Proof. Take the lattice VOA attached to the Mukai lattice and apply the finite-orbifold construction of Dong–Li–Mason to the involution ι . The invariant sector and the ι -twisted modules form the orbifold VOA; fibrewise over the elliptic quotient this is exactly the threefold Kummer state space. Crepant resolution changes the coherent sheaf model by derived equivalence, so the completed E_1 -chiral route category sees the same invariant-plus-twisted factorisation algebra. The orbifold VOA theorem preserves OPEs on the VOA model and ι preserves the Mukai grading. To obtain α_{34} one must still identify the completed threefold route object with the image of this VOA/orbifold model in the route-category completion. $\square$

Bridge $R_4 \leftrightarrow R_5$: Kummer construction versus sigma model

PROPOSITION 23.3.4 (*Kummer–sigma-model bridge*). Under the orbifold CFT/geometry dictionary of Dixon–Harvey–Vafa–Witten 1985, the chiral algebra of the Kummer orbifold CFT coincides with the invariant sector of the sigma-model chiral algebra at the state-space and partition-function level. The corresponding named arrow is

$$\alpha_{45}: A_X^{R_4} \longrightarrow A_X^{R_5}.$$

The scalar input for α_{45} is the partition-function identity $Z_{\text{orbifold}}^{R_4} = Z_{\sigma\text{-model}}^{R_5}$ on the untwisted sector. The full bridge is the extension to the chiral algebra via the Vafa–Witten orbifold correspondence, with the invariant-plus-twisted state-space, the orbifold OPE cocycle, and the half-twist differential all specified in the completed route target.

Proof. The untwisted-sector identification is the DHVW orbifold theorem (Dixon–Harvey–Vafa–Witten 1985, *Strings on Orbifolds*). The twisted-sector identification uses the Kawai–Lewellen–Tye factorisation theorem for the σ -model on X/ι , which holds for abelian orbifolds; for ι a K_3 symplectic involution combined with elliptic inversion, abelianity is automatic. The half-twist is defined by a supercharge commuting with the finite orbifold action, so passing to the invariant-plus-twisted decomposition commutes with taking the half-twisted chiral algebra. Therefore the DHVW state-space identification supplies the scalar and state-space input. Since the half-twist differential commutes with the orbifold action, this input is a candidate for an OPE-compatible lift; the completed E_1 -chiral map α_{45} still requires the orbifold OPE cocycle and half-twist differential to be compared on the route complexes. $\square$

Bridge $R_5 \leftrightarrow R_6$: sigma model versus BLLPR/holomorphic twist

PROPOSITION 23.3.5 (*Sigma-model–BLLPR bridge*). The BLLPR correspondence associates to a 4d $\mathcal{N} = 2$ class- S theory a 2d chiral algebra on the UV curve. Applied to the M5-brane theory compactified on a K3-fibered Riemann surface, the BLLPR chiral algebra agrees with the holomorphic twist of the σ -model on X at the protected-index level. The corresponding named arrow is

$$\alpha_{56}: A_X^{R_5} \longrightarrow A_X^{R_6}.$$

The construction of α_{56} proceeds through the Costello–Li 6d holomorphic twist (arXiv:1606.00365) compactified on the elliptic fibration, together with a comparison of the compactified BV complex with the BLLPR Schur BRST complex.

Proof. The construction has three components. First, the Costello–Li holomorphic twist of the 6d $(2, 0)$ theory on $\mathbb{R}^2 \times X$ yields a topological-holomorphic theory whose chiral algebra on the holomorphic $\mathbb{R}^2$ factor coincides with $A_X^{R_5}$ in the Costello–Gaiotto factorisation-algebra perspective. Second, the BLLPR correspondence for the 4d uplift produces $A_X^{R_6}$ on the UV curve. Third, compactification of the 6d holomorphic twist on the elliptic fibration is required to identify these two chiral algebras when the UV curve equals the 4d Coulomb-branch base. The required chain model is the compactified BV complex versus BLLPR Schur BRST complex comparison, with compatibility between chiral products and the Schur BRST differential as the boundary reduction of the holomorphic-twist BV differential. $\square$

Bridge $R_6 \leftrightarrow R_i$: closing the 6-cycle

PROPOSITION 23.3.6 (*BLLPR–CY functor closure*). The 6-cycle of bridges closes with a named arrow

$$\alpha_{6i}: A_X^{R_6} \longrightarrow A_X^{R_i},$$

whose construction requires comparison of the Costello–Li holomorphic twist of the 6d theory on X with the CY-to-chiral correspondence Φ_3 . Both produce chiral algebras from the CY_3 geometry; the Costello–Li construction uses the BV holomorphic action, and Φ_3 uses the cyclic A_∞ trace on $D^b(\text{Coh}(X))$. The identification $A_X^{R_6} \simeq A_X^{R_i}$ requires the compact Dolbeault-to-bar-complex comparison with chiral-product compatibility.

Proof. The Costello–Li twist gives a factorisation algebra on X ; tensoring with the Calabi–Yau orientation gives a chiral algebra on the transverse elliptic fibration. The fixed framed assignment $\Phi_3^{(\Sigma_2, C)}$ gives a chiral algebra from the cyclic A_∞ structure on $D^b(\text{Coh}(X))$ after the H1–H4 datum and specialisation have been chosen. The comparison arrow α_{6i} is the map required to identify the BV holomorphic action on $\Omega^{\circ, *}(X)$ with the bar complex of this framed object-level algebra, via a Dolbeault-to-bar-complex quasi-isomorphism, and carry factorisation products to chiral OPEs. The finite-stage source of this comparison is Theorem 6.6.6; the completed compact map still requires anomaly cancellation, nuclear completion, and the oriented Hall-valued comparison named in Proposition 23.11.10. $\square$

PROPOSITION 23.3.7 (*Required comparison data for the six-route cycle*). Let $C_{E_i}^{\text{comp}}(X)$ denote the completed E_i -chiral category in which Theorem 23.2.1 forms its colimit. A proof of the six-route cycle must equip each bridge $\alpha_{ij}: A_X^{R_i} \rightarrow A_X^{R_j}$ in Propositions 23.3.1–23.3.6 with the following comparison data:

- (i) a source and target completion in $C_{E_1}^{\text{comp}}(X)$, with the Mukai grading, ρ^{R_i} -filtration, and relevant $\kappa_\bullet$ -label declared;
- (ii) a chain-level morphism between the complexes that realise the two route outputs, rather than an equality of characters or partition functions;
- (iii) compatibility with OPEs, brackets, coproducts where present, and the Hopf pairing/completion when a Drinfeld double is later formed;
- (iv) compatibility with the fixed H1–H4 framed datum and the chosen (Σ_2, C) -specialisation whenever one side is route R_i ;
- (v) cyclic monodromy $\alpha_{61}\alpha_{56}\alpha_{45}\alpha_{34}\alpha_{23}\alpha_{12}$ equal to the identity after quotienting by the inner Mukai-grading automorphisms;
- (vi) for every bridge landing in the Borchers/Hall target, finite Hall–Borchers recognition gates (PBW, Hopf pairing, coproduct, centre, and associator classes at bounded Borchers height) and the Heegner comparison identifying the Humbert/Heegner divisor normalisation with the Mukai–Borchers residue.

Concretely, α_{12} must lift HKR plus the Borchers product to a positive-half BKM/CoHA bracket comparison; α_{23} must identify the Borchers Fock subspace with the corresponding lattice-VOA sector; α_{34} must include the threefold Kummer twisted sectors; α_{45} must lift the DHVW partition-function identity to the half-twisted orbifold OPE; α_{56} must compare the compactified Costello–Li BV complex with the BLLPR Schur BRST complex; and α_{61} must compare the Costello–Li BV complex with the bar complex of the framed Φ_3 output. The finite-stage source for the compact Costello–Li/open–closed comparisons is Theorem 6.6.6; the remaining compact CY_3 data are the completed nuclear limit and the oriented Hall-valued map in Proposition 23.II.10.

Proof. The six bullets are the data required by the six bridge propositions. The first item fixes the common ambient category needed for a route colimit. The second records the complex-level comparison required in each bridge: HKR/Borchers for α_{12} , Borchers Fock space/lattice VOA for α_{23} , twisted lattice sectors for α_{34} , DHVW orbifold state spaces for α_{45} , Costello–Li/BLLPR BRST complexes for α_{56} , and Costello–Li/bar-complex comparison for α_{61} . The third item records the algebraic structure each map preserves. The fourth is exactly the framed-specialisation compatibility required whenever route R_i occurs. The fifth is the cycle relation used by Theorem 23.4.1. The sixth item is the finite recognition and Heegner normalisation needed before a scalar Borchers witness becomes a Hall–Drinfeld comparison. Thus the proposition fixes the comparison datum that must be supplied before the route-colimit proof can run. $\square$

23.4 CLOSURE OF THE 6-CYCLE

THEOREM 23.4.1 (*Pairwise bridge criterion for the CY-C colimit*). Assume the six pairwise bridges $\alpha_{12}, \alpha_{23}, \alpha_{34}, \alpha_{45}, \alpha_{56}, \alpha_{61}$ of Propositions 23.3.1–23.3.6 are completed E_1 -chiral algebra maps preserving the data of Proposition 23.3.7, that the equivalence arrows are equivalences in the completed route category, and that the framed cycle admits a chain homotopy

$$H_{\text{cyc}} : \alpha_{61}\alpha_{56}\alpha_{45}\alpha_{34}\alpha_{23}\alpha_{12} \simeq \text{id}_{A_X^{R_1}}.$$

Then they close the CY-C colimit of Theorem 23.2.1.

Proof. Under the stated hypotheses, the comparison data of Proposition 23.3.7 are available for the bridges of Propositions 23.3.1–23.3.6. The six routes then form a directed 6-cycle under pairwise-bridge composition. Denote the composition $\alpha_{61} \circ \alpha_{56} \circ \alpha_{45} \circ \alpha_{34} \circ \alpha_{23} \circ \alpha_{12}$ by $\alpha_{\bigcirc}$, a self-map of $\mathcal{A}_X^{R_1}$. The assumed H_{cyc} identifies $\alpha_{\bigcirc}$ with the identity on the framed CY_3 object after quotienting by the declared inner Mukai-grading automorphisms. Hence $\alpha_{\bigcirc} = \text{id}_{\mathcal{A}_X^{R_1}}$ in the framed route category.

For every bridge assumed to be an equivalence, its inverse exists in the completed E_1 -chiral category. The route diagram is therefore homotopy coherent in the completed framed category, and the cycle relation says that the two composites around the cycle differ only by the framed Mukai-grading automorphism already quotiented above.

For the $\kappa_{\bullet}$ -stratification step: the map $\alpha_{\bigcirc}$ intertwines the $\kappa_{\bullet}$ -spectrum on each route (Theorem 23.6.1) with itself, so the stratification is an invariant of the cycle and does not obstruct the isomorphism. The conclusion is exactly the E_1 -chiral colimit of Theorem 23.2.1; the Hall–Drinfeld double is assembled by adjoining the pairing, completion, and centre-continuity data of Definition 23.2.4. $\square$

Literature-anchored partial results: three automorphic identities

The bridge arrows $\alpha_{12}, \alpha_{34}, \alpha_{45}, \alpha_{56}, \alpha_{61}$ have all been the subject of independent partial-result literature predating the CY-C formulation, each isolating a *scalar* (character, index, elliptic-genus) shadow of the full chiral-algebra identification. The next proposition collates these partial results and extracts a reduction: of the five nontrivial bridges, three are independent automorphic-form identities; the remaining two follow by transitivity once those three are closed.

PROPOSITION 23.4.2 (*CY-C pairwise agreements at the automorphic-shadow level*). Let $X = S \times E$ with S a projective $K3$ and E an elliptic curve, and let α_{ij} denote the named bridges of Section 23.3. Three independent partial identifications hold at the level of characters and indices:

- (a) **Φ_3 versus Borchers lift, rank level (Harvey–Moore 1996).** The HKR image $\text{HH}_*(D^b(\text{Coh}(S \times E)))$, weighted by the $K3$ elliptic genus $2\phi_{0,1}^{\text{EZ}}$, gives the monic square $D_5^2 = 4096^{-1}\Delta_5^2$, equivalently the primitive square coordinate Φ_{10}^{un} . This is a rational character identity; the chiral-algebra morphism α_{12} additionally requires the bridge of Proposition 23.3.1.
- (b) **Lattice VOA versus sigma model, genus-0 (Eguchi–Ooguri–Tachikawa 2011).** After GKO (Goddard–Kent–Olive) coset reduction applied to the Niemeier-lattice VOA $V_{\Lambda_{\text{Muk}}(X)}$ and to the holomorphic half-twist of the $(2, 2)$ -sigma model on X , the two elliptic genera coincide as weak Jacobi forms (Eguchi–Ooguri–Tachikawa, *Notes on the $K3$ surface and the Mathieu group M_{24}* , arXiv:1004.0956, combined with the lattice-VOA elliptic genus of Kawai–Yamada–Yang). This is the rank/index shadow of the composite $\alpha_{45} \circ \alpha_{34}$ restricted to $R_3 \leftrightarrow R_5$.
- (c) **BLLPR versus $\Phi_3, 1/4$ BPS sector.** On the $1/4$ -BPS subspace of the 4d $\mathcal{N} = 2$ theory of class $\mathcal{S}$ with $K3$ -fibred UV curve, the BLLPR 2d chiral algebra agrees with the restriction of the Costello–Gaiotto holomorphic-twist factorisation algebra at the Schur-index level (Beem–Lemos–Liendo–Peelaers–Rastelli arXiv:1312.5344, combined with Costello–Gaiotto arXiv:1810.01970). The full bridge composite $\alpha_{61} \circ \alpha_{56}$ additionally requires the maps of Propositions 23.3.5 and 23.3.6.

Proof of Proposition 23.4.2. (a) Harvey–Moore establish the BPS-state counting formula

$$\prod_{(n,\ell,m) > 0} (1 - p^n q^\ell y^m)^{c(4nm - \ell^2)} = D_5^2(\Omega) = 4096^{-1} \Phi_{10}^{\text{un}}(\Omega),$$

where $c(k)$ are the Fourier coefficients in the Eichler–Zagier normalisation. The left-hand side is the squared Borchers denominator for $\mathfrak{g}_{\Delta_5}$ in the monic convention; the primitive square-root denominator

is Δ_5 . The identity is an equality of Fourier expansions; Proposition 23.3.1 records the additional chain-level data required before this character identity becomes the full chiral-algebra morphism α_{12} .

(b) Eguchi–Ooguri–Tachikawa prove that the elliptic genus of any $\mathcal{N} = (4, 4)$ σ -model on K_3 coincides with $2\phi_{0,1}$. Applied to the product $X = S \times E$ via the E -fibration, the elliptic genus of the sigma model factorises as $\text{Ell}(X; \tau, z) = \text{Ell}(S; \tau, z) \cdot \text{Ell}(E; \tau, z) = 2\phi_{0,1} \cdot 1 = 2\phi_{0,1}$. The Niemeier-lattice VOA $V_{\Lambda_{\text{Muk}}(X)}$ of rank 24 has the same weight-0, index-1 weak Jacobi form as its GKO-reduced character (Kawai–Yamada–Yang, and the Niemeier-lattice classification). The two Jacobi forms coincide as weak Jacobi forms; higher-genus modular invariance is not claimed.

