gamma_1 + \gamma_2}.$$

PROPOSITION 33.4.10 (*Extension-stack transport*). Under the moduli equivalence $\mathcal{M}(X) \simeq \mathcal{M}(A)$ the extension stacks satisfy

$$\text{Ext}_{\gamma_1, \gamma_2}^X \simeq \text{Ext}_{\text{cl}_T(\gamma_1), \text{cl}_T(\gamma_2)}^A,$$

with the “ends” and “middle” morphisms intertwined by Φ_T . Combined with Theorem 33.4.9, this yields:

THEOREM 33.4.11 (*Hall-product transport along derived Morita; DHSM 2023 arXiv:2303.12592 Thm. A, with super-grading extension Thm. B*). Under hypotheses (H1)–(H2) on the tilting bundle T , there is an isomorphism of (super-graded) bialgebras

$$\star_T : \mathcal{H}(X) \xrightarrow{\sim} \mathcal{H}(A)$$

intertwining the Hall product, the natural coproduct (where defined), and the $T_{\mathbb{C}^\times}$ -equivariant structures. On charges, $\star_T$ is the $\mathbb{Z}$ -linear extension of cl_T . The $\mathbb{Z}/2$ -super grading (cohomological parity on $\varphi_{\text{tr}} W$) transports along the same equivalence, by DHSM Thm. B.

Proof. The Hall product is a composition of pullback-along-ends, intersection with the vanishing-cycle sheaf, and pushforward-along-middle. Each factor transports under derived Morita: the ends and middle morphisms transport by Proposition 33.4.10; the vanishing-cycle sheaf transports by Theorem 33.4.9; the equivariant structure transports because the tilting bundle is $T_{\mathbb{C}^\times}$ -equivariant in the toric setting (and equivariantly localisable at the fixed locus in the general local CY_3 setting). The $\mathbb{Z}/2$ -super grading transports because $\varphi_{\text{tr}} W_X$ and $\varphi_{\text{tr}} W_Q$ carry identically-graded sheaves of nearby cycles under the cohomological parity; DHSM Thm. B upgrades Thm. A from an isomorphism of bialgebras to an isomorphism of super-bialgebras. $\square$

Theorem 33.4.11 is established unconditionally by DHSM (2023, Thm. A + Thm. B) for $A = \text{Jac}(Q, W)$ the Jacobi algebra of any quiver-with-potential; the CY_3 hypothesis is absorbed into the assertion that the Ginzburg dg-lift $\Gamma(Q, W)$ is exact 3-Calabi–Yau (Proposition 33.4.6). For a smooth local CY_3 X with tilting presentation (Q, W) , this yields the full $\mathcal{H}(X) \simeq \mathcal{H}(\text{Jac}(Q, W))$ identification on $\mathbb{C}^3$, the conifold (Klebanov–Witten (Q, W)), local $\mathbb{P}^2$ (Beilinson cubic), and $\mathbb{C}^3/\mathbb{Z}_n$ for all n .

WHY HALL PRODUCT PRESERVATION IS FORCED

An alternative way to see the transport is purely representation-theoretic: both $\mathcal{H}(X)$ and $\mathcal{H}(A)$ are instances of the *universal positive-geometry grammar* $Y^+(X) = H_{\text{eq}}^\bullet(\mathcal{M}_{\text{eff}}^+(X), \varphi_W)$. The grammar is invariant under any derived equivalence that preserves the effective semistable moduli stack and the superpotential. Derived Morita preserves both, by construction. Hence the CoHAs agree, and the Hall product structure is preserved.

Gluing-preservation theorem for mutations

If T and T' are two tilting bundles on the same CY₃ X , they give two tilting algebras $A = \text{End}(T)$ and $A' = \text{End}(T')$, and by Theorem 33.4.11 the same CoHA $\mathcal{H}(X)$: both transports land on the same Hall-product object. This induces an isomorphism $\mathcal{H}(A) \simeq \mathcal{H}(A')$. When T and T' are related by a *mutation* (Derksen–Weyman–Zelevinsky 2008), the induced isomorphism has an explicit combinatorial presentation.

MUTATION AT A VERTEX

Definition 33.4.12 (Mutation of quiver-with-potential; DWZ 2008, arXiv:0704.0649 Def. 4.4 (trivial / reduced QP), Thm. 4.6 (splitting), Def. 5.1 (premutation), Def. 5.5 (mutation); non-degeneracy Def. 7.2). Let (Q, W) be a reduced quiver-with-potential (no 2-cycles in Q , no 2-cycle terms in W) with vertex set I , and fix a vertex $k \in I$ supporting no loops. The *mutation at k* , $\mu_k(Q, W) = (Q', W')$, factors as a composite of two moves: the *premutation* $\tilde{\mu}_k$ followed by the *reduction* red of DWZ Theorem 4.6,

$$\mu_k(Q, W) = \text{red}(\tilde{\mu}_k(Q, W)).$$

The premutation $\tilde{\mu}_k(Q, W) = (\tilde{Q}, \tilde{W})$ is the three-arrow arrow surgery:

- (M1) *Compose through k .* For each pair of arrows $a: i \rightarrow k$ and $b: k \rightarrow j$ with $i, j \neq k$, adjoin a formal composite $[ba]: i \rightarrow j$ to the arrow set.
- (M2) *Reverse k -incident arrows.* Replace each $a: i \rightarrow k$ by $a^*: k \rightarrow i$, and each $b: k \rightarrow j$ by $b^*: j \rightarrow k$; arrows not incident to k are unchanged.
- (M3) *Update the potential.* Set

$$\tilde{W} = [W]_{\{[ba]\}} + \sum_{\substack{a: i \rightarrow k \\ b: k \rightarrow j}} [ba] b^* a^*,$$

where $[W]_{\{[ba]\}}$ is the cyclic representative of W obtained by replacing every length-two path ba through k by the formal symbol $[ba]$.

The reduction splits the premutation: DWZ Theorem 4.6 provides a canonical right-equivalence decomposition $(\tilde{Q}, \tilde{W}) \simeq_{\text{r.e.}} (Q_{\text{red}}, W_{\text{red}}) \oplus (Q_{\text{triv}}, W_{\text{triv}})$ into a *reduced* summand (no 2-cycle terms in W_{red}) and a *trivial* summand (Jacobi algebra zero), unique up to right-equivalence. Set $(Q', W') = (Q_{\text{red}}, W_{\text{red}})$.

The reduction is not “Euler–Lagrange elimination” in the path-integral sense: it is the Derksen–Weyman–Zelevinsky right-equivalence (DWZ 2008 Def. 4.2, Thm. 4.6). Writing the 2-cycle part of $\tilde{W}$ as $W_{\text{triv}} = \sum_i c_i x_i y_i + (\text{higher})$ with non-degenerate scalars c_i after a linear change of variables on the 2-cycle generators, the automorphism $x_i \mapsto x_i - c_i^{-1} \partial_{y_i}(\tilde{W} - W_{\text{triv}})$, $y_i \mapsto y_i$, of the completed path algebra $\widehat{\mathbb{C}Q}$ separates $\tilde{W}$ into $W_{\text{red}} \oplus W_{\text{triv}}$ (DWZ Thm. 4.6), with W_{triv} supported on the trivial

summand $(Q_{\text{triv}}, W_{\text{triv}})$ whose Jacobi algebra vanishes. The splitting is unique up to right-equivalence by DWZ Prop. 4.5.

The *non-degeneracy hypothesis* on (Q, W) is that every iterated premutation admits a reduction. DWZ §7 prove that non-degenerate QPs are generic and that all QPs arising from local CY_3 tilting; the conifold, local $\mathbb{P}^2$, $\mathbb{C}^3/\mathbb{Z}_n$; are non-degenerate (DWZ 2008 §7, genericity of non-degenerate QPs; Prop. 7.3).

PROPOSITION 33.4.13 (*Mutation is an involution up to right-equivalence; DWZ 2008 Thm. 5.7*). In the category whose objects are reduced QPs and whose morphisms are right-equivalences, the reduced mutation $\mu_k = \text{red} \circ \tilde{\mu}_k$ satisfies

$$\mu_k(\mu_k(Q, W)) \simeq_{\text{r.e.}} (Q, W).$$

The involution is *not* a strict equality at the premutation level. Applied twice, premutation step (M2) reverses the k -incident arrows once and again, and step (M1) of the second application adjoins formal composites $[b^* a^*]$ running through the reversed vertex; these pair with the original $[ba]$ inserted in step (M1) of the first application to form 2-cycles through k , which the reduction red then splits off as the trivial summand (DWZ 2008 Thm. 5.7 proof, §5). The involution is therefore a theorem at the level of the *reduced* mutation, and the right-equivalence is constructive: it is the identity on arrows not adjacent to k and the DWZ reduction automorphism on the pair of reversed k -incident arrows.

Geometrically, $T' = \mu_k(T)$ is *not* a plain “dual-and-shift” $T_k^\vee[1]$ but a cone on the Ext^1 -arrow data at k . Replace the summand T_k by one of two mutation cones,

$$T_k^+ = \text{cone}\left(T_k \xrightarrow{\text{ev}} \bigoplus_{b: k \rightarrow j} T_j^{\oplus \dim b}\right), \quad T_k^- = \text{cone}\left(\bigoplus_{a: i \rightarrow k} T_i^{\oplus \dim a} \xrightarrow{\text{coev}} T_k\right)[-1],$$

the first built from arrows *out of* k and the second from arrows *into* k ; the two differ by a global shift (Iyama–Reiten 2008, arXiv:0707.1669 §5; Keller–Yang 2011, arXiv:0906.0761 §3). The involution Proposition 33.4.13 corresponds geometrically to $\mu_k^-(\mu_k^+(T)) \simeq T$, which is a Serre-duality statement on the two cones, *not* to the spurious $T_k^\vee[2] = T_k$.

THEOREM 33.4.14 (*Mutation gives a pair of derived equivalences; Keller–Yang 2011, arXiv:0906.0761 Thm. 3.2*). Assume (Q, W) is non-degenerate. The mutation $\mu_k: (Q, W) \mapsto (Q', W') = \mu_k(Q, W)$ lifts to a pair of triangulated equivalences

$$M_k^+ : \mathcal{D}(\Gamma(Q, W)) \xrightarrow{\sim} \mathcal{D}(\Gamma(Q', W')), \quad M_k^- : \mathcal{D}(\Gamma(Q, W)) \xrightarrow{\sim} \mathcal{D}(\Gamma(Q', W')),$$

where $\mathcal{D}(\Gamma) = D(\Gamma\text{-dg-mod})$. The two equivalences are constructed from a pair of silting objects T_k^+, T_k^- in $\text{per}(\Gamma(Q, W))$, built from the decomposition $\Gamma(Q, W) = \bigoplus_{i \in I} P_i$ into indecomposable projective dg-modules (Keller–Yang 2011 §3, construction preceding Thm. 3.2):

$$T_k^+ = \text{cone}\left(P_k \xrightarrow{(b)_{b: k \rightarrow j}} \bigoplus_{b: k \rightarrow j} P_{t(b)}\right) \oplus \bigoplus_{i \neq k} P_i,$$

with differential given by the arrows b *out of* k in Q (the sum ranges over $b \in Q_1$ with source k and target $t(b) = j$), and similarly T_k^- built from arrows *into* k . Keller–Yang Thm. 3.2 packages the content: (a) $T_k^\pm$ is silting, with $\text{Ext}^{>0}(T_k^\pm, T_k^\pm) = 0$; (b) $T_k^\pm$ compactly generates $\text{per}(\Gamma(Q, W))$; (c) the

endomorphism dg-algebra $\mathrm{REnd}_{\mathcal{D}(\Gamma(Q,W))}(T_k^\pm)$ is quasi-isomorphic to $\Gamma(Q', W')$, established via the Koszul-dual bar resolution of simples in Keller–Yang §6. Theorem 33.4.2 then yields the equivalences $M_k^\pm = \mathrm{RHom}(T_k^\pm, -) \dashv T_k^\pm \otimes_{\Gamma(Q', W')}^L (-)$.

Along $M_k^\pm$, the simple S_k (the simple at vertex k) over $\Gamma(Q, W)$ maps to $S_k^\pm[\mp 1]$ over $\Gamma(Q', W')$: the *shift direction is opposite* for M_k^+ and M_k^- , and the two equivalences differ by the spherical twist at S_k (Keller–Yang 2011 Prop. 6.4).

INDUCED COHA AUTOMORPHISM

THEOREM 33.4.15 (*Mutation-induced CoHA automorphism*). Let (Q, W) be a non-degenerate quiver-with-potential whose Ginzburg dg-lift $\Gamma(Q, W)$ is exact 3-Calabi–Yau, with Jacobi algebra $\mathcal{A} = \mathrm{Jac}(Q, W) = H^0(\Gamma(Q, W))$, and let μ_k denote mutation at vertex k . Let $M_k^+ : \mathcal{D}(\Gamma(Q, W)) \rightarrow \mathcal{D}(\Gamma(\mu_k(Q, W)))$ be the positive Keller–Yang equivalence of Theorem 33.4.14. Transporting Hall products via Theorem 33.4.11:

$$\mathcal{H}(A) \xrightarrow{M_{k,\star}^+} \mathcal{H}(A')$$

is an isomorphism of super-bialgebras. If (Q, W) and $(Q', W') = \mu_k(Q, W)$ arise as tilting presentations of the *same* geometric CY_3 X ; equivalently, μ_k relates two tilting bundles T, T' on X ; then $M_{k,\star}^+$ is an automorphism of the single CoHA $\mathcal{H}(X)$. The opposite mutation M_k^- gives the inverse automorphism $(M_{k,\star}^+)^{-1}$.

Proof. By Theorem 33.4.14, M_k^+ is a triangulated equivalence between the derived categories of the two CY_3 Ginzburg algebras, constructed as a derived Morita equivalence along the tilting object T_k^+ . By Theorem 33.4.11, any derived Morita equivalence between CY_3 Ginzburg algebras induces a super-bialgebra isomorphism on the critical CoHAs, with equivariant and $\mathbb{Z}/2$ -supergrading structure (DHSM 2023 Thm. B). When (Q, W) and (Q', W') arise as two tilting presentations of the same X , the corresponding tilting objects T, T' give two factorisations of the identity $\mathrm{id}_{\mathcal{H}(X)} = (\star_{T'})^{-1} \circ M_{k,\star}^+ \circ \star_T$, so $M_{k,\star}^+$ is an endomorphism of $\mathcal{H}(X)$. Non-degeneracy of (Q, W) (DWZ 2008 §7) ensures $M_{k,\star}^-$ exists and gives the inverse at the derived level, hence $M_{k,\star}^+$ is an automorphism. $\square$

GEOMETRIC INTERPRETATION: SEIBERG DUALITY

In the physics literature, mutation at a vertex is *Seiberg duality*: a quiver gauge theory undergoes an exact IR equivalence under a node mutation with appropriate matter content adjustment (Seiberg 1994; Berenstein–Douglas 2002). The present theorem is the derived-category / CoHA shadow of this physical statement: the non-perturbative BPS algebra is invariant under Seiberg duality.

Example 33.4.16 (*Conifold flop via mutation*). The Klebanov–Witten quiver $(Q_{\mathrm{con}}, W_{\mathrm{con}})$ has two vertices $I = \{0, 1\}$, four arrows $a_1, a_2 : 0 \rightarrow 1$ and $b_1, b_2 : 1 \rightarrow 0$, and the cyclic quartic potential

$$W_{\mathrm{con}} = a_1 b_1 a_2 b_2 - a_1 b_2 a_2 b_1.$$

Premutation $\tilde{\mu}_0$ (DWZ recipe applied at vertex $k = 0$). Arrow (M1) requires pairs of arrows $a : i \rightarrow k$ and $b : k \rightarrow j$ – i.e., arrows into 0 composed with arrows out of 0. The arrows into 0 are $b_1, b_2 : 1 \rightarrow 0$, and the arrows out of 0 are $a_1, a_2 : 0 \rightarrow 1$; the composites $a \cdot b$ through 0 run from 1 to 1, adjoined as formal arrows $[a_i b_j] : 1 \rightarrow 1$ for $i, j \in \{1, 2\}$; four new arrows. Arrow (M2) reverses the 0-incident arrows: $a_i : 0 \rightarrow 1$ becomes $a_i^* : 1 \rightarrow 0$, and $b_j : 1 \rightarrow 0$ becomes $b_j^* : 0 \rightarrow 1$. Arrow (M3) gives

$$\tilde{W} = [a_1 b_1] [a_2 b_2] - [a_1 b_2] [a_2 b_1] + \sum_{i,j} [a_i b_j] a_i^* b_j^*,$$

where the first two terms are the original W_{con} rewritten in the composite variables, and the last sum is the universal $[ba] b^* a^*$ piece. The premutation is a cyclic quartic-plus-cubic.

Reduction: writing $c_{ij} = [a_i b_j]$ for the new formal arrows $i \rightarrow j$, the premutation potential has the form

$$\tilde{W} = c_{11} c_{22} - c_{12} c_{21} + \sum_{i,j} c_{ij} a_i^* b_j^*.$$

The cyclic derivatives with respect to the c_{ij} read $\partial_{c_{ij}} \tilde{W} = c_{kl} \epsilon_{ij}^{kl} + a_i^* b_j^*$ (with ϵ the 2×2 antisymmetric tensor on the c -block quadratic form), so each c_{ij} is eliminated against a 2-cycle $a_i^* b_j^*$ through vertex o . The DWZ right-equivalence (DWZ 2008 Thm. 4.6) applied to the non-degenerate quadratic-plus-cubic block $c_{11} c_{22} - c_{12} c_{21} + \sum c_{ij} a_i^* b_j^*$ separates $\tilde{W}$ into $W_{\text{red}} \oplus W_{\text{triv}}$: the trivial summand absorbs the c_{ij} together with their paired 2-cycles, and the reduced potential is the reassembled quartic in the new arrows,

$$W' = a_1^* b_1^* a_2^* b_2^* - a_1^* b_2^* a_2^* b_1^*,$$

the same Klebanov–Witten quartic with roles $a \leftrightarrow a^*$ and $b \leftrightarrow b^*$ swapped. Hence $\mu_o(Q_{\text{con}}, W_{\text{con}})$ is right-equivalent to $(Q_{\text{con}}, W_{\text{con}})$ with the vertex labels $\{o, 1\}$ swapped; the $\mathbb{Z}/2$ symmetry interchanging the two chambers of the Klebanov–Witten quiver (DWZ 2008 Example 8.2; Nagao–Nakajima 2009 arXiv:0809.2992 §3).

The derived equivalence $M_o^+ : \mathcal{D}(\Gamma(Q_{\text{con}}, W_{\text{con}})) \xrightarrow{\sim} \mathcal{D}(\Gamma(\mu_o(Q_{\text{con}}, W_{\text{con}})))$ is exactly the Bridgeland–Chen derived equivalence $D^b(\tilde{Y}) \simeq D^b(\tilde{Y}^+)$ between the two small resolutions of the conifold singularity $xy = zw$ (Bridgeland 2002, arXiv:math/0009053; Chen 2002). On the Hall-algebra side, $M_{o,\star}^+ : \mathcal{H}(\tilde{Y}) \xrightarrow{\sim} \mathcal{H}(\tilde{Y}^+)$ transports the CoHA structure; under the identification $\tilde{Y} \simeq \tilde{Y}^+$ as abstract varieties (the two small resolutions of the same conifold are abstractly isomorphic, related by the Atiyah flop), this becomes a non-trivial automorphism

$$M_{o,\star}^+ \in \text{Aut}_{\text{bialg}}(\mathcal{H}(\tilde{Y}))$$

equal to the Kontsevich–Soibelman wall-crossing cocycle at the flop wall (KS 2008 §6; Nagao 2010, arXiv:1002.4884).

Braid structure at two vertices. For $|I| = 2$ the Artin braid group on two strands is $B_2 = \langle \sigma_1 \rangle \simeq \mathbb{Z}$, carrying one generator and no braid-length-three relation (these arise only from B_3 onward). Under ρ_X of Theorem 33.4.18, the generator σ_1 maps to the composite mutation $M_{o,\star}^+ M_{1,\star}^+$ acting as a translation on the cluster tube of the Klebanov–Witten quiver (Keller–Yang 2011 Prop. 6.4 identifies M_k^+ with the inverse of the spherical twist at S_k ; the composite $M_o^+ M_1^+$ acts as the shift $[2]$ on the cluster tube’s canonical 2-periodic resolution). The image $\rho_X(B_2) \subset \text{Aut}_{\text{bialg}}(\mathcal{H}(\tilde{Y}))$ is infinite cyclic, and its action on the chamber lattice reproduces the infinite stack of conifold walls in the Kontsevich–Soibelman wall-crossing diagram (KS 2008 §6; Nagao–Nakajima arXiv:0809.2992). The two individual Keller–Yang equivalences M_o^+, M_1^+ each generate their own cyclic subgroup of autoequivalences, and together (as a free subgroup of $\text{Auteq}(\mathcal{D}(\Gamma(Q_{\text{con}}, W_{\text{con}}))))$ they act through the single B_2 generator at the level of the CoHA bialgebra.

Example 33.4.17 (Local $\mathbb{P}^2$ nine-arrow Beilinson quiver and B_3 -braid). The Beilinson tilting $T = \mathcal{O}_{\mathbb{P}^2} \oplus \mathcal{O}_{\mathbb{P}^2}(1) \oplus \mathcal{O}_{\mathbb{P}^2}(2)$ on $K_{\mathbb{P}^2} = \text{Tot}(\mathcal{O}_{\mathbb{P}^2}(-3))$ gives a quiver $Q_{\mathbb{P}^2}$ on three vertices $I = \{o, 1, 2\}$, with arrow spaces

$$Q_{\mathbb{P}^2,1}(i, j) = \begin{cases} \text{Hom}(\mathcal{O}(i), \mathcal{O}(j)) = H^0(\mathbb{P}^2, \mathcal{O}(j-i)) = \mathbb{C}^3 & \text{if } j = i+1, \\ 0 & \text{otherwise,} \end{cases}$$

yielding three strands of three parallel arrows $x_\alpha: 0 \rightarrow 1$, $y_\alpha: 1 \rightarrow 2$, and (by descent through the (-3) twist) $z_\alpha: 2 \rightarrow 0$, $\alpha = 1, 2, 3$, indexed by a basis of $H^0(\mathbb{P}^2, \mathcal{O}(1)) = \mathbb{C}^3$. The superpotential is the antisymmetric cubic

$$W_{\mathbb{P}^2} = \sum_{\sigma \in S_3} \text{sgn}(\sigma) x_{\sigma(1)} y_{\sigma(2)} z_{\sigma(3)}$$

(Beilinson 1978; Beasley–Plesser 2001). The Jacobi algebra $\text{Jac}(Q_{\mathbb{P}^2}, W_{\mathbb{P}^2})$ is the NCCR of $\mathbb{C}^3/\mathbb{Z}_3$ in the McKay convention via Craw–Ishii 2004.

Three generators. Mutation at each vertex gives an operator $\mu_k \in \text{Aut}_{\text{r.e.}}(\text{QP})$ for $k \in \{0, 1, 2\}$. Because $W_{\mathbb{P}^2}$ is cyclically symmetric and $Q_{\mathbb{P}^2}$ is vertex-transitive under $\mathbb{Z}/3 \subset S_3$, the three μ_k are pairwise related by the cyclic automorphism of $Q_{\mathbb{P}^2}$.

B_3 -braid as Bondal–Polishchuk autoequivalences. The braid group $B_3 = \langle \mu_0, \mu_1 \mid \mu_0 \mu_1 \mu_0 = \mu_1 \mu_0 \mu_1 \rangle$ (two-generator presentation) acts on $D^b(\text{Coh } \mathbb{P}^2)$ via the Bondal–Polishchuk exceptional-collection twists $T_{\mathcal{O}(i)}$ (Bondal–Polishchuk 1993, “Homological properties of associative algebras: the method of helices”), extended to $D^b(\text{Coh } K_{\mathbb{P}^2})$ via the total-space pullback. On the Ginzburg dg-algebra side, each Bondal–Polishchuk twist T_i corresponds to a spherical twist at the simple S_i , and Keller–Yang 2011 Prop. 6.4 identifies the mutation μ_i with the inverse of this spherical twist in $\mathcal{D}(\Gamma(Q_{\mathbb{P}^2}, W_{\mathbb{P}^2}))$.

The braid relation $\mu_0 \mu_1 \mu_0 \simeq_{\text{r.e.}} \mu_1 \mu_0 \mu_1$ is the cluster-combinatorial shadow of the $\text{SL}_2(\mathbb{Z})$ -covariance of $\mathbb{P}^2$. The Artin braid group $B_3 = \pi_1(\text{Conf}_3(\mathbb{C}))$ – the fundamental group of unordered triples of distinct points in $\mathbb{C}$ – acts on the space of full exceptional collections on $D^b(\text{Coh } \mathbb{P}^2)$ by the Bondal–Polishchuk left/right mutations of a 3-helix $(\mathcal{O}, \mathcal{O}(1), \mathcal{O}(2))$ (Bondal–Polishchuk 1993, “Homological properties of associative algebras: the method of helices” Thm. 2.3; Kuznetsov 2007, arXiv:math/0610957, on B_n acting via exceptional-collection mutations). Bridgeland 2009, arXiv:0909.4299, identifies this B_3 with $\pi_1(\text{Stab}^\circ(D^b \mathbb{P}^2)/\widetilde{\text{GL}}_2^+)$ via the $\text{SL}_2(\mathbb{Z})$ -covering of the unordered-triples space, closing the loop: the nine-arrow quiver mutations generate a B_3 -action whose K_0 -image is $\text{SL}_3(\mathbb{Z}) \supset \widetilde{\text{SL}}_2(\mathbb{Z})$ and whose categorical image is the group of Bondal–Polishchuk twists.

Transport to CoHA. By Theorem 33.4.15, each μ_k transports to an automorphism $\mu_{k,\star} \in \text{Aut}_{\text{bialg}}(\mathcal{H}(K_{\mathbb{P}^2}))$, and the braid relation $\mu_{0,\star} \mu_{1,\star} \mu_{0,\star} = \mu_{1,\star} \mu_{0,\star} \mu_{1,\star}$ holds in the automorphism group. Under the identification $\mathcal{H}(K_{\mathbb{P}^2}) \simeq Y_{1,0,0}[\psi]$ with the Gaiotto–Rapčák corner VOA (Gaiotto–Rapčák 2018, arXiv:1703.00982), this B_3 -braid realises the triality $\epsilon_1 \leftrightarrow \epsilon_2 \leftrightarrow \epsilon_3$ of the three toric $\mathbb{C}^\times$ -weights at the McKay vertex of $\mathbb{C}^3/\mathbb{Z}_3$.

THE MUTATION COCYCLE AS A BRAID-GROUP REPRESENTATION

The mutations $\{\mu_k\}_{k \in I}$ satisfy the braid relations of $B_{|I|}$ at two distinct layers: at the level of derived equivalences, via Keller–Yang Theorem 33.4.14; and at the level of CoHA bialgebra automorphisms, via transport through Theorem 33.4.15. The combined statement is a bialgebra representation of the braid group.

THEOREM 33.4.18 (*Mutation cocycle; braid-group representation on the CoHA*). Let X be a smooth local CY_3 with tilting bundle $T = \bigoplus_{i \in I} T_i$ and non-degenerate QP presentation (Q, W) . Denote by $B_{|I|}$ the Artin braid group on $|I|$ strands, with standard generators $\sigma_0, \dots, \sigma_{|I|-2}$ subject to

$$\sigma_i \sigma_{i+1} \sigma_i = \sigma_{i+1} \sigma_i \sigma_{i+1}, \quad \sigma_i \sigma_j = \sigma_j \sigma_i \quad (|i - j| \geq 2).$$

The assignment $\sigma_k \mapsto M_k^+$ (Keller–Yang equivalence at vertex k) extends to a group homomorphism

$$\rho_X^{\text{der}} : B_{|I|} \longrightarrow \text{Auteq}(\mathcal{D}(\Gamma(Q, W)))$$

into the group of triangulated autoequivalences, and, composing with the Hall-product transport $M_{k,\star}$ of Theorem 33.4.15, to

$$\rho_X = (-)_\star \circ \rho_X^{\text{der}} : B_{|I|} \longrightarrow \text{Aut}_{\text{bialg}}(\mathcal{H}(X)), \quad \sigma_k \longmapsto M_{k,\star}^+.$$

The image $\rho_X(B_{|I|})$ is the *mutation cocycle subgroup* of bialgebra automorphisms of $\mathcal{H}(X)$.

Proof. Two parts: the braid relations at the derived level, and the functoriality of Hall-product transport.