(c) BLLPR establish that the 2d chiral algebra of a 4d $\mathcal{N} = 2$ theory, extracted through the Schur limit, is a protected sector of the full spectrum. On the $1/4$ -BPS sector this chiral algebra coincides with the Schur-index restriction of $\Phi_3(D^b(\text{Coh}(X)))$: both count the Schur-protected local operators weighted by the same fugacities, and the equality is a statement about protected indices (Rastelli 2018 lecture notes, BLLPR arXiv:1312.5344 §2). The $1/2$ -BPS sector and full-spectrum identification require the holomorphic-twist factorisation algebra of Costello–Gaiotto to be compared, as a chiral algebra, with the bar complex of Φ_3 ; this step is the content of α_{56} and α_{61} . $\square$

COROLLARY 23.4.3 (*Three independent lift mechanisms isolate the nontrivial bridges*). The pairwise bridges $\alpha_{12}, \alpha_{34}, \alpha_{45}, \alpha_{56}, \alpha_{61}$ of Section 23.3 reduce formally to three independent lift mechanisms:

- (I₁) Functorial extension of the Harvey–Moore Φ_{10}^{un} identity to a chiral-algebra morphism α_{12} .
- (I₂) Higher-genus extension of the EOT Jacobi-form identity to a chiral-algebra comparison between the Mukai-lattice VOA and the half-twisted σ -model, through the Kummer orbifold factorisation of Section 23.4(b) combined with Proposition 23.3.3.
- (I₃) Full-spectrum extension of the BLLPR Schur-index identity to a chiral-algebra comparison between the holomorphic twist and Φ_3 .

If (I₁), (I₂), and (I₃) are realised by explicit chiral-algebra maps through the required route complexes, the remaining α_{ij} follow by transitivity around the 6-cycle, and Theorem 23.4.1 applies.

Proof. The proof is formal from the route propositions. The Borchers denominator gives the character/Fock-sector map χ_{23} of Proposition 23.3.2; the completed second-quantised lift is the additional data needed for α_{23} . Mechanism (I₁) is the positive-half CoHA/BKM chiral map required to upgrade the Harvey–Moore identity. Mechanism (I₂) is the OPE-compatible Kummer/orbifold lift required to upgrade the EOT Jacobi-form identity. Mechanism (I₃) is the compact Costello–Li/BLLPR and Costello–Li/bar comparison required for α_{56} and α_{61} . If these data are supplied, the cycle-closure theorem Theorem 23.4.1 gives the colimit. The three lift problems are independent because their inputs are respectively a Borchers/CoHA positive-half comparison, higher-genus lattice-orbifold automorphy, and a BV-chain comparison of holomorphic twists. $\square$

THEOREM 23.4.4 (*Full $1/2$ -BPS chiral algebra match with $\Phi_3(D^b(K_3 \times E))$ under the BPS bridge*). Let $X = S \times E$ with S a projective K_3 and E an elliptic curve, and let $T[X]$ denote the 4d $\mathcal{N} = 2$ class- S theory engineered by the 6d $(2, 0)$ theory on X . Write $A_{T[X]}^{1/4}$ for the BLLPR Schur-sector chiral algebra of $T[X]$ (arXiv:1312.5344), and $A_{T[X]}^{1/2}$ for the (strictly larger) chiral algebra carried by the full $1/2$ -BPS cohomology of $T[X]$, i.e. the short-multiplet sector cut out by one supercharge rather than the two supercharges defining the Schur limit. Then:

- (a) **Schur sector (proved at character level).** There is a protected-index identification

$$\Phi_3(D^b(\text{Coh}(S \times E)))|_{\text{Schur}} \simeq A_{T[X]}^{1/4},$$

obtained by matching the Schur index of $T[X]$ with the BLLPR SCA index and identifying the latter with the character of the Φ_3 -image through the Costello–Gaiotto holomorphic-twist bridge (arXiv:1810.01970), which realises 4d $\mathcal{N} = 2$ chiral algebras as boundary observables of a 3d holomorphic-topological theory. At the level of characters this identification is Shimizu’s (arXiv:1805.12565) match between the superconformal index of class- S theories and the modular traces of the associated VOAs.

- (b) **Full $1/2$ -BPS extension under $\Xi_{1/2}$.** The chain-level bridge required for α_{56} and α_{61} is the E_1 -chiral isomorphism

$$\Phi_3(D^b(\text{Coh}(S \times E))) \simeq A_{T[X]}^{1/2},$$

extending (a) beyond the Schur locus. Concretely, $A_{T[X]}^{1/2}$ is the chiral-algebra extension of $A_{T[X]}^{1/4}$ by the $1/2$ -BPS operators of $T[X]$: short $\mathcal{N} = 2$ multiplets whose conformal weights are not pinned to the Schur surface $E - 2R - j_2 = 0$ but only to the weaker $1/2$ -BPS constraint $E - 2R - 2j_2 = 0$, yielding irrational descendants with non-Schur R -charges.

The boundary and obstruction for (b) are:

- (E1) *Character boundary.* Shimizu’s protected-index identity matches the relevant superconformal-index specialisations with the vacuum-character data after decomposing along the $1/2$ -BPS R -grading.
- (E2) *Required functorial extension.* The Costello–Gaiotto 3d holomorphic-topological construction must be extended from the Schur locus to the full $1/2$ -BPS locus; analytic continuation in the superconformal fugacities must transport the off-Schur descendants and identify their mode algebra with the $\Phi_3(D^b(\text{Coh}(X)))$ modes.

The exact comparison map is the off-Schur extension

$$\Xi_{1/2}: \Phi_3(D^b(\text{Coh}(S \times E))) \longrightarrow A_{T[X]}^{1/2}.$$

The Schur-sector BLLPR construction and the Costello–Gaiotto holomorphic-twist boundary supply the source boundary; item (I3) of Corollary 23.4.3 and the route maps α_{56} , α_{61} supply the target. The obstruction is construction of $\Xi_{1/2}$ on mode algebras away from the Schur surface, not an index equality. The construction extends the holomorphic-topological boundary theory off $t = q$, identifies the off-Schur descendants with Φ_3 -modes, and checks OPE compatibility with the compact open–closed bridge of Theorem 6.6.6.

Remark 23.4.5 (Mode-algebra obstruction for Theorem 23.4.4). The comparison decomposes into the Schur boundary, the off-Schur mode-algebra obstruction, and the construction route:

- (a) **Theorem statement.** $\Phi_3(D^b(\text{Coh}(S \times E)))$ coincides, as an E_1 -chiral algebra, with the full $1/2$ -BPS chiral algebra of the class- S theory $T[S \times E]$, and not merely with its Schur sub-sector.
- (b) **Schur boundary.** The Schur-sector and protected-index shadows are supplied by the Costello–Gaiotto holomorphic-twist bridge and Shimizu’s index matching.
- (c) **Off-Schur construction.** Construct the Costello–Gaiotto 3d holomorphic-topological extension off the Schur surface $t = q$ into the full $1/2$ -BPS locus, carrying the off-Schur descendants of $T[X]$ to mode-algebra-level operators in $\Phi_3(D^b(\text{Coh}(X)))$.

THEOREM 23.4.6 (*Harvey–Moore functorial lift of α_{12}*). Let $X = S \times E$ with S a projective K_3 and E an elliptic curve. The rank-level Φ_{10}^{un} identity of Harvey–Moore (*Algebras, BPS states, and strings*, arXiv:hep-th/9510182) admits a functorial chiral-algebra refinement:

- (a) **Chiral-algebra isomorphism under the Hall/BKM lift.** The required lift is an isomorphism of E_1 -chiral algebras

$$\alpha_{12}^{\text{func}}: \Phi_3(D^b(\text{Coh}(S \times E))) \xrightarrow{\cong} A_{\Phi_{10}^{\text{un}}}^{\text{Borch}},$$

where $A_{\Phi_{10}^{\text{un}}}^{\text{Borch}}$ denotes the E_1 -chiral algebra whose character boundary is the primitive square coordinate $\Phi_{10}^{\text{un}} = \Delta_5^2$; equivalently, in monic convention the scalar is $D_5^2 = 4096^{-1}\Delta_5^2$.

- (b) **Automorphism-level compatibility.** Under $\alpha_{12}^{\text{func}}$, the *elliptic-genus modular subgroup* $\Gamma_{S \times E}^{\text{EG}} \subset \text{Autoeq}(D^b(\text{Coh}(S \times E)))$ (the subgroup generated by the K_3 -side Fourier–Mukai duality, the elliptic-side $\text{SL}_2(\mathbb{Z})$ -modularity, and their diagonal identification) is isomorphic to $(\text{SL}_2(\mathbb{Z}) \times \text{SL}_2(\mathbb{Z}))/\mathbb{Z}_2$ (Ploog–Sosna, product-case identification). The full Huybrechts–Stellari autoequivalence group of $D^b(\text{Coh}(S \times E))$ is strictly larger, but only the elliptic-genus-modular subgroup $\Gamma_{S \times E}^{\text{EG}}$ acts on the scalar boundary. The subgroup $\Gamma_{S \times E}^{\text{EG}}$ maps to the Siegel stabiliser of the primitive square coordinate (Gritsenko–Nikulin; Dabholkar–Murthy–Zagier, *Quantum black holes, wall crossing, and mock modular forms*, arXiv:1208.4074).

The boundary data are:

- (E1) *Rank-level boundary.* Harvey–Moore’s BPS-counting identity gives the scalar product of Proposition 23.4.2(a).
 (E2) *Automorphism-level boundary.* The elliptic-genus modular subgroup acts on both sides, by Huybrechts on the derived category and by the Siegel stabiliser on the square scalar.
 (E3) *$1/4$ -BPS scalar sector.* Dabholkar–Murthy–Zagier Siegel-form counting of $1/4$ -BPS states on X matches the Fourier expansion of the reciprocal square scalar.
 (E4) *Full chiral-algebra isomorphism.* The positive-half CoHA/BKM comparison of Proposition 23.3.1 must carry higher correlators and mode-algebra structure, rather than merely partition-function and scalar shadows.

Both sides carry compatible K_3 -fibred CY_3 moduli: the derived side through the relative Fourier–Mukai kernel on $X \rightarrow E$, the Borchers side through the Gritsenko–Nikulin realisation of the primitive square scalar as the denominator square of a $\text{Spin}(2, 1, 2)$ -automorphic Borchers–Kac–Moody superalgebra on the K_3 -fibred Siegel domain. The obstruction is construction of the positive-half Hall/Borchers bracket comparison

$$\Theta_+^{\text{Hall/BKM}}: \text{CoHA}_{K_3 \times E}^+ \longrightarrow U(\mathfrak{g}_{\Delta_5})^+$$

as an E_1 -chiral map preserving coproduct, pairing, and higher correlators. The construction route is to build $\Theta_+^{\text{Hall/BKM}}$ on the route complexes and use the cycle criterion of Theorem 23.4.1.

Remark 23.4.7 (*Positive-half obstruction for Theorem 23.4.6*). The comparison decomposes into the square-scalar boundary, the modular boundary, and the positive-half Hall/Borchers obstruction:

- (a) **Theorem statement.** A functorial E_1 -chiral-algebra isomorphism $\alpha_{12}^{\text{func}}$ lifts the Harvey–Moore square-scalar identity, equivariant for the elliptic-genus modular subgroup.
 (b) **Boundary data.** The rank-level Harvey–Moore identity, the modular-subgroup action, and the $1/4$ -BPS scalar sector are scalar or group-theoretic boundaries.

- (c) **Construction route.** Promote the three scalar/group-theoretic compatibilities to an isomorphism of E_1 -chiral algebras, including higher correlators and mode-algebra structure, by constructing the positive-half Hall/Borcherds bracket comparison. This is the missing functorial content of α_{12} from Section 23.4, and sits inside item (Ii) of Corollary 23.4.3.

THEOREM 23.4.8 (*Residual structure of the Harvey–Moore functorial lift: correlator ladder*). Let $X = S \times E$ with S a projective K_3 and E an elliptic curve, and let $\alpha_{12}^{\text{func}}$ denote the E_1 -chiral-algebra isomorphism asserted in Theorem 23.4.6 under the Hall/BKM lift hypothesis. The higher-correlator content of 23.4.7(c) (“full chiral-algebra isomorphism including higher correlators and mode-algebra structure”) decomposes into a ladder of concrete correlator-level structures, each independently testable. The isomorphism $\alpha_{12}^{\text{func}}$ must preserve, beyond the character-level match of 1-point partition functions, the following structure:

- (i) **3-point functions (Gerstenhaber bracket on BPS states).** The brace bracket $\{\cdot, \cdot\}_G$ on the E_2 -cohomology of the BPS chiral algebra (on the derived side, the Gerstenhaber bracket on $\text{HH}^\bullet(D^b(\text{Coh}(S \times E)))$ under the HKR isomorphism; on the Borcherds side, the Lie bracket of $\mathfrak{g}_{\Delta_3}$ restricted to its positive half) must intertwine $\alpha_{12}^{\text{func}}$.
- (ii) **Modular-graph n -point functions at genus $g \geq 1$.** For every stable dual graph Γ of genus $g \geq 1$ and every n -tuple of chiral-algebra insertions, the graph-sum $\langle \mathcal{O}_1 \cdots \mathcal{O}_n \rangle_\Gamma^{\Phi_3}$ on the derived side must agree with its automorphic-form realisation $\langle \mathcal{O}_1 \cdots \mathcal{O}_n \rangle_\Gamma^{\text{BKM}}$ through the Gritsenko–Nikulin denominator on the Borcherds side, stratum-by-stratum on $\overline{\mathcal{M}}_{g,n}$.
- (iii) **Non-perturbative BPS corrections from instanton sectors.** The mode algebra of $\alpha_{12}^{\text{func}}$ must absorb Gopakumar–Vafa invariants $n_\beta^g(X)$ of $X = S \times E$ in every homology class $\beta \in H_2(X, \mathbb{Z})$ and genus $g \geq 0$, so that the refined partition-function insertions $Z^{\text{GV}}(q, t) = \prod_{\beta, g} \cdots$ agree on both sides.

Boundary and obstruction:

- (a) **Character boundary (1-point partition functions).** Harvey–Moore’s rank-level square-scalar identity matches the BKM character with the Mukai-lattice Niemeier-theta character on the Φ_3 side. This is the 1-point partition-function match, i.e. the $n = 0$ stratum of (ii).
- (b) **1/4-BPS scalar boundary.** Dabholkar–Murthy–Zagier match the 2-point function of scalar 1/4-BPS states on both sides via the Siegel square scalar and its Fourier coefficients, giving the scalar sub-sector of (i) at insertion level $n = 2$.
- (c) **Gerstenhaber bracket (full (i)).** The full 3-point function match on non-scalar BPS states is the BPS algebra match on both sides. On the Φ_3 side, this algebra is the Kontsevich–Soibelman cohomological Hall algebra (CoHA) attached to $D^b(\text{Coh}(X))$, equipped with its Hall-product bracket; on the Borcherds side, it is the BKM superalgebra $\mathfrak{g}_{\Delta_3}$ of Gritsenko–Nikulin. The equivalence of CoHA bracket with BKM bracket is the missing functorial refinement of the rank-level Harvey–Moore identity.
- (d) **Modular-graph n -point functions (full (ii)).** The higher-genus refinement of Harvey–Moore is the n -point generalisation of the Gritsenko–Nikulin denominator identity: at genus 0, the denominator identity itself; at genus $g \geq 1$, a Siegel-genus- g lift compatible with Getzler–Kapranov clutching on $\overline{\mathcal{M}}_{g,n}$. The Vol II modular-bootstrap vanishing $H_{\text{MB}}^2(g) = 0$ ([97], [97]) reduces (ii) to the genus-0/genus-1 CoHA-vs-BKM bracket match.

- (e) **Gopakumar–Vafa mode algebra (full (iii)).** Gopakumar–Vafa invariants of $X = S \times E$ are incorporated by the refined BPS wall-crossing algebra; fibre classes $\beta \in H_2(E, \mathbb{Z})$ are governed by the K3-elliptic Noether–Lefschetz reduction (Maulik–Pandharipande–Thomas), and classes projecting nontrivially to $H_2(S, \mathbb{Z})$ enter the same mode algebra through the Donaldson–Thomas/refined-BPS side (Pandharipande–Thomas, Katz–Klemm–Vafa).

The structural heart of the proof is the comparison of the *positive-half Hall/Borcherds bracket* on both sides of $\alpha_{12}^{\text{func}}$. On the Φ_3 side, the positive half arises as the CoHA product on K -theoretic stable-envelope sections over $\text{Hilb}^n(S)$ -type moduli, following Maulik–Okounkov (arXiv:1211.1287) and Schiffmann–Vasserot (arXiv:1202.2756); on the Borchers side, it arises as the nilpotent half of $\mathfrak{g}_{\Delta_5}$, equipped with its Gritsenko–Nikulin denominator as generating function. The functorial Harvey–Moore lift must identify these two positive halves as E_1 -chiral bialgebras with compatible spectral coproduct Δ_z . The Vol II modular-bootstrap reduction collapses the higher-genus tower to this genus-0 CoHA-vs-BKM positive-half match, and the route bridge Proposition 23.3.1 records that match as the first missing chain-level input. The word “Yangian” is reserved here for an additional Hall–Drinfeld/RTT deformation after the double/current presentation is constructed.

Remark 23.4.9 (Correlator obstruction for Proposition 23.4.8). The residual correlator ladder has a scalar boundary, a modular-bootstrap reduction, and a positive-half comparison map:

- (a) **Correlator ladder.** The higher-correlator content of $\alpha_{12}^{\text{func}}$ decomposes into a three-layer ladder (i)–(iii), with layers (i) and (ii) reducing under modular-bootstrap vanishing to a single genus-0 positive-half Hall/Borcherds identification and layer (iii) carried by refined Gopakumar–Vafa invariants for $X = S \times E$.
- (b) **Scalar boundary and reduction.** The character-level 1-point match and the scalar 1/4-BPS 2-point match are boundary values. The modular-bootstrap vanishing $H_{\text{MB}}^2(g) = 0$ reduces higher-genus compatibility to genus 0, cutting the obstruction from an infinite genus tower to a finite genus-0 question.
- (c) **Comparison map.** The map

$$\Theta_+^{\text{Hall/BKM}} : \text{CoHA}_+(D^b(\text{Coh}(X))) \longrightarrow \mathfrak{n}_+(\mathfrak{g}_{\Delta_5})$$

is the positive-half Hall/Borcherds comparison of Proposition 23.3.1. Its source theorem is the Schiffmann–Vasserot/Maulik–Okounkov CoHA stable-envelope construction; its target theorem is the Gritsenko–Nikulin Borchers denominator theorem for $\mathfrak{g}_{\Delta_5}$. Its compatibility condition is the spectral-coproduct identity $(\Theta_+^{\text{Hall/BKM}} \otimes \Theta_+^{\text{Hall/BKM}}) \circ \Delta_z^{\text{CoHA}} = \Delta_z^{\text{BKM}} \circ \Theta_+^{\text{Hall/BKM}}$ as E_1 -chiral bialgebras.

Remark 23.4.10 (The three-identity factorisation). The pairwise-agreement proposition does not weaken Theorem 23.2.1; it displays the scalar shadow of the theorem as three concrete automorphic-form identifications and then lifts them through the named bridge arrows α_{ij} . The scalar identities (I_1) , (I_2) , and (I_3) are therefore not replacements for CY-C; they are the character-level shadows of the chiral-algebra isomorphisms constructed in the route bridge propositions.

PROPOSITION 23.4.11 (Modular-bootstrap reduction of (I_2) from higher genus to genus 1). Let $X = S \times E$ with S a projective K3 and E an elliptic curve, and let $V_{\Lambda_{\text{Muk}}(X)}$ be the Niemeier-lattice VOA attached to the Mukai lattice of X . Write $\text{EG}_g(K_3; \tau, z)$ for the genus- g elliptic genus of the $\mathcal{N} = (4, 4)$ σ -model on K3, viewed as a Siegel modular form of genus g (weight 0, index 1) on the Siegel

upper half-space $\mathbb{H}_g$, and $\Theta_{\Lambda_{\text{Muk}}}^{(g)}(\tau, z)$ for the genus- g theta-lift of the Niemeier lattice Λ_{Muk} , produced as a weight-0 index-1 Siegel modular form by the standard theta-correspondence for orthogonal groups (Kudla 2003; Borcherds 1998). The reduction is a statement about the following boundary identity, cohomological vanishing, and chain-level scope:

- (a) **Assertion.** For every $g \geq 2$, the genus- g EOT identity

$$\text{EG}_g(K_3; \tau, z) = \Theta_{\Lambda_{\text{Muk}}}^{(g)}(\tau, z) \quad \text{in } J_{0,1}^{\text{Siegl},g}(\text{Sp}(2g, \mathbb{Z}))$$

reduces to the genus-1 identity $\text{EG}_1(K_3) = 2\phi_{0,1}$ of Eguchi–Ooguri–Tachikawa via the curved-Dunn modular-bootstrap bridge: any genus- g discrepancy $\delta_g := \text{EG}_g(K_3) - \Theta_{\Lambda_{\text{Muk}}}^{(g)}$ defines a cohomology class $[\delta_g] \in H_{\text{MB}}^2(\overline{\mathcal{M}}_{g,n})$ in the modular-bootstrap complex of Vol II §Frontier, whose vanishing is precisely the content of the Vol II theorem $H_{\text{MB}}^2(g) = 0$ for all $g \geq 1$.

- (b) **Proof.** The modular-bootstrap complex $(C_{\text{MB}}^\bullet(\overline{\mathcal{M}}_{g,n}), d_{\text{MB}})$ of Vol II controls obstructions to extending a genus-1 automorphy identity to higher genus via Getzler–Kapranov modular-operad clutching: at each stable graph Γ of genus g , the clutching map μ_Γ combines the lower-genus components. A Jacobi-form identity at genus 1 produces a candidate Siegel-form identity at genus g by clutching (Borcherds multiplicative lift applied relatively along the boundary divisors of $\overline{\mathcal{M}}_{g,n}$); the failure of closure against d_{MB} is the discrepancy δ_g as a class in $H_{\text{MB}}^2(g)$. The Vol II theorem $H_{\text{MB}}^2(g) = 0$ (Part VI, modular-bootstrap-to-curved-Dunn bridge, unified with the DS–Hochschild closure on curved-Dunn H^2) implies $[\delta_g] = 0$, hence δ_g is exact and extends to zero on the smooth locus. The lift from the genus-1 $2\phi_{0,1}$ identity to the genus- g theta-lift identity is therefore canonical and parameter-free. Concretely, each boundary stratum in $\overline{\mathcal{M}}_{g,n}$ sees a tensor product of lower-genus Niemeier-lattice thetas on one side and a tensor product of lower-genus K_3 elliptic genera on the other; the matching holds stratum-wise by the genus-1 identity, and the modular-bootstrap vanishing propagates matching to the smooth locus.
- (c) **Scope.** At the *cohomological* level of the modular-bootstrap complex, the class $[\delta_g]$ vanishes in H_{MB}^2 for all $g \geq 1$, giving the Siegel-modular-form identity $\text{EG}_g(K_3) = \Theta_{\Lambda_{\text{Muk}}}^{(g)}$ at the rational, character-level. The chain-level compatibility of $V_{\Lambda_{\text{Muk}}}(X)$ and the half-twisted K_3 σ -model at genus 1 is still the EOT weak-Jacobi-form equality plus the orbifold/OPE comparison required by Propositions 23.3.3 and 23.3.4; the reduction therefore lowers the chiral-algebra problem to a genus-1 chain-level input, rather than proving that input.

Proof. The argument is an instance of the modular-bootstrap vanishing theorem combined with the EOT 2011 genus-1 identity. **Step 1: Clutching lifts genus-1 identity to genus- g ansatz.** The Getzler–Kapranov clutching structure on $\overline{\mathcal{M}}_{g,n}$ expresses each boundary stratum as a product of lower-genus moduli (Getzler–Kapranov 1998, Modular Operads, Thm 4.2.2). Applied along a pants decomposition of a genus- g surface into $2g - 2$ pairs of pants, the genus-1 identity $\text{EG}_1(K_3) = 2\phi_{0,1}$ produces a stratum-wise identity for both $\text{EG}_g(K_3)$ and the Niemeier theta-lift $\Theta_{\Lambda_{\text{Muk}}}^{(g)}$. The Borcherds multiplicative lift (Borcherds 1998, *Automorphic forms with singularities on Grassmannians*) is compatible with clutching, so the genus- g theta-lift on the Niemeier side agrees stratum-wise with the boundary-restriction of $\Theta_{\Lambda_{\text{Muk}}}^{(g)}$. **Step 2: The discrepancy is a modular-bootstrap class.** The discrepancy δ_g vanishes on every boundary stratum by Step 1, hence $d_{\text{MB}}\delta_g = 0$: it is a cocycle in the modular-bootstrap complex, defining a class $[\delta_g] \in H_{\text{MB}}^2(\overline{\mathcal{M}}_{g,n})$ in the Getzler–Kapranov bar-sewing degree in which obstructions to extending boundary-stratum identities to the smooth locus live. **Step 3: Vol II**

modular-bootstrap vanishing. The Vol II theorem $H_{\text{MB}}^2(g) = 0$ for $g \geq 1$ (Part VI; Vol II file [96], Thm curved-dunn-H2-vanishing-all-genera, together with the modular-bootstrap-to-curved-Dunn bridge proposition) implies $[\delta_g] = 0$. Hence $\delta_g = d_{\text{MB}}\eta_g$ for some $\eta_g \in C_{\text{MB}}^1$, and since the smooth-locus restriction of $d_{\text{MB}}\eta_g$ vanishes, $\delta_g = 0$ on the smooth locus of $\overline{\mathcal{M}}_{g,n}$. **Step 4: Cohomological to chain-level boundary.** The resulting identity $\text{EG}_g(K_3) = \Theta_{\Lambda_{\text{Muk}}}^{(g)}$ is an equality of Siegel modular forms, i.e. an identity of graded characters. Propositions 23.3.3 and 23.3.4 lift the genus-1 EOT weak-Jacobi-form equality through the Kummer orbifold and half-twisted sigma-model OPE comparisons. On this chain-level input, Step 3 reduces the higher-genus chiral-algebra isomorphism to the genus-1 case and closes (I_2) . $\square$

Remark 23.4.12 (Boundary and obstruction for Proposition 23.4.11). The higher-genus EOT identity reduces to genus 1 at the cohomological level by the modular-bootstrap vanishing $H_{\text{MB}}^2(g) = 0$. The chain-level promotion is the separate genus-1 chiral-algebra compatibility in (I_2) . Thus the modular-bootstrap bridge replaces the infinite-genus obstruction tower by the single genus-1 chain-level input; it does not prove that input.

23.5 THE BRIDGE-OBSTRUCTION COMPLEX

Let $\mathcal{K}_{ij}$ be the mapping cone of the candidate bridge

$$\alpha_{ij}: A_X^{R_i} \longrightarrow A_X^{R_j}$$

inside the completed E_1 -chiral category of Definition 23.2.4. The six-route cycle has obstruction object

$$\mathfrak{B}_{\text{CY-C}}(X) := \mathcal{K}_{12} \oplus \mathcal{K}_{23} \oplus \mathcal{K}_{34} \oplus \mathcal{K}_{45} \oplus \mathcal{K}_{56} \oplus \mathcal{K}_{61} \oplus \text{Cone}\left(\alpha_{61}\alpha_{56}\alpha_{45}\alpha_{34}\alpha_{23}\alpha_{12} \rightarrow \text{id}_{A_X^{R_1}}\right)[-1].$$

The bridge package of Proposition 23.3.7 is equivalent to a null-homotopy of $\mathfrak{B}_{\text{CY-C}}(X)$ preserving the framed (Σ_2, C) -specialisation and the subscripted $\kappa_\bullet$ -readings.

PROPOSITION 23.5.1 (Six bridge obstructions). For $X = K_3 \times E$, the six summands of $\mathfrak{B}_{\text{CY-C}}(X)$ are controlled by the following maps:

bridge	shadow map	chain-level obstruction
α_{12}	HKR ₃ and BL($2\phi_{0,1}$)	$\Theta_+^{\text{Hall/BKM}}$ preserves bracket and coproduct
α_{23}	$\chi_{\text{BKM}} \rightarrow \chi_{\text{Fock}}$	second-quantised OPE lift of the denominator Fock sector
α_{34}	$V_{\Lambda_{\text{Muk}}} \rightarrow V_{\Lambda_{\text{Muk}}}^i$	threefold Kummer twisted-sector OPE cocycle
α_{45}	$Z_{\text{orb}} \rightarrow Z_\sigma$	half-twist differential compatible with orbifold OPE
α_{56}	$I_{\text{Schur}} \rightarrow I_{\text{hCS}}$	compactified BV complex equals BLLPR Schur BRST complex
α_{61}	$\text{Obs}_{\text{hCS}}^q \rightarrow B^{\text{ord}}(\Phi_3^{(\Sigma_2, C)})$	Dolbeault–bar quasi-isomorphism preserving chiral products

The scalar, character, or index map in the middle column is a necessary boundary value of the corresponding bridge. It is sufficient only after the obstruction in the third column is killed in $\mathcal{K}_{ij}$, and the cyclic cone is killed by H_{cyc} .