(i) *Braid relations at the derived level.* By Theorem 33.4.14, each M_k^+ is the derived equivalence induced by the tilting object $T_k^+ = \text{cone}(P_k \rightarrow \bigoplus_{b: k \rightarrow j} P_{t(b)}) \oplus \bigoplus_{i \neq k} P_i$. Keller–Yang 2011 Prop. 6.4 identifies M_k^+ with the inverse of the spherical twist $\text{Tw}_{S_k}^{-1}$ at the simple module S_k over $\Gamma(Q, \mathcal{W})$. Each S_k is a 3-spherical object in the sense of Seidel–Thomas 2001 arXiv:math/0001043 Def. 2.14 ($\text{REnd}(S_k) \simeq \mathbb{C} \oplus \mathbb{C}[-3]$, Serre twist $S_k \mapsto S_k[3]$). The Seidel–Thomas braid theorem for spherical twists (arXiv:math/0001043 Thm. 1.2) produces the relation

$$\text{Tw}_{S_k} \text{Tw}_{S_\ell} \text{Tw}_{S_k} = \text{Tw}_{S_\ell} \text{Tw}_{S_k} \text{Tw}_{S_\ell}$$

when $\text{RHom}(S_k, S_\ell)$ is adjacent in the Seidel–Thomas sense. For a Ginzburg CY_3 algebra $\Gamma(Q, \mathcal{W})$ the Ext-quiver computation gives

$$\text{RHom}_{\Gamma(Q, \mathcal{W})}(S_k, S_\ell) \simeq \mathbb{C}\langle a \in Q_1: k \rightarrow \ell \rangle[-1] \oplus \mathbb{C}\langle b \in Q_1: \ell \rightarrow k \rangle[-2],$$

(Keller 2011, arXiv:1102.4148 Prop. 2.5; Ext^2 Serre-dual to $\text{Ext}^1(S_\ell, S_k)$). When the QP comes from a coherently oriented CY_3 quiver (exactly one arrow in each direction, at most) between distinct Q -adjacent pairs, the Ext-form specialises to $\mathbb{C}[-1] \oplus \mathbb{C}[-2]$. The Seidel–Thomas mechanism then gives the braid relation between $\text{Tw}_{S_k}, \text{Tw}_{S_\ell}$; for Q -disconnected k, ℓ the Hom-complex vanishes and the twists commute.

Therefore the assignment $\sigma_k \mapsto M_k^+$ respects both the braid relation (for adjacent k, ℓ) and the commutation relation (for non-adjacent), and extends to the group homomorphism ρ_X^{der} on $B_{|I|}$.

(ii) *Functoriality of Hall-product transport.* By Theorem 33.4.11, every derived Morita equivalence between two CY_3 Ginzburg algebras induces a bialgebra isomorphism on the critical CoHAs. This assignment is functorial: the composition $M_k^+ \circ M_\ell^+$ transports to $M_{k,\star}^+ \circ M_{\ell,\star}^+$ by the universal property of critical cohomology with respect to derived Morita, which descends from the functoriality of DHSM 2023 arXiv:2303.12592 Thm. A.

Combining (i) and (ii): $\rho_X = (-)_\star \circ \rho_X^{\text{der}}$ is a group homomorphism from $B_{|I|}$ to $\text{Aut}_{\text{bialg}}(\mathcal{H}(X))$. $\square$

COROLLARY 33.4.19 (*Chamber-independence of the CoHA bialgebra*). Let X be as above. The CoHA bialgebra $\mathcal{H}(X)$, viewed as an abstract bialgebra, is *invariant* under the mutation cocycle: for any $\gamma \in B_{|I|}$ and any homogeneous elements $x, y \in \mathcal{H}(X)$, writing $\star$ for the Hall product,

$$\rho_X(\gamma)(x \star y) = \rho_X(\gamma)(x) \star \rho_X(\gamma)(y), \quad \rho_X(\gamma)\Delta = \Delta \rho_X(\gamma).$$

The chamber-dependent structure carried by $\mathcal{H}(X)$ is not the bialgebra itself but the *PBW/BPS decomposition* of $\mathcal{H}(X)$: in each chamber $\mathfrak{C} \subset \text{Stab}(X)$, the BPS sheaf $\mathcal{BPS}_{\mathfrak{C}}$ on $\mathcal{M}(X)$ picks out a different t -structure heart, and the PBW basis of $\mathcal{H}(X)$ depends on this choice. The mutation cocycle translates between PBW bases but leaves the bialgebra structure constants invariant.

Proof. Invariance under each generator $\sigma_k: M_{k,\star}^+$ is by Theorem 33.4.15 a bialgebra isomorphism. The braid-group extension ρ_X is a composition of generators, hence bialgebra-preserving.

Chamber dependence of the PBW basis: the BPS sheaf $\mathcal{BPS}_{\mathfrak{C}}$ depends on the stability condition $\mathfrak{C}$ (KS 2008 §6), and the PBW-type factorisation

$$\mathcal{H}(X) \simeq \text{Sym}(\mathfrak{g}_{\text{BPS},\mathfrak{C}}[-1])$$

(Davison–Meinhardt 2020, arXiv:1601.02479 Thm. A) is indexed by the chamber-dependent BPS Lie algebra $\mathfrak{g}_{\text{BPS},\mathfrak{C}}$. Chamber-independence of the underlying bialgebra $\mathcal{H}(X)$ is the Kontsevich–Soibelman wall-crossing cocycle condition (KS 2008 §6, consistency on chamber triple-intersections), upgraded in DHSM 2023 arXiv:2303.12592 Thm. A to a bialgebra isomorphism between any two derived-Morita-equivalent stability presentations. The mutation cocycle implements this equivalence in the cluster chamber graph. $\square$

The mutation cocycle is the algebraic shadow of the Donaldson–Thomas wall-crossing formula (Kontsevich–Soibelman 2008 §6): each wall-crossing transformation is a chamber-to-chamber BPS reindexing, and the mutation cocycle realises this at the level of bialgebra automorphisms, preserving the underlying $\mathcal{H}(X)$.

FOMIN–ZELEVINSKY CLUSTER MUTATION ON $K_{\circ}$ VS. WEYL REFLECTION

At the class level, the mutation μ_k induces an involutive linear transformation on the Grothendieck group.

PROPOSITION 33.4.20 (*FZ cluster mutation on $K_{\circ}$; Fomin–Zelevinsky 2002, arXiv:math/0104151 Def. 4.2 and Prop. 4.8*). Let (Q, W) be a non-degenerate QP and μ_k the mutation at vertex k . The induced map on $K_{\circ}(A\text{-mod}) = \mathbb{Z}^I$ is

$$\mu_k^{K_{\circ}} : \mathbb{Z}^I \longrightarrow \mathbb{Z}^I, \quad e_i \longmapsto \begin{cases} -e_k & \text{if } i = k, \\ e_i + [b_{ik}]_+ e_k & \text{if } i \neq k, \end{cases}$$

where $b_{ik} = \#\{\text{arrows } k \rightarrow i\} - \#\{\text{arrows } i \rightarrow k\}$ is the signed arrow count and $[x]_+ = \max(x, 0)$. This is the Fomin–Zelevinsky cluster mutation of the exchange matrix $B = (b_{ij})$: $\mu_k(B) = B'$ with $b'_{ij} = -b_{ij}$ if $i = k$ or $j = k$, and $b'_{ij} = b_{ij} + \text{sgn}(b_{ik}) [b_{ik} b_{kj}]_+$ otherwise (FZ §4).

PROPOSITION 33.4.21 (*Cluster mutation is not a Weyl reflection on CY_3*). On a CY_3 Ginzburg algebra $\Gamma(Q, W)$ the Euler form

$$\chi_{K_{\circ}} : \mathbb{Z}^I \times \mathbb{Z}^I \rightarrow \mathbb{Z}, \quad \chi_{K_{\circ}}(\gamma, \delta) = \sum_{i=0}^3 (-1)^i \dim \text{Ext}_A^i(M_{\gamma}, M_{\delta})$$

is *antisymmetric*: $\chi_{K_{\circ}}(\gamma, \delta) = -\chi_{K_{\circ}}(\delta, \gamma)$. Serre duality $\text{Ext}^i(M, N) \simeq \text{Ext}^{3-i}(N, M)^{\vee}$ on the CY_3 Ginzburg bimodule forces

$$\chi_{K_{\circ}}(M, N) = \sum_i (-1)^i \dim \text{Ext}^i(M, N) = - \sum_i (-1)^{3-i} \dim \text{Ext}^{3-i}(N, M) = -\chi_{K_{\circ}}(N, M).$$

Consequently $\chi_{K_{\circ}}$ defines a symplectic rather than an orthogonal pairing on $\mathbb{Z}^I$, and every simple class $\alpha_i = [S_i]$ is *isotropic*: $\chi_{K_{\circ}}(\alpha_i, \alpha_i) = 0$ forced by antisymmetry. Weyl reflections $s_{\alpha}(\gamma) = \gamma - 2 \langle \alpha, \gamma \rangle \alpha / \langle \alpha, \alpha \rangle$ are undefined when the reflecting root is isotropic; the CY_3 mutation is instead the

Fomin–Zelevinsky cluster mutation (arXiv:math/0104151 Def. 4.2), which depends only on the anti-symmetric exchange matrix $B = (b_{ij}) = (\chi_{K_o}(\alpha_i, \alpha_j))$ and not on any symmetric bilinear form. The image $\rho_X^{K_o}(B_{|I|}) \subset \mathrm{GL}_{|I|}(\mathbb{Z})$ is in general infinite and does not factor through any finite Weyl group.

Antisymmetry of χ_{K_o} is the CY_3 -specific feature distinguishing the cluster picture from the surface (CY_2) Yangian picture, where the Mukai pairing is symmetric: on surfaces the FZ mutation coincides with a Weyl reflection, and the mutation group is the affine Weyl group $\widehat{W}_{\mathrm{aff}}$ of the McKay Dynkin diagram (Nakajima 1998; Maulik–Okounkov 2019). The CY_3 mutation picture is strictly richer: ρ_X factors through $B_{|I|}$ rather than through $\widehat{W}_{|I|}$, and the braid relations of Theorem 33.4.18 encode information orthogonal to the quadratic Weyl relations $s_k^2 = 1$.

Summary and placement

§33.4 has collapsed the Čech and McKay atlases of Parts I–III onto a single finite-dimensional algebra $\mathcal{A} = \mathrm{End}(T)^{\mathrm{op}}$ with Ginzburg dg-lift $\Gamma(Q, W)$ via the Van den Bergh derived Morita equivalence (Theorem 33.4.4). The CY_3 property is carried by the dg-lift Γ , not by its degree-zero cohomology $\mathrm{Jac}(Q, W) = H^0(\Gamma)$ (Proposition 33.4.6). The tilting bundle $T = \bigoplus_i T_i$ serves as universal gluing data (Theorem 33.4.7): all chart-wise transitions fold into the Jacobi relations $\partial_a W = 0$. The derived Morita equivalence is the adjoint pair $L \dashv R$ satisfying compact generation and higher-Ext vanishing (hypotheses (H1)–(H2) of Theorem 33.4.2). The Hall product transports along any such equivalence between tilting algebras (Theorems 33.4.8–33.4.11, DHSM 2023 arXiv:2303.12592 Thms. A–B), and the Derksen–Weyman–Zelevinsky–Keller–Yang mutation machinery (Theorems 33.4.14–33.4.18, arXiv:0704.0649 and arXiv:0906.0761) realises the Artin braid group $B_{|I|}$ as explicit CoHA bialgebra automorphisms $\rho_X: B_{|I|} \rightarrow \mathrm{Aut}_{\mathrm{bialg}}(\mathcal{H}(X))$, with chamber-independence (Corollary 33.4.19) of the bialgebra structure under this action. At the class level, the induced map on $K_o = \mathbb{Z}^I$ is the Fomin–Zelevinsky cluster mutation (Proposition 33.4.20), *not* a Weyl reflection: the CY_3 Euler form is antisymmetric, the simple classes are isotropic (Proposition 33.4.21), and no root-system structure on the quiver lattice exists. Concretely: $|I| = 2$ (conifold) gives $B_2 \simeq \mathbb{Z}$ with image an infinite cyclic Atiyah-flop cocycle subgroup (Example 33.4.16); $|I| = 3$ (local $\mathbb{P}^2$) gives $B_3 = \pi_1(\mathrm{Conf}_3(\mathbb{C}))$ acting through the Bondal–Polishchuk helix autoequivalences (Example 33.4.17). The four subsections above furnish the tilting toolkit that downstream parts of the gluing chapter deploy: §33.5 (factorisation-algebra gluing) extends the tilting picture to non-tilting-admitting varieties via local factorisation presentations; §33.6 (wall-crossing) frames the mutation cocycle as the chamber-to-chamber KS quantum-dilogarithm factorisation; §33.8 (the $K_3 \times E$ principal example) invokes the *Serre-equivariant quasi-NCCR* as the obstruction-aware analogue of Van den Bergh, where a global tilting fails but a locally-defined Serre-equivariant tilting patches via the factorisation pushforward.

33.5 FACTORISATION-ALGEBRA GLUING

The gluing modes developed in Parts II–IV record, chart-wise, the Hall datum of a local CoHA and transmit it across overlaps by a cocycle whose values are Fourier–Mukai kernels, Bridgeland–King–Reid equivalences, or Van den Bergh tilting modules. The gluing mode developed now records the chart-wise datum as a *factorisation algebra* in the sense of Costello–Gwilliam [30, 143] and transmits it by the Weiss cosheaf axiom of [30] Vol. I Definitions 6.1.0.5 (Weiss cover), 6.1.0.6 (Weiss refinement), and 6.1.2.1 (homotopy-cosheaf/factorisation axiom). The two presentations will coincide, for toric CY_3 and for $K_3 \times E$, at the level of sections of the assembled sheaf; the factorisation-algebra framing exposes the piece of

the data the other modes silence, namely the *global* compatibility along the Ran space of the reference curve.

Four sections. Section 33.5 defines a Weiss cover, derives why a two-chart open cover is never a Weiss cover, and records the subordinate polydisc refinement that turns any open cover into a Weiss cover of the form appropriate to factorisation-algebra locality. Section 33.5 constructs the Ran space $\text{Ran}(C)$ of a smooth complex curve C as a colimit of symmetric products and names the Beilinson–Drinfeld chiral algebra as a factorisation cosheaf on $\text{Ran}(C)$, together with the Francis–Gaitsgory [41] chiral Koszul duality and its higher-dimensional E_n -analogue [40]; it also isolates finite DWR/Ran Rees comparison as an ordered E_1 Hall descent, with the E_2 centre or double left to the separate Drinfeld-centre operation. Section 33.5 derives the two-stage factorisation $\Phi_3 = \text{Sp}_{\Sigma_2, C}^{\text{ch}} \circ \Phi_3^{\text{FA}}$ from first principles, reading Stage 1 as a factorisation-algebra assembly on the CY_3 target and Stage 2 as a specialisation by factorisation homology over a transverse E_2 -fibre. Section 33.5 separates the holomorphic and topological factors of 5D holomorphic Chern–Simons on $\mathbb{R} \times \mathbb{C}^2$ and names the stratified manifold structure (Costello–Gwilliam Volume II [143] §4.10) along which the two factor-wise factorisation algebras glue.

The super-factorisation axiom on a super-factorisation algebra valued in $\text{Ch}(\text{sVect})$ is a *strict* equality of structure maps after Koszul super-interchange, not a coherence datum: the target $\text{Ch}(\text{sVect})$ is 1-categorical symmetric monoidal, with associator and symmetry equalities of functors rather than higher coherences. The $\mathbb{Z}/2$ -grading on the super-Yangian arising from the conifold two-chart gluing is therefore read off an equality of factorisation sections, not a homotopy datum. This 1-categorical super-interchange and the $(\infty, 1)$ -categorical Ran-local refinement of factorisation locality belong to different layers of the construction.

Weiss covers

THE FACTORISATION LOCAL-TO-GLOBAL AXIOM

Fix M a smooth manifold (the eventual use will take M to be either a smooth complex curve C , a smooth complex surface, or a smooth complex threefold; the definition is uniform across these cases). A *prefactorisation algebra* $\mathcal{F}$ on M valued in chain complexes over k [30] Definition 3.1.1 assigns to each open $U \subset M$ a chain complex $\mathcal{F}(U)$ and to each finite collection of pairwise-disjoint opens $U_1, \dots, U_n \subset V$ inside an open $V \subset M$ a structure map

$$m_{U_1, \dots, U_n; V}: \mathcal{F}(U_1) \otimes \cdots \otimes \mathcal{F}(U_n) \longrightarrow \mathcal{F}(V) \quad (33.8)$$

subject to the associativity and symmetry axioms of a prefactorisation algebra. A prefactorisation algebra is a *factorisation algebra* if, in addition, it satisfies the *factorisation local-to-global axiom*: for every open $V \subset M$ and every *Weiss cover* $\mathfrak{U}$ of V , the natural map from the homotopy colimit of the Čech complex of $\mathcal{F}$ over $\mathfrak{U}$ to $\mathcal{F}(V)$ is an equivalence.

The axiom is useless without a definition of Weiss cover that makes it hold for the examples of interest; the combinatorics of Weiss covers is what distinguishes factorisation-algebra locality from ordinary sheaf locality.

Definition 33.5.1 (Weiss cover; [30] Vol. I Definition 6.1.0.5). Let $V \subset M$ be an open subset. A collection $\mathfrak{U} = \{U_\alpha\}$ of open subsets $U_\alpha \subset V$ is a *Weiss cover* of V if, for every finite set of points $\{x_1, \dots, x_k\} \subset V$, there exists an index α with $\{x_1, \dots, x_k\} \subset U_\alpha$. The Weiss covers of V generate the *Weiss Grothendieck topology* on $\text{Opens}(V)$.

Equivalently: the cover $\mathfrak{U}$ is closed under finite disjoint unions inside V , up to refinement by a cofinal subset. The formulation in terms of finite subsets is operational: to check that $\mathfrak{U}$ is a Weiss cover one exhibits, for each finite point-configuration S in V , one open $U_\alpha \in \mathfrak{U}$ containing S .

The reason the axiom demands Weiss covers and not ordinary open covers is the following. A factorisation algebra $\mathcal{F}$ records the *joint* algebraic data of observables localised near finite point-configurations. Two observables supported near disjoint point-configurations $S_1 \sqcup S_2$ must multiply through the structure map $m_{U_1, U_2, V}$ where $U_1 \supset S_1$ and $U_2 \supset S_2$ are disjoint enlargements; the structure is reconstructed locally only if the cover contains opens separating every such pair. Ordinary open covers need not; Weiss covers do, by the finite-point-configuration criterion.

WHY A TWO-CHART COVER IS NOT A WEISS COVER

The sharpest elementary illustration arises in the conifold two-chart atlas of §33.2. Let $Y = U_+ \cup U_-$ with $U_\pm \cong \mathbb{C}^3$ and $U_+ \cap U_- \cong \mathbb{G}_m \times \mathbb{C}^2$. One asks whether $\mathfrak{U}_o = \{U_+, U_-\}$ is a Weiss cover of Y .

Take a two-point configuration $S = \{p_+, p_-\} \subset Y$ with $p_+ \in U_+ \setminus U_-$ and $p_- \in U_- \setminus U_+$; such configurations exist because U_+ and U_- are each proper subsets of Y (neither chart covers the whole variety). The finite subset S is contained in neither U_+ nor U_- : $p_- \notin U_+$ rules out U_+ , and $p_+ \notin U_-$ rules out U_- . Consequently no member of $\mathfrak{U}_o$ contains S , and $\mathfrak{U}_o$ fails the finite-subset criterion of Definition 33.5.1.

PROPOSITION 33.5.2 (*Two-chart atlases do not satisfy Weiss locality*). Let M be a connected smooth manifold of positive dimension and $\mathfrak{U} = \{U_1, U_2\}$ a two-element open cover of M with $U_1 \setminus U_2 \neq \emptyset$ and $U_2 \setminus U_1 \neq \emptyset$. Then $\mathfrak{U}$ is not a Weiss cover of M .

Proof. Choose $p_1 \in U_1 \setminus U_2$ and $p_2 \in U_2 \setminus U_1$. The two-point configuration $S = \{p_1, p_2\}$ is not contained in either U_1 (because $p_2 \notin U_1$) or U_2 (because $p_1 \notin U_2$), nor in any other member of $\mathfrak{U}$ (there are none). The finite-subset criterion fails at S . $\square$

The conifold two-chart cover is the prototype: every Čech-style two-chart gluing in §33.2 produces a two-element cover failing Weiss locality. Gluing by factorisation-algebra locality therefore requires a refinement of the two-chart cover to a Weiss cover, and the refinement is what injects the *finitely many* many-point configurations which the Čech nerve of the two-chart atlas cannot see.

WEISS REFINEMENT PROCEDURE

The refinement procedure is explicit. Given an open cover $\mathfrak{U}_o = \{U_\alpha\}$ of M , choose the subordinate polydisc basis

$$\mathfrak{B}(\mathfrak{U}_o) := \{D \subset M \mid D \text{ is a sufficiently small coordinate polydisc and } \overline{D} \subset U_\alpha \text{ for some } \alpha\}.$$

Form the *disjoint-union closure*

$$\mathfrak{B}(\mathfrak{U}_o)^\sqcup := \{D_1 \sqcup \cdots \sqcup D_n \mid n \geq 1, D_i \in \mathfrak{B}(\mathfrak{U}_o), D_i \cap D_j = \emptyset \text{ for } i \neq j\}. \quad (33.9)$$

Every finite subset $S = \{p_1, \dots, p_m\} \subset M$ admits, by first choosing $U_{\alpha_i} \ni p_i$ and then shrinking inside coordinate charts, pairwise-disjoint polydiscs $D_i \in \mathfrak{B}(\mathfrak{U}_o)$ with $p_i \in D_i$. The disjoint union $D_1 \sqcup \cdots \sqcup D_m \in \mathfrak{B}(\mathfrak{U}_o)^\sqcup$ contains S ; hence $\mathfrak{B}(\mathfrak{U}_o)^\sqcup$ is a Weiss cover. The subordinate-polydisc step is essential: the disjoint-union closure of the original members of $\mathfrak{U}_o$ need not add any open set.

Remark 33.5.3 (Weiss refinement of the conifold two-chart atlas). For the conifold $Y = U_+ \cup U_-$, the disjoint-union closure of the original two chart opens reduces to $\mathfrak{U}_0$ itself: the only disjoint families of members of $\mathfrak{U}_0$ are the two singletons $\{U_+\}$ and $\{U_-\}$ (the pair U_+, U_- is not disjoint since $U_+ \cap U_- \cong \mathbb{G}_m \times \mathbb{C}^2 \neq \emptyset$), and the disjoint-union of a singleton equals its single member. The disjoint-union closure produces no new opens, and Proposition 33.5.2 continues to apply to $\mathfrak{U}_0$. The refinement therefore requires enlarging $\mathfrak{U}_0$ with subordinate opens sharper than the two charts: for each $p \in Y$ choose a contractible open neighbourhood $D_p \subset U_{\pm}$ (whichever chart contains p), small enough that finitely many such D_p can be made pairwise disjoint by shrinkage. The family $\mathfrak{D} = \{D_p : p \in Y\}$ is an ordinary open cover of Y ; its disjoint-union closure $\mathfrak{D}^{\sqcup}$ is a Weiss cover of Y by the argument following equation (33.9). The original two-chart cocycle is pulled back to the Čech nerve of $\mathfrak{D}^{\sqcup}$, which keeps track of all finite multi-point configurations, including the pairs in $U_+ \cap U_-$.

The refinement produces, in particular, Weiss-cover cells indexed by finite point-configurations rather than pairs of charts. Its ordered lift is indexed by $C_n(Y)$, $n \geq 1$, while its unordered quotient maps to the Ran stratification; this is the factorisation-algebra analogue of the Ran-space decomposition of Section 33.5. The ordered lift is the layer on which Hall multiplication remembers the direction of short exact sequences.

Ran space and Beilinson–Drinfeld chiral algebras

THE RAN SPACE OF A CURVE

Let C be a smooth complex curve. The *Ran space* of C is the set of non-empty finite subsets of C topologised by the colimit

$$\mathrm{Ran}(C) = \varinjlim_{n \geq 1} C^n / S_n \quad (33.10)$$

in the category of (ind-)topological spaces, where the transition maps $C^n / S_n \rightarrow C^{n+1} / S_{n+1}$ send a tuple $(x_1, \dots, x_n)$ to $(x_1, x_1, x_2, \dots, x_n)$ (repeating the first entry). The presentation (33.10) identifies configurations differing only by repetition, so $\mathrm{Ran}(C)$ parameterises finite subsets of C regardless of multiplicity.

The Ran space is the natural index of factorisation data on C . A prefactorisation algebra on C assigns observables to finite point-configurations; the assignment extends along the transition maps (33.10) by the structure maps (33.8) (at repeated points, the structure map at a pair of coinciding points specialises to the diagonal). The factorisation local-to-global axiom, specialised to $M = C$, becomes the condition that the output factorisation cosheaf on $\mathrm{Ran}(C)$ satisfies the homotopy-cosheaf axiom [30] Vol. I Definition 6.1.2.1 evaluated on the Ran site generated by Weiss covers of the symmetric-product stratum C^n / S_n ; equivalently, by Francis–Gaitsgory [41] Theorem 5.2.1, the cosheaf is supported on the diagonal stratification of $\mathrm{Ran}(C)$, with factorisation data determined by restriction to each multi-point stratum.

FINITE DWR/RAN REES COMPARISON

The Weiss condition is infinite in arity, but every perturbative hCS–Hall comparison is made at finite height before any completed limit is taken. Fix a subordinate DWR polydisc refinement $\mathfrak{U}$, a charge monoid Γ , and finite bounds

$$N \quad (\text{holomorphic jets}), \quad r \quad (\text{renormalisation order}), \quad L \quad (\text{charge}), \quad m \quad (\text{Ran arity}).$$

Let

$$N_{\leq m}^{\mathrm{Ran}, \mathrm{ord}}(\mathfrak{U}; \Gamma_{\leq L})$$

be a chosen finite full, refinement-closed sub-nerve whose p -simplices are ordered finite families

$$\sigma = (s_1 < \cdots < s_q; P_{s_i} \in U_{i,0} \cap \cdots \cap U_{i,p}, \gamma_{s_i} \in \Gamma_{\leq L}), \quad q \leq m,$$

with the P_{s_i} pairwise disjoint subordinate polydiscs. Faces and refinements are generated by deleting an overlap, shrinking a polydisc, and passing to a subordinate intersection; refinement-closed means that every higher simplex has a vertex refinement inside the same finite sub-nerve. This is the ordered lift of the finite Ran stratum; the order is not a time parameter, but the Hall order on short exact sequences.

PROPOSITION 33.5.4 (*Finite DWR/Ran Rees descent and the ordered Hall layer*). For every simplex $\sigma \in N_{\leq m}^{\text{Ran,ord}}(\mathfrak{U}; \Gamma_{\leq L})$, assume the following data.

- (i) A finite hCS complex $\text{Obs}_{\text{hCS}}^{q, \leq r, \leq N}(\sigma)_{\leq L}$ with its compact-support refinement maps.
- (ii) A finite cyclic critical model $(V_\sigma, W_\sigma, \omega_\sigma)$ over $\Omega^\bullet(\Delta^p)$ and the Rees Hall complex

$$\text{Hall}_\sigma^{\text{Rees,or}} = \left(C^\bullet(\mathfrak{g}_\sigma, \Gamma(V_\sigma, \wedge^\bullet T_{V_\sigma})[[\hbar]] \otimes \Omega^\bullet(\Delta^p))^{G_\sigma}, d_{\text{CE}} + \iota_{d_V W_\sigma} + \hbar \Delta_{\omega_\sigma} + d_{\Delta^p} \right) \otimes o_\sigma[s_\sigma](t_\sigma).$$

- (iii) A continuous degree-zero relative map

$$\theta_\sigma^{\text{rel}} : B\text{Obs}_{\text{hCS}}^{q, \leq r, \leq N}(\sigma)_{\leq L} \longrightarrow \text{Hall}_\sigma^{\text{Rees,or}}$$

compatible with faces, refinements, orientations, shifts, and Tate twists.

Assume also multiplicativity on disjoint ordered families:

$$\text{Obs}(\sigma \sqcup \tau) \simeq \text{Obs}(\sigma) \widehat{\otimes} \text{Obs}(\tau), \quad W_{\sigma \sqcup \tau} = W_\sigma \boxplus W_\tau, \quad \omega_{\sigma \sqcup \tau} = \omega_\sigma \oplus \omega_\tau,$$

with $o_{\sigma \sqcup \tau} \simeq o_\sigma \otimes o_\tau$ and $[s_{\sigma \sqcup \tau}](t_{\sigma \sqcup \tau}) = [s_\sigma + s_\tau](t_\sigma + t_\tau)$. Then

$$\Theta_{\text{hCS} \rightarrow \text{Hall}}^{\text{Rees,or}; N, r, L, m} := \sum_{\sigma \in N_{\leq m}^{\text{Ran,ord}}(\mathfrak{U}; \Gamma_{\leq L})} \int_{\Delta^{|\sigma|}} \theta_\sigma^{\text{rel}}$$

is a multiplicative natural transformation on the finite DWR/Ran nerve. If the vertex maps are quasi-isomorphisms, it induces a quasi-isomorphism on finite DWR/Ran descent.

For disjoint σ and τ , the Hall product appearing in this statement is the Rees Thom–Sebastiani product

$$\text{DR}_{W_\sigma, \hbar} \widehat{\otimes} \text{DR}_{W_\tau, \hbar} \xrightarrow{\text{TS}} \text{DR}_{W_\sigma \boxplus W_\tau, \hbar}, \quad \text{DR}_{W, \hbar} := (\Gamma(V, \wedge^\bullet T_V)[[\hbar]], \iota_{dW} + \hbar \Delta_\omega).$$

Thus the descended object is an ordered E_1 Hall factorisation cosheaf. An E_2 object is obtained only after applying the Drinfeld centre to Rep^{E_1} of this ordered layer, or after constructing a completed Drinfeld double from a non-degenerate Hall pairing and compatible completion. Neither operation is part of the finite DWR/Ran descent map.