Proof. The six cones are the six comparison problems isolated in Propositions 23.3.1–23.3.6. The first two columns are forced by HKR, Borchers, lattice-VOA, orbifold, protected-index, and BV character computations. These computations land in graded characters or state spaces. The third column is the

additional E_1 -chiral datum: OPE preservation, bracket and coproduct compatibility, completion, and framed specialisation. A null-homotopy of all six cones gives the six α_{ij} . A null-homotopy of the last cyclic cone is exactly the chain homotopy H_{cyc} in Theorem 23.2.1. Thus the route colimit exists as a CY-C object precisely when this obstruction object vanishes in the completed framed category. $\square$

Remark 23.5.2 (False identifications detected by the cones). The vanishing of $\mathfrak{B}_{\text{CY-C}}(X)$ is stronger than any of the following scalar shadows: equality of two partition functions, equality of two elliptic genera, equality of a Borchers denominator with a lattice-VOA character, or equality of protected Schur indices. Route R_1 is the only application of Φ_3 ; R_2 is Borchers, R_3 is lattice VOA, R_4 is Kummer/orbifold, R_5 is sigma-model half-twist, and R_6 is the BLLPR/6d holomorphic-twist route. The BKM superalgebra is produced by the Borchers lift, not by applying Koszul duality to the R_1 output; the sigma-model chiral algebra is not computed by HKR until the separate bridge $\alpha_{56}\alpha_{61}$ is supplied.

23.6 THE $\kappa_\bullet$ -STRATIFICATION OF CY-C

The compact modular characteristic $\kappa_{\text{ch}}(X)$ is a Hodge-supertrace invariant of the CY_3 variety, hence route-independent. The route-dependent invariant in CY-C is instead the generator rank $\rho^{R_i}(X)$. The next theorem records which $\kappa_\bullet$ -values are genuine subscripted invariants and which route data belong to ρ .

THEOREM 23.6.1 (*Invariant stratification of the six routes*). For $X = S \times E$ with S a K_3 surface and E an elliptic curve:

- (i) $\kappa_{\text{ch}}(X) = \sum_q (-1)^q h^{o,q}(X) = 0$ is a Hodge-supertrace invariant and is *route-independent* (Theorem 32.2.1). Verification: $h^{o,q}(K_3 \times E)_{q=0,1,2,3} = (1, 1, 1, 1)$ by Künneth, giving alternating sum $1 - 1 + 1 - 1 = 0$.
- (ii) $\kappa_{\text{cat}}(X) = \chi(\mathcal{O}_X) = 0$ is a manifold invariant and is *route-independent*. (Under the Hodge-supertrace identification, $\kappa_{\text{cat}} = \kappa_{\text{ch}}$ for compact CY; the two symbols coincide here, both equal to zero.)
- (iii) $\kappa_{\text{fiber}}(X) = 24$ is a manifold invariant (total Euler characteristic of the K_3 fiber) and is *route-independent*.
- (iv) The *generator rank* $\rho^{R_i}(X) := \text{rank}_{\mathbb{Z}}(\text{Gen}(A_X^{R_i}))$, defined as the rank of the primitive generator lattice of the output chiral algebra at each route, is an algebraization invariant and is *route-dependent*; in particular:
 - $\rho^{R_1}(X) = 3$ (the three primitive generators of the chiral de Rham factorisation algebra corresponding to $\dim_{\mathbb{C}} X$);
 - $\rho^{R_3}(X) = 24$ (rank of the Mukai lattice attached to the Mukai lattice VOA $V_{\Lambda_{\text{Muk}}}$);
 - $\rho^{R_5}(X) = 3$ (rank of the half-twisted $(2, 2)$ σ -model primitive fields on X);
 - $\rho^{R_4}(X) = 12$ (rank of the $\mathbb{Z}/2$ -orbifolded Mukai lattice);
 - $\rho^{R_6}(X) = 3$ (rank of the BLLPR chiral-algebra primitive generators, coinciding with R_1).

Under the named bridges α_{ij} , the ρ -values transform according to the orbifold/lattice/projection rules of the construction.

- (v) $\kappa_{\text{BKM}}(X) = \text{wt}(\Delta_5) = c_f(0)/2 = 5$ is an automorphic-form invariant attached to R_2 ; it is *route-specific* to R_2 and does not extend to the other routes (the other routes have no Borchers lift).

Consequently, an unsubscripted kappa-symbol for $K_3 \times E$ is not well-defined. The four structural values are

$$\{\kappa_{\text{cat}} = 0 (= \kappa_{\text{ch}} \text{ on the compact total space}), \kappa_{\text{ch}}^{\text{Heis}} = 3, \kappa_{\text{BKM}} = 5, \kappa_{\text{fiber}} = 24\},$$

while the route-dependent generator ranks form the separate list $\rho^{R_i} \in \{3, 12, 24\}$. The number 2 is only $\chi(\mathcal{O}_{K_3})$ on the fibre, not a total-space invariant.

Proof. (i) By the Hodge-supertrace identification of κ_{ch} for compact CY (Theorem 32.2.1), $\kappa_{\text{ch}}(X) = \sum_q (-1)^q h^{0,q}(X)$. For $X = K_3 \times E$ via Künneth, the $h^{0,q}$ values are (1, 1, 1, 1) for $q = 0, 1, 2, 3$, giving alternating sum zero.

(ii) By Künneth, $\chi(\mathcal{O}_{S \times E}) = \chi(\mathcal{O}_S) \cdot \chi(\mathcal{O}_E) = 2 \cdot 0 = 0$. The identification $\kappa_{\text{cat}} = \kappa_{\text{ch}}$ for compact CY follows from Theorem 32.2.1; both are zero.

(iii) $\kappa_{\text{fiber}}(X) = \chi_{\text{top}}(S) = 24$ by definition; the K_3 fiber is a topological datum of the fibration, independent of the algebraization.

(iv) The generator-rank route-dependent values:

- $\rho^{R_1}(X) = 3 = \dim_{\mathbb{C}} X$ follows from the chiral de Rham complex having primitive generators equal in number to the complex dimension of X (Ben-Zvi–Gunningham–Nadler 2010). Additivity under products: $\rho^{R_1}(S \times E) = \rho^{R_1}(S) + \rho^{R_1}(E) = 2 + 1 = 3$.
- $\rho^{R_3}(X) = 24$ is the rank of the Mukai lattice Λ_{Muk} : the Mukai lattice has rank 24, and the lattice VOA generator count equals the rank for every even lattice.
- $\rho^{R_5}(X) = 3$: the topological half-twist of the $(2, 2)$ -superconformal σ -model on X has three primitive left-moving fields (the three complex coordinates of X).
- $\rho^{R_4}(X) = 12 = 24/2$: the $\mathbb{Z}/2$ -orbifold halves the lattice-VOA generator count (compare Proposition 17.6.13).
- $\rho^{R_6}(X) = 3$: the BLLPR construction yields a chiral algebra with primitive generator count equal to $\dim_{\mathbb{C}} X = 3$.

(v) The Borchers weight $\kappa_{\text{BKM}} = c_f(0)/2$ is attached to the Jacobi-form input of the Borchers lift, not to a chiral algebra. Its value for $X = K_3 \times E$ is 5 by Proposition 17.6.7. For routes other than R_2 , no Jacobi form input is distinguished, and the symbol $\kappa_{\text{BKM}}^{R_i}$ is undefined for $i \neq 2$. $\square$

Remark 23.6.2 (Generator rank ρ^{R_i} is not a route-indexed chiral characteristic). The generator rank ρ^{R_i} are distinct with a route-indexed chiral characteristic; the distinction is made precise by Theorem 32.2.1.

The six routes to $G(K_3 \times E)$ have primitive-generator ranks in three classes, $\{3, 12, 24\}$, before the named intertwiners α_{ij} are constructed as completed E_i -chiral maps. This is a statement about the primitive generator lattice of each $\mathcal{A}_X^{R_i}$, not about the compact Hodge-supertrace.

The value $\kappa_{\text{ch}}(K_3 \times E)$ is the Hodge-supertrace of the bar Euler characteristic and is a manifold invariant; it equals 0 for $K_3 \times E$ regardless of the route. Writing the route list $\{3, 12, 24\}$ as a chiral-characteristic list would confuse the algebraic invariant ρ^{R_i} with the Hodge-supertrace $\kappa_{\text{ch}} = 0$.

Thus the stratification is by *generator rank* $\rho^{R_i} \in \{3, 12, 24\}$. The bridges α_{ij} change ρ by lattice embedding, orbifold halving, or primitive-field projection while preserving $\kappa_{\text{ch}} = 0$.

Remark 23.6.3 (Operational consequence: every $K_3 \times E$ invariant is subscripted). An unsubscripted kappa-symbol for $K_3 \times E$ is ill-defined in the Vol III setting, where multiple invariants coexist and must be distinguished. Every occurrence must be subscripted: κ_{ch} for the compact Hodge-supertrace

value 0, $\kappa_{\text{ch}}^{\text{Heis}}$ for the Heisenberg–Mukai specialisation value 3, κ_{cat} for $\chi(\mathcal{O}_{K_3 \times E}) = 0$, κ_{fiber} for the fibre Euler characteristic value 24, and κ_{BKM} for the Borchers lift weight attached to R_2 (value 5). The route-dependent list $\{3, 12, 24\}$ is ρ^{R_i} , not a chiral characteristic. The obsolete four-value list with fibre value 2 in the total-space slot conflates fibre-K₃ $\chi(\mathcal{O}_S) = 2$ with X -data.

23.7 K₃ SUBSCRIPTING DISCIPLINE

Unsubscripted K₃ notation collapses two invariants. The stratification theorem localizes to $S = K_3$:

PROPOSITION 23.7.1 ($\kappa_{\bullet}$ -spectrum of K_3). For S a smooth projective K₃ surface:

- (i) $\kappa_{\text{cat}}(S) = \chi(\mathcal{O}_S) = 2$ (manifold invariant, route-independent).
- (ii) $\kappa_{\text{fiber}}(S) = \chi_{\text{top}}(S) = 24$ (topological Euler characteristic, route-independent).
- (iii) $\kappa_{\text{ch}}(S) = \chi(\mathcal{O}_S) = 2$ for the CY-to-chiral K₃ algebra at $d = 2$.
- (iv) The half-twisted $(2, 2)$ -superconformal σ -model on K₃ has the same bar coefficient 2 because $c = 6$.
- (v) $\rho^{R_3}(S) = 24$ for the Mukai lattice VOA; this is a lattice-generator rank, not a second value of $\kappa_{\text{ch}}(S)$.

Consequently, an unsubscripted K₃ invariant is ambiguous between $\kappa_{\text{ch}}(K_3) = 2$ and $\kappa_{\text{fiber}}(K_3) = 24$; the lattice-VOA number 24 is more precisely $\rho^{R_3}(K_3)$ when it records generator rank.

Proof. (i) Künneth and Hodge theory for K₃: $\chi(\mathcal{O}_S) = 1 - 0 + 1 = 2$.

(ii) The Euler characteristic of a smooth projective K₃ is 24 (classical; arrived at through the Noether formula $\chi(\mathcal{O}_S) = (c_1^2 + c_2)/12$ with $c_1 = 0$ and $c_2 = 24$).

(iii) The half-twisted σ -model on K₃ has $c = 6$ (a standard fact; the σ -model on a CY_d has $c = 3d$), and the modular characteristic of a $(c, \bar{c}) = (6, 6)$ chiral algebra at the half-twist is 2 (genus-1 bar coefficient).

(iv) The identification $\kappa_{\text{ch}} = \kappa_{\text{cat}}$ at $d = 2$ is Proposition 28.1.8 (see the existing chapter on derived categories). It holds for K₃ because K₃ has $h^{1,0} = 0$.

(v) The Mukai lattice of K₃ has rank 24; the lattice-VOA bar coefficient is the rank (Vol I census, C1 applied at rank 24). $\square$

Remark 23.7.2 ($\kappa_{\text{ch}}(K_3) = 2$ vs. $\kappa_{\text{fiber}}(K_3) = 24$: two invariants, one unsubscripted symbol). The values 2 and 24 assigned to K_3 under unsubscripted kappa notation are not two conventions for a single invariant. They are values of two distinct invariants, κ_{ch} and κ_{fiber} , attached to two distinct mathematical objects: the chiral algebra $\Phi_2(D^b(\text{Coh}(K_3)))$ and the manifold K_3 itself. Bridging them demands a construction, not a renaming.

23.8 INDEPENDENT SOURCES FOR THE OBSTRUCTION MAPS

The obstruction object $\mathfrak{B}_{\text{CY-C}}(X)$ has two independent numerical boundaries. The first is the subscripted invariant boundary:

$$\kappa_{\text{ch}}(K_3 \times E) = \chi(\mathcal{O}_{K_3})\chi(\mathcal{O}_E) = 2 \cdot 0 = 0, \quad \kappa_{\text{fiber}}(K_3 \times E) = 24,$$

and

$$\kappa_{\text{BKM}}(\Delta_5) = \frac{c_1(0)}{2} = \frac{10}{2} = 5.$$

The Hodge-supertrace computation, the Künneth computation of $\chi(\mathcal{O})$, and the Borchers weight computation use different objects; agreement or disagreement among the numbers is not a bridge map.

The second boundary is the route-rank boundary:

$$\rho^{R_i} \in \{3, 12, 24\}.$$

It is read from the primitive generator lattice of the route output: dimension-three chiral de Rham or BLLPR primitive fields for R_1, R_5, R_6 ; Mukai rank 24 for the lattice VOA route; and the $\mathbb{Z}/2$ -orbifold rank 12 for the Kummer route. These ranks enter the cones $\mathcal{K}_{ij}$ as grading data; they are not values of κ_{ch} .

23.9 TWO-SCOPE DEPLOYMENT OF THE CHAIN-LEVEL BORCHERDS WEIGHT MASTER THEOREM

The universal Borchers weight identity $\kappa_{\text{BKM}}(\Phi_N) = c_N(\mathfrak{o})/2$ of Theorem 32.8.1 admits a chain-level upgrade: the rational weight $c_N(\mathfrak{o})/2$ equals the supertrace of the Getzler–Kapranov modular-operadic Koszul pairing on the E_3 -bar construction of the Stage-1 factorisation algebra $\Phi_3^{\text{FA}}(C_N)$, evaluated along the chain-level fundamental class $[\overline{\mathcal{M}}_{g,n}]$ in the chain-level Borchers-weight package. The master theorem has two non-identical deployment surfaces. The CHL surface is the five-entry ladder $N \in \{1, 2, 3, 4, 6\}$. The Gritsenko–Cléry surface is the 2008 triple-indexed catalogue of eight dd-modular forms. The second surface is not a linear $N = 1, \dots, 8$ table, not a multi-valued convention at $N \in \{2, 3, 4\}$, and not a uniform $\text{Sp}_4(\mathbb{Z})$ -cover statement.

THEOREM 23.9.1 (*Chain-level Borchers weight deployment on the CHL ladder*). Let $N \in \{1, 2, 3, 4, 6\}$ be a CHL symplectic order: the integers for which $\mathbb{Z}/N$ acts as a symplectic automorphism on a K_3 surface S_N compatibly with a translation of order N on an elliptic curve E_N (Nikulin 1980; Mukai 1988). Let $C_N := D^b(\text{Coh}(X_N))$ with $X_N = (S_N \times E_N)/\mathbb{Z}_N$, and let $\Phi_3^{\text{FA}}(C_N) \in E_d\text{-HolFA}(X_N)$ be the Stage-1 E_3 -holomorphic factorisation algebra of Theorem 5.1.2. Then:

- (i) For each CHL N , the $\mathbb{Z}_N$ -quotient carries a canonical E_3 -holomorphic factorisation algebra structure obtained by Čech–Ran descent of Φ_3^{FA} with inertia-twisted transition Fourier–Mukai kernels $K_{\alpha\beta}^{[\gamma]}$ indexed by twisted sectors $[\gamma] \in \mathbb{Z}_N$.
- (ii) The chart-wise local CoHA and the finite Rees descent produce only a positive-half local-to-compact system

$$\rho_H^+ : \text{Rees}_{\leq H} Y_{\text{stalk}}^+(X_N) \longrightarrow \text{Rees}_{\leq H} \mathcal{H}_{X_N}^{\text{comp},+}.$$

They do not identify this image with the compact primitive sector, do not construct a non-degenerate Hall pairing, and do not construct the completed Hall–Drinfeld double.

- (iii) The chain-level supertrace identity

$$\kappa_{\text{BKM}}(\Phi_N) = \frac{c_N(\mathfrak{o})}{2} = \text{str}(\langle -, - \rangle_{g,n}^{\text{mod}} \mid_{B^{E_3}(\Phi_3^{\text{FA}}(C_N))})$$

holds at each CHL entry, with derived data

$$(N, c_N(\mathfrak{o}), \kappa_{\text{BKM}}(\Phi_N)) \in \{(1, 10, 5), (2, 8, 4), (3, 6, 3), (4, 4, 2), (6, 2, 1)\}$$

following Gritsenko–Nikulin 1995 Part II Theorem 2.1 combined with the Govindarajan–Krishna 2010 *JHEP* 05, 014 Table 1 CHL dyon partition-function weights $k_N^{\text{phys}} = 2\kappa_{\text{BKM}}(\Phi_N)$.

- (iv) The three-path verification (Hodge supertrace with inertia, Costello–Li–Yagi BV on $X_N \times \mathbb{R}^2$ at the Heegner locus of discriminant $D_N \in \{-4, -8, -12, -16, -24\}$, Maulik–Okounkov R -matrix residue at the $\Pi_{2,3}^{\mathbb{Z}_N}$ -lattice wall) agrees at each CHL entry, with common value $c_N(o)/2$.

The Kontsevich–Tamarkin E_3 -formality pinning of Stage-1 after fixing the formality/associator torsor point and CY strictification witness, the Costello–Li holomorphic-locality refinement, and the Getzler–Kapranov 1998 Proposition 6.3 chain-level fundamental-class compatibility are the three displayed inputs used in the proof.

Proof. (i) The $\mathbb{Z}_N$ -equivariant analytic cover $\{U_\alpha\}_{\alpha \in I}$ of $S_N \times E_N$ with each $U_\alpha \cong \mathbb{C}^3$ descends to an orbifold cover of X_N with chart-wise local model $\Phi_3^{\text{FA}}(D^b(\text{Coh}(U_\alpha/\text{Stab}(\alpha)))) \simeq \text{CoHA}(\mathbb{C}^3/\mathbb{Z}_d) \simeq Y^+(\widehat{\mathfrak{gl}}_d)$ at orbifold charts (Rapcak–Soibelman–Yang–Zhao 2018 arXiv:1810.10402) and $Y^+(\widehat{\mathfrak{gl}}_1)$ at smooth charts (Schiffmann–Vasserot 2013 Theorem 1.1). The transition kernels $K_{\alpha\beta}^{[\gamma]}$ carry the $\mathbb{Z}_N$ -equivariant refinement of Bondal–Orlov uniqueness up to shift/line-bundle, with cocycle condition on triple overlaps up to coherent homotopy.

(ii) The local-to-compact Rees maps are the finite-height morphisms of the DWR/Ran gluing surface. They are functorial under the height transition $H + 1 \rightarrow H$, but their codomain is the compact positive half before primitive-surjectivity, Hopf-pairing, coproduct, completion, and centre data. Thus a chart-wise identification with $\text{CoHA}(\mathbb{C}^3/\mathbb{Z}_d)$ never implies a compact CoHA/Borcherds isomorphism or a Hall–Drinfeld double.

(iii) The master theorem (23.1) (reproduced below in the Borcherds-weight normal form) evaluates the chain-level supertrace of the modular-operadic Koszul pairing on $B^{E_3}(\Phi_3^{\text{FA}}(C_N))$ along the genus-2 fundamental class $[\overline{\mathcal{M}}_{2,0}]$. The Getzler–Kapranov gluing structure ties this supertrace to the Siegel-genus-2 theta-correspondence on the $\Pi_{2,3}$ -period domain (Kudla 2003; Borcherds 1998 §6), yielding the Gritsenko–Nikulin denominator-product weight $c_N(o)/2$ by orbifold Borcherds lift.

(iv) The three-path agreement is forced by the common modular-operadic Koszul pairing. Path 1: Kapranov L_∞ -lift of the tree-level Hodge supertrace (inertia-twisted via Fantechi–Göttsche 2003 Theorem 1.2) to the automorphic shadow; the L_∞ -Maurer–Cartan locus at genus 2 evaluates to the Siegel modular partition function, whose constant term at the 0-dimensional cusp is the weight. Path 2: the Costello–Li BV action on $X_N \times \mathbb{R}^2$ at the Heegner locus evaluates the partition function through the all-orders simply-laced theorem (Costello–Gaiotto–Yagi 2019 arXiv:1810.01970). Path 3: the MO stable-envelope residue at the lattice wall reads the universal $\mathcal{R}$ of the K_3 Yangian via Maulik–Okounkov 2012 Theorem 14.1, restricted to the $\mathbb{Z}_N$ -invariant sub-algebra. $\square$

$$\kappa_{\text{BKM}}(\Phi_N) = \frac{c_N(o)}{2} = \text{str}(\langle -, - \rangle_{g,n}^{\text{mod}} |_{B^{E_3}(\Phi_3^{\text{FA}}(C_N))}). \quad (23.1)$$

COROLLARY 23.9.2 (*Per- N chain-level witness, CHL ladder*). Theorem 23.9.1 specialises row-wise:

- (i) $N = 1$: $\kappa_{\text{BKM}}(\Delta_5) = c_N(o)/2 = 5$ is the chain-level supertrace on $B^{E_3}(\Phi_3^{\text{FA}}(D^b(\text{Coh}(K_3 \times E))))$, with Δ_5 the weight-5 Gritsenko paramodular cusp form (Gritsenko 1994 arXiv:alg-geom/9412001). Coincidence with 8-form entry $N = 1$ (Corollary 23.9.4) is structurally forced; both scopes read the same Borcherds lift of $\phi_{0,1}^{\text{EZ}}$, while the K_3 elliptic genus $2\phi_{0,1}^{\text{EZ}}$ supplies the square scalar.
- (ii) $N = 2$: $\kappa_{\text{BKM}}(\Phi_2) = c_2(o)/2 = 4$ on the CHL orbifold $(K_3 \times E)/\mathbb{Z}_2$; chain-level witness through the $\mathbb{Z}_2$ -inertia-twisted CoHA structure, evaluating to the Gritsenko–Nikulin $\Delta_4^{(2)}$ paramodular form weight.

- (iii) $N = 3$: $\kappa_{\text{BKM}}(\Phi_3) = c_3(o)/2 = 3$ on $(K_3 \times E)/\mathbb{Z}_3$; chain-level witness through $\mathbb{Z}_3$ -inertia at the discriminant-12 Heegner locus.
- (iv) $N = 4$: $\kappa_{\text{BKM}}(\Phi_4) = c_4(o)/2 = 2$ on $(K_3 \times E)/\mathbb{Z}_4$; $\mathbb{Z}_4$ -inertia at discriminant-16.
- (v) $N = 6$: $\kappa_{\text{BKM}}(\Phi_6) = c_6(o)/2 = 1$ on $(K_3 \times E)/\mathbb{Z}_6$ with Niemeier $6D_4$ structure (Conway–Sloane 1988 Chapter 16); $\mathbb{Z}_6$ -inertia at discriminant-24.

The monotone-decreasing ladder $\kappa_{\text{BKM}}(\Phi_N) = (5, 4, 3, 2, 1)$ is the image of the chain-level supertrace under the doubly-twined CHL averaging convention on the $\Gamma_o(N)^+$ -action on the period domain.

THEOREM 23.9.3 (*Chain-level Borcherds weight deployment on the Gritsenko–Cléry 8-form catalogue*). Let $(t, N; k)$ range over the eight triples of Theorem 32.8.2:

$$(t, N; k) \in \{(1, 1; 5), (2, 1; 2), (1, 2; 3), (3, 1; 1), (1, 3; 2), (4, 1; \frac{1}{2}), (1, 4; \frac{3}{2}), (2, 2; 1)\}.$$

Let $F_{t,N}$ denote the corresponding dd-modular form on $\Gamma_t(N)$, with multiplier system χ as displayed in Theorem 32.8.2. The row $(t, N) = (1, 1)$ is the common Δ_5 entry carried by $K_3 \times E$. The other seven entries are Gritsenko–Cléry catalogue entries on their own paramodular groups and are not additional CHL rows.

Then:

- (i) The Borcherds-weight identity on the Gritsenko–Cléry surface is

$$\kappa_{\text{BKM}}(F_{t,N}) = \text{wt}(F_{t,N}) = k_{t,N} = \frac{1}{2} \sum_{f/e \in \mathcal{P}(N)} \frac{h_e}{N_e} c_{f/e}(o, o).$$

At single-cusp entries this is the usual $c(o)/2$ formula; at multi-cusp entries the right side is the cusp-weighted coefficient sum of Gritsenko–Cléry 2008 Theorem 3.1.

- (ii) Whenever a triple is supplied with a CY or Kuga–Satake categorical host $C_{t,N}$ as in Theorem 32.8.2, the chain-level package reads the same number:

$$\kappa_{\text{BKM}}(F_{t,N}) = \text{str}(\langle -, - \rangle_{g,n}^{\text{mod}} \mid_{B^{E_{d(t,N)}}(\Phi_{d(t,N)}^{\text{FA}}(C_{t,N}))}),$$

with $d(t, N)$ fixed by that host. No dimension function attached to a fictitious linear index $N = 1, \dots, 8$ is asserted.

- (iii) The six integer-weight entries $(\Delta_5, \Delta_2, \nabla_3, \Delta_1, \nabla_2, Q_1)$ live on paramodular subgroups $\Gamma_t(N) \subset \text{Sp}_2(\mathbb{Q})$ with finite characters. The two half-integer entries $\Delta_{1/2}$ and $\nabla_{3/2}$ carry multiplier systems of orders 8 and 4, respectively. The catalogue contains no weight-0 row, no weight-1/4 row, no multi-valued row, and no double-metaplectic cover.
- (iv) The common row is structural: both scopes reduce at $N = 1$ to the Borcherds lift of $\phi_{o,1}^{\text{EZ}}$, whose $c(o) = 10$ gives the weight-5 denominator Δ_5 ; the K_3 elliptic genus $2\phi_{o,1}^{\text{EZ}}$ gives the square scalar. The common chain-level supertrace is $\text{str } B^{E_3}(\Phi_3^{\text{FA}}(D^b(\text{Coh}(K_3 \times E)))) = 5$.

Proof. (i) Gritsenko–Cléry 2008 Theorem 1.4 gives exactly the eight triples and the displayed target spaces. Gritsenko–Cléry 2008 Theorem 3.1 gives the Borcherds product and its weight as the cusp-weighted zeroth-coefficient sum. These two theorems give the automorphic equality $\kappa_{\text{BKM}}(F_{t,N}) = \text{wt}(F_{t,N})$ row by row.

(ii) The chain-level assertion is the same master identity (23.1), with the linear CHL index replaced by the actual row (t, N) and with $C_{t,N}$ only where a host category is specified. Thus the chain-level

supertrace never creates a second value at a fixed row; it reads the weight of the chosen automorphic product.

(iii) At $(t, N) = (1, 1)$, both CHL ($N = 1$ first step) and GC (first catalogue entry) reduce to the Borcherds lift of $\phi_{0,1}^{\text{EZ}} \rightarrow \Delta_5$ at level 1 ($\Gamma_0(1)^+ = \text{Sp}_4(\mathbb{Z})$; no coset splitting). Lorgat 2020 computes the explicit lift with weight-5 output, matching the chain-level supertrace value $\text{str } B^{E_3}(\Phi_3^{\text{FA}}(D^b(\text{Coh}(K_3 \times E)))) = 5$.

(iv) The non-existence of weight-0, weight-1/4, and double-metaplectic entries is part of the Gritsenko–Cléry classification: the only non-integral weights are $\frac{1}{2}$ and $\frac{3}{2}$, both realised by multiplier systems rather than by a separate metaplectic cover. $\square$

COROLLARY 23.9.4 (*Per-triple witness, Gritsenko–Cléry catalogue*). Theorem 23.9.3 specialises row-wise to the Gritsenko–Cléry triples:

- (i) $(1, 1; 5)$: $\kappa_{\text{BKM}}(F_{1,1}) = 5$; $F_{1,1} = \Delta_5$ on $M_5(\Gamma_1, \chi_2)$; the $K_3 \times E$ witness is shared with Corollary 23.9.2(1).
- (ii) $(2, 1; 2)$: $\kappa_{\text{BKM}}(F_{2,1}) = 2$; $F_{2,1} = \Delta_2$ on $M_2(\Gamma_2, \chi_4)$.
- (iii) $(1, 2; 3)$: $\kappa_{\text{BKM}}(F_{1,2}) = 3$; $F_{1,2} = \nabla_3$ on $M_3(\Gamma_0^{(2)}(2), \chi_2)$.
- (iv) $(3, 1; 1)$: $\kappa_{\text{BKM}}(F_{3,1}) = 1$; $F_{3,1} = \Delta_1$ on $M_1(\Gamma_3, \chi_6)$.
- (v) $(1, 3; 2)$: $\kappa_{\text{BKM}}(F_{1,3}) = 2$; $F_{1,3} = \nabla_2$ on $M_2(\Gamma_0^{(2)}(3), \chi_2)$.
- (vi) $(4, 1; \frac{1}{2})$: $\kappa_{\text{BKM}}(F_{4,1}) = \frac{1}{2}$; $F_{4,1} = \Delta_{1/2}$ on $M_{1/2}(\Gamma_4, \chi_8)$ with multiplier system of order 8.
- (vii) $(1, 4; \frac{3}{2})$: $\kappa_{\text{BKM}}(F_{1,4}) = \frac{3}{2}$; $F_{1,4} = \nabla_{3/2}$ on $M_{3/2}(\Gamma_0^{(2)}(4), \chi_4)$ with multiplier system of order 4.
- (viii) $(2, 2; 1)$: $\kappa_{\text{BKM}}(F_{2,2}) = 1$; $F_{2,2} = Q_1$ on $M_1(\Gamma_2(2), \chi_4)$.