Proof. The relative map $\theta_\sigma^{\text{rel}}$ is a chain map over $\Omega^\bullet(\Delta^p)$ precisely when it solves the relative Maurer–Cartan equation in the bar–Rees convolution Lie algebra:

$$(d_{\text{Hall}} + d_{\Delta^p})\theta_\sigma^{\text{rel}} - \theta_\sigma^{\text{rel}} d_{B\text{Obs}} + \frac{1}{2}[\theta_\sigma^{\text{rel}}, \theta_\sigma^{\text{rel}}]_{\text{conv}} = 0.$$

Integrating this identity over Δ^p and applying Stokes' formula turns the d_{Δ^p} term into the alternating sum over faces. Because the maps are compatible with faces and refinements, these boundary terms are exactly the Čech/Ran differential of the finite sub-nerve. Summing over all simplices gives a Maurer–Cartan element in the finite total convolution complex, equivalently a natural transformation on $N_{\leq m}^{\text{Ran,ord}}(\mathbf{U}; \Gamma_{\leq L})$.

The finite sub-nerve is a finite diagram of complexes. Objectwise quasi-isomorphisms on vertices extend to objectwise quasi-isomorphisms on all simplices by the refinement compatibility built into the datum. Finite totalisations, or equivalently finite homotopy colimits of complexes, preserve quasi-isomorphisms; the induced descent map is therefore a quasi-isomorphism.

For multiplicativity, disjointness gives the tensor-product decomposition of hCS observables: no Feynman graph has an edge joining two disjoint supports. On the Hall side, the sum potential $W_\sigma \boxplus W_\tau$ has differential $\iota_{dW_\sigma} + \hbar\Delta_{\omega_\sigma}$ on the first factor plus $\iota_{dW_\tau} + \hbar\Delta_{\omega_\tau}$ on the second. Hence the Rees twisted de Rham complex of the sum is the completed tensor product of the two Rees twisted de Rham complexes. This is the Thom–Sebastiani isomorphism for vanishing cycles in Rees form, compatible with the orientation and Tate factors by the hypotheses and with the Hall correspondence product by the Kontsevich–Soibelman construction of critical CoHA [235]. The product square for Θ commutes.

The ordered set $\{s_1 < \cdots < s_q\}$ records the order of extensions in the Hall correspondence, so the algebra produced by the proposition is associative E_1 data. No half-braiding, universal R -matrix, or positive–negative Hopf pairing occurs in the hypotheses. Those are exactly the extra structures supplied by the Drinfeld centre or by a completed Drinfeld double; hence they cannot be consequences of the finite DWR/Ran descent alone. $\square$

BEILINSON–DRINFELD CHIRAL ALGEBRAS AS FACTORISATION COSHEAVES

A *chiral algebra* on C in the sense of Beilinson–Drinfeld [10] is a $\mathcal{D}$ -module $\mathcal{A}$ on C equipped with a chiral bracket

$$\mu: j_* j^*(\mathcal{A} \boxtimes \mathcal{A}) \longrightarrow \Delta_! \mathcal{A} \quad (33.11)$$

on the complement $j: C^2 \setminus \Delta \hookrightarrow C^2$ of the diagonal $\Delta: C \hookrightarrow C^2$, subject to a symmetry axiom and a Jacobi-type associativity axiom ([10] §3.4). The bracket μ quantifies the short-distance singularity of the operator product expansion of two chiral operators on C and is the structure one expects in any conformal-field-theoretic construction on a Riemann surface.

The reformulation in factorisation-algebra terms is the content of Francis–Gaitsgory [41] §3.2. To a chiral algebra $\mathcal{A}$ on C one associates a factorisation cosheaf $\mathcal{F}_{\mathcal{A}}$ on $\text{Ran}(C)$ by the *factorisation envelope* construction: at a finite configuration $\{x_1, \dots, x_n\} \in \text{Ran}(C)$ the sections of $\mathcal{F}_{\mathcal{A}}$ are given by

$$\mathcal{F}_{\mathcal{A}}(\{x_1, \dots, x_n\}) = \bigotimes_{i=1}^n \mathcal{A}|_{x_i}, \quad (33.12)$$

the restriction of $\mathcal{A}$ to each point and the external tensor product over the configuration. The chiral bracket μ equips $\mathcal{F}_{\mathcal{A}}$ with the factorisation-cosheaf structure: at a configuration with coinciding points the bracket (33.11) supplies the specialisation map; at distinct points the structure is the tensor-product factorisation of (33.12).

THEOREM 33.5.5 (*Francis–Gaitsgory chiral Koszul duality*; [41] *Theorem 1.2.4, with support criterion Theorem 5.2.1; Beilinson–Drinfeld* [10] §3.4.11 and *Theorem 3.4.9*). There is an $(\infty, 1)$ -categorical Koszul-duality equivalence, on a smooth complex curve C , between chiral Lie algebras on $\text{Ran}C$ supported on C and factorisation coalgebras on $\text{Ran}(C)$ ([41] *Theorem 1.2.4*):

$$\text{Bar}^{\text{ch}} : \text{Lie}_{\text{nu}}^*(C) \xrightarrow{\simeq} \text{coCom}_{\text{nu}}^{\text{fact}}(\text{Ran}C) : \Omega^{\text{ch}},$$

with factorisation support on $\text{Ran}(C)$ characterised by the diagonal stratification ([41] *Theorem 5.2.1*: a factorisation coalgebra on $\text{Ran}(C)$ is determined by its restriction to each open $(\text{Ran}C)^{\leq n}$ and the compatibility maps across strata). Under the Beilinson–Drinfeld equivalence between Lie- $*$ algebras on C and chiral algebras on C ([10] §3.4.11, *Theorem 3.4.9*; chiral envelope §3.7), the factorisation-envelope functor $\mathcal{A} \mapsto \mathcal{F}_{\mathcal{A}}$ identifies chiral algebras on C with non-unital factorisation cosheaves on $\text{Ran}(C)$, and the factorisation homology of $\mathcal{A}$ is the Koszul-dual object:

$$\int_{\text{Ran}(C)} \mathcal{F}_{\mathcal{A}} \simeq C_{\bullet}^{\text{chiral}}(\mathcal{A}),$$

with the right-hand side the chiral chain complex of [10] §4.2.

This equivalence repackages the chiral-algebra calculus of [10] as the factorisation-algebra calculus of [30, 143] on a curve. The two frameworks are equivalent; each makes different operations convenient. The chiral-algebra framing produces, by factorisation envelope, the vertex-algebra image one expects in conformal field theory. The factorisation-algebra framing produces the gluing-cocycle presentation one expects in the present chapter: chiral observables on C are reconstructed from their local sections on Weiss covers of $\text{Ran}(C)$.

HIGHER-DIMENSIONAL VARIANTS

The Francis–Gaitsgory equivalence of *Theorem 33.5.5* admits an E_n -analogue due to Francis [40]. Let M be a smooth manifold of dimension n . An E_n -factorisation algebra on M is a factorisation algebra whose structure maps (33.8) are indexed by n -dimensional disc configurations rather than 0-dimensional point configurations; equivalently, a factorisation cosheaf on the n -dimensional Ran space

$$\text{Ran}_n(M) = \varinjlim_{n_{\text{discs}} \geq 1} C_{n_{\text{discs}}}(M) / S_{n_{\text{discs}}}$$

with $C_{n_{\text{discs}}}(M)$ the configuration space of n_{discs} pairwise-disjoint n -discs in M .

THEOREM 33.5.6 (*Francis E_n -Koszul duality*; [40] *Theorem 1.1*). There is an equivalence between the $(\infty, 1)$ -category of E_n -factorisation algebras on a smooth n -manifold M and the $(\infty, 1)$ -category of E_n -algebras in $\text{Ch}(k)$ augmented over k , given by factorisation-envelope integration.

This is the tool required in Section 33.5: a CY_3 target X is a smooth real 6-manifold, and the E_3 -factorisation algebra $\Phi_3^{\text{FA}}(C)$ attached to a CY_3 category C is, by *Theorem 33.5.6*, equivalently an E_3 -algebra in $\text{Ch}(k)$ augmented over k . Costello–Li [145, 146] refine the E_3 -structure to its *holomorphic* incarnation on the complex threefold X via the BV-quantisation of 6D holomorphic Chern–Simons.

Remark 33.5.7 (Strict super-factorisation in $\text{Ch}(\text{sVect})$). When the target chain complexes are super-vector-space-valued, the braiding in the structure map (33.8) is the Koszul super-braiding $\sigma_{V,W} : V \otimes W \rightarrow W \otimes V, v \otimes w \mapsto (-1)^{|v||w|} w \otimes v$, computed from the $\mathbb{Z}/2$ -grading of $\text{sVect} = \mathbb{Z}/2\text{-Vect}_k$. The

symmetric monoidal category $(\mathrm{Ch}(\mathrm{sVect}), \otimes_k, k^{1|0}, \alpha, \sigma)$ is a strict 1-categorical symmetric monoidal category: the associator $\alpha_{A,B,C}: (A \otimes B) \otimes C \xrightarrow{\sim} A \otimes (B \otimes C)$ and the symmetry σ are equalities (not higher homotopies) of chain-complex morphisms, since $\mathrm{Ch}(\mathrm{sVect})$ is built component-wise from the 1-category sVect and the Koszul sign rule pins σ uniquely as the canonical natural transformation (Deligne, *Catégories tensorielles*, Moscow Math. J. 2002, §0.1; Costello–Gwilliam Vol. 1 §A [30]). Consequently the super-factorisation axiom for a super-factorisation algebra $\mathcal{F}$ valued in $\mathrm{Ch}(\mathrm{sVect})$; the compatibility of the structure maps $m_{U_1, \dots, U_n; V}$ under the super-interchange σ on the left; is a *strict equality* of chain maps in the 1-categorical sense, not a coherence datum parameterised by an $(\infty, 1)$ -mapping space.

The strict super-braiding and the $(\infty, 1)$ -categorical Ran-locality refinement live on different pieces of the construction. The Francis–Gaitsgory equivalence of Theorem 33.5.5 and the Francis E_n -equivalence of Theorem 33.5.6 are $(\infty, 1)$ -categorical in source and target (Lie-algebra and factorisation-coalgebra $(\infty, 1)$ -categories), but the super-braiding σ in the target is 1-categorical strict, inherited from sVect ; the two levels act on different parts of the structure and do not collide. The $\mathbb{Z}/2$ -grading on the super-Yangian arising from the conifold gluing (§33.2, §2.1) is read off a strict equality of factorisation sections under Koszul super-braiding, and does not require higher-categorical coherence data.

The two-stage factorisation $\Phi_3 = \mathrm{Sp}_{\Sigma_2, C}^{\mathrm{ch}} \circ \Phi_3^{\mathrm{FA}}$

STAGE I: E_3 -FACTORISATION ALGEBRA ON A CY_3 TARGET

Fix a CY_3 category C and a smooth complex CY_3 variety X with Calabi–Yau form $\Omega_X \in H^0(X, K_X)$. Stage I of the two-stage factorisation assembles an E_3 -holomorphic factorisation algebra $\Phi_3^{\mathrm{FA}}(C)$ on X from the Hochschild-cochain E_3 -algebra of C . The assembly has three components, each elementary but each drawing on a distinct piece of first-principles input.

Arrow (a): Kontsevich–Tamarkin formality. The Hochschild cochain complex $\mathrm{HH}^\bullet(C)$ carries a Gerstenhaber bracket of degree $1-d$, descending on cohomology from the composition-circle $\circ$ of cochain operations (Deligne conjecture; Kontsevich [155, 181], Tamarkin 1998 preprint arXiv:math/9803025 / [162]). At $d=3$ the bracket has degree $1-3=-2$. The E_d -formality theorem asserts that under hypotheses (H_1) – (H_3) of Chapter 5, the Gerstenhaber bracket lifts, up to the contractible space of choices controlled by the Grothendieck–Teichmüller group $\mathrm{GRT}_1(\mathbb{Q})$, to an E_d -algebra structure on $\mathrm{HH}^\bullet(C)$. The lift is canonical up to the $\mathrm{GRT}_1(\mathbb{Q})$ -torsor of Drinfeld associators; any two lifts are connected by an $(\infty, 1)$ -isomorphism in the E_d -algebra mapping space. At $d=3$ the lift supplies an E_3 -algebra in $\mathrm{Ch}(k)$. *Super caveat:* in the super-graded case $\mathrm{HH}^\bullet(C_{\mathrm{sVect}})$, Ginzburg–Schedler (arXiv:0807.0174) establish super-formality only at E_2 , not at E_3 ; the E_3 -lift on super Hochschild cochains is open, bounding the applicability of Arrow (a) to the bosonic Gerstenhaber side unless a super-extension is supplied by hand.

Arrow (b): Costello–Gwilliam factorisation envelope on X . An E_3 -algebra A in $\mathrm{Ch}(k)$ assembles, by the factorisation-envelope construction of [30] Vol. I §3.6 and Theorem 3.4.0.1 (locally constant factorisation algebras on framed n -manifolds are equivalent to E_n -algebras; compare Lurie [60] §5.5.4, Francis [40] Theorem 1.1), into a topological E_3 -factorisation algebra $\mathcal{E}_3(A)$ on any smooth framed real 6-manifold. The assignment $A \mapsto \mathcal{E}_3(A)$ is an $(\infty, 1)$ -functorial equivalence between E_3 -algebras in $\mathrm{Ch}(k)$ and framed locally constant E_3 -factorisation algebras on $\mathbb{R}^6$, and extends by Weiss local-to-global to an E_3 -factorisation algebra on any framed smooth real 6-manifold $M \cong X_{\mathrm{top}}$. At this step the algebra is still topological: it uses only the framed real 6-manifold structure of X , ignoring the complex structure on X .

Arrow (c): Costello–Li holomorphic refinement via Ω_X . The Calabi–Yau form $\Omega_X \in H^\circ(X, K_X)$ supplies, by contraction with the Dolbeault operator $\bar{\partial}_X$, the BV pairing of 6D holomorphic Chern–Simons on X [145, 146]: the BV action $S[\mathcal{A}] = \int_X \text{CS}_3(\mathcal{A}) \wedge \Omega_X$ pairs the $(\circ, \bullet)$ -form part of a connection $\mathcal{A}$ against the CY form, producing a (-1) -shifted symplectic structure on the BV phase space. The BV-quantised observables of 6D hCS form a holomorphic E_3 -factorisation algebra on X which, by Costello–Li’s classification, is equivalent to the topological E_3 -FA of Arrow (b) refined by $\bar{\partial}_X$ and the Ω_X -induced CY pairing. The holomorphic refinement is unconditional at $d = 1, 2$ and is the chain-level CY- A_d obstruction at $d = 3$, resolved $(\infty, 1)$ -categorically by Theorem 5.11.1 and chain-level at $d = 3$ by Theorem 5.6.1 (three obstruction vanishings plus Bott periodicity $\pi_3(B \text{Sp}(2m)) = 0$).

The composite assembles

$$\Phi_3^{\text{FA}}(C) \in E_3\text{-HolFA}(X) \quad (33.13)$$

as an E_3 -holomorphic factorisation algebra on X . Stage 1 is canonical up to the contractible space of choices jointly controlled by Kontsevich–Tamarkin E_3 -formality (Arrow (a), torsor under $\text{GRT}_1(\mathbb{Q})$) and Costello–Gwilliam–Li holomorphic locality (Arrow (c), torsor under gauge transformations of the BV action); the space of Stage 1 liftings is contractible as a fibration of two contractible torsors over the initial datum (C, X, Ω_X) . The factorisation axiom

$$\Phi_3^{\text{FA}}(C)(U \sqcup V) \simeq \Phi_3^{\text{FA}}(C)(U) \otimes \Phi_3^{\text{FA}}(C)(V)$$

for disjoint opens $U, V \subset X$ is the local datum of the Stage-1 gluing; the Weiss-cover locality axiom (Definition 6.1.2.1 of [30] Vol. I) supplies the global assembly.

STAGE 2: SPECIALISATION BY FACTORISATION HOMOLOGY OVER Σ_2

Stage 2 descends the E_3 -holomorphic factorisation algebra of (33.13) to an E_1 -chiral algebra on a reference curve $C \subset X$ by factorisation homology over a transverse 2-dimensional closed cycle $\Sigma_2 \subset X$ which fibres, in a neighbourhood of C , as $\Sigma_2 \times C \hookrightarrow X$. The tensor product of operads $E_n \otimes E_m$ (Boardman–Vogt tensor) is, by Dunn’s additivity theorem [36] in its ∞ -categorical formulation due to Lurie [60] Theorem 5.1.2.2,

$$E_{n+m} \simeq E_n \otimes E_m, \quad E_3 \simeq E_2 \otimes E_1. \quad (33.14)$$

Equation (33.14) identifies an E_3 -algebra with an E_1 -algebra in E_2 -algebras, or symmetrically an E_2 -algebra in E_1 -algebras; the E_2 -braided monoidal structure on the inner category is the content of Lurie [60] §5.1.2.4 (the characterisation of E_2 -algebras in $\text{Ch}(k)$ as braided monoidal objects). Reading (33.14) geometrically, the framed real 6-manifold X near C factors as a product $\Sigma_2 \times C$ (up to tubular neighbourhood), with Σ_2 supplying the transverse E_2 -directions and C supplying the longitudinal E_1 -direction; factorisation homology over Σ_2 ([60] §5.5.3; Francis [40] Theorem 1.1, equivalently the push-forward formula [40] §3.4) integrates the E_2 -directions against the transverse fibre and leaves an E_1 -factorisation algebra on C .

PROPOSITION 33.5.8 (*Factorisation homology over a transverse fibre; Lurie [60] §5.5.3, Francis [40] Theorem 1.1 with push-forward §3.4*). Let X be a smooth framed real 6-manifold, $\Sigma_2 \subset X$ a smooth closed framed 2-submanifold, and $C \subset X$ a smooth framed curve transverse to Σ_2 such that a tubular neighbourhood of $\Sigma_2 \cap C$ inside X is framed-diffeomorphic to $\Sigma_2 \times C$. Then factorisation homology over Σ_2 defines an $(\infty, 1)$ -functor

$$\int_{\Sigma_2} : E_3\text{-FA}(X) \longrightarrow E_1\text{-FA}(C), \quad (33.15)$$

given by push-forward along the transverse projection $\pi: \Sigma_2 \times C \rightarrow C$ of the E_2 -factor of the Dunn–Lurie splitting.

Sketch. By Dunn–Lurie (33.14), an E_3 -factorisation algebra on a framed real 6-manifold is locally an $E_2 \otimes E_1$ -algebra. On the tubular neighbourhood $\Sigma_2 \times C$, the E_2 -structure is carried by the Σ_2 -direction and the E_1 -structure by the C -direction. Factorisation homology of an E_2 -algebra $\mathcal{A}$ over a framed closed surface Σ_2 is a chain complex $\int_{\Sigma_2} \mathcal{A} \in \text{Ch}(k)$ (Lurie [60] §5.5.3; Francis [40] Theorem 1.1 for the general framed n -manifold case), functorial in $\mathcal{A}$ as an E_2 -algebra. Applied fibrewise over C to the E_2 -factor of an $E_2 \otimes E_1$ -algebra, the E_1 -structure on the C -factor is preserved, yielding an E_1 -factorisation algebra on C . The explicit push-forward along π is the product-manifold push-forward of factorisation homology [40] §3.4, equivalent on the Ran-space presentation to the factorisation restriction of [41] Theorem 5.2.1. $\square$

The composite of Stage 1 with Stage 2 is the specialisation functor

$$\text{Sp}_{\Sigma_2, C}^{\text{ch}}: E_3\text{-HolFA}(X) \longrightarrow E_1\text{-HolFA}(C), \quad \mathcal{F} \longmapsto \left(\int_{\Sigma_2} \mathcal{F} \right) \Big|_C,$$

with the holomorphic refinement of (33.15) preserved by restriction to C . The two-stage factorisation of $\Phi_3^{(\Sigma_2, C)}$ is then

$$\Phi_3^{(\Sigma_2, C)} = \text{Sp}_{\Sigma_2, C}^{\text{ch}} \circ \Phi_3^{\text{FA}}, \quad (33.16)$$

reading the left-hand side as the chart-specialised CY-to-chiral functor at $d = 3$ and the right-hand side as the composite of the Stage-1 factorisation-algebra assembly (chart-independent up to a GRT_1 -torsor) and the Stage-2 specialisation along (Σ_2, C) .

EACH STAGE IS ITSELF A GLUING

The two-stage factorisation is a gluing in two layers. Stage 1 is a factorisation-algebra assembly: the local data on Weiss-cover cells of X are E_3 -algebras determined chart-wisely by the BV quantisation of 6D hCS, and the global assembly is the Weiss local-to-global axiom applied to the disjoint-union closure of a disc atlas on X . Stage 2 is a specialisation assembly: the local data on Weiss-cover cells of C are E_1 -algebras obtained by integrating the E_3 -data of Stage 1 against the transverse Σ_2 -fibre, and the global assembly is the Weiss local-to-global axiom on C applied to a disc atlas on C .

Remark 33.5.9 (Six specialisations of a single Stage-1 output). A single CY_3 category $\mathcal{C}$ produces, via Stage 1, a single E_3 -holomorphic factorisation algebra $\Phi_3^{\text{FA}}(\mathcal{C})$ on a fixed CY_3 target X . Different specialisation data $(\Sigma_2, C), (\Sigma'_2, C'), \dots$ on X produce different E_1 -chiral shadows $\text{Sp}_{\Sigma_2, C}^{\text{ch}}(\Phi_3^{\text{FA}}(\mathcal{C})), \text{Sp}_{\Sigma'_2, C'}^{\text{ch}}(\Phi_3^{\text{FA}}(\mathcal{C})), \dots$; the multiplicity of chiral images attached to $\mathcal{C}$ is the multiplicity of Stage-2 specialisation cycles on X , not the multiplicity of $\Phi_3^{(\Sigma_2, C)}$ -applications to $\mathcal{C}$. The six routes to $G(K_3 \times E)$ are six different (Σ_2, C) -specialisations of the single Stage-1 output $\Phi_3^{\text{FA}}(D^b(\text{Coh}(K_3 \times E)))$.

Holomorphic vs topological factors

5D HOLOMORPHIC CHERN–SIMONS ON $\mathbb{R} \times \mathbb{C}^2$

The principal example of a factorisation algebra with distinct holomorphic and topological factors is 5D holomorphic Chern–Simons on $Y = \mathbb{R}_t \times \mathbb{C}_{z_1, z_2}^2$, introduced by Costello [27] (arXiv:1303.2632), quantised to all orders by Costello–Yagi [29] (arXiv:1810.01970; two-author paper), with holomorphic-topological factorisation controlled by Costello–Gwilliam Vol. 2 §4.10 (arXiv:2210.13036) [30]. The

manifold Y is a real 5-manifold, product of the real 1-dimensional topological factor $\mathbb{R}_t$ and the complex 2-dimensional (real 4-dimensional) holomorphic factor $\mathbb{C}_{z_1, z_2}^2$. The separation of holomorphic from topological directions at the level of factorisation algebras is Francis [40] (arXiv:1303.0305) Theorem 1.1: $\text{Ch}(k)$ -valued factorisation algebras on a product of a topological p -manifold and a holomorphic q -manifold are classified by $E_p^{\text{top}} \otimes E_q^{\text{hol}}$ -algebras.

Let $\mathfrak{g}$ be a finite-dimensional reductive Lie algebra with non-degenerate invariant symmetric bilinear form tr (Killing form in the simple case) and let $\Omega_{\mathbb{C}^2} = dz_1 \wedge dz_2$ be the flat holomorphic volume form. The BV superfield is the total $(\circ, \bullet) \otimes \bullet$ -form

$$\mathcal{A} \in \Omega^{\circ, \bullet}(\mathbb{C}^2) \otimes \Omega^{\bullet}(\mathbb{R}_t) \otimes \mathfrak{g}[1], \quad \mathcal{A} = A_t(t, z, \bar{z}) dt + \sum_{i=1,2} A_{\bar{z}_i}(t, z, \bar{z}) d\bar{z}_i + \text{ghosts} + \text{antifields}, \quad (33.17)$$

including the ghost $c \in \Omega^{\circ, \circ} \otimes \Omega^{\circ} \otimes \mathfrak{g}[1]$ and antifields in $\Omega^{\circ, \geq 1}(\mathbb{C}^2) \otimes \Omega^{\geq 1}(\mathbb{R}_t) \otimes \mathfrak{g}$ as required by the BV shift. The BV action of 5D hCS is

$$S_{5\text{D hCS}}[\mathcal{A}] = \int_{\mathbb{R}_t \times \mathbb{C}^2} \Omega_{\mathbb{C}^2} \wedge \text{tr} \left(\mathcal{A} \wedge \bar{\partial}_{\mathbb{C}^2} \mathcal{A} + \mathcal{A} \wedge d_t \mathcal{A} + \frac{2}{3} \mathcal{A} \wedge \mathcal{A} \wedge \mathcal{A} \right), \quad (33.18)$$

with d_t the de Rham differential along $\mathbb{R}_t$ and $\bar{\partial}_{\mathbb{C}^2}$ the Dolbeault operator on $\mathbb{C}^2$ [27, 146]. The classical equation of motion is $(d_t + \bar{\partial}_{\mathbb{C}^2})\mathcal{A} + \mathcal{A} \wedge \mathcal{A} = 0$: the mixed flat-connection equation wedge-paired with $\Omega_{\mathbb{C}^2}$. The normalisation $2/3$ in the cubic term arises from cyclic symmetrisation of tr on $\mathfrak{g}^{\otimes 3}$, matching the BV-invariant master-equation form of the Chern–Simons action.

Lorenz gauge. The BV differential $Q_{\text{BV}} = d_t + \bar{\partial}_{\mathbb{C}^2} + [\mathcal{A}, -]$ has a residual gauge freedom absorbed by the mixed Lorenz condition

$$d_t^* A_t + \bar{\partial}_{\mathbb{C}^2}^* (A_{\bar{z}_1} d\bar{z}_1 + A_{\bar{z}_2} d\bar{z}_2) = 0, \quad (33.19)$$

with $d_t^*, \bar{\partial}_{\mathbb{C}^2}^*$ the formal adjoints for the flat Hermitian metric on $\mathbb{C}^2 \times \mathbb{R}_t$. On a contractible open of $\mathbb{R}_t$ the admissible gauge slice sets $A_t = 0$, reducing the topological factor to the E_t -multiplication of $\mathbb{C}^2$ -observables along the interval. On $\mathbb{C}^2$ the residual $\bar{\partial}_{\mathbb{C}^2}$ -harmonic sector carries the propagator

$$\langle A_{\bar{z}_i}(z, t) A_{\bar{z}_j}(w, s) \rangle \propto \delta_{ij} \delta(t - s) \frac{1}{z_i - w_i},$$

the pole source driving the all-orders Costello–Yagi $\hbar$ -expansion. The choice of Lorenz gauge fixes a BV-equivalent representative of (33.18); factorisation-algebra output is gauge-invariant.

The factorisation algebra of observables of 5D hCS admits a natural tensor-product decomposition

$$\text{Obs}^{5\text{D hCS}}(\mathbb{R}_t \times \mathbb{C}^2) \simeq \text{Obs}^{1\text{D top}}(\mathbb{R}_t) \boxtimes \text{Obs}^{4\text{D hol}}(\mathbb{C}^2) \quad (33.20)$$

with $\text{Obs}^{1\text{D top}}(\mathbb{R}_t)$ a locally constant E_t -factorisation algebra on the topological factor $\mathbb{R}_t$ and $\text{Obs}^{4\text{D hol}}(\mathbb{C}^2)$ a *holomorphic* E_2^{hol} -factorisation algebra on $\mathbb{C}^2$: the structure maps depend holomorphically on the centres of $\mathbb{C}^2$ -discs, with the two $\bar{\partial}_{\mathbb{C}^2}$ -directions of (33.17) supplying the two-dimensional OPE indexed by holomorphic-disc configurations. The decomposition (33.20) is the factorisation-algebra incarnation of Francis' holomorphic-topological splitting theorem (Francis [40] Theorem 1.1, applied to the product of a topological $\mathbb{R}_t$ -factor and a holomorphic $\mathbb{C}^2$ -factor).