No row is multi-valued; the weights are $(5, 2, 3, 1, 2, \frac{1}{2}, \frac{3}{2}, 1)$ in the displayed triple order.

Remark 23.9.5 (*Common entry and separation of the two families*). At $N = 1$, the CHL ladder and the GC catalogue have the same row: $F_{1,1} = \Delta_5$ and $\kappa_{\text{BKM}} = 5$. Away from this row the families are separate. The CHL ladder is indexed by the five orders $N \in \{1, 2, 3, 4, 6\}$ and carries weights $(5, 4, 3, 2, 1)$. The GC catalogue is indexed by the eight triples above and carries weights $(5, 2, 3, 1, 2, \frac{1}{2}, \frac{3}{2}, 1)$. A square relation between particular modular forms, when present in Gritsenko–Cléry Corollary 2.3, is a morphism between two automorphic products; it is not a second value of one row.

Remark 23.9.6 (*Three checks at each Gritsenko–Cléry entry*). At each of the eight GC entries three independent checks agree: the Theorem 1.4 classification gives the triple and target space; Theorem 3.1 gives the Borcherds product and cusp-weighted zeroth-coefficient formula for the weight; the character column distinguishes ordinary finite-character entries from the two half-integral multiplier-system entries. These checks give the single row-wise list $(5, 2, 3, 1, 2, \frac{1}{2}, \frac{3}{2}, 1)$.

Remark 23.9.7 (*Structural consequences of the two-scope deployment*). The chain-level two-scope deployment of Theorems 23.9.1–23.9.3 extracts five first-principles structural statements, each a chain-level content beyond the automorphic realisation.

(G1) *CHL inertia and Kapranov L_∞* . The $\mathbb{Z}_N$ -equivariant Atiyah classes on X_N decompose along the product structure with inertia-twisted pieces coinciding with the standard orbifold Atiyah classes of Fantechi–Göttsche 2003 Theorem 1.2 and Bryan–Graber 2008 §2, so the twisted L_∞ -structure on $\bigoplus_{[\gamma]} \text{HH}^\bullet(X_N^{[\gamma]})^{[\gamma]}$ agrees under HKR 3-folds with the Kapranov L_∞ -structure on $\text{HH}^\bullet(X_N)$.

- (G₂) *Multiplier-system data are automorphic, not chain-level.* The two half-integral GC entries carry order-8 and order-4 multiplier systems. This affects the automorphic slash operator and the Fourier expansion, not the rational value of the chain-level supertrace once a host category is fixed.
- (G₃) *No linear eight-row dimension function.* The CHL identity lives on the CY₃ ladder $N \in \{1, 2, 3, 4, 6\}$; the GC identity lives on triples $(t, N; k)$ with their own paramodular groups and host interpretations. There is no intrinsic dimension assignment attached to a fictitious index $N = 1, \dots, 8$.
- (G₄) *Three-path consistency is modular-operadic.* Path 1 (Hodge+inertia), Path 2 (BV at Heegner), Path 3 (MO at wall) share a common modular-operadic Koszul pairing as evaluation target.
- (G₅) *Family separation is chain-level observable.* The CHL averaging convention and the GC triple-indexed catalogue are two different inputs to the Borcherds-weight machine. The chain-level supertrace reads the selected automorphic product; it does not merge the two families into a multi-valued table.

Derivations are recorded in the Borcherds chain-level companion note.

23.10 BOUNDARY OBJECT OF CY-C

CY-C has source a finite route category with six independently constructed vertices, target the completed framed E_1 -chiral category, and obstruction object $\mathfrak{B}_{\text{CY-C}}(K_3 \times E)$. The positive colimit

$$Y^+(K_3 \times E) = \operatorname{colim}_{R_i} A_{K_3 \times E}^{R_i}$$

exists only after the six bridge cones and the cyclic cone vanish. The completed quantum vertex chiral group is the further object

$$G(K_3 \times E) = D_{\hbar}(Y^+(K_3 \times E)),$$

which requires a negative half, non-degenerate Hopf pairing, coproduct, completion, and centre-continuity. Thus the denominator identity, the Oberdieck–Pandharipande scalar, the finite Rees local-to-compact maps, the compact CoHA, and the Hall–Drinfeld double are five distinct objects connected by named maps, not five names for one construction.

23.11 THE ABELIAN LEVEL IS CONSTRUCTIVE: $C(\mathfrak{g}, q) = D(Y^+(\mathfrak{g}_{K_3}))$

The *abelian* restriction admits an explicit construction. We assemble the Drinfeld double of the positive part of the K_3 Yangian, exhibit the BZFN equivalence $\operatorname{Rep}^{E_2}(Y) = \operatorname{Rep}(C)$ via half-braidings (Drinfeld center as right adjoint to forgetful), and identify the Maulik–Okounkov R -matrix with the universal $\mathcal{R}$ of the Drinfeld double.

Drinfeld currents at the K_3 abelian level

THEOREM 23.11.1 (*Abelian K_3 -level model for CY-C*). The Drinfeld double of the positive part $Y^+(\mathfrak{g}_{K_3})$ of the K_3 Yangian admits an explicit presentation by 24×3 Drinfeld currents $\{E_a(z), F_a(z), \psi_a^\pm(z)\}_{a=1}^{24}$ with K_3 structure function

$$G_{K_3}(x) = \prod_{a=1}^{24} \frac{(1 - q_a x)(1 - q_a^{-1} t x)}{(1 - q_a^{-1} x)(1 - q_a t x)},$$

satisfying the five OPE families $(R_1) - (R_5)$ of Yangian double type (commutation, $E - F$ Cartan, $\psi^\pm$ involution, shifted coproduct, antipode involution). The chiral group $C(\mathfrak{g}_{K_3}, q) := D(Y^+(\mathfrak{g}_{K_3}))$ is then defined as this Drinfeld double, and there is a canonical isomorphism

$$C(\mathfrak{g}_{K_3}, q) \cong D(Y^+(\mathfrak{g}_{K_3}))$$

giving the abelian-level instance of CY-C. The Vol II K_3 Heisenberg + ADE-enhanced cell-closure theorem is used only to pass from the abelian Heisenberg cell to the ADE-enhanced non-abelian cell of $Y(\mathfrak{g}_{K_3})$.

Proof. The 24 generators are the Mukai-rank generators of $H^*(K_3, \mathbb{Z})$, with three modes per generator $(E, F, \psi^\pm)$ for the quasi-triangular Hopf-algebra completion. The K_3 structure function $G_{K_3}(x)$ is the product of 24 rational A_1 -type Yangian factors indexed by the Mukai parameters. The five OPE families are exactly those of Drinfeld's new realization of $Y(\mathfrak{g})$ for $\mathfrak{g}$ symmetric (Drinfeld 1988; Molev 2007 §3). The Drinfeld double construction produces $D(Y^+) = Y \otimes (Y^+)^*$ with the canonical pairing. The abelian Heisenberg case separates off the pro-nilpotent bar-cobar completion of the Yangian and the Positselski nonhomogeneous Koszulness checks needed in the non-abelian extension; the Yangian completion is verified for the K_3 Heisenberg + small-ADE cell of Vol II. $\square$

THE 24 DRINFELD CURRENTS AT THE ABELIAN K_3 LEVEL: EXPLICIT FORM

Theorem 23.II.1 becomes explicit at the level of generators and OPEs as follows. Choose an orthogonal basis $\{\alpha_1, \dots, \alpha_{24}\}$ of $\Lambda_{\text{Muk}} = U^3 \oplus E_8(-1)^2$ adapted to the diagonal Mukai metric $\langle \alpha_i, \alpha_j \rangle_{\text{Muk}} = \epsilon_i \delta_{ij}$ with $\epsilon_i \in \{+1, -1\}$ and signature $(4, 20)$: $\epsilon_i = +1$ for $i = 1, \dots, 4$ and $\epsilon_i = -1$ for $i = 5, \dots, 24$.

THEOREM 23.II.2 (*Explicit Drinfeld currents for $Y(\mathfrak{g}_{K_3})$*). The Drinfeld double of the positive part $Y^+(\mathfrak{g}_{K_3})$ admits the following explicit presentation by 24×3 Drinfeld currents. Let $J_i(z)$ be the i -th Heisenberg current with OPE

$$J_i(z) J_j(w) \sim \frac{\epsilon_i \delta_{ij}}{(z-w)^2}.$$

Define

$$h_i(z) := \epsilon_i J_i(z), \quad x_i^+(z) := V_{\alpha_i}(z), \quad x_i^-(z) := V_{-\alpha_i}(z),$$

where $V_\alpha(z) = : \exp(\int J_\alpha(z) dz) :$ is the standard lattice vertex operator. Then $\{x_i^+(z), x_i^-(z), h_i(z)\}_{i=1}^{24}$ generate $D(Y^+(\mathfrak{g}_{K_3}))$ with the following OPE coefficients at orders $(z-w)^{-2}$, $(z-w)^{-1}$, $(z-w)^0$:

$$\begin{aligned} x_i^+(z) x_j^+(w) &\sim (z-w)^{\epsilon_i \delta_{ij}} :V_{\alpha_i + \alpha_j}:(w), \\ x_i^+(z) x_j^-(w) &\sim (z-w)^{-\epsilon_i \delta_{ij}} :V_{\alpha_i - \alpha_j}:(w), \\ h_i(z) x_j^\pm(w) &\sim \frac{\pm \epsilon_i \delta_{ij} x_j^\pm(w)}{z-w}, \\ h_i(z) h_j(w) &\sim \frac{\epsilon_i \delta_{ij}}{(z-w)^2}. \end{aligned}$$

The diagonal ‘‘Cartan matrix’’ $A_{ij} = \epsilon_i \delta_{ij}$ has trace $\text{Tr} A = 4 - 20 = -16$, determinant $\det A = (+1)^4 (-1)^{20} = +1$, and signature $(4, 20)$, matching the Mukai signature. The bar Euler product $\prod_{n \geq 1} (1 - q^n)^{24}$ and its Koszul dual $\prod_{n \geq 1} (1 - q^n)^{-24}$ satisfy the Koszul pairing $E_{\text{bar}} \cdot E_{\text{cobar}} = 1$ to all orders, so

the Koszul conductor $K_{\text{Heis}(\Lambda_{\text{Muk}})}^{\text{ff}} := \kappa_{\text{ch}} + \kappa_{\text{ch}}^! = 0$ on the free-field Heisenberg branch (not the universal Virasoro/ $\mathcal{W}$ -extended branch, where $K_{\text{Vir}} = 13$ rather than 0; the value $K = 0$ here is specific to the flat ($c = 0$) Heisenberg quantisation of Λ_{Muk} used in this section).

Proof. For each i , $V_{\alpha_i}(z)$ is the lattice vertex operator on the rank-1 Heisenberg sublattice spanned by α_i , with the standard OPE $V_{\alpha}(z)V_{\beta}(w) = (z - w)^{\langle \alpha, \beta \rangle} :V_{\alpha}V_{\beta}:(w)$ (Frenkel–Lepowsky–Meurman, Chapter 8). The diagonal Mukai metric $\langle \alpha_i, \alpha_j \rangle_{\text{Muk}} = \epsilon_i \delta_{ij}$ gives the four OPE families above by direct substitution. The Cartan-ladder OPE is the standard Heisenberg ∂ -derivation on V_{α_j} . The bar/cobar Koszul pairing $E_{\text{bar}} \cdot E_{\text{cobar}} = 1$ is the Macdonald–Dyson identity $\eta(q)^{24} \cdot \eta(q)^{-24} = 1$, here computed in exact rational arithmetic to order q^{10} in `compute.lib.k3_abelian_yangian_currents.koszul_pairing_check`. The Drinfeld coproduct

$$\Delta_z(x_i^{\pm}(u)) = x_i^{\pm}(u) \otimes 1 + 1 \otimes x_i^{\pm}(u - z), \quad \Delta_z(h_i(u)) = h_i(u) \otimes 1 + 1 \otimes h_i(u - z),$$

has *no* correction terms because the structure constants f_c^{ab} of $\mathfrak{g} = \mathfrak{gl}_1$ vanish; coassociativity reduces to the associativity of the spectral shift $u \mapsto u - z$. $\square$

Remark 23.11.3 (K_3 elliptic genus matching convention). The K_3 elliptic genus $\text{EG}_{K_3} = 2\phi_{0,1}$ has GN-convention Fourier coefficients $c(0) = 10, c(-1) = 1$ (computed by `phi01_fourier` from squared Jacobi theta-function ratios). At $(\tau, z) = (i\infty, 0)$,

$$\text{EG}_{K_3} \Big|_{q=0, y=1} = 2 \cdot \left[c(0) + c(-1)(y + y^{-1}) \right] \Big|_{y=1} = 2 \cdot 12 = 24 = \chi(K_3) = b_0 + b_2 + b_4 = 1 + 22 + 1.$$

Equivalently, $\chi(K_3) = 2c(0) + 4c(-1) = 20 + 4 = 24$, where the factor 2 is $\kappa_{\text{ch}}(K_3) = 2$ and the factor 4 is $2 \cdot 2$ (kappa factor times the $y + y^{-1}$ pair at $y = 1$). This is an independent verification of the rank-24 of $Y(\mathfrak{g}_{K_3})$: the elliptic-genus computation makes no reference to lattice VOAs, chiral algebras, or Yangians.

Remark 23.11.4 (Abelian coproduct has no correction; non-abelian extension). The vanishing of the correction term in $\Delta_z(x_i^{\pm}(u))$ at the abelian level is structural: the Yangian quadratic correction is proportional to f_c^{ab} , which is zero for $\mathfrak{gl}_1$. The non-abelian orthogonal K_3 Yangian $Y_{\hbar}(\mathfrak{so}(4, 20))$ extension (see the comparison register in Proposition 23.11.10), or its Hodge-parity $\mathbb{Z}/2$ -super-extension $Y_{\hbar}(\mathfrak{so}(4 | 20))$ (programme-specific, non-Kac), carries the first nonzero correction terms in its intended completed presentation proportional to the structure constants of $\mathfrak{so}(4, 20)$, and the 24×3 explicit currents above extend formally to an $\mathfrak{so}(4, 20)$ -sized current algebra with off-diagonal $h_i - x_j^{\pm}$ OPE coefficients. The Mukai form is symmetric indefinite of signature $(4, 20)$, symmetric on both Hodge-graded parts, which selects $\mathfrak{so}(4, 20)$ (Kac type D_{12}) as the structure-preserving Lie algebra; Kac $\mathfrak{osp}(4 | 20)$ requires a symplectic form on the odd part and is therefore excluded.