At the level of the operad governing the $\text{Ch}(k)$ -valued algebra of global observables, Kontsevich–Tamarkin E_d -formality on the holomorphic factor identifies the holomorphic operad $E_2^{\text{hol}}(\mathbb{C}^2)$ with its

topological shadow $E_2^{\text{top}}(\mathbb{R}^4)$ (Kontsevich [155]; Tamarkin [162], 2D Deligne conjecture). Combined with Dunn–Lurie [60] Theorem 5.1.2.2 for the additivity of topological E_n -operads, this produces the operad identification

$$\text{Op}(\text{Obs}^{5\text{D hCS}}) \simeq E_1^{\text{top}} \otimes E_2^{\text{hol}} \xrightarrow{\text{formality}} E_1^{\text{top}} \otimes E_2^{\text{top}} \simeq E_3^{\text{top}}, \quad (33.21)$$

with the arrow labelled “formality” encoding the Kontsevich–Tamarkin equivalence $E_2^{\text{hol}} \simeq E_2^{\text{top}}$ at the level of $\text{Ch}(k)$ -valued operads over $\mathbb{Q}$. At the *chain-level* sheaf geometry the holomorphic structure of $\mathbb{C}^2$ is retained (equation (33.20) is a strict external tensor product of sheaves on $\mathbb{R}_t \times \mathbb{C}^2$); at the $(\infty, 1)$ -categorical operad level equation (33.21) places global observables in $E_3\text{-Alg}(\text{Ch}(k))$ after formality. The reading (33.21) differs from the Stage-2 reading $E_3 \simeq E_2^{\Sigma_2} \otimes E_1^C$ of §33.5 only in which complex-geometric data interprets the E_2 -factor; the two readings coincide as abstract E_3 -algebras in $\text{Ch}(k)$.

FACTORISATION ALGEBRAS ON EACH FACTOR SEPARATELY

On the topological factor $\mathbb{R}$, a locally constant factorisation algebra is equivalent to an E_1 -algebra in $\text{Ch}(k)$ by Lurie [60] §5.5.4 (specialisation to $n = 1$; equivalently, the Costello–Gwilliam [30] Vol. I Theorem 3.4.0.1 identification of locally constant factorisation algebras on $\mathbb{R}^n$ with E_n -algebras). The factor $\text{Obs}^{1\text{D top}}$ is the topological reduction of 5D hCS along $\mathbb{R}_t$: integrating the BV action (33.18) against dt and setting $A_t = 0$ in Lorenz gauge leaves an effective E_1 -algebra on $\mathbb{R}$ whose multiplication $\mathcal{A}(U_1) \otimes \mathcal{A}(U_2) \rightarrow \mathcal{A}(U_1 \cup U_2)$ for disjoint $U_1, U_2 \subset \mathbb{R}_t$ is the $\hbar$ -deformed multiplication of the Yangian (Costello–Yagi 2018 arXiv:1810.01970 Theorem A, simply-laced bosonic case). Reading the Yangian as a topological E_1 -algebra on $\mathbb{R}_t$ alone discards the $\mathbb{C}^2$ -OPE data that lives on the holomorphic factor; the sharp joint statement identifies the full factorisation algebra on $\mathbb{R} \times \mathbb{C}^2$ with the Yangian VOA (Proposition 33.5.10 below).

On the holomorphic factor $\mathbb{C}^2$, $\text{Obs}^{4\text{D hol}}$ is a holomorphic E_2 -factorisation algebra, equivalently a 2-dimensional vertex-algebra object in $\text{Ch}(k)$ by the Francis higher-dimensional analogue (arXiv:1303.0305 Theorem 1.1) of Theorem 33.5.5. The vertex-algebra output of $\text{Obs}^{4\text{D hol}}$ is pinned by the $\tilde{\partial}_{\mathbb{C}^2}$ -OPE of the A -field in (33.18): the propagator $\langle A_{\bar{z}_i}(z) A_{\bar{z}_j}(w) \rangle$ has a pole of order 1 on the diagonal $z = w$, and the residue carries the Yangian coproduct structure in the Koszul-dual presentation supplied by Proposition 33.5.10.

PROPOSITION 33.5.10 (*Non-abelian 5D hCS $\rightarrow$ Yangian VOA, simply-laced bosonic; Costello–Yagi [29] (arXiv:1810.01970, two-author paper), Theorem 4.1*). Let $\mathfrak{g}$ be a finite-dimensional simply-laced bosonic simple Lie algebra (of type A_n, D_n, E_6, E_7, E_8) with non-degenerate invariant Killing form. The BV-quantised factorisation algebra of observables of 5D holomorphic Chern–Simons (33.18) on $\mathbb{R}_t \times \mathbb{C}^2$ with gauge algebra $\mathfrak{g}$, after compactification along the topological factor $\mathbb{R}_t$, is equivalent to the Yangian VOA $Y^{\text{VOA}}(\mathfrak{g})$ to all orders in $\hbar$:

$$\text{Obs}^{5\text{D hCS, quant}}(\mathbb{R}_t \times \mathbb{C}^2, \mathfrak{g}) \Big|_{\mathbb{R}_t\text{-compact}} \simeq Y^{\text{VOA}}(\mathfrak{g}).$$

The perturbative expansion is convergent, not merely asymptotic, by the Costello–Yagi construction. This is not the consequence of the vanishing of a cubic invariant on every ADE algebra. First, Kontsevich–Tamarkin E_2 -formality on the holomorphic factor $\mathbb{C}^2$ (two-dimensional Deligne conjecture; Kontsevich [155], Tamarkin [162]) collapses the $\hbar$ -tower on $\text{Obs}^{4\text{D hol}}(\mathbb{C}^2)$ to its tree-level OPE, with the Kontsevich weight formula bounding higher-loop Feynman integrals. Second, in Lorenz gauge (33.19) setting $A_t = 0$ on $\mathbb{R}_t$ -opens, the only 1D Feynman diagrams on the topological factor are tadpoles, which

cancel by the antisymmetry of tr on $[\mathfrak{g}, \mathfrak{g}]$; this collapses the $\hbar$ -tower on $\text{Obs}^{\text{ID}^{\text{top}}}(\mathbb{R}_t)$ to its tree-level E_1 -multiplication. The two collapses combined with the holomorphic-topological splitting (33.20) determine the all-orders factorisation algebra from its one-loop approximation. The one-loop r -matrix of 5D hCS equals the Yangian r -matrix under the identification Costello–Witten–Yamazaki [147] Theorem 4.2.

Cubic-versus-quadratic anomaly split. The one-loop BV anomaly on the $\text{tr}(A \bar{\partial} A \bar{\partial} A \bar{\partial} A)$ -wheel splits as

$$A^{(1)}(\mathfrak{g}) = A_{\text{cohom}}^{(1)} + A_{\text{w.f.}}^{(1)}, \quad A_{\text{cohom}}^{(1)}(\mathfrak{g}) = \frac{d^{abc} d_{abc}}{(2\pi)^3}, \quad A_{\text{w.f.}}^{(1)}(\mathfrak{g}) = -\frac{C_2(\mathfrak{g})}{(2\pi)^3} = -\frac{2h^\vee}{(2\pi)^3},$$

with $d^{abc} = \text{tr}(T^a \{T^b, T^c\})$ the totally symmetric rank-3 invariant tensor and $C_2(\mathfrak{g}) = 2h^\vee$ the quadratic Casimir of the adjoint (dual Coxeter number $h^\vee$). The cohomological component $A_{\text{cohom}}^{(1)}$ is scheme-independent and carries the obstruction; the field-renormalisation component $A_{\text{ren}}^{(1)}$ is scheme-dependent and absorbed into a BV-trivial counter-term. The cubic tensor vanishes for the simple types whose exponent list does not contain 2: $A_1, B_n, C_n, D_n, E_6, E_7, E_8, F_4, G_2$. It is non-zero for $A_n, n \geq 2$. Thus cubic-anomaly freedom is not the same condition as simple-lacing. The Costello–Yagi theorem for simply-laced $\mathfrak{g}$ is an external all-orders theorem for the 5d theory; the cubic-Casimir gate used later for 6d hCS must be applied separately.

Remark 33.5.11 (Super gauge algebras: all-orders open). The Costello–Yagi all-orders equivalence is established for simply-laced *bosonic* $\mathfrak{g}$. The super case $\mathfrak{g} \in \{\widehat{\mathfrak{gl}}(m|n), \widehat{\mathfrak{osp}}(m|2n)\}$ – the regime of the K_3 Yangian envelopes $Y_{\hbar}(\mathfrak{so}(4, 20))$ and its Hodge-parity $\mathbb{Z}/2$ -super-extension $Y_{\hbar}(\mathfrak{so}(4 | 20))$ (Hodge-parity, non-Kac; Kac $\mathfrak{osp}(4 | 20)$ excluded because its odd form is symplectic) and the conifold two-chart super-Yangian; requires super Kontsevich–Tamarkin formality, and Ginzburg–Schedler [82] (Selecta Math. 16, 2010; arXiv:0807.0174) establish *super Deligne* in the form of super E_2 -formality for Hochschild cochains of a Koszul Frobenius super-algebra: the super Gerstenhaber bracket of degree -1 on super Hochschild cochains lifts canonically to a super E_2 -algebra structure. The super E_n -formality at $n \geq 3$; in particular the super E_3 -formality required to lift the Hochschild cochain bracket of a super CY_3 category to a super E_3 -algebra, and the super E_4 -formality required for the 4D holomorphic twist of super hCS on $\mathbb{C}^2$ with super gauge $\mathfrak{g}$; is established only at E_2 -level and is open beyond.

The 1-loop BV anomaly coefficient $d_{\text{super}}^{abc} = \text{str}(T^a \{T^b, T^c\})$ vanishes identically on $\mathfrak{gl}(1|1)$ by direct basis computation. With bosonic Cartan pair H, N and fermionic pair ψ^+, ψ^- satisfying $\{\psi^+, \psi^-\} = N$, the non-zero super-symmetric rank-3 contractions reduce to $\text{str}(H\{N, N\}) + \text{str}(N\{H, N\}) + \text{str}(\psi^+\{\psi^-, H\}) + \text{str}(\psi^-\{\psi^+, H\})$, and each term vanishes: the bosonic Cartan pair contributes $\text{str}(H^2) = \text{str}(N^2) = 0$ by direct trace on the fundamental $(1|1)$ -representation, and the fermionic pair carries opposite supertrace signs $\text{str}(\psi^+\psi^-) = -\text{str}(\psi^-\psi^+)$ which cancel under symmetric contraction. The 1-loop wheel on $\mathfrak{gl}(1|1)$ is therefore verified. Higher-loop local cohomology $H_{\text{loc}}^1(\mathfrak{g}_{\text{super}}, \mathcal{O}_{\text{loc}})^{\geq 2}$ is not automatically killed in the absence of super E_n -formality for $n \geq 3$, and the all-orders super case remains open even on $\mathfrak{gl}(1|1)$.

The proposition is the sharpest instance of the holomorphic-vs-topological factor decomposition: the topological factor $\mathbb{R}$ supplies the E_1 -multiplication of the Yangian, the holomorphic factor $\mathbb{C}^2$ supplies the vertex-algebra/OPE structure, and the Dunn–Lurie splitting (33.20) packages the two into a single E_3 -factorisation algebra on $\mathbb{R} \times \mathbb{C}^2$.

GLUING ALONG STRATIFIED MANIFOLD STRUCTURE

The product $\mathbb{R}_t \times \mathbb{C}^2$ is the simplest stratified manifold with a holomorphic-topological decomposition: a single top stratum, trivially stratified. General CY_3 targets carrying a 5D hCS factorisation structure require the stratified-manifold machinery of Costello–Gwilliam Vol. 1 §8 [30] (local-to-global on locally conical stratified spaces), building on Ayala–Francis–Tanaka [3, 4] (*Local structures on stratified spaces*, Adv. Math. 307; *Factorization homology of stratified spaces*, Selecta Math. 23), which extends the factorisation-algebra local-to-global axiom to stratified manifolds by replacing ordinary Weiss covers with *stratified Weiss covers* respecting the stratification.

Definition 33.5.12 (Stratified Weiss cover; Costello–Gwilliam Vol. 1 §8 [30] Definition 8.3.0.1; Ayala–Francis–Tanaka [3] §2–3, exit-path category of a conically smooth stratified space). Let M be a conically smooth stratified manifold with stratification $M = M_0 \sqcup M_1 \sqcup \cdots \sqcup M_r$, each M_i a locally closed smooth submanifold, the closures satisfying $\overline{M_i} \subset \sqcup_{j \leq i} M_j$. A collection $\mathfrak{U}$ of open subsets of M is a *stratified Weiss cover* if, for every finite subset $S \subset M$, there exists $U_\alpha \in \mathfrak{U}$ with $U_\alpha \cap M_i \supset S \cap M_i$ simultaneously for every stratum M_i , $i = 0, 1, \dots, r$. Equivalently, $\mathfrak{U}$ is a Weiss cover in the Grothendieck topology on the exit-path category of M ([4] §3.4).

The extension of the factorisation local-to-global axiom to stratified Weiss covers is Costello–Gwilliam Vol. 1 Theorem 8.4.0.1 [30], equivalently Ayala–Francis–Tanaka [4] Theorem 1.1 (factorisation homology of stratified spaces is a homotopy invariant of the exit-path category). The effect for the present chapter is that the gluing of Stage 1 on a stratified CY_3 target proceeds stratum by stratum, with the top-dimensional stratum carrying the ambient 5D hCS factorisation structure and finer (lower-dimensional) strata carrying corrections supported on singular or exceptional loci.

Example 33.5.13 (Local $\mathbb{P}^2$ gluing via stratified Weiss covers). Local $\mathbb{P}^2 = \text{Tot}(K_{\mathbb{P}^2})$ is a complex 3-fold (real 6-manifold) carrying the toric $T^2 = (\mathbb{C}^\times)^2$ action: the standard T^2 acts on $\mathbb{P}^2$ by rescaling homogeneous coordinates modulo the diagonal, and extends to the total space via the anti-canonical character on the fibre of $K_{\mathbb{P}^2}$. Stratify $\text{Tot}(K_{\mathbb{P}^2})$ by locating each point either on the zero section $\mathbb{P}^2$ (three toric T^2 -orbit types) or in its open complement:

$$\text{Tot}(K_{\mathbb{P}^2}) = M_{\text{pts}} \sqcup M_{\text{edges}} \sqcup M_{\text{bulk}} \sqcup M_{\text{fibre}}. \quad (33.22)$$

The four layers are:

- (i) M_{pts} consists of the three T^2 -fixed points $p_1, p_2, p_3 \in \mathbb{P}^2 \subset \text{Tot}(K_{\mathbb{P}^2})$, each an isolated 0-real-dimensional stratum on the zero section;
- (ii) M_{edges} is the disjoint union of the three toric edges $\mathbb{P}_{ij}^1 \setminus \{p_i, p_j\} \cong \mathbb{C}^\times$ on the zero section (each the free orbit of a 1-dimensional sub- $\mathbb{C}^\times \subset T^2$), a 2-real-dimensional locus;
- (iii) $M_{\text{bulk}} \cong (\mathbb{C}^\times)^2$ is the open toric-bulk of the zero section: the single free T^2 -orbit, the 4-real-dimensional complement of the three toric edges in $\mathbb{P}^2$;
- (iv) $M_{\text{fibre}} = \text{Tot}(K_{\mathbb{P}^2}) \setminus \mathbb{P}^2$ is the open complement of the zero section, a real 6-manifold on which $T^2 \times \mathbb{C}_{\text{fibre}}^\times$ acts freely. The slice $M_{\text{fibre}}/\mathbb{C}_{\text{fibre}}^\times$ is a 5-real-dimensional unit-link bundle over $\mathbb{P}^2$ (topologically the 5-sphere link of the zero section), and we refer to M_{fibre} as the 5-real-dimensional generic fibre stratum in this link-quotient sense.

The four layers partition the total space $\text{Tot}(K_{\mathbb{P}^2}) = \sqcup_\bullet M_\bullet$ with closure relations $\overline{M_{\text{pts}}} = M_{\text{pts}}$, $\overline{M_{\text{edges}}} = M_{\text{pts}} \cup M_{\text{edges}}$, $\overline{M_{\text{bulk}}} = \mathbb{P}^2 = M_{\text{pts}} \cup M_{\text{edges}} \cup M_{\text{bulk}}$, and $\overline{M_{\text{fibre}}} = \text{Tot}(K_{\mathbb{P}^2})$.

A stratified Weiss cover $\mathbf{U}^{\text{strat}}$ of local $\mathbb{P}^2$ assigns, to each finite configuration $S \subset \text{Tot}(K_{\mathbb{P}^2})$, an open $U \in \mathbf{U}^{\text{strat}}$ whose intersection with each of the four strata in (33.22) contains the corresponding slice $S \cap M_{\bullet}$. The stratum-by-stratum factorisation algebra reads: $\mathcal{M}_{\text{pts}}$ contributes the McKay-quiver CoHA centred on each toric fixed point's local $\mathbb{C}^3$ chart via the Bridgeland–King–Reid equivalence $D^b(\text{Coh}([\mathbb{C}^3/\mathbb{Z}_3])) \simeq D^b(\text{mod-Beil}_3)$ for the Beilinson quiver Beil_3 of $\mathbb{P}^2$ (§33.2, §3.2, Szendrői–Nakajima); $\mathcal{M}_{\text{edges}}$ contributes three $\mathbb{P}^1$ -normal-bundle chiral algebras, each an E_2 -factorisation algebra on an edge curve (Costello–Li [145] 4D hCS reduction over the edge); $\mathcal{M}_{\text{bulk}}$ and $\mathcal{M}_{\text{fibre}}$ together recover the bulk 5D hCS reduction of local $\mathbb{P}^2$ at T^2 -generic parameter, matching the BKR equivalence on the zero section (Beilinson quiver of $\mathbb{P}^2$). The toric stratification is the reason the CoHA of local $\mathbb{P}^2$ decomposes, via the Weiss-cover gluing of Definition 33.5.12, into the three quiver-CoHAs at $\mathcal{M}_{\text{pts}}$ plus the three edge corrections at $\mathcal{M}_{\text{edges}}$ plus the bulk contribution at $\mathcal{M}_{\text{bulk}} \sqcup \mathcal{M}_{\text{fibre}}$, and not merely into the open-versus-zero-section pair $\text{Tot}(K_{\mathbb{P}^2}) \setminus \mathbb{P}^2 \sqcup \mathbb{P}^2$ which ignores the toric equivariance structure.

Remark 33.5.14 (Connection to Costello–Paquette $\mathbb{C}^3$ M-theory). The Costello–Paquette construction (Costello–Paquette arXiv:1810.06490 for $\mathbb{C}^3$ and arXiv:2009.04834 for the Omega-background extension) identifies the twisted M-theory factorisation algebra on $\mathbb{R} \times \mathbb{C}^2 \times S^1$ with the $\mathbb{R}$ -quantised 5D hCS theory of Proposition 33.5.10, specialised to $\mathfrak{g} = \widehat{\mathfrak{gl}}_{\infty}$ and twisted by an Omega-background on the $\mathbb{C}^2$ holomorphic factor. The stratified Weiss cover of the M-theory $\mathbb{C}^3$ -geometry decomposes as the toric T^3 -stratification of $\mathbb{C}^3$ (one open stratum plus three $\mathbb{C}^2 \subset \mathbb{C}^3$ toric-divisor strata plus three $\mathbb{C} \subset \mathbb{C}^2$ toric-edge strata plus the origin $o \in \mathbb{C}^3$), and the reduction to 5D hCS on $\mathbb{R} \times \mathbb{C}^2$ amounts to compactifying the S^1 -factor and restricting to the generic $T^2 \subset T^3$ -invariant slice. The $\widehat{\mathfrak{gl}}_{\infty}$ Yangian VOA arising in this reduction is the M-theoretic extension of the finite-rank Yangian VOA of Proposition 33.5.10, with the T^3 -stratified Weiss-cover gluing supplying the degeneration structure across the codimension-1 toric-divisor walls.

Remark 33.5.15 (Strict super-factorisation across strata). The strict super-factorisation axiom of Remark 33.5.7 extends to stratified Weiss covers: the Koszul super-braiding in the structure maps (33.8) restricted to each stratum remains a strict equality in $\text{Ch}(\text{sVect})$, and the stratum- $\mathbb{Z}/2$ -grading compatibility along codimension-1 strata is a strict equality of interchange isomorphisms rather than a coherence homotopy. The stratification does not promote the super-factorisation axiom to a coherence datum. The reason the $K_3 \times E$ fibre stratification (compact fibre $K_3 \times \{\text{pt}\}$ over an elliptic base $\{\text{pt}\} \times E$) carries a strict $\mathbb{Z}/2$ -grading on the global chiral algebra is that each of the two strata is itself a factorisation algebra in $\text{Ch}(\text{sVect})$ with the strict interchange, and the gluing along the stratum boundary uses only the strict 1-categorical symmetry of $\text{Ch}(\text{sVect})$; no $(\infty, 1)$ -categorical homotopy datum is required at this step. The same strict extension applies to the local $\mathbb{P}^2$ toric stratification of Example 33.5.13 with the three fixed-point $\mathbb{C}^3$ -CoHAs carrying strict $\mathbb{Z}/2$ -gradings inherited from the conifold prototype of §33.2, §2.1.

Section summary

Sections 33.5–33.5 establish the factorisation-algebra gluing mode of §33.5 at four elementary levels. The Weiss-cover criterion (Definition 33.5.1) replaces ordinary open covers with finite-point-configuration covers; a two-chart atlas is not a Weiss cover (Proposition 33.5.2), and the disjoint-union closure of a subordinate polydisc basis is the Weiss refinement (33.9). The Ran space of a curve indexes chiral observables as a factorisation cosheaf, and the Francis–Gaitsgory chiral Koszul duality (Theorem 33.5.5) identifies chiral algebras on a curve with factorisation cosheaves on the Ran space. Proposition 33.5.4 states the finite DWR/Ran hCS–Rees–Hall comparison on this same finite-configuration site: finite descent is over an

ordered E_1 Hall layer, the Hall product is the Rees Thom–Sebastiani product, and the E_2 centre or Drinfeld double requires its own pairing/completion operation. The higher-dimensional Francis E_n -analogue (Theorem 33.5.6) underlies the CY_3 construction. The two-stage factorisation $\Phi_3^{(\Sigma_2, C)} = \mathrm{Sp}_{\Sigma_2, C}^{\mathrm{ch}} \circ \Phi_3^{\mathrm{FA}}$ (equations (33.13)–(33.16)) assembles Stage 1 by the Costello–Gwilliam factorisation-envelope refinement of Kontsevich–Tamarkin E_3 -formality and descends to Stage 2 by factorisation homology over a transverse Σ_2 -fibre (Proposition 33.5.8); each stage is itself a Weiss-cover gluing. The 5D holomorphic Chern–Simons BV action $S_{5D\mathrm{hCS}}[\mathcal{A}] = \int_{\mathbb{R}_t \times \mathbb{C}^2} \Omega_{\mathbb{C}^2} \wedge \mathrm{tr}(\mathcal{A} \wedge \bar{\partial}_{\mathbb{C}^2} \mathcal{A} + \mathcal{A} \wedge d_t \mathcal{A} + \frac{2}{3} \mathcal{A} \wedge \mathcal{A} \wedge \mathcal{A})$ of (33.18), in mixed Lorenz gauge (33.19), produces a factorisation algebra on $\mathbb{R}_t \times \mathbb{C}^2$ decomposing (33.20) into a topological E_1 -factor on $\mathbb{R}_t$ and a holomorphic E_2^{hol} -factor on $\mathbb{C}^2$ by Francis’s holomorphic-topological splitting [40] Theorem 1.1; Kontsevich–Tamarkin formality then identifies the operad with E_3 via (33.21). Non-abelian 5D hCS converges to the Yangian VOA at all orders for simply-laced bosonic $\mathfrak{g}$ of types A_n, D_n, E_6, E_7, E_8 by the Costello–Yagi theorem (Proposition 33.5.10). This is not the same as cubic-anomaly freedom: d^{abc} is non-zero for $A_n, n \geq 2$, and the cubic-Casimir gate is a separate 6d hCS condition. The super case remains open except for the verified 1-loop cancellation on $\mathfrak{gl}(1|1)$ (Remark 33.5.11). Stratified Weiss covers (Definition 33.5.12; Ayala–Francis–Tanaka [3, 4]) extend the local-to-global axiom to stratified targets; the local $\mathbb{P}^2$ toric T^2 -stratification (Example 33.5.13) has four layers $M_{\mathrm{pts}} \sqcup M_{\mathrm{edges}} \sqcup M_{\mathrm{bulk}} \sqcup M_{\mathrm{fibre}}$ of real dimensions 0, 2, 4, 5 respectively (three isolated fixed points of dim 0; three toric $\mathbb{P}^1$ -edges minus fixed points of dim 2; one open toric bulk $(\mathbb{C}^\times)^2 \subset \mathbb{P}^2$ of dim 4; and the fibre-direction-open link of dim 5), each carrying a stratum-specific factorisation algebra whose gluing reproduces the CoHA of local $\mathbb{P}^2$. The Costello–Paquette $\mathbb{C}^3$ M-theory picture (arXiv:1810.06490, arXiv:2009.04834; Remark 33.5.14) identifies the T^3 -stratified $\mathbb{C}^3$ -geometry of twisted M-theory with the S^1 -compactification of 5D hCS on $\mathbb{R} \times \mathbb{C}^2$, specialised to $\mathfrak{g} = \widehat{\mathfrak{gl}}_\infty$. The strict super-factorisation axiom in $\mathrm{Ch}(\mathrm{sVect})$ (Remarks 33.5.7 and 33.5.15) is 1-categorical and is inherited strictly by stratified Weiss covers: the $\mathbb{Z}/2$ -grading on the super-Yangian arising from the conifold two-chart gluing (§33.2, §2.1), on the global chiral algebra of $K3 \times E$, and on the three fixed-point CoHAs of local $\mathbb{P}^2$ is a strict equality, not a coherence datum. §33.6 turns to wall-crossing gluing, stratum-independent and complementary to Weiss-cover locality.

33.6 WALL-CROSSING GLUING

The Kontsevich–Soibelman quantum torus

CHARGE LATTICE AND SKEW-EULER FORM

Fix a CY_3 triangulated category C with finitely generated Grothendieck group $\Gamma := K_0(C)$. Every object $E \in C$ defines a class $[E] \in \Gamma$, and every short exact triangle $E' \rightarrow E \rightarrow E''$ gives $[E] = [E'] + [E'']$ in Γ . The Euler form is

$$\chi(E, F) := \sum_{i \in \mathbb{Z}} (-1)^i \dim \mathrm{Ext}_C^i(E, F),$$

a bilinear pairing $\Gamma \times \Gamma \rightarrow \mathbb{Z}$. Set

$$\langle \gamma, \gamma' \rangle := \chi(\gamma, \gamma') - \chi(\gamma', \gamma).$$

The antisymmetrisation cancels the symmetric part; what remains is the *skew-Euler form*. On any triangulated category it is integer-valued and bilinear in both slots; on a CY_d category Serre duality provides an identification $\mathrm{Ext}^i(E, F) \cong \mathrm{Ext}^{d-i}(F, E)^\vee$, which forces a symmetry relation we exploit below.

Definition 33.6.1 (Quantum torus [235, §2.3]). Let $\mathbb{L}^{1/2}$ be a formal variable (motivic square-root of the Lefschetz motive $\mathbb{L} = \mathbb{L}^{1/2} \cdot \mathbb{L}^{1/2}$). The *Kontsevich–Soibelman quantum torus* of $(\Gamma, \langle \cdot, \cdot \rangle)$ is the algebra

$$\mathcal{T}_\Gamma := \left(\bigoplus_{\gamma \in \Gamma} \mathbb{Z}[\mathbb{L}^{\pm 1/2}] \hat{x}_\gamma \right), \quad \hat{x}_\gamma \cdot \hat{x}_{\gamma'} = \mathbb{L}^{\langle \gamma, \gamma' \rangle / 2} \hat{x}_{\gamma + \gamma'}.$$

Passing to the appropriate completion over the positive cone $\Gamma^+ \subset \Gamma$ gives the *completed quantum torus* $\hat{\mathcal{T}}_\Gamma = \prod_{\gamma \in \Gamma^+} \mathbb{Z}[\mathbb{L}^{\pm 1/2}] \hat{x}_\gamma$, which is where the wall-crossing formula lives.

Remark 33.6.2 (Conventions). The convention for the exponent varies among sources: Kontsevich–Soibelman use $\langle \gamma, \gamma' \rangle / 2$ with $\langle \cdot, \cdot \rangle$ the skew-Euler form; Joyce–Song use $\chi(\gamma, \gamma')$ (not antisymmetrised) with a sign in the Lie bracket; Nagao et al. use $-\chi(\gamma, \gamma')$. All three conventions produce isomorphic quantum tori via a gauge change on $\hat{x}_\gamma$. We adopt the KS convention.

THE SKEW-EULER FORM ON A CY_3 CATEGORY

The crucial feature of dimension three is that the Serre duality operator *makes the Euler form itself antisymmetric up to sign*. Elementary:

PROPOSITION 33.6.3 (CY₃ Serre antisymmetry). For $\mathcal{C}$ a CY_3 triangulated category,

$$\chi(\gamma, \gamma') = -\chi(\gamma', \gamma) \quad \text{for all } \gamma, \gamma' \in \Gamma.$$

Proof. Serre duality on a CY_d category gives $\text{Ext}^i(E, F) \cong \text{Ext}^{d-i}(F, E)^\vee$ as $\mathbb{Z}$ -modules. Taking alternating dimensions,

$$\chi(E, F) = \sum_i (-1)^i \dim \text{Ext}^i(E, F) = \sum_i (-1)^i \dim \text{Ext}^{d-i}(F, E) = (-1)^d \sum_j (-1)^j \dim \text{Ext}^j(F, E) = (-1)^d \chi(F, E).$$

At $d = 3$ the factor is $(-1)^3 = -1$, establishing antisymmetry. □

COROLLARY 33.6.4 (Skew-Euler equals 2χ on CY_3). On any CY_3 category $\mathcal{C}$,

$$\langle \gamma, \gamma' \rangle = \chi(\gamma, \gamma') - \chi(\gamma', \gamma) = \chi(\gamma, \gamma') + \chi(\gamma, \gamma') = 2\chi(\gamma, \gamma').$$

The Euler form itself is *already* antisymmetric, and the skew-Euler form is 2χ .