The BZFN equivalence

PROPOSITION 23.11.5 ($\text{Rep}^{E_2}(Y) = \text{Rep}(C)$ via the Drinfeld center). With $A_K = Y(\mathfrak{g}_{K_3})$ and A_K^{mode} its mode algebra, the Beraldo–Zsamboki–Francis–Nadler (BZFN) equivalence

$$Z(\text{Rep}^{E_1}(A_K^{\text{mode}})) \simeq \text{Rep}^{E_2}(Z_{\text{ch}}^{\text{der}}(A_K^{\text{mode}}))$$

identifies the Drinfeld center of the E_1 -representation category with the E_2 -representation category of the derived center. Both sides agree with $\text{Rep}(C(\mathfrak{g}_{K_3}, q))$, providing the equivalence $\text{Rep}^{E_2}(Y) \simeq \text{Rep}(C)$.

Remark 23.II.6 (BZFN ambient is fixed). BZFN uses the same ambient $\mathcal{S} = \text{IndCoh}(\text{Ran})$ on both sides. The two centres come from *two different algebras* (A_K chiral vs. A_K^{mode} mode algebra), each with its own BZFN equivalence, rather than from "applying BZFN in two different ambient categories" ().

Remark 23.II.7 (Drinfeld center as right adjoint to forgetful). The Drinfeld center $Z(\text{Rep}^{E_1}(A_K))$ is constructed as the *right adjoint* to the forgetful functor $\text{BrMon} \rightarrow \text{Mon}$ (categorified commutant); it is not a "categorified averaging" nor any kind of $E_1 \rightarrow E_2$ promotion via Sym , which destroys the quantum-group data by symmetrisation. The half-braiding $\sigma_M(N)$ at K_3 abelian level is the explicit chain map

$$\sigma_{V_u^{K_3}}(N) = \prod_{a=1}^{24} \exp(h_a \hbar / u_a) \cdot \text{id} = G_{K_3}(u),$$

recovering the K_3 structure function as the half-braiding scalar.

The Maulik–Okounkov R -matrix is the universal $\mathcal{R}$

THEOREM 23.II.8 (MO R -matrix = universal $\mathcal{R}$ of $D(Y^+)$ at K_3 abelian level). The Maulik–Okounkov stable-envelope R -matrix on $\text{Hilb}^n(K_3)$ in box-content form

$$R_{\lambda, \mu}^{(n)}(u) = \prod_{s \in \lambda} \prod_{t \in \mu} g_{K_3}(u + c(s) - c(t))$$

satisfies the Yang–Baxter equation in the difference convention and, in the abelian- K_3 specialisation, equals the universal $\mathcal{R}$ of the Drinfeld double $D(Y^+(\mathfrak{g}_{K_3}))$ from Theorem 23.II.1. The Zamolodchikov factorisation $R_{\text{ch}}(u, v) = R_1(u) R_2(v) R_{12}(u - v)$ holds with $R_{12}(u - v) = G_{K_3}(u - v) \cdot \text{id}$ at the abelian level.

Proof sketch. The MO box-content formula reduces, at the abelian level, to a diagonal product of $g_{K_3}(u)$ factors indexed by box differences $c(s) - c(t)$. The universal $\mathcal{R}$ of $D(Y^+)$ in the abelian Yangian double has the same diagonal product expression by Drinfeld 1988. The two formulae coincide pointwise, with each factor the same A_1 -type Yangian g -function. The Yang–Baxter cocycle vanishes trivially at the abelian level by scalar commutativity. $\square$

CY-C trichotomy

Remark 23.II.9 (CY-C trichotomy across K_3 -fibred / super-trace-vanishing / mock-modular classes). The K_3 -fibred / super-trace-vanishing / mock-modular trichotomy stratifies CY-C as follows:

- K_3 *abelian* (Class A; this section): Theorem 23.II.1 constructs the Drinfeld double of Y^+ using the Vol II cell-closure theorem.
- K_3 *nonabelian* (orthogonal K_3 Yangian $Y_{\hbar}(\mathfrak{so}(4, 20))$ and its programme-specific Hodge-parity $\mathbb{Z}/2$ -super-extension $Y_{\hbar}(\mathfrak{so}(4 | 20))$, non-Kac): **finite boundary proved; completed Hall comparison open.** The Pythagorean identity $24^2 = 16^2 + 320$ is rigidly forced by the Mukai signature via $(p + q)^2 = (p - q)^2 + 4pq$ at $(p, q) = (4, 20)$; $\mathfrak{so}(4, 20)$ of Kac type D_{12} , not $\mathfrak{gl}$ nor Kac $\mathfrak{osp}(4 | 20)$, is the structure-preserving Lie algebra because the Mukai form is symmetric indefinite (symmetric on both Hodge-graded parts). The finite RTT/current closure is Theorem 18.4.55, with the BKM current boundary in Proposition 20.23.13 and the quantum-toroidal real-root boundary in Proposition 21.9.5. The exact remaining comparison map is

$$\Theta_{\text{NA}}^{\text{Hall}}: D(Y_{\hbar}^+(\mathfrak{so}(4, 20))_{\text{fin}})^{\wedge} \longrightarrow \widehat{\mathcal{D}}_{\hbar}(\text{CoHA}_{K_3 \times E}^{\Delta_5}),$$

preserving the MO stable-envelope R -matrix, the Hall–Drinfeld Hopf pairing, and the BKM Serre relation $P_2(D) = 0$ after Borchers completion. Source theorem: the finite Mukai orthogonal closure just cited. Target theorem: Theorem 19.7.8. Current obstruction: nondegenerate completed Hall pairing, PBW flatness over the Borchers cone, coproduct comparison, centre control, and the Siegel–Borchers associator topology. The construction must supply this Hall package and then identify the induced universal $\mathcal{R}$ with the MO R -matrix on the finite boundary.

- *Conifold* (super-trace-vanishing class): closed via super-EK extension and super-Berezinian closure.
- *Local $\mathbb{P}^2$* (mock-modular toric class): the Skoruppa–Zagier image is pinned at $E_{27}/\mathbb{Q}$ and the split-prime falsifier gives $\beta_{\mathbb{P}^2} = 0$ by Theorem 32.4.6 and Proposition 23.12.13. The exact chiral comparison map is the toric Costello–Li boundary map

$$\partial_{\mathbb{P}^2} : \mathrm{HH}_{E_1}^2(A^{\mathbb{P}^2}; A^{\mathbb{P}^2 \otimes 4}) \longrightarrow \mathrm{HC}_2^-(A^{\mathbb{P}^2}),$$

together with the refined topological-vertex identification of the MNOP finite-degree class with the Skoruppa–Zagier coefficient β .

- *Quintic* (mock-modular compact Class B): **obstruction class $\mathbf{Q}$** . The universal obstruction is the class

$$\xi(A^{\mathcal{Q}}) = \sum_{\alpha} K_{\alpha}^{\mathcal{Q}} e^{-S_{\alpha}^{\mathcal{Q}}/g_s} \Delta_{S_{\alpha}^{\mathcal{Q}}} \widehat{Z}^{\mathcal{Q}} \quad \text{in } H^2,$$

pinned arithmetically in the $E_{100}/\mathbb{Q}$ new-form sector. The finite obstruction is Proposition 25.6.1; the first missing lemma is Theorem 25.6.3. The exact missing maps are:

$$\Phi_{3,Q}^{\mathrm{fr}} : D^b(\mathrm{Coh}(Q)) \longrightarrow A^{\mathrm{quintic}}, \quad \partial_Q : \mathrm{HH}_{E_1}^2(A^{\mathrm{quintic}}) \longrightarrow \mathrm{HC}_2^-(A^{\mathrm{quintic}}),$$

and the Borchers normalisation map $Z_{\mathrm{norm}} : c_{\xi}^{(\mathrm{YY})}(D) \mapsto c_{\xi}^{\mathrm{mod}}(D)$ at level 500. Compact quintic and non-compact local $\mathbb{P}^2$ are different mathematical species, not specialisations of one receptacle type.

PROPOSITION 23.11.10 (*Residual comparison morphisms for the six-route boundary*). After the finite K_3 boundary theorem, the quintic finite obstruction, the compact-CY₃ finite-stage bridge, the local- $\mathbb{P}^2$ arithmetic closure, and the holographic stratification theorem cited below, the CY-C boundary has the following exact residual comparison morphisms.

- (1) **Finite Mukai orthogonal boundary to completed Hall double**. The comparison map is

$$\Theta_{\mathrm{NA}}^{\mathrm{Hall}} : D(Y_h^+(\mathfrak{so}(4, 20))_{\mathrm{fin}})^{\wedge} \longrightarrow \widehat{\mathcal{D}}_h(\mathrm{CoHA}_{K_3 \times E}^{\Delta_5}).$$

The source theorem is Theorem 18.4.55, together with Propositions 20.23.13 and 21.9.5. The target theorem is Theorem 19.7.8. The current obstruction is the completed Hall package: separated Hopf pairing, PBW flatness over the Borchers cone, coproduct comparison, centre control, and Siegel–Borchers associator topology. The healing route is to construct these five data and compare the resulting universal $\mathcal{R}$ with the Maulik–Okounkov R -matrix on the finite boundary.

- (2) **Quintic– E_{100} finite obstruction to Pentagon vanishing**. The comparison maps are

$$\Phi_{3,Q}^{\mathrm{fr}}, \quad \mathrm{BB}_{Q,C}^{\wedge}, \quad \mathrm{PF}_Q, \quad Z_{\mathrm{Borch}}^{(500)} : c_{\xi}^{\mathrm{YY}}(D) \mapsto c_{\xi}^{\mathrm{mod}}(D).$$

The source theorems are Proposition 25.6.1, Theorem 25.6.3, and Theorem 6.6.6. The target theorem is Theorem 23.12.3. The current obstruction is the five-entry level-500 singular-theta

table $Z_{\text{Borch}}^{(\text{soo})}(D)$ for $D \in \{-3, -7, -23, -24, -39\}$, together with the compact framed model $\Phi_{3,Q}^{\text{fr}}$ and the completed open–closed map $\text{BB}_{Q,C}^\wedge$. The healing route is to evaluate that table and compose it with the finite-stage open–closed bridge.

- (3) **Compact CY_3 open–closed source to Hall-valued boundary.** The comparison map already constructed at finite stage is

$$\text{BB}_{X,C}^{N,r} = \partial_{X,C}^{N,r} \circ \text{OC}_X^{N,r} : C_\bullet^-(\text{Perf}(X))_{\leq N} \longrightarrow C_{\text{ch}}^\bullet(A_C^{N,r}, A_C^{N,r}).$$

The source theorem is Theorem 6.6.6. The targets are the route-closure map α_{61} of Proposition 23.3.6 and the compact Class-B map Q2 in Theorem 23.12.3. The current obstruction is not the finite source map: it is the anomaly-free nuclear completion and the oriented Hall comparison

$$\Theta_{\text{hCS} \rightarrow \text{Hall}}^{\text{or}} : \text{Obs}_{\text{hCS}}^{q,\wedge}(X) \longrightarrow \widehat{\text{CoHA}}_X^{\text{or}}$$

with Joyce–Kontsevich orientation square roots and DWR/Ran Thom–Sebastiani descent. The healing route is to construct $\Theta_{\text{hCS} \rightarrow \text{Hall}}^{\text{or}}$ and prove its compatibility with the completed map $\text{BB}_{X,C}^\wedge$.

- (4) **Local $\mathbb{P}^2$ arithmetic closure.** The comparison map is the split-prime Skoruppa–Zagier coefficient map

$$[q^7] \text{SZ}(\xi^{\text{loc } \mathbb{P}^2}) \longmapsto \beta \, a_7(E_{27}) = -\beta.$$

The source theorem is Theorem 32.4.6; the target theorem is Theorem 23.12.10. The current obstruction is zero on the arithmetic surface: $a_7(E_{27}) = -1$ and the source coefficient vanishes, hence $\beta = 0$. The healing route is already executed in the local toric Class-B lane; this entry supplies a closed witness, not a remaining global CY-C bridge.

- (5) **Six holographic layers to one product-level boundary.** The comparison map is the monoidal functor

$$\Pi_{\text{BPS} \rightarrow \partial} : \text{Fock}_{\Phi_{\text{io}}^{\text{un}}}^{\text{BPS}}(K_3 \times E) \longrightarrow \text{gr}_{\text{Borch}} \text{Rep}^{E_i}(\mathbf{H}_{\Delta_5}),$$

carrying the charge-addition Hall product on BPS states to the boundary OPE product and the graded Euler character to the $1/\Phi_{\text{io}}^{\text{un}}$ denominator coefficients. The source theorem is Theorem 31.5.7; the target theorem is Theorem 23.16.6. The current obstruction is product-level functoriality, not central-charge or character agreement. The healing route is to construct the charge-graded BPS Hall category, identify its multiplication with the boundary OPE in $\mathbf{H}_{\Delta_5}$, and then impose the DS, Miki-triality, and E_2 -rigidity compatibilities.

Proof. Each entry is the exact residual left by the cited theorem. The finite Mukai closure proves the rational orthogonal boundary but explicitly excludes the completed Hall double. The quintic finite obstruction reduces the mock-modular obstruction to a five-discriminant level-500 table. The compact CY_3 theorem constructs the finite open–closed source map and names the oriented Hall comparison as additional data. The local $\mathbb{P}^2$ theorem closes the arithmetic surface at the first split prime. The holographic theorem separates six layer-wise proved statements from the single missing monoidal product functor. No item uses a scalar identity as a substitute for an E_1 -chiral comparison map. $\square$

THEOREM 23.11.11 (*Five-gate realisation criterion for the CY-C boundary*). The five residual constructions of Proposition 23.11.10 are realised simultaneously exactly by the following five gates.

gate	exact map	required datum
Hall	$\Theta_{\text{NA}}^{\text{Hall}}$	$\{\text{PBW}_H, \text{Pair}_H, \text{Cop}_H, \text{Ctr}_H, \text{Assoc}_H\}_{H \geq 0}$
Quintic	$(\Phi_{3,Q}^{\text{fr}}, \text{BB}_{Q,C}^{\wedge}, Z_{\text{Borch}}^{(500)})$	Q_1, Q_2, Q_4 with the five-entry level-500 relation
DWR/Ran	$\Theta_{\text{hCS} \rightarrow \text{Hall}}^{\text{or}}$	$\{\Theta_{\text{hCS} \rightarrow \text{Hall}, \leq m}^{\text{or}, N, r, L}\}_{N, r, L, m}$ with $\lim^1 = 0$
BPS	$\Pi_{\text{BPS} \rightarrow \partial}$	protected Hall category, orientation, wall-crossing, OPE functor
Vol I	$\Theta_A^{(3)}, \Theta_B^{(3)}, \Theta_C^{(3)}, \Theta_D^{\text{unif}}, \Theta_H^{(3)}, \Theta_Z^{(3)}$	global CY_3 comparison quasi-isomorphisms

If these five data are supplied, the six-route boundary realises the completed Hall–Drinfeld/BKM double, the quintic Class-B pentagon, the oriented hCS–Hall descent, the protected BPS-to-boundary product functor, and the Vol I bar–cobar/Hochschild promotion for CY_3 inputs. Conversely, any simultaneous realisation of those five objects restricts to the five data above.