Substituting $\langle \gamma, \gamma' \rangle = 2\chi(\gamma, \gamma')$ into 33.6.1,

$$\hat{x}_\gamma \cdot \hat{x}_{\gamma'} = \mathbb{L}^{\langle \gamma, \gamma' \rangle / 2} \hat{x}_{\gamma + \gamma'} = \mathbb{L}^{\chi(\gamma, \gamma')} \hat{x}_{\gamma + \gamma'}.$$

The commutator is computed directly from antisymmetry of χ :

$$\hat{x}_\gamma \hat{x}_{\gamma'} = \mathbb{L}^{\chi(\gamma, \gamma')} \hat{x}_{\gamma + \gamma'}, \quad \hat{x}_{\gamma'} \hat{x}_\gamma = \mathbb{L}^{\chi(\gamma', \gamma)} \hat{x}_{\gamma + \gamma'} = \mathbb{L}^{-\chi(\gamma, \gamma')} \hat{x}_{\gamma + \gamma'},$$

so

$$\hat{x}_\gamma \hat{x}_{\gamma'} \hat{x}_\gamma^{-1} \hat{x}_{\gamma'}^{-1} = \mathbb{L}^{\chi(\gamma, \gamma') - \chi(\gamma', \gamma)} = \mathbb{L}^{\langle \gamma, \gamma' \rangle} = \mathbb{L}^{2\chi(\gamma, \gamma')}.$$

The factor 2 is a feature of the CY_3 skew-Euler form, not a convention. At the motivic level the quantum torus is non-commutative with this explicit commutator; in the classical limit $\mathbb{L}^{1/2} \rightarrow 1$, every power of $\mathbb{L}$ trivialises and $\hat{x}_\gamma \hat{x}_{\gamma'} = \hat{x}_{\gamma + \gamma'}$ is the group algebra $\mathbb{Z}[\Gamma]$.

Remark 33.6.5 (χ is antisymmetric, not symmetric, on CY_3). The quantity that is antisymmetric on a CY_3 category is χ itself, by Serre duality through the middle dimension. It is *not* the case that one starts with a symmetric form and antisymmetrises to obtain the skew-Euler pairing; in lower dimension d even, χ is symmetric, and skew-Euler is a genuine antisymmetrisation. At $d = 3$ the symmetrisation $\chi(\gamma, \gamma') + \chi(\gamma', \gamma)$ already vanishes, the Euler form is already antisymmetric, and the notation $\langle \cdot, \cdot \rangle$ redundantly duplicates χ by a factor of two. This is the only dimension on which the distinction collapses in this way; the quantum-torus commutator $\mathbb{L}^2 \chi$ is the motivic shadow of the $d = 3$ collapse.

Remark 33.6.6 (*Hall-product non-commutativity lives elsewhere*). The non-commutativity $\hat{x}_\gamma \hat{x}_{\gamma'} = \mathbb{L}^2 \chi_{\gamma+\gamma'}$ of the quantum torus is the *charge-level* non-commutativity: it sees only the K_0 -grading, not the moduli-space geometry. The Hall-product non-commutativity on the full critical-cohomology CoHA $\mathcal{H}(C)$ is a strictly richer datum, involving the vanishing-cycle complexes on moduli stacks of extensions and not merely the Euler pairing of their classes. The passage from the quantum torus to the full CoHA is the subject of 33.6; the two non-commutativities agree on the K_0 -graded pieces but disagree on finer cohomological data.

Chambers as gluing cells

THE STABILITY MANIFOLD AND ITS STRATIFICATION

Bridgeland's stability manifold $\text{Stab}(C)$ is a complex manifold carrying the data needed to specify BPS counts. A point $\sigma \in \text{Stab}(C)$ consists of a group homomorphism $Z: \Gamma \rightarrow \mathbb{C}$ (the *central charge*) together with a heart $\mathcal{A} \subset C$ of a bounded t -structure, subject to the compatibility that Z maps nonzero objects of $\mathcal{A}$ into the upper half plane $\mathbb{H} \cup \mathbb{R}_{<0}$.

PROPOSITION 33.6.7 (*Stab dimension = numerical Grothendieck rank, Bridgeland (2007, arXiv:math/0212237) Thm 7.1*). For C a triangulated category with finite-rank numerical Grothendieck group $K_0^{\text{num}}(C) := K_0(C)/\text{rad}(\chi)$, the stability manifold $\text{Stab}(C)$ is a complex manifold of complex dimension

$$\dim_{\mathbb{C}} \text{Stab}(C) = \text{rk } K_0^{\text{num}}(C).$$

The CY dimension d does *not* enter this formula; the rank is a numerical invariant of C alone.

Example 33.6.8 (*Conifold versus strict CY_3*). On the resolved conifold $\tilde{Y}$ the numerical Grothendieck group is generated by the two simples γ_0, γ_1 of the Klebanov–Witten quiver, so $\text{rk } K_0^{\text{num}}(\tilde{Y}) = 2$ and $\text{Stab}(\tilde{Y})$ is four-real-dimensional. On a compact strict CY_3 threefold X (projective with $\omega_X \cong \mathcal{O}_X$ and $h^1(\mathcal{O}_X) = 0$), Chern-character provides a numerical isomorphism $K_0^{\text{num}}(X) \otimes \mathbb{Q} \cong \bigoplus_i H^{2i, 2i}(X, \mathbb{Q})$, so

$$\text{rk } K_0^{\text{num}}(X) = 2 + 2h^{1,1}(X),$$

accounting for $[\mathcal{O}_{\text{pt}}]$ and $[X]$ (two) plus one divisor/curve pair per Picard generator (two per $h^{1,1}$). $K_3 \times E$ has $h^{1,1}(K_3 \times E) = 21$, hence $\text{rk } K_0^{\text{num}}(K_3 \times E) = 44$. The conifold's rank 2 is the smallest non-trivial value; the CY_3 dimension is 3 in both cases, so rank is independent of d .

The stability manifold is stratified by *walls*: codimension-one real hypersurfaces where the set of semistable objects of a given phase changes. The open dense complement decomposes into *chambers*, on each of which the BPS spectrum is locally constant:

$$\text{Stab}(C) \setminus \{\text{walls}\} = \bigsqcup_{\alpha} \text{Ch}_{\alpha}, \quad \Omega_{\alpha}: \Gamma \rightarrow \mathbb{Z} \text{ constant on each } \text{Ch}_{\alpha}.$$

A BPS invariant $\Omega_\alpha(\gamma)$ counts (motivically, or virtually) the stable objects of class γ with respect to $\sigma \in \text{Ch}_\alpha$. Walls are loci where semistable objects of class γ develop with Hom-extensions crossing between chambers.

Definition 33.6.9 (Chamber boundary). A wall of marginal stability for class $\gamma \in \Gamma$ is the locus $W_\gamma = \{\sigma : Z(\gamma) \in \mathbb{R}_{>0} \cdot Z(\gamma') \text{ for some proper sub-object class } \gamma' <_\sigma \gamma\}$. Walls are real codimension-one; their collection stratifies $\text{Stab}(C)$ into chambers Ch_α .

THE QUANTUM DILOGARITHM

Central to the KS wall-crossing formula is the *quantum dilogarithm*. We derive it from scratch.

Definition 33.6.10 (Quantum dilogarithm). For a formal variable x commuting with $\mathbb{L}^{1/2}$, set

$$\Psi(x) := \prod_{k \geq 0} \left(1 - \mathbb{L}^{k+1/2} x\right)^{-1} = \sum_{n \geq 0} \frac{\mathbb{L}^{n^2/2} x^n}{\prod_{j=1}^n (1 - \mathbb{L}^j)}.$$

The second equality is the q -binomial theorem / Durfee-square identity; we derive it below.

PROPOSITION 33.6.11 (Durfee-staircase derivation of Ψ). The two formulas for $\Psi(x)$ in 33.6.10 agree as formal power series in x over $\mathbb{Z}[\mathbb{L}^{\pm 1/2}]$.

Durfee staircase. Expand each factor geometrically:

$$\Psi(x) = \prod_{k \geq 0} \sum_{n_k \geq 0} \mathbb{L}^{(k+1/2)n_k} x^{n_k} = \sum_{(n_0, n_1, \dots)} \mathbb{L}^{\sum_k (k+1/2)n_k} x^{\sum_k n_k}.$$

Index the sum by $n := \sum_k n_k$. A sequence $(n_k)_{k \geq 0}$ with $\sum n_k = n$ parametrises a partition $\lambda = (\lambda_1 \geq \lambda_2 \geq \dots \geq \lambda_n \geq 0)$ into exactly n parts ≥ 0 (allowing $\lambda_i = 0$), where $n_k = \#\{i : \lambda_i = k\}$. The exponent of $\mathbb{L}$ is

$$\sum_k (k + \tfrac{1}{2})n_k = \sum_k k n_k + \tfrac{n}{2} = |\lambda| + \tfrac{n}{2}.$$

Extract the Durfee staircase $\delta_n = (n-1, n-2, \dots, 1, 0)$: every partition λ with n (possibly zero) parts decomposes uniquely as $\lambda = \delta_n + \lambda^\bullet$ where $\lambda^\bullet = (\lambda_1 - (n-1), \lambda_2 - (n-2), \dots, \lambda_n - 0)$ is an arbitrary partition with $\leq n$ parts ≥ 0 . The staircase contributes $|\delta_n| = \binom{n}{2} = \frac{n(n-1)}{2}$; the residual $\lambda^\bullet$ has generating function $\prod_{j=1}^n (1 - \mathbb{L}^j)^{-1}$ (Euler: partitions into $\leq n$ parts). Substituting,

$$\Psi(x) = \sum_{n \geq 0} x^n \mathbb{L}^{n^2/2} \cdot \mathbb{L}^{n(n-1)/2} \cdot \prod_{j=1}^n (1 - \mathbb{L}^j)^{-1} = \sum_{n \geq 0} \frac{\mathbb{L}^{n^2/2} x^n}{\prod_{j=1}^n (1 - \mathbb{L}^j)},$$

using $\frac{n}{2} + \frac{n(n-1)}{2} = \frac{n^2}{2}$. This is the q -binomial form of the quantum dilogarithm; the derivation is Faddeev–Kashaev (hep-th/9310070) in motivic form, with the staircase providing the canonical $\mathbb{L}^{n^2/2}$ Gaussian shift. $\square$

Remark 33.6.12 (Why the $1/2$ -shift). The shift $\mathbb{L}^{k+1/2}$ in each factor (rather than $\mathbb{L}^k$ or $\mathbb{L}^{k+1}$) is dictated by the motivic square-root convention and is the choice that makes Ψ invariant under the involution $\mathbb{L} \mapsto \mathbb{L}^{-1}$ up to prefactor. The half-integer exponent becomes the Gaussian factor $\mathbb{L}^{n^2/2}$ in the summation form, which is the motivic avatar of the theta-function shadow of the quantum dilogarithm at $|\mathbb{L}| = 1$. In the classical limit $\mathbb{L} \rightarrow 1$, Ψ degenerates to $\exp(\text{Li}_2(x))$, the exponentiated classical dilogarithm.

THEOREM 33.6.13 (*Faddeev–Kashaev pentagon, canonical form*). Let $\hat{x}_0, \hat{x}_1$ be generators of a rank-two quantum torus with relation $\hat{x}_1 \hat{x}_0 = \mathbb{L} \hat{x}_0 \hat{x}_1$ (equivalently $\langle \gamma_1, \gamma_0 \rangle = 1$ in the KS skew-pairing convention $\hat{x}_\gamma \hat{x}_{\gamma'} = \mathbb{L}^{\langle \gamma, \gamma' \rangle / 2} \hat{x}_{\gamma + \gamma'}$). Then inside $\hat{\mathcal{T}}_\Gamma$,

$$\Psi(\hat{x}_0) \Psi(\hat{x}_1) = \Psi(\hat{x}_1) \Psi(\mathbb{L}^{-1/2} \hat{x}_0 \hat{x}_1) \Psi(\hat{x}_0).$$

The middle factor $\hat{x}_{\gamma_0 + \gamma_1} = \mathbb{L}^{-1/2} \hat{x}_0 \hat{x}_1$ is the bound-state class $[S_0] + [S_1]$ produced at the wall.

Derivation from A_2 wall-crossing. Specialise 33.6.15 to the A_2 sublattice $V = \mathbb{Z}\gamma_0 \oplus \mathbb{Z}\gamma_1$ with $\langle \gamma_1, \gamma_0 \rangle = 1$ (so $\langle \gamma_0, \gamma_1 \rangle = -1$ by antisymmetry). Then $\hat{x}_0 \hat{x}_1 = \mathbb{L}^{-1/2} \hat{x}_{\gamma_0 + \gamma_1}$ and $\hat{x}_1 \hat{x}_0 = \mathbb{L}^{1/2} \hat{x}_{\gamma_0 + \gamma_1}$, so the commutation $\hat{x}_1 \hat{x}_0 = \mathbb{L} \hat{x}_0 \hat{x}_1$ holds and $\hat{x}_{\gamma_0 + \gamma_1} = \mathbb{L}^{1/2} \hat{x}_1 \hat{x}_0 = \mathbb{L}^{-1/2} \hat{x}_0 \hat{x}_1$. Cross a single wall where the phases of $Z(\gamma_0), Z(\gamma_1)$ align.

- LHS chamber: BPS spectrum $\{\gamma_0, \gamma_1\}$ with $\Omega = 1$ each; phase order $\arg Z(\gamma_0) < \arg Z(\gamma_1)$, producing the increasing-phase ordered product $\Psi(\hat{x}_0) \Psi(\hat{x}_1)$.
- RHS chamber: BPS spectrum $\{\gamma_1, \gamma_0 + \gamma_1, \gamma_0\}$ with $\Omega = 1$ on each; the bound-state class $[S_0] + [S_1] = \gamma_0 + \gamma_1$ has materialised; phase order reversed, producing $\Psi(\hat{x}_1) \Psi(\hat{x}_{\gamma_0 + \gamma_1}) \Psi(\hat{x}_0) = \Psi(\hat{x}_1) \Psi(\mathbb{L}^{-1/2} \hat{x}_0 \hat{x}_1) \Psi(\hat{x}_0)$.

Equality of the two chamber products is the pentagon.

Algebraic verification (Faddeev–Kashaev hep-th/9310070 (1994)): expand both sides as formal series in $\hat{x}_0, \hat{x}_1$ using the sum form of Ψ and the commutation relation $\hat{x}_1 \hat{x}_0 = \mathbb{L} \hat{x}_0 \hat{x}_1$; bidegree-by-bidegree matching reduces to the q -Pascal recursion

$$\binom{m+n}{n}_{\mathbb{L}} = \binom{m+n-1}{n}_{\mathbb{L}} + \mathbb{L}^m \binom{m+n-1}{n-1}_{\mathbb{L}}$$

for the Gaussian binomial coefficients, which is the identity dual to the pentagon under the KS motivic Fourier transform. The three BPS contributions $\Omega(\gamma_0) + \Omega(\gamma_1) + \Omega(\gamma_0 + \gamma_1) = 3$ count the three Ψ -factors on the RHS. $\square$

Remark 33.6.14 (*Pentagon as BPS conservation law*). The pentagon is the first non-trivial consequence of the KS wall-crossing formula and, read as a cluster identity, controls the combinatorics of the A_2 cluster algebra (Fock–Goncharov, Fomin–Zelevinsky). In the DT / motivic dictionary the A_2 wall has exactly three BPS states with charges $\gamma_1, \gamma_2, \gamma_1 + \gamma_2$; the pentagon is the assertion that these three quantum dilogarithms re-order consistently. All higher wall-crossings (hexagons, octagons, and the continuum of Kontsevich–Soibelman wall crossings for BPS rays of irrational slope) are consequences of the pentagon plus the cocycle condition 33.6.16.

THE KS WALL-CROSSING FORMULA

THEOREM 33.6.15 (*Kontsevich–Soibelman wall-crossing formula* [235, §6.3]). Let $\sigma_1, \sigma_2 \in \text{Stab}(C)$ be points in adjacent chambers Ch_1, Ch_2 separated by a wall W . Let $V \subset \Gamma$ be the rank-two sublattice of charges whose phases align on W , and let $\Omega_i(\gamma)$ denote the motivic BPS invariants of chamber i . Then

$$\prod_{\gamma \in V^+}^{\leftarrow} \Psi(\hat{x}_\gamma)^{\Omega_1(\gamma)} = \prod_{\gamma \in V^+}^{\rightarrow} \Psi(\hat{x}_\gamma)^{\Omega_2(\gamma)},$$

where the left (resp. right) product is taken in order of decreasing (resp. increasing) phase of $Z(\gamma)$ at σ_1 (resp. σ_2).

The formula is a chamber-to-chamber gluing relation: the LHS is the product of quantum-dilogarithm factors built from chamber-1 data; the RHS from chamber-2 data; and the formula asserts they are equal as automorphisms of the completed quantum torus.

COROLLARY 33.6.16 (*Cocycle condition*). Passing around a codim-2 stratum where three chambers meet along three walls, the three pairwise wall-crossing formulas compose to the identity. In cohomological language: the quantum-dilogarithm factors $\{\Psi(\hat{x}_\gamma)^{\Omega(\gamma)}\}$ define a Čech cocycle for the open cover of $\text{Stab}(C)$ by chambers. The global BPS spectrum is the cohomology class of this cocycle in $\check{H}^1(\text{Stab}(C), \text{Aut}(\hat{\mathcal{T}}_\Gamma))$.

Sketch. Crossing three walls and returning to the starting chamber is the identity automorphism of $\text{Stab}(C)$; the wall-crossing formula applied three times must therefore compose to the identity of $\hat{\mathcal{T}}_\Gamma$. This is the familiar Čech 1-cocycle condition on triple overlaps of the chamber-indexed cover. $\square$

Remark 33.6.17 (*Why this is gluing*). The data

$$\{\Omega_\alpha(\gamma)\}_{\alpha,\gamma} \longleftrightarrow \{\text{gluing automorphism } \Psi^{\Omega_\alpha}(\gamma) \text{ on wall } W_{\alpha,\alpha+1}\}$$

is the chamber-indexed gluing datum. The chambers are the *local charts* of a global BPS sheaf; the quantum-dilogarithm factors are the *transition functions*; the wall-crossing formula is the *cocycle condition*. This is the same formal structure as Čech-gluing of a line bundle on a manifold, with $U(1)$ replaced by $\text{Aut}(\hat{\mathcal{T}}_\Gamma)$ and the sheaf cohomology replaced by pointed non-abelian sheaf cohomology H^1 .

THE JOYCE–SONG INTEGRATION MAP

An alternative, equivalent gluing is provided by the Joyce–Song integration map. We state it at the chain level.

THEOREM 33.6.18 (*Joyce–Song integration map, Joyce–Song (2012, arXiv:0810.5645) Thm 5.8*). Let C be a CY_3 category with stability condition σ and charge lattice Γ . The moduli stack $\mathfrak{M}_\sigma^{\text{ss}}(\gamma)$ of σ -semistable objects of class γ is an Artin stack of finite type, and its characteristic function $\bar{\delta}_\sigma^{\text{ss}}(\gamma) \in \text{SF}^{\text{ind}}(\mathfrak{M})$ is a constructible stack function supported on the semistable locus, weighted by the motivic Behrend function $\nu_{\mathfrak{M}}$. Joyce–Song (2012, arXiv:0810.5645) Thm 5.8 constructs an algebra homomorphism (the *Joyce–Song integration map*),

$$I_\sigma : \text{SF}_{\text{alg}}^{\text{ind}}(\mathfrak{M}) \longrightarrow \hat{\mathcal{T}}_\Gamma \otimes_{\mathbb{Z}} \mathbb{Q},$$

from the stack-function Hall algebra (with Behrend weighting) to the completed quantum torus, characterised on generators by

$$I_\sigma(\bar{\delta}_\sigma^{\text{ss}}(\gamma)) = \bar{\Omega}_\sigma(\gamma) \hat{x}_\gamma, \quad \bar{\Omega}_\sigma(\gamma) = \sum_{k|\gamma} \frac{1}{k^2} \Omega_\sigma(\gamma/k),$$

where $\Omega_\sigma(\gamma) \in \mathbb{Q}$ is the motivic BPS invariant and $\bar{\Omega}_\sigma$ is the Joyce–Song “rational” DT invariant (Joyce–Song Def 5.13). The map I_σ is an algebra homomorphism (Joyce–Song Thm 5.8): the Hall product $\bar{\delta}_\sigma^{\text{ss}}(\gamma_1) \star \bar{\delta}_\sigma^{\text{ss}}(\gamma_2)$ on the source (moduli stack of extensions) maps to the quantum-torus product $\hat{x}_{\gamma_1} \hat{x}_{\gamma_2} = \mathbb{L}^{\chi(\gamma_1, \gamma_2)} \hat{x}_{\gamma_1 + \gamma_2}$ on the target.

Chamber-equivariance upgrades the numerical wall-crossing identity to the stack-function level:

COROLLARY 33.6.19 (*Chamber-equivariance of I* (Joyce–Song §6.5, Kontsevich–Soibelman §6.3)). Under a wall-crossing $\sigma_1 \rightarrow \sigma_2$ across wall W , the integration maps satisfy

$$I_{\sigma_2} = \text{Ad}_{U_W} \circ I_{\sigma_1}, \quad U_W = \prod_{\gamma \in V^+}^{\arg Z_{\sigma_1}\text{-ordered}} \Psi(\hat{x}_\gamma)^{\bar{\Omega}_{\sigma_1}(\gamma)} \in \text{Aut}(\hat{\mathcal{T}}_\Gamma), \quad \bar{\Omega}_{\sigma_1}(\gamma) = \sum_{k|\gamma} \frac{1}{k^2} \Omega_{\sigma_1}(\gamma/k),$$

where $V \subset \Gamma$ is the rank-two sublattice whose phases align on W and $\bar{\Omega}_\sigma$ is the Joyce–Song rational DT invariant (Joyce–Song (2012, arXiv:0810.5645) Def. 5.4, Thm. 5.8). Equivalently, after the change of coordinates on $\hat{\mathcal{T}}_\Gamma$ prescribed by Ad_{U_W} , the two chamber images $I_{\sigma_1}(\bar{\delta}_{\sigma_1}^{\text{ss}})$ and $I_{\sigma_2}(\bar{\delta}_{\sigma_2}^{\text{ss}})$ agree as elements of $\hat{\mathcal{T}}_\Gamma$.

The corollary upgrades the numerical wall-crossing identity to a statement at the level of stack functions, and at the level of the target Lie algebra it says that the generators $\hat{x}_\gamma$ transform by an inner automorphism of $\hat{U}(\mathfrak{g}_{\text{BPS}})$.

Seiberg-duality mutation as gluing

MUTATION AT A VERTEX

For Q a quiver with potential (Q, W) and $i \in Q_0$ a vertex with no loops and no 2-cycles, the *Keller–Yang mutation* $\mu_i(Q, W)$ produces a new quiver with potential, related to (Q, W) by a derived equivalence of their cluster categories. Geometrically, mutation-equivalent quivers correspond to Seiberg-dual gauge theories on the same underlying CY_3 , and their Jacobi algebras are Morita-equivalent at the derived level.

Definition 33.6.20 (*Quiver mutation*). The mutation μ_i at vertex i reverses all arrows at i , composes paths through i to introduce new arrows $\alpha\beta$ for each incoming α and outgoing β at i , and removes cancelling 2-cycles. The potential W pulls back with the adjusted arrows, producing $\mu_i W$.

THEOREM 33.6.21 (*Derived equivalence under mutation, Keller–Yang (2011, arXiv:0906.0761) Thm 6.3*). The Ginzburg CY_3 dg-algebras $\Gamma(Q, W)$ and $\Gamma(\mu_i Q, \mu_i W)$ have equivalent derived categories

$$\text{Mut}_i^R: \mathcal{D}^b(\Gamma(Q, W)) \xrightarrow{\sim} \mathcal{D}^b(\Gamma(\mu_i Q, \mu_i W)),$$

the equivalence being the right-mutation functor at the cluster tilting object canonically attached to the quiver. The equivalence restricts to the finite-dimensional derived categories $D_{\text{fd}}^b(\Gamma(Q, W)) \xrightarrow{\sim} D_{\text{fd}}^b(\Gamma(\mu_i Q, \mu_i W))$ of the Jacobi algebras, and commutes with the CY_3 Serre functor $[3]$ (Keller–Yang (2011, arXiv:0906.0761) Thm 6.3).

Remark 33.6.22 (*Restatement of the §33.4 master theorem*). The theorem as stated here is a restatement of the §33.4 master theorem (33.4.14), specialised to the wall-crossing context where the mutation is indexed by the chamber boundary rather than by a choice of tilting object. Both forms rest on Keller–Yang Keller–Yang (2011, arXiv:0906.0761) (arXiv:0906.0761), whose content is the derived-equivalence half of the mutation statement; the cluster-level shadow at K_0 (Derksen–Weyman–Zelevinsky quiver-mutation identity, arXiv:0812.3781) is a numerical consequence, not the primary datum.

MUTATION INDUCES A BIALGEBRA AUTOMORPHISM

The Keller–Yang derived equivalence Mut_i^R induces, by functoriality of the Davison–Meinhardt critical-cohomology construction, a bialgebra automorphism of the CoHA.

THEOREM 33.6.23 (*Mutation-induced bialgebra automorphism*). The right-mutation functor Mut_i^R of 33.6.21 induces, via the functoriality of the critical-cohomology CoHA, a bialgebra automorphism

$$\mu_i^{\mathcal{H}}: \mathcal{H}(Q, W) \xrightarrow{\sim} \mathcal{H}(\mu_i Q, \mu_i W),$$

intertwining the Hall products, the Drinfeld-new coproducts, and the bialgebra pairings (at leading residue). On the quantum-torus image, $\mu_i^{\mathcal{H}}$ acts on generators by

$$\mu_i^{\mathcal{H}}(\hat{x}_{\gamma_j}) = \hat{x}_{\text{FZ}_i(\gamma_j)},$$

where FZ_i is the Fomin–Zelevinsky cluster mutation Fomin–Zelevinsky (2002, math/0104151) at the i -th simple on the Grothendieck lattice, defined in terms of the signed adjacency matrix $B = (b_{ij})$ of the quiver (with $b_{ij} = \#\{\text{arrows } i \rightarrow j\} - \#\{\text{arrows } j \rightarrow i\}$) by $\text{FZ}_i(\gamma_i) = -\gamma_i$ and $\text{FZ}_i(\gamma_j) = \gamma_j + [b_{ji}]_+ \cdot \gamma_i$ for $j \neq i$, where $[x]_+ = \max(x, 0)$. The K_0 -level action is not the naive Weyl reflection on CY_3 (where $\chi(\gamma_i, \gamma_i) = 0$, 33.6.3; cf. also), but the Fomin–Zelevinsky cluster mutation which carries the signed arrow-count information through B ; the lift to the critical CoHA is the Davison–Meinhardt Sym-decomposition pullback along the derived equivalence.

From derived Morita to bialgebra automorphism. The Keller–Yang right-mutation functor Mut_i^R is an equivalence of CY_3 triangulated categories Keller–Yang (2011, arXiv:0906.0761), hence induces an equivalence of moduli stacks $\text{Mut}_i^R: \mathfrak{M}(Q, W) \xrightarrow{\sim} \mathfrak{M}(\mu_i Q, \mu_i W)$ compatible with the Koszul potential ($W \mapsto \mu_i W$ matches the potential pullback on the Jacobi algebra side). Functoriality of critical cohomology $\mathfrak{M} \mapsto H^\bullet(\mathfrak{M}, \phi_W)$ under stack equivalences preserving the Koszul potential produces the isomorphism of critical-cohomology complexes $\mathcal{H}(Q, W) \xrightarrow{\sim} \mathcal{H}(\mu_i Q, \mu_i W)$.

Hall product compatibility: the Hall product is the critical-cohomology pushforward along the moduli stack of extensions $\text{Ext}_{\mathfrak{M}}$, which is preserved by the equivalence Mut_i^R because extensions in $D^b(\text{Jac}(Q, W))$ correspond under derived equivalence to extensions in $D^b(\text{Jac}(\mu_i Q, \mu_i W))$ up to the canonical Koszul sign.

Coproduct compatibility: the Drinfeld-new coproduct $\Delta(e^{(a)}(z)) = e^{(a)}(z) \otimes 1 + \phi^{+, (a)}(z) \otimes e^{(a)}(z)$ pulls back along Mut_i^R to the Drinfeld-new coproduct for the mutated generators because the Cartan currents $\phi^{+, (a)}(z)$ are Serre-duality-derived data and transform under derived equivalence by conjugation $\phi^{+, (a)} \mapsto w \phi^{+, (a)} w^{-1}$ with w the KY tilting element, preserving the coproduct structure.

Bialgebra pairing (leading residue): the Mukai-pairing integration $\int_{\mathfrak{M}} \text{pr}_1^* \cdot \text{pr}_2^* \cdot \phi_W$ is a $\text{Aut}(\mathfrak{M})$ -invariant bilinear form; the equivalence Mut_i^R acts by an $\text{Aut}(\mathfrak{M})$ -element, hence preserves the residue. The Fomin–Zelevinsky cluster mutation FZ_i on $K_0(C)$ is the projection of $\mu_i^{\mathcal{H}}$ to the Grothendieck group; the lift to $\mathcal{H}(C)$ provides the bialgebra-automorphism enhancement. $\square$

Remark 33.6.24 (*Etingof–Kazhdan bialgebra-automorphism identity*). The mutation-induced $\mu_i^{\mathcal{H}}$ is an instance of the more general Etingof–Kazhdan classification of bialgebra automorphisms of a QUE bialgebra [89, §5]: every derived Morita equivalence of CY_3 quiver-with-potential categories descends to a classical bialgebra automorphism of their critical CoHAs, with K_0 -shadow the Fomin–Zelevinsky cluster mutation and BPS-Lie-algebra shadow a piecewise-linear transformation on $\mathfrak{g}_{\text{BPS}}$ (the Weyl reflection when the quiver is Dynkin; the cluster transformation otherwise). This is the mechanism by which the mutation groupoid (Dynkin-ADE: the Weyl group; CY_3 in general: the cluster groupoid) acts on $\mathcal{H}(C)$ by bialgebra automorphisms.

COROLLARY 33.6.25 (*Mutation groupoid in $\text{Aut}_{\text{bialg}}(\mathcal{H}(C))$*). The mutation groupoid, generated by $\{\mu_i^{\mathcal{H}}\}_{i \in Q_0}$, is a subgroupoid of the bialgebra-automorphism groupoid $\text{Aut}_{\text{bialg}}(\mathcal{H}(C))$ for $\mathcal{H}(C) = \mathcal{H}(Q, W)$. Its action on chambers is compatible (via 33.6.40) with the KS wall-crossing cocycle: for chambers Ch_1, Ch_2 related by a sequence of mutations $\mu_{i_1} \cdots \mu_{i_r}$,

$$\mu_{i_r}^{\mathcal{H}} \circ \cdots \circ \mu_{i_1}^{\mathcal{H}} = \text{Ad}_{U_{W_{12}}},$$

where $U_{W_{12}} = \prod_j \Psi(\hat{x}_{\gamma_j})^{\Omega_{12}(\gamma_j)}$ is the KS ordered product across the intermediate walls between Ch_1 and Ch_2 .

CONIFOLD SEIBERG-DUALITY CHAIN: NCDT $\rightarrow$ DT $\rightarrow$ PT

For the resolved conifold $\tilde{Y}$ the stability manifold is four-real-dimensional with three canonical chambers related by Seiberg-duality mutations at the two vertices of the Klebanov–Witten quiver:

THEOREM 33.6.26 (*Conifold three-chamber chain*). *emph(Nagao–Nakajima Nagao–Nakajima (2011, arXiv:0809.2992).)* The stability manifold $\text{Stab}(D^b(\tilde{Y}))$ contains three adjacent chambers

$$\text{Ch}_0 \xleftrightarrow{\mu_0} \text{Ch}_1 \xleftrightarrow{\mu_1} \text{Ch}_2$$

with BPS spectra

- Ch_0 : NCDT (non-commutative Donaldson–Thomas), $\Omega_0(\gamma_0) = \Omega_0(\gamma_1) = 1$, $\Omega_0(k\gamma_0 + \ell\gamma_1) = -1$ for $k, \ell \geq 1$;
- Ch_1 : DT (Donaldson–Thomas), $\Omega_1(\gamma_0) = \Omega_1(\gamma_1) = 1$, $\Omega_1(k(\gamma_0 + \gamma_1)) = -2$ for $k \geq 1$, generating function $Z^{\text{DT}} = \mathcal{M}(-q)^2 \prod_k (1 - Q(-q)^k)^k$;
- Ch_2 : PT (Pandharipande–Thomas), $\Omega_2(\gamma_0) = \Omega_2(\gamma_1) = 1$, $\Omega_2(k(\gamma_0 + \gamma_1)) = -2$ for $k \geq 1$ (same curve BPS count), but phase-ordered differently; generating function $Z^{\text{PT}} = \prod_k (1 - Q(-q)^k)^k$.

The mutations μ_0, μ_1 at the two vertices of the KW quiver induce the bialgebra automorphisms $\mu_0^{\mathcal{H}}, \mu_1^{\mathcal{H}} \in \text{Aut}_{\text{bialg}}(\mathcal{H}(\tilde{Y}))$ realising the three chamber transitions.

Chain-level. Chamber structure is Nagao–Nakajima Nagao–Nakajima (2011, arXiv:0809.2992) and Bridgeland Bridgeland (2011, arXiv:1002.4372) arXiv:1002.4372; NCDT is Szendrői Szendrői (2008, arXiv:0705.3419) arXiv:0705.3419. The DT/PT transform $Z^{\text{DT}}/Z^{\text{PT}} = \mathcal{M}(-q)^2$ is the Behrend-weighted generating function of 0-dimensional subschemes of $\tilde{Y}$ (Bryan–Morrison (2009, arXiv:0812.5007) Thm. 1.1). The induced bialgebra automorphisms are the 33.6.23 instantiation with $i \in \{0, 1\}$ the KW vertices.

Explicitly, μ_0 reverses the arrows $a_{1,2}: 0 \rightarrow 1$ and $b_{1,2}: 1 \rightarrow 0$ at vertex 0, producing the mutated quiver with arrows $a_{1,2}^*: 1 \rightarrow 0$ and $b_{1,2}^*: 0 \rightarrow 1$ plus introduced composites; the KW potential $\mathcal{W}_{\text{con}} = a_1 b_1 a_2 b_2 - a_1 b_2 a_2 b_1$ pulls back to $\mu_0 \mathcal{W}_{\text{con}}$ via the Keller–Yang prescription.

At the Grothendieck-lattice level, the KW B -matrix $b_{ij} = \#\{\text{arrows } i \rightarrow j\} - \#\{\text{arrows } j \rightarrow i\} = 2 - 2 = 0$ is symmetric (both directions carry two arrows); FZ mutation on a symmetric B -matrix fixes the simple roots at the Grothendieck-lattice level: $\text{FZ}_0(\gamma_j) = \gamma_j$ for $j \neq 0$ and $\text{FZ}_0(\gamma_0) = -\gamma_0$ only on the mutated vertex. The non-trivial content of the mutation lives *above* K_0 : at the critical-cohomology level, $\mu_0^{\mathcal{H}}$ exchanges the NCDT and DT Sym-decompositions of $\mathcal{H}(\tilde{Y})$ by permuting the BPS tensor-factors along the Fomin–Zelevinsky cluster exchange. The K_0 -shadow is the identity; the bialgebra-automorphism is non-trivial on $\mathcal{H}(\tilde{Y})$.

Compatibility with chamber-transported pairings (33.6.36): the Cartan currents $H(z) = \phi^{+,(\circ)}(z)$, $K(z) = \phi^{+,(1)}(z)$ are exchanged under the conifold $\mathbb{Z}/2$ -symmetry τ swapping the two vertices; mutation μ_o fixes K and acts on H by the cluster transformation $H(z) \mapsto H(z)^{-1}$ (the FZ inverse on the single mutated coordinate), preserving the leading residue of the pairing. The all-mode preservation remains conjectural at the full-mode level. $\square$

Remark 33.6.27 (Pure mutations on the conifold generate $B_2 \cong \mathbb{Z}$, not B_3). The Klebanov–Witten quiver has $|Q_o| = 2$ vertices. The two mutations $\mu_o^{\mathcal{H}}, \mu_i^{\mathcal{H}} \in \text{Aut}_{\text{bialg}}(\mathcal{H}(\tilde{Y}))$ are involutions on K_o , and their cluster-algebra interaction is the rank-two $\mathcal{A}_1^{(1)}$ -affine story: the product $\mu_o \mu_i$ has infinite order. The subgroup $\langle \mu_o^{\mathcal{H}}, \mu_i^{\mathcal{H}} \rangle \subseteq \text{Aut}_{\text{bialg}}(\mathcal{H}(\tilde{Y}))$ generated by pure mutations is cyclic, $B_{|Q_o|} = B_2 \cong \mathbb{Z}$, on the single generator $\mu_o \mu_i$ (Nagao–Nakajima arXiv:0809.2992). A braid relation $\sigma_1 \sigma_2 \sigma_1 = \sigma_2 \sigma_1 \sigma_2$ defining B_3 requires three strands and cannot arise from two mutation generators alone.

Conjecture 33.6.28 ($B_3 \subseteq \text{Aut}_{\text{bialg}}(\mathcal{H}(\tilde{Y}))$ via mutations and taste shift). The bialgebra-automorphism group $\text{Aut}_{\text{bialg}}(\mathcal{H}(\tilde{Y}))$ contains a subgroup isomorphic to B_3 , generated by the three elements $\{\mu_o^{\mathcal{H}}, \mu_i^{\mathcal{H}}, \tau^{\mathcal{H}}\}$, where $\tau^{\mathcal{H}}$ is the *taste-shift* automorphism induced by the $\mathbb{Z}$ -shift on $D^b(\tilde{Y})$ along the $\text{Aut}^o(\tilde{Y}) = \mathbb{C}^\times$ -rotation of the $\mathbb{P}^1$ zero-section (equivalently, the cyclic generator of the Picard lattice on the $\mathcal{O}_{\mathbb{P}^1}(-1)$ factor). Setting $\sigma_1 = \mu_o^{\mathcal{H}} \tau^{\mathcal{H}}$ and $\sigma_2 = \mu_i^{\mathcal{H}} \tau^{\mathcal{H}}$, the braid relation

$$\sigma_1 \sigma_2 \sigma_1 = \sigma_2 \sigma_1 \sigma_2$$

is conjectured to hold in $\text{Aut}_{\text{bialg}}(\mathcal{H}(\tilde{Y}))$, realising a B_3 -action. The pure-mutation subgroup $\langle \mu_o^{\mathcal{H}}, \mu_i^{\mathcal{H}} \rangle$ is only $B_2 \cong \mathbb{Z}$ (33.6.27); the taste generator $\tau^{\mathcal{H}}$ supplies the third braid generator.

Remark 33.6.29 (Primary source and scope). The conifold quiver is rank-two $\mathcal{A}_1^{(1)}$ -affine; the K_o -level cluster combinatorics is Fomin–Zelevinsky (2002, math/0104151). The lift to a genuine B_3 -action on $\mathcal{H}(\tilde{Y})$ at the critical-cohomology level is open: no published theorem asserts it, and the taste generator $\tau^{\mathcal{H}}$ is the geometric candidate for the third braid generator derived from $\text{Aut}^o(\tilde{Y}) = \mathbb{C}^\times$. Automorphism-compatibility is stated in $\text{Aut}_{\text{bialg}}$ because $\mathcal{H}(\tilde{Y})$ is a bialgebra; antipode compatibility is a statement on the double $D(\mathcal{H}(\tilde{Y})) = Y_{\hat{h}}(\widehat{\mathfrak{gl}}(1|1))$.

WEYL GROUP ACTION ON CHAMBERS

For a simply-laced Dynkin quiver Q , iterated mutations generate the Weyl group $W(Q)$. More generally, for quivers arising from CY_3 via tilting, mutations generate a *mutation groupoid* acting on the space of tilting objects; this groupoid acts on $\text{Stab}(C)$ by permuting chambers. Explicitly:

PROPOSITION 33.6.30 (Mutation action on chambers). The mutation μ_i induces a homeomorphism $\mu_i: \text{Stab}(C) \rightarrow \text{Stab}(C)$ permuting chambers; two chambers Ch_1, Ch_2 lie in the same μ -orbit if and only if the tilting objects T_1, T_2 realising them are related by iterated mutation.

COROLLARY 33.6.31 (Weyl action on chamber lattice). For Q of ADE type with acyclic orientation, the mutation groupoid is exactly $W(Q)$. The action on the chamber lattice matches the reflection action of $W(Q)$ on the root lattice of the associated simple Lie algebra.

CHAMBER-INDEPENDENCE OF THE COHA

The key gluing theorem connects the local (chamber-by-chamber) and global (chamber-free) pictures:

THEOREM 33.6.32 (Chamber-independence of CoHA, Davison–Meinhardt (2020, arXiv:1601.02479) Thm A+B). Let $\mathcal{H}(C)$ denote the Davison–Meinhardt critical CoHA of

a CY_3 category (Thm A). Then $\mathcal{H}(C)$ is canonically independent of the stability condition $\sigma \in \text{Stab}(C)$. The Sym-decomposition (Thm B / integrality) is σ -dependent, but the underlying bialgebra is not: different chambers give *isomorphic* Hall algebras with the isomorphism $\phi_{12}: \mathcal{H}_{\sigma_1}(C) \xrightarrow{\sim} \mathcal{H}_{\sigma_2}(C)$ realised explicitly by the adjoint action of the KS wall-crossing cocycle.

Chain-level sketch via Davison–Meinhardt Thm A+B. The Davison–Meinhardt (2020, arXiv:1601.02479) critical CoHA is $\mathcal{H}(C) := H^\bullet(\mathfrak{M}(C), \phi_W)$, the critical cohomology of the moduli stack of objects with its Koszul potential W induced by the CY_3 pairing. This datum is intrinsic to the dg-structure of C and does not reference any stability condition σ : Davison–Meinhardt Thm A constructs $\mathcal{H}(C)$ directly from (C, W) without choosing σ . What σ furnishes is a *Sym-decomposition* (Davison–Meinhardt Thm B / integrality),

$$\mathcal{H}(C) \cong \bigotimes_{\gamma \in \Gamma^+}^{\arg Z_\sigma(\gamma)\text{-ordered}} \text{Sym}^\bullet(\text{BPS}_\sigma(\gamma) \otimes H^\bullet(\tilde{B}\mathbb{G}_m)),$$

where $\text{BPS}_\sigma(\gamma)$ is the BPS cohomology in charge γ at stability σ and the tensor factor $H^\bullet(\tilde{B}\mathbb{G}_m) = \mathbb{Q}[u]$ records the overall $\mathbb{G}_m$ -equivariant direction. Two chambers σ_1, σ_2 produce distinct σ -ordered Sym-decompositions of the *same* bialgebra $\mathcal{H}(C)$; the KS wall-crossing formula is the algebra isomorphism $\phi_{12}: \mathcal{H}_{\sigma_1}(C) \xrightarrow{\sim} \mathcal{H}_{\sigma_2}(C)$ conjugating one decomposition into the other, realised at the motivic-cohomology level by the adjoint action of the ordered product $\prod_\gamma \Psi(\hat{x}_\gamma)^{\Omega_i(\gamma)}$. The underlying algebra is the same; only its Sym-presentation changes. $\square$

COROLLARY 33.6.33 (*Representations are chamber-parametrised*). While $\mathcal{H}(C)$ is chamber-independent, individual irreducible representations of $\mathcal{H}(C)$ depend on the chamber. A BPS brick $\text{BPS}_\sigma(\gamma)$ is an irreducible $\mathcal{H}(C)$ -module in chamber σ ; its $\mathcal{H}(C)$ -module structure changes under wall-crossing by the KS cocycle.

SHIFTED QUIVER YANGIANS INDEX CHAMBERS

Galakhov–Li–Yamazaki (GLY) Galakhov–Li–Yamazaki (2021, arXiv:2008.07006) Galakhov–Li–Yamazaki (2022, arXiv:2108.10286) constructed the *shifted quiver Yangian* $Y_{\hbar, \zeta}(Q, W)$ associated to a quiver-with-potential (Q, W) and a *shift parameter* $\zeta \in \Gamma^\vee$. The shift parameter precisely records the chamber data:

THEOREM 33.6.34 (*Shifted quiver Yangian indexes chambers, GLY*). Let $\sigma \in \text{Stab}(C)$ lie in chamber Ch_σ . Associated to σ is a shift $\zeta_\sigma \in \Gamma^\vee$, and the corresponding representation-theoretic CoHA-image is the shifted quiver Yangian $Y_{\hbar, \zeta_\sigma}(Q, W)$. Wall-crossing changes ζ by the KS- Ψ -shift; the abstract Yangian $Y_{\hbar, \zeta}(Q, W)$ at generic ζ is chamber-independent, but the *representation at a specific BPS spectrum* is ζ_σ -dependent.

The shift parameter is thus a *local coordinate on the chamber lattice*; the shifted Yangian provides a concrete parametrised algebra whose specialisation at ζ_σ realises the BPS-brick module of chamber σ .

Joyce–Song integration and chamber-invariance of the bialgebra pairing

THE POSITIVE-HALF BIALGEBRA AND ITS DRINFELD DOUBLE

The critical CoHA $\mathcal{H}(C)$ on a CY_3 category is a $\mathbb{Z}_2$ -graded *associative bialgebra* in super-vector spaces over $\mathbb{Q}((\hbar))$. Its four structure maps

$$\mu: \mathcal{H}(C) \otimes \mathcal{H}(C) \rightarrow \mathcal{H}(C), \quad \iota: \mathbb{Q} \rightarrow \mathcal{H}(C), \quad \Delta: \mathcal{H}(C) \rightarrow \mathcal{H}(C) \otimes \mathcal{H}(C), \quad \epsilon: \mathcal{H}(C) \rightarrow \mathbb{Q},$$

are the Davison–Meinhardt Hall product, the vacuum inclusion, the Drinfeld–new coproduct $\Delta(e^{(a)}(z)) = e^{(a)}(z) \otimes 1 + \phi^{+, (a)}(z) \otimes e^{(a)}(z)$, and the standard augmentation. An antipode S on $\mathcal{H}(C)$ itself is obstructed: $\mathcal{H}(C)$ is the positive half of a larger Hopf-algebraic completion and satisfies the bialgebra axioms without the Hopf axiom. The antipode is installed only after passage to the Drinfeld double

$$D(\mathcal{H}(C)) = \mathcal{H}(C) \otimes_{\mathcal{H}^0} \mathcal{H}(C)^{\text{op}, \text{cop}},$$

paired with the negative-half shadow $\mathcal{H}(C)^{\text{op}, \text{cop}}$ along the bialgebra pairing below. Etingof–Kazhdan [89, Prop. 3.4] derive the double’s antipode from a non-degenerate bialgebra pairing: S is the unique $\mathbb{Q}((\hbar))$ -linear map on $D(\mathcal{H})$ intertwining the pairing of $\mathcal{H}$ with $\mathcal{H}^{\text{op}, \text{cop}}$, characterised by $\mu \circ (S \otimes \text{id}) \circ \Delta = \iota \circ \epsilon$.

The bilinear form the chamber-invariance statement tracks is therefore a *bialgebra pairing*

$$(-, -)_{\mathcal{H}}: \mathcal{H}(C) \otimes \mathcal{H}(C) \longrightarrow \mathbb{Q}((\hbar)),$$

in the Etingof–Kazhdan sense [89, §3]: bilinear, compatible with μ and Δ by $(\xi\eta, \zeta)_{\mathcal{H}} = (\xi \otimes \eta, \Delta\zeta)_{\mathcal{H}}$, and non-degenerate on each K_0 -graded piece. Antipode-compatibility $(S\xi, \eta)_{\mathcal{H}} = (\xi, S\eta)_{\mathcal{H}}$ is a statement on the double, not on $\mathcal{H}(C)$. For elements $[E], [F] \in \mathcal{H}(C)$ represented by critical cohomology classes on the moduli stack,

$$([E], [F])_{\mathcal{H}} = \int_{\mathfrak{M}} \text{pr}_1^*[E] \cdot \text{pr}_2^*[F] \cdot \phi_W,$$

where ϕ_W is the vanishing-cycle functor for the Koszul potential W and the integral is the equivariant pushforward to the point. On the conifold, $D(\mathcal{H}(\tilde{Y})) = Y_{\hbar}(\widehat{\mathfrak{gl}}(1|1))$ is the full quantum super–Yangian with antipode $S(e^{(a)}(z)) = -\phi^{+, (a)}(z)^{-1}e^{(a)}(z)\phi^{+, (a)}(z)$; the positive half $\mathcal{H}(\tilde{Y}) = Y_{\hbar}^+(\widehat{\mathfrak{gl}}(1|1))^{\text{con}}$ carries only $(\mu, \iota, \Delta, \epsilon)$.

Remark 33.6.35 (Hopf structure stratified by equivariance). The double $D(\mathcal{H}(C))$ is strict $\mathbb{Z}_2$ -graded Hopf at the rational, trigonometric, and toroidal equivariance strata, by the Etingof–Kazhdan quantisation theorem [89]. At the elliptic stratum the double is quasi-Hopf, carrying the Felder–Jimbo–Konno dynamical associator: the coassociator $\Phi(\lambda) \in D(\mathcal{H}(C))^{\otimes 3}$ depends on a dynamical Cartan parameter $\lambda \in \mathfrak{h}^*$ and satisfies the pentagon up to the Weyl-translation shift $\lambda \mapsto \lambda + h^{(i)}$ on the i -th tensor factor (Felder’s dynamical elliptic R -matrix, Felder (1994, hep-th/9407154); elliptic quantum affine instantiation, Jimbo–Konno (1997, q-alg/9610013)). Chamber-invariance in this section concerns the bialgebra $\mathcal{H}(C)$ and $(-, -)_{\mathcal{H}}$; the stratum-dependent (quasi-)Hopf structure of $D(\mathcal{H}(C))$ is its downstream consequence.

CHAMBER-INVARIANCE OF THE BIALGEBRA PAIRING

Decomposing along the K_0 -grading, the bialgebra pairing splits into homogeneous residues

$$c_{ab}(m, n) = (e_m^{(a)}, f_n^{(b)})_{\mathcal{H}}, \quad m, n \in \mathbb{Z}, \quad (a, b) \in I \times I,$$

where $m + n$ tracks the K_0 -degree sum. Chamber-invariance stratifies: the leading residue ($m + n = 0$, K_0 -orthogonality regime) is preserved by every wall-crossing automorphism as a theorem; propagation to all modes is conjectural.

THEOREM 33.6.36 (*Residue-level chamber-invariance of $(-, -)_{\mathcal{H}}$, Etingof–Kazhdan*). Let $u = U_W \in \hat{\mathcal{T}}_{\Gamma} \subset \mathcal{H}(C)$ be the wall-crossing element of 33.6.32. On each leading-residue matrix element $c_{ab}(m, n)$ with $m + n = 0$ (i.e. on the K_0 -diagonal),

$$(\mathrm{Ad}_u(\xi_m^{(a)}), \mathrm{Ad}_u(\eta_n^{(b)}))_{\mathcal{H}} = (\xi_m^{(a)}, \eta_n^{(b)})_{\mathcal{H}} \quad \text{whenever } m + n = 0 \text{ in } K_0.$$

Consequently the leading-residue coefficients $c_{ab}(0, 0)$ are chamber-free: they depend only on the bialgebra $\mathcal{H}(C)$, not on $\sigma \in \mathrm{Stab}(C)$.

K_0 -orthogonality of α_W corrections. The bialgebra pairing is K_0 -diagonal: $(\xi_\gamma, \eta_{\gamma'})_{\mathcal{H}} = 0$ unless $\gamma + \gamma' = 0$ (Serre-duality complementary charges, 33.6.3). Expand the wall-crossing automorphism as $\mathrm{Ad}_u = \mathrm{id} + \alpha_W$ with correction α_W landing strictly inside the positive cone $V^+ = \mathbb{Z}_{\geq 0}\gamma_1 \oplus \mathbb{Z}_{\geq 0}\gamma_2$ of the rank-two sublattice V through W :

$$\alpha_W(\xi_\alpha) \in \bigoplus_{\substack{k, \ell \geq 0 \\ k + \ell \geq 1}} \mathcal{H}(C)_{\alpha + k\gamma_1 + \ell\gamma_2}.$$

For ξ_α, η_β with $\alpha + \beta = 0$, bilinearity gives

$$(\mathrm{Ad}_u \xi_\alpha, \mathrm{Ad}_u \eta_\beta)_{\mathcal{H}} = (\xi_\alpha, \eta_\beta)_{\mathcal{H}} + (\alpha_W \xi_\alpha, \eta_\beta)_{\mathcal{H}} + (\xi_\alpha, \alpha_W \eta_\beta)_{\mathcal{H}} + (\alpha_W \xi_\alpha, \alpha_W \eta_\beta)_{\mathcal{H}}.$$

The three correction terms pair elements of K_0 -degrees $(\alpha + k\gamma_1 + \ell\gamma_2, \beta)$, $(\alpha, \beta + k'\gamma_1 + \ell'\gamma_2)$, and $(\alpha + k\gamma_1 + \ell\gamma_2, \beta + k'\gamma_1 + \ell'\gamma_2)$ with $(k, \ell) \neq (0, 0)$ or $(k', \ell') \neq (0, 0)$; the total degree sum is strictly positive in V^+ , so K_0 -orthogonality forces each correction term to vanish. Thus $(\mathrm{Ad}_u \xi_\alpha, \mathrm{Ad}_u \eta_\beta)_{\mathcal{H}} = (\xi_\alpha, \eta_\beta)_{\mathcal{H}}$ on the K_0 -diagonal. The identity transports from $\hat{\mathcal{T}}_{\Gamma}$ to $\mathcal{H}(C)$ along the Davison–Meinhardt critical-cohomology lift: the Sym-decomposition is natural in σ and the projection $\mathcal{H}(C) \rightarrow \hat{\mathcal{T}}_{\Gamma}$ commutes with Ad_u on the K_0 -diagonal. Etingof–Kazhdan [89, Prop. 3.4] supplies the classical-limit K_0 -orthogonality; Davison–Meinhardt (2020, arXiv:1601.02479) supplies the critical-cohomology instantiation. $\square$

Conjecture 33.6.37 (*All-mode chamber-invariance, Etingof–Kazhdan + GLY*). *emph(S₅-level conjecture.)* The full bialgebra pairing is chamber-invariant at all mode indices: for every $\xi, \eta \in \mathcal{H}(C)$,

$$(\mathrm{Ad}_{U_W}(\xi), \mathrm{Ad}_{U_W}(\eta))_{\mathcal{H}} = (\xi, \eta)_{\mathcal{H}}.$$

Equivalently, the asymmetric super-trace correction $c_{ab}(m, n) \mapsto c_{ab}(m, n) \cdot (1 + \hbar \cdot c_{ab} \cdot \delta_{m+n, 0})$ with $c_{00} = 0$, $c_{11} = -1$ on $\widehat{\mathfrak{gl}}(1|1)^{\mathrm{con}}$ is preserved under wall-crossing at every mode, including the leading residue.

Remark 33.6.38 (*Why the all-mode statement is conjectural*). The $c_{11} = -1$ asymmetric correction on the odd root’s Killing form is derived from the super-trace sign in the Davison super-shuffle presentation and is consistent with $\widehat{\mathfrak{gl}}(1|1)$ structure; it has *not* been verified against published $Y(\mathfrak{gl}(m|n))$ Hopf pairings (Nazarov 1991, Arnaudon–Crampé–Doikou–Frappat–Ragoucy 2003, Gow 2005, Peng 2011). The wall-crossing-compatibility of the all-mode propagated correction is therefore an S₅ conjecture pending primary-source verification. The residue-level 33.6.36 is established independently via K_0 -orthogonality of the wall-crossing corrections.

Geometric proof of 33.6.36 via Behrend-weighted symmetry. A second derivation of the residue-level statement: the wall-crossing automorphism $\phi_{12} = \text{Ad}_{U_W}$ is inner in $\text{Aut}_{\text{bialg}}(\mathcal{H}(C))$, with $U_W = \prod_{\gamma} \Psi(\hat{x}_{\gamma})^{\tilde{\Omega}_{\sigma_1}(\gamma)} \in \hat{\mathcal{T}}_{\Gamma}$ and $\tilde{\Omega}_{\sigma}$ the rational DT invariants (Joyce–Song (2012, arXiv:0810.5645) §5.2). The Behrend-weighted integration $\int_{\mathfrak{M}} \text{pr}_1^*(-) \cdot \text{pr}_2^*(-) \cdot \phi_W$ computing $(-, -)_{\mathcal{H}}$ is $\text{Aut}(\mathfrak{M})$ -invariant under symmetries of the moduli stack, and the CY_3 property of ϕ_W delivers the symmetry required: the vanishing-cycle sheaf ϕ_W for a CY_3 Koszul potential carries a canonical self-duality (Brav–Bussi–Dupont–Joyce–Szendrői, arXiv:1211.3259), which combined with K_0 -grading preservation forces $(\text{Ad}_u \xi, \text{Ad}_u \eta)_{\mathcal{H}} = (\xi, \eta)_{\mathcal{H}}$ on K_0 -complementary charges. The argument extends to higher modes under 33.6.37. $\square$

COROLLARY 33.6.39 (*Bialgebra Hilbert series is chamber-independent*). The Hilbert series $\sum_{\gamma} \dim \mathcal{H}^{\gamma}(C) \cdot \hat{x}_{\gamma}$ has chamber-independent coefficients, and the generating function of leading-residue pairing values $([E], [E])_{\mathcal{H}}|_{\text{res}}$ on any fixed basis is chamber-invariant. The all-mode generating function is chamber-invariant conditional on 33.6.37.

JOYCE–SONG INTEGRATION MAP IS CHAMBER-EQUIVARIANT

The Joyce–Song integration map 33.6.18 upgrades the numerical wall-crossing relation 33.6.15 to a statement at the level of stack functions; at the bialgebra level it is the chamber-equivariance statement:

THEOREM 33.6.40 (*Joyce–Song Thm 5.8 chamber-equivariance, bialgebra form*). For any wall-crossing $\sigma_1 \rightarrow \sigma_2$ across wall W ,

$$I_{\sigma_2} = \text{Ad}_{U_W} \circ I_{\sigma_1}, \quad U_W = \prod_{\gamma \in V^+}^{\arg Z_{\sigma_1}\text{-ordered}} \Psi(\hat{x}_{\gamma})^{\tilde{\Omega}_{\sigma_1}(\gamma)}, \quad \tilde{\Omega}_{\sigma_1}(\gamma) = \sum_{k|\gamma} \frac{1}{k^2} \Omega_{\sigma_1}(\gamma/k),$$

as algebra homomorphisms from the stack-function Hall algebra to the completed quantum torus; the exponent is the Joyce–Song rational DT invariant, not the integer Ω . Three assertions compose:

- (i) (*Joyce–Song (2012, arXiv:0810.5645) Thm 5.8*) I_{σ} is an algebra homomorphism for every σ , and the identity $I_{\sigma_2} = \text{Ad}_{U_W} \circ I_{\sigma_1}$ holds on generators.
- (ii) (*Kontsevich–Soibelman [235, §6.3]*) $U_W \in \text{Aut}_{\text{bialg}}(\hat{\mathcal{T}}_{\Gamma})$ is a bialgebra automorphism (not merely an algebra automorphism) of the completed quantum torus.
- (iii) (*Davison–Meinhardt (2020, arXiv:1601.02479) Thm A+B*) The commutative triangle of (i) and (ii) lifts from the K_0 -graded quotient $\hat{\mathcal{T}}_{\Gamma}$ to the full critical CoHA $\mathcal{H}(C)$ via the Sym-decomposition, preserving the bialgebra structure pointwise in each K_0 -degree.

The composite is the statement that the ordered product $U_W = \prod \Psi(\hat{x}_{\gamma})^{\tilde{\Omega}_{\sigma_1}(\gamma)}$ is the explicit bialgebra-automorphism witness of the chamber change $\sigma_1 \rightarrow \sigma_2$; the rational-DT exponent $\tilde{\Omega}$ absorbs the multicover strict-semistability corrections (Joyce–Song (2012, arXiv:0810.5645) §5.2, Def. 5.4).

Structural. (i) is Joyce–Song (2012, arXiv:0810.5645): the Hall product $\tilde{\delta}_{\sigma}^{\text{ss}}(\gamma_1) \star \tilde{\delta}_{\sigma}^{\text{ss}}(\gamma_2)$ on the stack-function side maps to $\tilde{\Omega}_{\sigma}(\gamma_1) \tilde{\Omega}_{\sigma}(\gamma_2) \hat{x}_{\gamma_1} \hat{x}_{\gamma_2} = \mathbb{L}^{\chi(\gamma_1, \gamma_2)} \tilde{\Omega}_{\sigma}(\gamma_1) \tilde{\Omega}_{\sigma}(\gamma_2) \hat{x}_{\gamma_1 + \gamma_2}$ on the quantum-torus side, compatibly with the Behrend-weighted integration.

(ii) is the observation that each $\Psi(\hat{x}_{\gamma})$ is a bialgebra automorphism of $\hat{\mathcal{T}}_{\Gamma}$: it preserves the coproduct $\Delta(\hat{x}_{\gamma}) = \hat{x}_{\gamma} \otimes \hat{x}_{\gamma}$ (grouplike) and intertwines the Euler-form-twisted multiplication, a direct verification on generators using the pentagon identity 33.6.13. Products of bialgebra automorphisms are bialgebra automorphisms; hence $U_W \in \text{Aut}_{\text{bialg}}(\hat{\mathcal{T}}_{\Gamma})$.

(iii) is the critical-cohomology upgrade. Davison–Meinhardt (2020, arXiv:1601.02479) show that the Sym-decomposition $\mathcal{H}(C) \cong \bigotimes \text{Sym}^\bullet(\text{BPS}_\sigma \otimes H^\bullet(\tilde{B}\mathbb{G}_m))$ is natural in σ : different chambers permute the tensor factors, and the chamber-isomorphism ϕ_{12} of 33.6.32 intertwines the two Sym-decompositions. The induced map on K_0 -quotients is exactly Ad_{U_W} ; the lift to $\mathcal{H}(C)$ preserves the bialgebra structure because each Sym factor is a commutative Hopf ideal in the critical-cohomology complex (Davison–Meinhardt integrality).

The three assertions compose to the claim that U_W is the explicit bialgebra-automorphism witness: $I_{\sigma_2} = \text{Ad}_{U_W} \circ I_{\sigma_1}$. $\square$

WHAT CHANGES UNDER WALL-CROSSING, AND WHAT DOES NOT

Five items:

- (i) The BPS invariants $\Omega_\sigma(\gamma)$ *change* chamber-by-chamber; this is the content of the wall-crossing formula.
- (ii) The tensor-factor ordering in the BPS Sym-decomposition of $\mathcal{H}(C)$ *changes*;
- (iii) The isomorphism class of the bialgebra $\mathcal{H}(C)$ *does not change*;
- (iv) The leading-residue bialgebra pairing $(-, -)_\mathcal{H}|_{\text{res}}$ *does not change* numerically (theorem);
- (v) The all-mode bialgebra pairing is chamber-invariant under 33.6.37 (conjecture).

Items (3) and (4) state: the bialgebra $\mathcal{H}(C)$ together with its leading-residue pairing is a chamber-free invariant of the CY_3 category. Item (5) extends chamber-invariance of the pairing to all modes conditional on 33.6.37. The KS wall-crossing cocycle is the explicit bialgebra-automorphism witness that glues the chamber-by-chamber *presentations* of $\mathcal{H}(C)$ into a single bialgebra; the Joyce–Song integration map 33.6.40 is the concrete chain-level formula. The Drinfeld-double antipode is installed downstream (33.6.35), outside the chamber-gluing datum.

Stratum-independence

Unlike the gluing modes of Parts II–V (toric charts, McKay orbifolds, derived-Morita tilting, factorisation-homology assembly), wall-crossing gluing *does not rely on the four-stratum taxonomy*. The KS quantum torus and the Joyce–Song map are intrinsic to any CY_3 category with a stability condition, regardless of whether the underlying geometry is:

- toric (Stratum i): wall-crossing chambers stratify the Kähler cone, and the KS- Ψ -cocycle matches the GLY bond-factor cocycle of 33.2;
- automorphism-equivariant (Stratum ii): the automorphism group acts on $\text{Stab}(C)$ and permutes chambers; the chamber-quotient is preserved;
- orbifold-inertia (Stratum iii): each conjugacy-class component of the inertia stack has its own stability manifold, and wall-crossing within each component produces its own KS cocycle;
- lattice-polarised (Stratum iv): the Gritsenko–Borcherds-lift automorphic form produces generating functions of the same chamber-dependent BPS data; wall-crossing is a modular cocycle on the Kuga–Satake period domain.

In every case the Čech-cocycle structure is the same: chambers index local charts; wall-crossing formulas provide transition maps; the BPS spectrum is globally a section of the chamber sheaf.

Remark 33.6.41 (Relationship to the motivic KS conjecture). The content of 33.6.15 is one-half of the Kontsevich–Soibelman integrality conjecture; the other half, that the motivic BPS series factorises across

the universal Pochhammer product, is now a theorem of Davison–Meinhardt in the critical-cohomology category. Together they give the full gluing picture: chamber-by-chamber local data, motivic wall-crossing cocycle, and global chamber-free algebra, all at the chain level.

Worked example: the conifold

To demonstrate the formalism at chain level, we work out the wall-crossing structure for the resolved conifold $\tilde{Y} = \text{Tot}(\mathcal{O}_{\mathbb{P}^1}(-1) \oplus \mathcal{O}_{\mathbb{P}^1}(-1))$.

CHARGE LATTICE AND EULER FORM

The derived category $D^b(\tilde{Y})$ admits a Nagao–Nakajima / Szendrői NCCR Szendrői (2008, arXiv:0705.3419) presenting it as $D^b(\text{mod-Jac}(Q_{\text{con}}, W_{\text{con}}))$ where Q_{con} is the two-vertex Klebanov–Witten quiver with arrows $a_{1,2}: 0 \rightarrow 1$, $b_{1,2}: 1 \rightarrow 0$ and potential $W_{\text{con}} = a_1 b_1 a_2 b_2 - a_1 b_2 a_2 b_1$. The charge lattice is $\Gamma = K_0(D^b(\tilde{Y})) \cong \mathbb{Z}^2$ generated by simples $\gamma_0 = [S_0]$, $\gamma_1 = [S_1]$ of the two vertices. The CY_3 Jacobi-algebra Ext-pattern between distinct simples reads $\dim \text{Ext}^0(S_i, S_j) = 0 = \dim \text{Ext}^3(S_i, S_j)$ for $i \neq j$, while $\dim \text{Ext}^1(S_i, S_j) = \#\{\text{arrows } i \rightarrow j\} = 2$ and $\dim \text{Ext}^2(S_i, S_j) = \dim \text{Ext}^1(S_j, S_i) = 2$ by CY_3 Serre duality. The Euler pairing is therefore

$$\chi(\gamma_0, \gamma_1) = 0 - 2 + 2 - 0 = 0, \quad \chi(\gamma_i, \gamma_i) = 1 - 0 + 0 - 1 = 0.$$

The Euler form vanishes identically on Γ : the symmetric contribution from Ext^1 and Ext^2 cancels, and the diagonal vanishes by CY_3 antisymmetry (33.6.3). The skew-Euler form is $\langle \gamma_0, \gamma_1 \rangle = 0$ and the quantum torus generators strictly commute,

$$\hat{x}_{\gamma_0} \hat{x}_{\gamma_1} = \hat{x}_{\gamma_0 + \gamma_1} = \hat{x}_{\gamma_1} \hat{x}_{\gamma_0},$$

for the K_0 -only charge lattice. Non-commutativity on the conifold enters only when the lattice is enlarged to include the Chern-character refinements $[\mathcal{O}_{\text{pt}}] = \gamma_0 + \gamma_1$ and $[\mathcal{O}_{\mathbb{P}^1}(-1)]$ whose pairing with the simples generates the non-trivial commutators; the motivic non-commutativity in the KS wall-crossing is carried by the Chern-character refinement, not the simple-object lattice.

STABILITY CHAMBERS AND DT/PT GENERATING FUNCTIONS

The stability manifold $\text{Stab}(D^b(\tilde{Y}))$ is four-real-dimensional; its chamber structure (Bridgeland Bridgeland (2011, arXiv:1002.4372), Nagao–Nakajima Nagao–Nakajima (2011, arXiv:0809.2992)) is indexed by a discrete family of NCCR tiltings related by mutations. Two canonical chambers:

- **DT chamber:** stable bundle $\mathcal{O}_{\tilde{Y}} \rightarrow \tilde{Y}$ is a generator; generating function

$$Z^{\text{DT}}(\tilde{Y})(q, Q) = M(-q)^2 \prod_{k \geq 1} (1 - Q(-q)^k)^k,$$

where $M(q) = \prod_{k \geq 1} (1 - q^k)^{-k}$ is the MacMahon function (Maulik–Nekrasov–Okounkov–Pandharipande Maulik–Nekrasov–Okounkov–Pandharipande (2006, math/0312059, math/0406092)).

- **PT chamber:** stable Pandharipande–Thomas pairs; generating function $Z^{\text{PT}}(\tilde{Y})(q, Q) = \prod_{k \geq 1} (1 - Q(-q)^k)^k$, the DT/PT transform dropping the MacMahon prefactor $M(-q)^2$.

The DT/PT ratio $Z^{\text{DT}}/Z^{\text{PT}} = M(-q)^2$ is the Behrend-weighted generating function of 0-dimensional subschemes of $\tilde{Y}$ (two copies of $\text{Hilb}^\bullet(\mathbb{C}^3)$, one per conifold chart; Bryan–Morrison (2009, arXiv:0812.5007) Thm. 1.1).

WALL-CROSSING AS PENTAGON IDENTITY

The wall-crossing between DT and PT chambers is the motivic shadow of the pentagon identity 33.6.13. To make this explicit: the DT chamber generates BPS states $\{n\gamma_o + m\gamma_i : n, m \geq 0\}$ with $\Omega^{\text{DT}}(\gamma_o) = \Omega^{\text{DT}}(\gamma_i) = 1$, $\Omega^{\text{DT}}(\gamma_o + \gamma_i) = -2$ (the two curve classes $\mathcal{O}_{\mathbb{P}^1}(-1)$), and $\Omega^{\text{DT}}(k(\gamma_o + \gamma_i)) = -2$ for all $k \geq 1$. The PT chamber has the mutated spectrum with the same $\Omega(\gamma_o + \gamma_i)$ but reorganised phase ordering. The wall-crossing relation reads

$$\prod_{k \geq 1} \Psi(\hat{x}_{k(\gamma_o + \gamma_i)})^{-2k} \cdot \Psi(\hat{x}_{\gamma_i})^1 \cdot \Psi(\hat{x}_{\gamma_o})^1 = \Psi(\hat{x}_{\gamma_o})^1 \cdot \Psi(\hat{x}_{\gamma_i})^1 \cdot \prod_{k \geq 1} \Psi(\hat{x}_{k(\gamma_o + \gamma_i)})^{-2k},$$

which restricts on the sublattice $\mathbb{Z}\gamma_o \oplus \mathbb{Z}\gamma_i$ to a repeated application of the pentagon 33.6.13, one per curve class $k(\gamma_o + \gamma_i)$. Expanding both sides as formal series in $\hat{x}_{\gamma_o}, \hat{x}_{\gamma_i}$ recovers $Z^{\text{DT}} = M(-q)^2 \cdot Z^{\text{PT}}$, matching the MNOP formula.

CHAMBER-FREE COHA AND SHIFTED QUIVER YANGIAN

The chamber-free critical CoHA on the conifold is

$$\mathcal{H}(\tilde{Y}) \cong Y_h^+(\widehat{\mathfrak{gl}}(1|1)),$$

the shifted affine super-Yangian of $\mathfrak{gl}(1|1)$ in the GLY normalisation Galakhov–Li–Yamazaki (2021, arXiv:2008.07006). The two supercharges reflect the two simples γ_o, γ_i ; the $\mathbb{Z}/2$ parity records the two mutation-related tilting presentations. The chamber dependence lives entirely in the shift parameter $\zeta_\sigma \in \Gamma^\vee$, which parametrises which tilting presentation realises the shifted Yangian at σ . The leading-residue bialgebra pairing on $Y_h^+(\widehat{\mathfrak{gl}}(1|1))^{\text{con}}$ takes chamber-invariant numerical values by 33.6.36 (theorem, bialgebra scope; antipode reserved for the Drinfeld double $D(Y^+) = Y_h(\widehat{\mathfrak{gl}}(1|1))$); the all-mode propagation of the asymmetric super-trace correction $c_{11} = -1$ is chamber-invariant conditional on 33.6.37. The DT and PT generating functions differ only by the chamber-dependent prefactor $M(-q)^2$, which is the “ $\mathbb{G}_m$ -equivariant zero-dimensional” factor orthogonal to the bialgebra pairing at leading residue.

Summary and forward pointers

- 33.6: the quantum torus $\mathcal{T}_\Gamma$ encodes the Euler form on the charge lattice; on CY_3 , Serre duality forces Euler antisymmetry, so the torus is motivically non-commutative with commutator $\mathbb{L}^{2\mathcal{K}(\gamma, \gamma')}$; in the classical limit it is the commutative group algebra of Γ .
- 33.6: chambers are local charts of $\text{Stab}(C)$; walls are the codim-one boundaries; the quantum-dilogarithm cocycle $\prod \Psi(\hat{x}_\gamma)^{\Omega(\gamma)}$ provides the Čech-gluing transition maps; the global BPS structure is a class in $\check{H}^1(\text{Stab}(C), \text{Aut}(\hat{\mathcal{T}}_\Gamma))$.
- 33.6: Seiberg duality / quiver mutation is the *quiver-level* gluing automorphism; the mutation groupoid (a Weyl group for ADE) acts on the chamber lattice and lifts through Keller–Yang derived Morita (33.6.21) to a group of bialgebra automorphisms $\mu_i^{\mathcal{H}} \in \text{Aut}_{\text{bialg}}(\mathcal{H}(C))$ (33.6.23); the CoHA is chamber-independent as a bialgebra, chamber data is carried by the shift parameter of the shifted quiver Yangian, and the conifold admits a three-chamber chain $\text{NCDT} \rightarrow \text{DT} \rightarrow \text{PT}$ (33.6.26) with conjectural B_3 -braid lift (33.6.28).
- 33.6: the Joyce–Song integration map realises wall-crossing at the stack-function level, with the chamber-equivariance $I_{\sigma_2} = \text{Ad}_{U_W} \circ I_{\sigma_1}$ and exponent the rational DT invariant $\tilde{\Omega}_{\sigma_i}$. The critical CoHA is an associative bialgebra $(\mu, \iota, \Delta, \epsilon)$ and its leading-residue bialgebra pairing is preserved by

every inner bialgebra automorphism Ad_{U_W} of $\mathcal{H}(C)$ by K_0 -orthogonality of the α_W -corrections (theorem); all-mode chamber-invariance is conditional on 33.6.37. The Drinfeld-double antipode is installed downstream and is strict Hopf at rational/trigonometric/toroidal strata, quasi-Hopf with Felder–Jimbo–Konno dynamical associator at the elliptic stratum.

Soibelman voice. The content of this Part is the motivic gluing cocycle: the BPS spectrum of a CY_3 category is not a chamber-local datum but a Čech-cohomological class on $\mathrm{Stab}(C)$ taking values in $\mathrm{Aut}(\hat{\mathcal{T}}_T)$. Every chamber furnishes a presentation of the same chamber-free algebra $\mathcal{H}(C)$; the wall-crossing automorphisms are the transition functions; the pentagon identity is the local-model cocycle condition at a rank-two wall. Integrality (Kontsevich–Soibelman 2008, Davison–Meinhardt 2020) is the statement that this cohomology class descends to the $\mathbb{G}_m$ -fixed BPS Lie algebra $\mathfrak{g}_{\mathrm{BPS}}$, and its generating function is the motivic refined DT invariant.

§33.7 takes up the lattice-polarised / automorphic gluing, which is the gluing mode specifically adapted to K_3 -type geometries where the Borchers lift organises the chamber-free algebra into a modular form on the Kuga–Satake period domain. The two gluing modes (wall-crossing and automorphic) cooperate rather than compete on $K_3 \times E$: wall-crossing organises the BPS spectrum chamber-by-chamber on Stab , while the Borchers lift Δ_5 organises the same spectrum globally as Fourier coefficients of an automorphic form.

Primary sources cited in this Part. Kontsevich–Soibelman [235] §2.3–6.3 for the quantum torus, the quantum dilogarithm, and the wall-crossing formula. Joyce–Song Joyce–Song (2012, arXiv:0810.5645) Thm 5.8, §6.5 for the integration map I and its chamber-equivariance. Keller–Yang Keller–Yang (2011, arXiv:0906.0761) for mutation-as-derived-equivalence. Galakhov–Li–Yamazaki Galakhov–Li–Yamazaki (2021, arXiv:2008.07006) for shifted quiver Yangians indexing chambers. Davison–Meinhardt Davison–Meinhardt (2020, arXiv:1601.02479) for the chamber-independence of the critical CoHA. All statements in this Part are stated at chain level; the upgrades to $(\infty, 1)$ -categorical functoriality under Φ are treated in the subsequent sections of this chapter.

33.7 LATTICE-POLARISED / AUTOMORPHIC GLUING (STRATUM IV)

The preceding parts assembled CoHAs by Čech, orbifold-McKay, tilting, factorisation-algebra, and wall-crossing cocycles. Each of those cocycles is *geometric*: it lives on the variety X or on a stack quotient of X . §33.7 opens a different register. The gluing datum here does not live on X at all; it lives on the period domain of X . Its Fourier coefficients, read off a single meromorphic Siegel modular form, determine the automorphic/BKM target arithmetic and the Euler or superdimension shadow visible from that target. CoHA multiplication constants require a finite Hall source fixture and a recognition comparison with this shadow. This is the automorphic lane of the gluing atlas, the register on which the Borchers-Monster and $K_3 \times E$ data are read.

The derivation has four parts. The Mukai lattice and the reduced period projection (§33.7). Weak Jacobi forms and the Borchers lift (§33.7). The Gritsenko–Cléry eight-form family and the universal identity $\kappa_{\mathrm{BKM}}(\Phi_N) = c_N(o)/2$ (§33.7). The $\Delta_5 / K_3 \times E$ gluing, which assembles the local Hall–Drinfeld pieces into the global BKM algebra $\mathfrak{g}_{\Delta_5}$ (§33.7).

*The Mukai lattice and the period map*EVEN INTEGRAL COHOMOLOGY OF K_3 AS A LATTICE

Fix a K_3 surface X over $\mathbb{C}$. Its even integral cohomology

$$\tilde{H}(X, \mathbb{Z}) := H^0(X, \mathbb{Z}) \oplus H^2(X, \mathbb{Z}) \oplus H^4(X, \mathbb{Z})$$

has rank $1 + 22 + 1 = 24$. The cup product makes $H^2(X, \mathbb{Z})$ into the K_3 lattice $E_8(-1)^{\oplus 2} \oplus U^{\oplus 3}$ of signature $(3, 19)$, where U denotes the hyperbolic plane $\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$ and $E_8(-1)$ the negative-definite E_8 root lattice. The unit classes $1 \in H^0$ and $[\text{pt}] \in H^4$ contribute a further hyperbolic plane when one pairs them by Poincaré duality. Altogether

$$\tilde{H}(X, \mathbb{Z}) \cong U^{\oplus 4} \oplus E_8(-1)^{\oplus 2} = \Pi_{4,20}.$$

The subscripts $(4, 20)$ record the signature.

The Hodge structure on $\tilde{H}(X, \mathbb{C})$ is not the grading $H^0 \oplus H^2 \oplus H^4$ but the Mukai-enhanced weight-2 Hodge structure

$$\tilde{H}^{2,0}(X) = H^{2,0}(X), \quad \tilde{H}^{1,1}(X) = H^0(X) \oplus H^{1,1}(X) \oplus H^4(X), \quad \tilde{H}^{0,2}(X) = H^{0,2}(X),$$

with $\dim_{\mathbb{C}} \tilde{H}^{2,0} = \dim_{\mathbb{C}} \tilde{H}^{0,2} = 1$ and $\dim_{\mathbb{C}} \tilde{H}^{1,1} = 1 + 20 + 1 = 22$. On real cohomology the Mukai form has signature

$$(1, 1)_{H^0 \oplus H^4} \oplus (2, 0)_{(H^{2,0} \oplus H^{0,2})_{\mathbb{R}}} \oplus (1, 19)_{H^{1,1}_{\mathbb{R}}} = (4, 20).$$

The cohomological Hodge involution fixing $H^0 \oplus H^{1,1} \oplus H^4$ and negating $H^{2,0} \oplus H^{0,2}$ has eigenspaces of signatures $(2, 20)$ and $(2, 0)$. The orthogonal decomposition used by the K_3 Yangian is different: it is the Mukai polarisation

$$\tilde{H}(K_3, \mathbb{R}) = V_+ \oplus V_-, \quad \text{sig}(V_+) = (4, 0), \quad \text{sig}(V_-) = (0, 20),$$

where V_+ is spanned by the Hodge two-plane, the Kähler line, and a positive line in $H^0 \oplus H^4$, while V_- is its Mukai-orthogonal complement. Alternative splits $(22, 2)$ or $(1, 23)$ are not compatible with the Mukai form and the K_3 period.

THE MUKAI PAIRING

Cup product alone does not see the grading $0 + 2 + 4$; it symmetrises between H^0 and H^4 but forgets them. Mukai's observation is that a *sign-twist* on the middle degree yields the correct pairing for Hodge-isometric period geometry. For

$$v = (v_0, v_1, v_2), \quad w = (w_0, w_1, w_2),$$

write $v_0, w_0 \in H^0$, $v_1, w_1 \in H^2$, $v_2, w_2 \in H^4$. The *Mukai pairing* is

$$\langle v, w \rangle_M = v_0 \smile w_2 + v_2 \smile w_0 - v_1 \smile w_1 \tag{33.23}$$

with the minus sign on the middle contraction. Under the identifications $H^0 \cong \mathbb{Z}$, $H^4 \cong \mathbb{Z}$ (via the fundamental class) this is

$$\langle (r, L, s), (r', L', s') \rangle_M = rs' + r's - L \cdot L'.$$

The minus sign is forced by the requirement that the Chern character

$$\mathrm{ch}: K_0(X) \longrightarrow \tilde{H}(X, \mathbb{Q}), \quad \mathrm{ch}([\mathcal{F}]) = (\mathrm{rk} \mathcal{F}, c_1(\mathcal{F}), c_2(\mathcal{F}))$$

turn Euler characteristic $\chi(\mathcal{F}, \mathcal{G}) := \sum_i (-1)^i \dim \mathrm{Ext}^i(\mathcal{F}, \mathcal{G})$ into Mukai pairing on the Mukai vector $v(\mathcal{F}) := \mathrm{ch}(\mathcal{F}) \cdot \sqrt{\mathrm{td}(X)}$ for K_3 with trivial canonical bundle,

$$\chi(\mathcal{F}, \mathcal{G}) = -\langle v(\mathcal{F}), v(\mathcal{G}) \rangle_M.$$

The Riemann–Roch computation is elementary: $\chi = \int_X \mathrm{ch}(\mathcal{F}^\vee \otimes \mathcal{G}) \cdot \mathrm{td}(X)$, expand, and the cross term between $\mathrm{ch}_1(\mathcal{F}^\vee)$ and $\mathrm{ch}_1(\mathcal{G})$ produces the $-L \cdot L'$ summand. That single minus sign distinguishes $\Pi_{4,20}$ from the naive totally split $(3, 21)$ form; it encodes Poincaré duality plus Hirzebruch–Riemann–Roch simultaneously.

THREE-GRADED MUKAI VECTORS AND RANK/ c_1/c_2

A coherent sheaf $\mathcal{F}$ on X carries three primary discrete invariants: its rank $r = \mathrm{rk} \mathcal{F}$, first Chern class $c_1(\mathcal{F}) \in H^2(X, \mathbb{Z})$, and Chern character $\mathrm{ch}_2(\mathcal{F}) = \frac{1}{2}c_1^2 - c_2 \in H^4(X, \mathbb{Z})$. The Mukai vector repackages these into a single element of $\tilde{H}$:

$$v(\mathcal{F}) = \mathrm{ch}(\mathcal{F}) \cdot \sqrt{\mathrm{td}(X)} = (r, c_1, \frac{1}{2}c_1^2 - c_2 + r).$$

The degree-4 component acquires $+r$ from the Todd square root: for K_3 , $c_1(X) = 0$ and $c_2(X) = 24$ give $\mathrm{td}_2(X) = \frac{1}{12}(c_1(X)^2 + c_2(X)) = 2$, whence $\mathrm{td}(X) = 1 + 2[\mathrm{pt}]$ and $\sqrt{\mathrm{td}(X)} = 1 + [\mathrm{pt}]$ (the $[\mathrm{pt}]$ -coefficient of the square root being $\mathrm{td}_2(X)/2 = 1$ since higher-order corrections vanish on a surface). Multiplication by $1 + [\mathrm{pt}]$ shifts the degree-4 Chern slot by the rank r . The *three-graded structure* of $\tilde{H} = H^0 \oplus H^2 \oplus H^4$ is visible in this display: rank sits in the first slot, c_1 in the second, the Todd-shifted $(\frac{1}{2}c_1^2 - c_2 + r)$ in the third. The Mukai pairing (33.23) then computes Euler pairings directly.

KUGA–SATAKE CORRESPONDENCE TO A SHIMURA VARIETY

The period domain of polarised K_3 is the non-compact Hermitian symmetric space

$$\mathcal{D}_{K_3} = \{ \Omega \in \mathbb{P}(H^2(X, \mathbb{C})) : \Omega \cdot \Omega = 0, \Omega \cdot \bar{\Omega} > 0 \}$$

with action of the orthogonal group $O(\Lambda_{K_3})$ of the K_3 lattice. Its dimension is 20, matching $h^{1,1}(X) = 20$.

The *Kuga–Satake construction* sends X ; or more generally, a Hodge structure of K_3 type on a lattice T of signature $(2, n-2)$; to a complex abelian variety $\mathrm{KS}(T)$ with

$$\dim_{\mathbb{C}} \mathrm{KS}(T) = 2^{n-2} \tag{33.24}$$

(Deligne, *La conjecture de Weil pour les surfaces K3*, Invent. Math. 15, 1972, Prop. 4.5) and $\mathrm{End}(\mathrm{KS}(T)) \supset \mathrm{Cl}^+(T)$, the even Clifford algebra. The periods of $\mathrm{KS}(T)$ determine the periods of T : there is a canonical morphism of Shimura data

$$\mathrm{KS}: (\mathrm{SO}(T), \mathcal{D}_T) \hookrightarrow (\mathrm{Sp}_{2^{n-2}}, \mathcal{H}_{2^{n-2}})$$

identifying the K_3 -type period domain $\mathcal{D}_T$ with a sub-locus of the genus- 2^{n-2} Siegel upper half-space. This embeds Hodge-theoretic K_3 data into Shimura-varietal data, opening the door to automorphic forms.

Two specialisations of (33.24) are decisive for this section:

Transcendental K_3 , Picard rank $\rho = 1$. The transcendental lattice has rank $n = 22 - 1 = 21$; (33.24) gives $\dim \mathrm{KS}(X) = 2^{19}$. This is the generic case; the Kuga–Satake target is a 2^{19} -dimensional abelian variety.

Lattice-polarised with a rank-5 $\Lambda^{3,2}$ branch. When the selected Hodge lattice has signature $(2, 3)$, (33.24) gives the full Kuga–Satake abelian variety dimension $2^{5-2} = 8$. The genus-2 object used by Δ_5 is not this full Kuga–Satake variety. It is the reduced spin-factor projection coming from the exceptional isogeny $\mathrm{Sp}_4 \simeq \mathrm{Spin}(2, 3)$, which identifies the corresponding orthogonal period domain with the Siegel upper half-space $\mathcal{H}_2$. This reduced projection is the reason Siegel modular forms of genus 2, and not more exotic modular objects, are the natural automorphic cocycles for the BKM algebra $\mathfrak{g}_{\Delta_5}$.

For the Mukai-enhanced lattice $\mathrm{II}_{4,20}$ the relevant period domain enlarges to

$$\mathcal{D}_{4,20} = \{ \Omega \in \mathbb{P}(\tilde{H}_{\mathbb{C}}) : \langle \Omega, \Omega \rangle_M = 0, \langle \Omega, \bar{\Omega} \rangle_M > 0 \}$$

which is of complex dimension 22. This is the natural home for Bridgeland stability conditions: the positive cone $\{ \Omega : \langle \Omega, \bar{\Omega} \rangle_M > 0 \}$ is precisely where $Z(v) = \langle \Omega, v \rangle_M$ defines a central charge satisfying the support property. The period map to $\mathcal{D}_{4,20}$, modulo the arithmetic group $\mathrm{O}(\mathrm{II}_{4,20})$, is the target of the Borchers lift.

HUMBERT DIVISORS AS POLARISATION STRATA

Inside $\mathcal{A}_2 = \mathcal{H}_2/\mathrm{Sp}_4(\mathbb{Z})$ the *Humbert divisors* $\mathcal{H}_D \subset \mathcal{A}_2$ parametrise abelian surfaces whose endomorphism ring contains an order of discriminant D . The divisor $\mathcal{H}_1$ corresponds to products $E_1 \times E_2$ of elliptic curves; $\mathcal{H}_4$ to $E \times E$ with E having an order-4 endomorphism. Under the reduced spin projection these divisors pull back to sub-loci of the selected K_3 period branch where the Néron–Severi lattice acquires extra classes. The *lattice-polarised* K_3 s of rank- n Néron–Severi live on such Humbert-style loci, and the moduli space $\mathcal{F}_{\Lambda}$ of Λ -polarised K_3 s is an $(20 - \mathrm{rk} \Lambda)$ -dimensional arithmetic quotient of $\mathcal{D}_{K_3}$. It is on these arithmetic quotients that Borchers lifts live.

Borchers lifts

WEAK JACOBI FORMS: THE ELEMENTARY DEFINITION

A *weak Jacobi form* of weight $k \in \mathbb{Z}$ and index $m \in \frac{1}{2}\mathbb{Z}$ is a holomorphic function

$$\phi: \mathcal{H} \times \mathbb{C} \longrightarrow \mathbb{C}, \quad (\tau, z) \longmapsto \phi(\tau, z),$$

satisfying two transformation laws and a Fourier expansion.

Modular law. For $\gamma = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \mathrm{SL}_2(\mathbb{Z})$,

$$\phi\left(\frac{a\tau + b}{c\tau + d}, \frac{z}{c\tau + d}\right) = (c\tau + d)^k e^{2\pi i m c z^2 / (c\tau + d)} \phi(\tau, z).$$

Heisenberg (elliptic) law. For $(\lambda, \mu) \in \mathbb{Z}^2$,

$$\phi(\tau, z + \lambda\tau + \mu) = e^{-2\pi i m(\lambda^2\tau + 2\lambda z)} \phi(\tau, z).$$

Fourier expansion. The double periodicity plus the modular law force a Fourier series

$$\phi(\tau, z) = \sum_{n, \ell} c(n, \ell) q^n y^\ell, \quad q := e^{2\pi i \tau}, \quad y := e^{2\pi i z},$$

where (n, ℓ) runs over $\mathbb{Z} \times \mathbb{Z}$ (resp. $\mathbb{Z} \times (\mathbb{Z} + \frac{1}{2})$ if m is half-integral). A *weak* Jacobi form allows negative n with $4mn - \ell^2 \geq -N$ for some $N \geq 0$; equivalently, the polar part at the cusp is controlled.

The space $J_{k,m}^{\text{weak}}$ is a finite-dimensional $\mathbb{C}$ -vector space, and its structure for small (k, m) is computable by a Riemann–Roch argument on the modular curve; classical references are Eichler–Zagier. For K_3 the critical instance is

$$\phi_{\mathbf{o}, \mathbf{1}}^{K_3} \in J_{\mathbf{o}, \mathbf{1}}^{\text{weak}},$$

a weight-0, index-1 form whose Fourier coefficients compute the elliptic genus of K_3 :

$$\phi_{\mathbf{o}, \mathbf{1}}^{K_3}(\tau, z) = 4 \left[\frac{\theta_2(\tau, z)^2}{\theta_2(\tau, \mathbf{o})^2} + \frac{\theta_3(\tau, z)^2}{\theta_3(\tau, \mathbf{o})^2} + \frac{\theta_4(\tau, z)^2}{\theta_4(\tau, \mathbf{o})^2} \right].$$

The Laurent expansion at the cusp reads

$$\phi_{\mathbf{o}, \mathbf{1}}^{K_3}(\tau, z) = y^{-1} + \mathbf{10} + y + O(q),$$

so the polar discriminant comes from the coefficients $(n, \ell) = (\mathbf{o}, \pm \mathbf{1})$, and the singular-theta constant term is $c_1(\mathbf{o}, \mathbf{o}) = \mathbf{10}$. The Witten index at $y = \mathbf{1}$ is the Euler number $\chi(K_3) = 24$. The constant $c_1(\mathbf{o}, \mathbf{o}) = \mathbf{10}$ is the input to the Borcherds weight formula $k_\Psi = c_\phi(\mathbf{o}, \mathbf{o})/2$, yielding $k_{\Delta_5} = 5$.

THE BORCHERDS PRODUCT FORMULA

The passage from Jacobi form to automorphic form on a bigger orthogonal group is Borcherds’s *singular theta lift*. For a weak Jacobi form $\phi = \sum c(n, \ell) q^n y^\ell$ of index m , the Borcherds lift is the function

$$\Psi_\phi(v) = e^{2\pi i \langle \rho, v \rangle} \prod_{\alpha > 0} (1 - e^{2\pi i \langle \alpha, v \rangle})^{c(|\alpha|^2/2)} \quad (33.25)$$

on a Grassmannian $\mathcal{G}$ attached to a lattice L of signature $(n, 2)$. Unpacking:

- The product runs over positive roots α of an infinite-dimensional root system inside L ; *positive* means lying on a fixed side of a Weyl wall.
- The Weyl vector ρ is determined by ϕ ; its role is to absorb the leading term of the product.
- The exponent $c(|\alpha|^2/2)$ is a Fourier coefficient of ϕ ; only the value of $n - \ell^2/(4m)$, i.e. $|\alpha|^2/2$, enters.
- The product converges in a neighbourhood of the cusp; the singular theta lift extends it meromorphically to the full Hermitian symmetric domain.

The key fact is Borcherds’s *automorphy theorem* (Borcherds, *The singular theta correspondence and automorphic forms*, arXiv:alg-geom/9609022 = *Invent. Math.* 132 (1998), Theorem 13.3): Ψ_ϕ is a meromorphic automorphic form of weight k_Ψ on $O^+(L)$, with divisor supported on Heegner divisors (rational quadratic divisors of $\mathcal{G}$) and order of zero/pole along each Heegner divisor determined by the principal-part Fourier coefficients of ϕ . The weight is

$$k_\Psi = \frac{1}{2} c_\phi(\mathbf{o}, \mathbf{o}), \quad (33.26)$$

where $c_\phi(\mathbf{o}, \mathbf{o})$ is the cusp constant term of the vector-valued input at the principal $\mathbf{o}$ -dimensional cusp. In the Borcherds theta-decomposition $\phi(\tau, z) = \sum_\gamma f_\gamma(\tau) \theta_\gamma(\tau, z)$ of a Jacobi form of index m into a vector-valued form (f_γ) on $L^\vee/L$ with $|L^\vee/L| = 2m$ components, $c_\phi(\mathbf{o}, \mathbf{o})$ equals the coefficient of q^0 in the zero-component f_0 ; this is the input to Theorem 13.3 in its vector-valued statement. Theorem 10.1 of the same paper gives the singular-theta product and its automorphy. The weight formula (33.26) is Theorem 13.3. This is the direct source of the $\kappa_{\text{BKM}}(\Phi_N) = c_N(\mathbf{o}, \mathbf{o})/2$ identity we pursue below.

MODULAR COVARIANCE UNDER $O(\Pi_{n,2})$

The lift Ψ_ϕ transforms under the arithmetic subgroup

$$O^+(\Pi_{n,2}) \subset O(\Pi_{n,2})$$

of the lattice of signature $(n, 2)$, with a specified character (typically trivial modulo a cover, detailed for each ϕ). For our purposes $n = 2$ (the unnormalised Igusa square $\Phi_{10}^{\text{un}} = \Delta_5^2$ on the $\Pi_{2,2}$ boundary) and the discriminant-two paramodular lattice $\Lambda^{3,2}$ of Gritsenko's Δ_5 are decisive. Modular covariance means: the Fourier coefficients of Ψ_ϕ , read in a neighbourhood of any cusp of $\mathcal{D}/O^+$, determine the *same* form globally; equivalently, the BKM root-multiplicity and Euler/superdimension data agree across cusps of the period domain. A Hall-algebra multiplication table is compared with this automorphic table only after choosing a finite source fixture.

AUTOMORPHIC COEFFICIENTS AS BKM TARGET DATA

The gluing statement we extract from all this is concrete. Consider a BKM-type algebra $\mathfrak{g}$ whose denominator identity takes the form

$$\Psi_\phi(v) = \sum_{w \in W} \text{sgn}(w) w \left(e^{2\pi i \langle \rho, v \rangle} \prod_{\alpha > 0}^{\text{real}} (1 - e^{2\pi i \langle \alpha, v \rangle}) \right) \quad (33.27)$$

with Weyl group W acting on positive roots. Expanding both sides of (33.25) = (33.27) and comparing Fourier coefficients determines the denominator-side arithmetic of $\mathfrak{g}$: imaginary-root multiplicities and the superdimension/Euler coefficients of root spaces appear as Fourier coefficients $c_\phi(n, \ell)$ with specific (n, ℓ) . The Cartan matrix, parity conventions, and Serre relations are part of the BKM presentation; they are not recovered as Hall multiplication constants by coefficient projection alone.

For a CoHA-side identification, suppose $\mathfrak{g} = \mathfrak{g}(X)$ is the BKM associated to a CY_3 compactification X with lattice-polarised period (Stratum iv). The CoHA product

$$\mathcal{H}(X) \otimes \mathcal{H}(X) \longrightarrow \mathcal{H}(X)$$

is source-side data. One first fixes a finite Hall source fixture, computes its multiplication constants in that fixture, and then projects to the Euler/superdimension shadow indexed by a rank-2 Cartan-torus direction $v \in \widetilde{H}(X)$. The theorem to prove is equality of that projected table with the automorphic table $c_\phi(n, \ell)$, not an a priori identification of CoHA products with Fourier coefficients. This is the *automorphic cocycle* on the period side: CoHA locally looks like a shuffle algebra on each lattice cusp; globally it is compared with the Borchers-lifted target, and the target data are the Fourier coefficients of Ψ_ϕ . The explicit chain-level statement, for the $K_3 \times E$ case, is the content of §33.7.

The Gritsenko–Cléry eight-form family

TWO SCOPES OF THE BORCHERS IDENTITY

Write $J_{o,m}^{\text{weak}}$ for the space of weight- o , index- m weak Jacobi forms. Two indexings of the Gritsenko–Cléry classification recur in the literature, enumerating distinct scopes of the universal identity $\kappa_{\text{BKM}}(\Phi_N) = c_N(o, o)/2$.

Scope (A): CHL ladder. At the integer levels

$$N \in \{1, 2, 3, 4, 6\},$$

cyclic $\mathbb{Z}/N$ symplectic orbifolds of $K_3 \times E$ (Chaudhuri–Hockney–Lykken 1995) admit Borchers products Φ_N whose Jacobi inputs are $\phi_{0,1}^{K_3} \otimes T_N$ for explicit Hecke-type twists T_N . The cusp constant terms tabulate as

$$(c_N(o, o))_{N \in \{1, 2, 3, 4, 6\}} = (10, 8, 6, 4, 2),$$

matching Gritsenko–Nikulin, *Automorphic forms and Lorentzian Kac–Moody algebras, Part II*, arXiv:alg-geom/9504006, Theorem 2.1 (1995), Eguchi–Hikami, arXiv:1104.3747 for the $N = 2$ Mathieu-twined entry, and Govindarajan–Krishna, arXiv:0907.1410 for $N \in \{3, 4, 6\}$. The level $N = 5$ is absent: the elliptic curve E carries no automorphism of order 5, so the CHL orbifold construction stops at $N = 6$.

Scope (B): Full Gritsenko–Cléry eight-form atlas. The paramodular-form classification (Gritsenko–Cléry, *The eight-form Gritsenko–Cléry catalogue*, 2013 and 2018) enumerates eight canonical reflective automorphic products by paramodular type:

$$\phi_{0,m} \in J_{0,m}^{\text{weak}}, \quad m \in \{1, 2, 3, 4, 5, 6\}, \quad \phi_{0,1/2}, \phi_{0,3/2}.$$

Indexing the eight forms by their position in the catalogue and denoting the Borchers weights by w_N , the per-form table reads

$$(w_N)_{N=1,\dots,8} = (5, 2, 3, 1, 2, 1/2, 3/2, 1), \quad (c_N(o, o)) = (10, 4, 6, 2, 4, 1, 3, 2),$$

with the per-position identity $w_N = c_N(o, o)/2$ holding verbatim row by row (Gritsenko–Cléry 2013/*J. Reine Angew. Math.* 678 §3). Half-integral entries (at positions 6 and 7) live on double-cover paramodular groups via multiplier systems $v_\eta^3 \times v_H$; no entry is metaplectic and no entry is weight zero.

Two scopes, one identity. The two indexings agree at $N = 1$ (both give $c_1(o, o) = 10$ and $\kappa_{\text{BKM}}(\Delta_5) = 5$) and otherwise enumerate distinct paramodular witnesses. Scope (A) reads the CHL Jacobi input $\phi_{0,1}^{K_3} \otimes T_N$ at $N \in \{2, 3, 4, 6\}$ with constants $(8, 6, 4, 2)$; Scope (B) reads the Gritsenko–Cléry $(t, N; k)$ catalogue at the eight positions above with constants $(4, 6, 2, 4, 1, 3, 2)$ at $N = 2, \dots, 8$. Every invocation of the universal formula $\kappa_{\text{BKM}}(\Phi_N) = c_N(o, o)/2$ must name which scope.

THE UNIVERSAL IDENTITY $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2$

Each Jacobi input in either scope has a Borchers-style lift Φ_N to the appropriate paramodular group, with multiplier system when the weight is half-integral. The lift Φ_N has weight

$$k_{\Phi_N} = \frac{1}{2} c_N(o, o)$$

by the Borchers automorphy theorem from §33.7. Identifying this weight with the Cartan–Killing invariant of the associated BKM algebra gives

$$\kappa_{\text{BKM}}(\Phi_N) = \frac{1}{2} c_N(o, o) \tag{33.28}$$

in both scopes. Numerical witnesses:

$$\text{Scope (A, CHL): } (\kappa_{\text{BKM}}(\Phi_N))_{N \in \{1, 2, 3, 4, 6\}} = (5, 4, 3, 2, 1),$$

via the Gritsenko–Nikulin 1995 Pt II Thm 2.1 CHL ladder;

$$\text{Scope (B, GC atlas): } (w_N)_{N=1,\dots,8} = (5, 2, 3, 1, 2, 1/2, 3/2, 1),$$

via Gritsenko–Cléry 2013 §3.

The universality of (33.28) is that *one* extraction rule; weight equals half the cusp constant term of the Jacobi input; governs all eight forms across both scopes. The scope declares which Jacobi input $\phi_{o,N}$ is being lifted; the extraction rule is the same.

COVER GROUP STRATIFICATION

The eight-form family stratifies by the arithmetic of the multiplier:

weight type	automorphic datum
integral, $k \in \mathbb{Z}_{\geq 1}$	$\Gamma_t(N)^+ \subset \mathrm{Sp}_2(\mathbb{Q})$
half-integral, $k \in \mathbb{Z} + \frac{1}{2}$	$\Gamma_t(N)^+$ with multiplier $v_\eta^3 \times v_H$

There is no weight-0 form, no weight-1/4 form, and no double-metaplectic cover in the Gritsenko–Cléry catalogue. The integer-weight forms live on paramodular subgroups and their normal extensions. The two half-integral forms, of weights $\frac{1}{2}$ and $\frac{3}{2}$, are holomorphic Siegel modular forms with multiplier systems of orders 8 and 4.

EACH FORM IS A GLUING DATUM

Take Φ_N fixed. The Borcherds product formula (33.25) expresses Φ_N as a product over positive roots of a BKM algebra $\mathfrak{g}_N$. The Cartan of $\mathfrak{g}_N$ is the Mukai lattice of a specific CY_3 geometry X_N : for $N = 1$, $X_1 = K_3 \times E$ as elaborated below; for $N = 2, 3, 4, 6$, the CY_3 is the Nikulin–Scheithauer CHL compactification on orbifolds $(K_3 \times T^2)/\mathbb{Z}_N$ with Mukai-type lattice reduction. The *gluing datum* is: Φ_N supplies the automorphic/BKM target table for the positive-root arithmetic of $\mathfrak{g}_N$. A CoHA product on $\mathcal{H}(X_N)$ matches this datum only after a finite Hall source fixture has been chosen, its multiplication constants computed, and their Euler/superdimension projection compared with the Fourier coefficients of Φ_N .

This is the Stratum-(iv) gluing in its most compact form. The local data on each equivariant chart of X_N produces local Hall-algebra pieces; Φ_N is the automorphic recognition target against which their finite-source shadows are compared. Different N give different gluings because different N produce different lattice-polarisations on the period domain.

The Δ_5 and $K_3 \times E$ gluing

FROM $\phi_{o,1}^{K_3}$ TO Δ_5

The K_3 weak Jacobi form $\phi_{o,1}^{K_3}$ introduced in §33.7 is the input to Gritsenko’s lift in the $N = 1$ case. Gritsenko’s construction, refined from Maass’s additive lift, produces a holomorphic *Siegel modular form* $\mathrm{Grit}(\phi)$ of weight $\frac{1}{2}c_\phi(o, o)$ on the genus-2 Siegel upper half-space $\mathcal{H}_2 = \{Z \in \mathcal{M}_{2 \times 2}(\mathbb{C}) : Z = Z^T, \mathrm{Im} Z > 0\}$. For $\phi = \phi_{o,1}^{K_3}$ we have $c_\phi(o, o) = 10$, hence

$$\Delta_5 := \mathrm{Grit}(\phi_{o,1}^{K_3}) \in \mathcal{M}_5(\mathrm{Sp}_4(\mathbb{Z})),$$

a Siegel cusp form of weight 5.

Explicitly, Gritsenko’s formula writes the additive lift as

$$\mathrm{Grit}(\phi)(Z) = \sum_{m \geq 1} (\phi|V_m)(\tau, z) e^{2\pi i m w}, \quad Z = \begin{pmatrix} \tau & z \\ z & w \end{pmatrix} \in \mathcal{H}_2,$$

with $V_m : J_{k,m_0}^{\text{weak}} \rightarrow J_{k,m_0m}^{\text{weak}}$ the m -th Jacobi Hecke operator. This additive lift agrees with the Borcherds multiplicative lift on the common domain by uniqueness of weight-5 Siegel cusp forms of level $\text{Sp}_4(\mathbb{Z})$.

The form Δ_5 is the unique (up to scalar) weight-5 Siegel cusp form of level $\text{Sp}_4(\mathbb{Z})$, vanishing to first order on the diagonal locus $z = 0$ (which is the Humbert divisor $\mathcal{H}_1 \subset \mathcal{A}_2$ of split abelian surfaces $E_1 \times E_2$) and possessing an order-1 zero along each $\text{Sp}_4(\mathbb{Z})$ -translate of this locus. Its multiplicative Borcherds expansion reads

$$\Delta_5(Z) = q^{1/2} r^{1/2} s^{1/2} \prod_{\substack{(n,\ell,m) > 0 \\ 4nm - \ell^2 \geq -1}} (1 - q^n r^\ell s^m)^{C_1(4nm - \ell^2)}, \quad (33.29)$$

with $(q, r, s) = (e^{2\pi i \tau}, e^{2\pi i z}, e^{2\pi i w})$, the triple $(n, \ell, m) > 0$ running over the positive Weyl chamber of the real-simple-root system, and $C_1(D)$ the discriminant-indexed Fourier coefficient of $\phi_{0,1}^{K_3}$. The seed exponent at $D = -1$ is

$$C_1(-1) = 1,$$

extracted from the $q^0 y^{\pm 1}$ coefficients of $\phi_{0,1}^{K_3} = y^{-1} + 10 + y + O(q)$. This seed $C_1(-1) = 1$ is what generates the denominator identity $(1 - q^n r^\ell s^m) \cdots$ at $(n, \ell, m) = (0, \pm 1, 0)$ -type combinations and drives the Weyl-vector triple-product $q^{1/2} r^{1/2} s^{1/2}$ prefactor; it is the arithmetic input that turns the Borcherds product (33.29) into the Weyl–Kac–Borcherds denominator expansion of the BKM superalgebra $\mathfrak{g}_{\Delta_5}$ (Lorgat, arXiv:2007.14218).

THE BKM ALGEBRA $\mathfrak{g}_{\Delta_5}$

The denominator identity for Δ_5 , written in Borcherds-product form (33.25) and in Weyl-sum form (33.27), produces a BKM superalgebra $\mathfrak{g}_{\Delta_5}$ with:

- Cartan subalgebra $\mathfrak{h}_{\Delta_5}$ of rank 3, with real-simple-root Gram matrix $\text{diag}(2) - 2 \cdot (\mathbb{1} - \text{diag}(\mathbb{1}))$ having eigenvalues $(4, 4, -2)$ and hence signature $(2, 1)$ (Lorgat 2020 Lemma 1 and the $\Lambda_{II}^{2,1}$ sublattice of $\Lambda^{3,2}$);
- Real simple roots $\{\delta_1, \delta_2, \delta_3\}$ forming an $\widetilde{A}_2$ -like Dynkin diagram with off-diagonal entries -2 ;
- Imaginary simple roots with multiplicities read off the Fourier coefficients $C_1(D)$ of $\phi_{0,1}^{K_3}$, enumerated by the discriminant $D = 4nm - \ell^2$ of a positive root $\alpha = (n, \ell, m)$;
- Weight (Borcherds singular-theta normalisation) $\kappa_{\text{BKM}}(\Delta_5) = k_{\Delta_5} = 5$.

The value $5 = c_1(0, 0)/2 = 10/2$ is the exemplar of the universal identity (33.28). First-principles derivation: by Borcherds's theorem the weight of Δ_5 is half the constant term of $\phi_{0,1}^{K_3}$, which in the normalisation $\phi_{0,1}^{K_3}(0, 0) = c_1(0, 0) = 10$ gives 5. On the BKM side the Killing form restricted to the Cartan, together with the twist by the Weyl vector, produces precisely $c_1(0, 0)/2$ as the normalisation integer. The matching is not a coincidence; it is a *structural identity* forced by the Howe-duality pair $(\text{SL}_2, \text{O}(n, 2))$ underlying the theta lift.

THE $K_3 \times E$ GEOMETRY

The CY_3 carrying $\mathfrak{g}_{\Delta_5}$ is

$$X = K_3 \times E,$$

with E an elliptic curve. Its Mukai-enhanced even cohomology is

$$\widetilde{H}(X, \mathbb{Z}) = \widetilde{H}(K_3, \mathbb{Z}) \otimes H^\bullet(E, \mathbb{Z}) = \Pi_{4,20} \otimes (\mathbb{Z} \oplus \mathbb{Z}[1] \oplus \mathbb{Z}),$$

and the Künneth-multiplicative Calabi–Yau Euler invariant is

$$\kappa_{\text{cat}}(X) = \chi(\mathcal{O}_X) = \chi(\mathcal{O}_{K_3}) \cdot \chi(\mathcal{O}_E) = 2 \cdot 0 = 0.$$

(The K_3 fibre value $\chi(\mathcal{O}_{K_3}) = 2$ is *not* the total-space value; Künneth on products is multiplicative, not additive.) The K_3 -fibre Mukai rank 24 remains visible as $\kappa_{\text{fiber}}(X) = 24$ of the K_3 factor.

On the chiral side, Costello–Gaiotto (2, 2) supersymmetric σ -model data on $K_3 \times E$ produces a Heisenberg chiral shadow of central charge 3:

$$\kappa_{\text{ch}}^{\text{Heis}}(K_3 \times E) = 3,$$

computed via the Heisenberg–Mukai specialisation of $\Phi_3^{(\Sigma_2, C)}$ along the E -factor. On the BKM side, the Borcherds lift Δ_5 yields

$$\kappa_{\text{BKM}}(\Delta_5) = 5.$$

Five separate constructions produce five separate $\kappa_\bullet$ invariants, altogether

$$\{0, 0, 3, 5, 24\} = \{\kappa_{\text{cat}}(K_3 \times E), \kappa_{\text{ch}}^{\text{Hodge}}(K_3 \times E), \kappa_{\text{ch}}^{\text{Heis}}, \kappa_{\text{BKM}}(\Delta_5), \kappa_{\text{fiber}}(K_3)\},$$

the first two values 0 entering by Künneth ($\kappa_{\text{cat}}(K_3 \times E) = \chi(\mathcal{O}_{K_3}) \cdot \chi(\mathcal{O}_E) = 2 \cdot 0$) and by Hodge supertrace ($\kappa_{\text{ch}}^{\text{Hodge}} = \sum_q (-1)^q h^{0,q}(K_3 \times E) = 0$ via Serre pairwise cancellation at $d = 3$). No two values arise from a shared formula. They are five *distinct constructions* producing five distinct invariants. The Δ_5 -gluing speaks only to the fourth, $\kappa_{\text{BKM}}(\Delta_5) = 5$.

AUTOMORPHIC COCYCLE: ASSEMBLING LOCAL HALL–DRINFELD PIECES

The local $\mathbb{C}^3$ charts of $K_3 \times E$ (in the elliptic- K_3 presentation, twenty-four I_1 -fibre loci each fibered over E , producing curve-supported local data of Jordan-triple type) each carry a Schiffmann–Vasserot CoHA $Y^+(\widehat{\mathfrak{gl}}_1)$. Locally these are the chart-wise CoHAs of §33.2 of the gluing chapter. Globally they do not glue by a Čech cocycle alone: the curve-supported nature of the $I_1 \times E$ stalks, the $\text{Aut}(K_3 \times E)$ -equivariance, and the Humbert-monodromy action combine to enforce an automorphic gluing constraint.

The *automorphic cocycle* is Δ_5 . The statement, to be established chain-level in the $K_3 \times E$ master-example chapter (§33.8 of the gluing atlas), is as follows.

Conjecture 33.7.1 (Automorphic assembly of $K_3 \times E$ CoHA). Let $\mathcal{H}_\alpha$ denote the local Schiffmann–Vasserot CoHA on the α -th $\mathbb{C}^3$ -chart in the elliptic- K_3 atlas, $\alpha = 1, \dots, 24$. Then the global CoHA $\mathcal{H}(K_3 \times E)$ fits into an exact sequence

$$\bigoplus_{\alpha} \mathcal{H}_{\alpha} \xrightarrow{\partial} \mathcal{H}(K_3 \times E) \xrightarrow{\pi} U(\mathfrak{g}_{\Delta_5})^+ \longrightarrow 0$$

in which the cokernel is the positive half of the universal enveloping algebra of $\mathfrak{g}_{\Delta_5}$, and the gluing cocycle ∂ is recognised by comparing a finite Hall source fixture with the Fourier coefficients $c_1(n, \ell)$ of $\phi_{0,1}^{K_3}$. The Fourier expansion of Δ_5 determines the BKM target arithmetic and the Euler/superdimension shadow of the desired assembly; the multiplication constants of $\mathcal{H}(K_3 \times E)$ are those of the source fixture whose projected table satisfies this recognition criterion.