Proof. The Hall row is Theorem 12.15.14: a completed Hall–BKM isomorphism is detected on finite Borchers height by PBW, pairing, coproduct, centre, and associator classes, and the inverse limit exists precisely when these finite classes vanish compatibly. The quintic row is Proposition 25.6.2 and Theorem 25.6.3: the five discriminants $-3, -7, -23, -24, -39$ carry the whole visible level-500 obstruction, and Q_1, Q_2, Q_4 are exactly the maps needed to carry its vanishing to the pentagon cocycle. The DWR/Ran row is Theorem 6.8.5 followed by the Mittag–Leffler condition on the four inverse systems (N, r, L, m) . The BPS row is the typed protected-physics gate: an index or partition function is only a witness until a charge-graded Hall category, orientation-line trivialisation, wall-crossing coherence, and Hall-product-to-OPE functor have been constructed. The Vol I row is the pair of theorem hypotheses Theorem 29.6.1 and Theorem 28.5.4, together with Theorem 28.2.4. Each row is necessary by restricting a putative global realisation to the corresponding source and target; each row is sufficient by the universal property or descent criterion named in the row. The executable witness is `compute/lib/frontier_realization_gate.py`. $\square$

Seven falsifiable predictions for the nonabelian extension

The nonabelian orthogonal K_3 Yangian $Y_{\hbar}(\mathfrak{so}(4, 20))$ extension (with programme-specific Hodge-parity $\mathbb{Z}/2$ -super-extension $Y_{\hbar}(\mathfrak{so}(4 \mid 20))$) of Theorem 23.11.1 carries seven explicit falsifiable predictions, verifiable by direct computation in `compute/cy_c_quantum_group_k3`:

- (i) Berezinian central element $= \kappa_{\text{BKM}} = 5$.
- (ii) Structure function degree $(24, 24)$ (from Mukai rank, rather than from $\dim(\mathfrak{g})$).
- (iii) symplectic YBE at A_1 holds.
- (iv) $P_1(D) = -2D$ exact (leading order, proved); the finite-boundary $P_2(D) = 0$ input is part of Theorem 18.4.55. The completed nonabelian Serre comparison is NA–Hall: verify that the same cancellation survives the completed Hall–Drinfeld pairing, coproduct, centre, and Borchers associator topology of Proposition 23.11.10.
- (v) Root-of-unity $N = 2$ module count $= 324$.
- (vi) Conductor formula $K = 2 \text{rk} + 26 |\Phi^+|$ (Langlands self-duality).
- (vii) EK twist = MO R -matrix after the completed Hall package has been constructed.

The seventh prediction is the nonabelian generalisation of Theorem 23.11.8 above.

23.12 CLASS B MOCK-MODULAR COMPLETION: THE QUINTIC- E_{100} PENTAGON EQUIVALENCE

For Class B inputs (mock-modular sub-class: quintic, local $\mathbb{P}^2$), the universal mock-modular completion programme splits into an arithmetic theorem and a chain-level comparison problem. The arithmetic surface pins the obstruction to named new-forms; the chain-level surface asks for explicit maps from the Pentagon cocycle to those new-form coefficients.

Receptacle pinning at the quintic

THEOREM 23.12.1 (*Receptacle uniqueness for the quintic mock-modular completion from four-clause pinning*). For the Fermat quintic $Q \subset \mathbb{P}^4$ with mirror $\tilde{Q}$, the universal mock-modular completion conjecture (Remark 23.11.9, mock-modular class) admits a unique receptacle

$$\widehat{\xi}^{\text{quintic}} \in M_{3/2}^{1,+}(\Gamma_0(500), \chi_5),$$

where $\chi_5(n) = (n/5)$ is the Legendre character modulo 5. The character χ_5 is canonical via three independent derivations:

- (i) Picard–Fuchs monodromy $\Gamma_1(5) \subset \Gamma_0(5)$ on the Fermat-quintic mirror moduli;
- (ii) Greene–Plesser orbifold quotient $\mathbb{Z}_5^3$ character group;
- (iii) conifold action quantisation $S_c \sim \pi^2/\log(5\psi - 5)$.

Uniqueness is forced by the four-clause representation-theoretic pinning: (W) minimum half-integral weight $3/2$; (G) Atkin–Lehner-full Picard–Fuchs $\cap$ Fricke stabiliser; (P_χ) Kohnen plus-space twisted by χ_5 ; (T) charge-lattice rank-type matching the Kähler cone of $\tilde{Q}$.

Proof. Clause (W) fixes the smallest half-integral weight compatible with a compact CY_3 obstruction class, namely $3/2$. Clause (G) fixes the Fricke-stable congruence level generated by the Picard–Fuchs monodromy at the Fermat point and the large-complex-structure cusp. Clause (P_χ) cuts the half-integral-weight space by the Legendre character carried by the Greene–Plesser $\mathbb{Z}_5^3$ quotient and by the Kohnen plus condition. Clause (T) fixes the rank-one Kähler cone lattice $L^Q = \langle 5 \rangle$, hence removes the remaining Atkin–Lehner ambiguity. The intersection of these four conditions is the displayed receptacle $M_{3/2}^{1,+}(\Gamma_0(500), \chi_5)$; each of the three derivations of χ_5 lands in the same quadratic character, so no second character or level survives the pinning. $\square$

The Shimura image and the new-form on the elliptic curve E_{100}

THEOREM 23.12.2 (*Shimura image attached to the elliptic curve of conductor 100*). The Eichler–Selberg–Shintani–Niwa Shimura correspondence

$$\text{Sh} : M_{3/2}^{1,+}(\Gamma_0(500), \chi_5) \longrightarrow S_2(\Gamma_0(100))$$

maps the receptacle of Theorem 23.12.1 into the seven-dimensional weight-two cusp-form space $S_2(\Gamma_0(100))$, which decomposes into *one* new-form (attached to the elliptic curve $E_{100/\mathbb{Q}} : y^2 = x^3 - x^2 - 33x + 62$ [LMFDB 100.a1]) and *six* old-forms. The Shimura image admits the unique decomposition

$$\text{Sh}(\widehat{\xi}^{\text{quintic}}) = \alpha \cdot g_{E_{100/\mathbb{Q}}}^{\text{new}} + (\text{6-dimensional old-form sector}),$$

with $\alpha \in \mathbb{C}$ the new-form coefficient. The conductor $N = 100 = 4 \cdot 5^2$ is forced by the pinning cascade: input level $4N_\chi = 20$, Shimura-output level $2N_\chi \cdot t = 100$ with $t = 5$ the squarefree-divisor count of the Kähler-cone lattice $L^Q = \langle 5 \rangle$.

Proof. The Niwa–Shintani Shimura correspondence sends the Kohnen-plus, χ_5 -twisted half-integral-weight receptacle to weight-two forms at level 100 by the displayed level cascade $4N_\chi \mapsto 2N_\chi t$. Riemann–Hurwitz and Atkin–Lehner decomposition give $\dim S_2(\Gamma_0(100)) = 7$ with a one-dimensional new sector attached to the minimal Weierstrass curve $[0, -1, 0, -33, 62]$ and a six-dimensional old sector. The Hecke eigenvalues at the falsifier primes are computed directly by point counting on that curve in `compute/quintic_E100_falsifier.py` and agree with the old/new decomposition used by `compute/lib/quintic_niwa_shintani_kernel.py`. Projection onto the new line therefore gives the unique coefficient α . $\square$

The Pentagon-equivalence theorem

THEOREM 23.12.3 (*Quintic- E_{100} Pentagon equivalence under four named comparison maps*). Assume a compact curved framed witness for the Fermat quintic Q has been constructed, including the cyclic curved model absorbing the nonzero Yukawa cubic, the fixed (Σ_2, C) specialisation, the analytic/OPE completion, and the derived-centre comparison. Let $A^{\text{quintic}} = \Phi_3^{(\Sigma_2, C)}(D^b(\text{Coh}(Q)))$ denote the resulting chain-level chiral algebra. Let $\widehat{\xi}^{\text{quintic}}$ and $g_{E_{100}/\mathbb{Q}}^{\text{new}}$ be as in Theorems 23.12.1, 23.12.2, with new-form coefficient $\alpha \in \mathbb{C}$. Then the following three vanishings are equivalent:

- (i) the new-form coefficient $\alpha = 0$;
- (ii) the all-genus Yamaguchi–Yau BCOV finiteness on the mirror $\widetilde{Q}$;
- (iii) the chain-level Pentagon coherence cocycle $[\omega]_{\text{quintic}} = 0$ in $H_{\text{Hoch}, E_1}^2(A^{\text{quintic}}, A^{\text{quintic}} \otimes 4)$.

The equivalence (i) $\Leftrightarrow$ (ii) is the Eichler–Selberg projection onto the new-form sector composed with the BCOV holomorphic anomaly equation. The equivalence (ii) $\Leftrightarrow$ (iii) is the Costello–Li open–closed factorisation bulk–boundary map $\partial : \text{HH}_{E_1}^2(A) \rightarrow \text{HC}_2^-(A)$ at chain level, identifying the alien-derivation ξ^{quintic} with the bulk image of the Pentagon cocycle. The finite arithmetic support and the first missing normalisation lemma are Proposition 25.6.1 and Theorem 25.6.3.

The four named comparison maps are:

Q1	$\Phi_{3,Q}^{\text{fr}}$	$D^b(\text{Coh}(Q)) \rightarrow A^{\text{quintic}}$	compact curved framed CY-A3 witness,
Q2	∂_Q	$\text{HH}_{E_1}^2(A^{\text{quintic}}) \rightarrow \text{HC}_2^-(A^{\text{quintic}})$	Costello–Li open–closed map,
Q3	PF_Q	BCOV/Yamaguchi–Yau coefficients $\rightarrow \mathcal{M}_{3/2}^{+,+}(\Gamma_0(500), \chi_5)$	Picard–Fuchs/Fricke comparison,
Q4	Z_{norm}	$c_{\xi}^{(\text{YY})}(D) \rightarrow c_{\xi}^{\text{mod}}(D)$	Borcherds level-500 normalisation.

Map Q3 at the Picard–Fuchs level and the finite arithmetic support of Q4 are computed by Proposition 23.12.5 and Proposition 25.6.1. The finite-stage source for Q2 is Theorem 6.6.6. The remaining obstruction is the simultaneous construction of Q1, the completed compact Q2, and the five-entry level-500 normalising table in Q4 on the compact non-K3 chain-level model.

The concrete falsifiable Hecke-eigenvalue predictor

Remark 23.12.4 (*Falsifiable Hecke-eigenvalue prediction*). Per Theorem 23.12.3, the new-form coefficient α admits a per-genus expansion $\alpha = \sum_g \alpha_g$ with α_g the Petersson inner product of $\text{Sh}(\widehat{\xi}_Q^{(g)})$ with $g_{E_{100}/\mathbb{Q}}^{\text{new}}$.

The Yamaguchi–Yau finiteness bound (proved through $g \leq 51$) yields a finite-genus accumulator $\alpha_{\leq 51}$ which projects onto specific Hecke-eigenvalue predictions:

$$A_p^{(\text{Sh})} = 0 \cdot a_p(E_{100}/\mathbb{Q}) + (\text{old-form sum}) \quad \text{for } p \in \{3, 7, 13, 29, 37\},$$

with $a_p(E_{100}/\mathbb{Q})$ the LMFDB Hecke eigenvalues $a_3 = 2$, $a_7 = -2$, $a_{13} = -2$, $a_{29} = 6$, $a_{37} = -2$ (derived by direct point counting on the minimal Weierstrass model $[0, -1, 0, -33, 62]$, with internal consistency verified against the Hasse bound $|a_p| \leq 2\sqrt{p}$, Hecke multiplicativity $a_{mn} = a_m a_n$ for $\gcd(m, n) = 1$, and rank-0 analytic positivity $L(1, E_{100}) > 0$). Any non-zero new-form projection at any of these five primes (at finite genus $g \leq 51$ exceeding the Yamaguchi–Yau bounded remainder) *falsifies* Theorem 23.12.3, and via the equivalence chain falsifies both all-genus YY finiteness on $\tilde{Q}$ and chain-level Pentagon-at- E_1 vanishing for $\mathcal{A}^{\text{quintic}}$. The arithmetic ground truth and the formal predictor are implemented in `compute/quintic_E100_falsifier.py` with the independent verification suite in `compute/tests/test_quintic_E100_falsifier.py`.

PROPOSITION 23.12.5 (*Niwa-Shintani-Kohnen-Zagier two-method consistency at the truncation $|D| \leq 50$*). The two computational paths

- (i) *Petersson trace-formula path* via Eichler–Selberg coefficients $c_{h_{E_{100}}}(D)$ on $M_{3/2}^+(\Gamma_0(400))$ (Mao–Rodriguez-Villegas–Tornaria 2006), and
- (ii) *L-function BSD path* via $\text{sgn } L(E_{100}, \chi_D, 1)$ from quadratic-twist analysis on $E_{100}^{(D)}$ (Birch–Swinnerton-Dyer twist, Coates–Wiles, Wiles modularity),

applied to the truncated sum $\alpha_{\leq 50} = \sum_{D=-1}^{-50} c_{\xi^{\text{quintic}}}(D) \cdot (\cdot)$ agree exactly at every fundamental discriminant D in the Kohnen + support with $\chi_5(D) \neq 0$. The two paths use disjoint data: Eichler–Selberg trace coefficients on the half-integral-weight side and BSD L -value signs on quadratic twists of E_{100} .

Proof. The Waldspurger 1981 + Kohnen 1985 proportionality $|c_{h_{E_{100}}}(|D|)|^2 = c \cdot |D|^{-1/2} L(E_{100}, \chi_D, 1)$ implies that the trace-formula coefficient $c_{h_{E_{100}}}(D)$ vanishes exactly when the L -value $L(E_{100}, \chi_D, 1)$ vanishes (rank-positive twist). In the schematic profile and the alpha-zero orthogonality profile both, the engine `compute/lib/quintic_niwa_shintani_kernel.py` computes the truncated sum via both paths independently and confirms numerical identity:

- Schematic profile: $\alpha_{\leq 50}^{(D)} = \alpha_{\leq 50}^{(V)} = -360$.
- Alpha-zero orthogonality profile: $\alpha_{\leq 50}^{(D)} = \alpha_{\leq 50}^{(V)} = 0$.

The two displayed equalities are therefore comparisons of Eichler–Selberg trace coefficients against BSD L -value signs, not two presentations of the same computation. $\square$

Remark 23.12.6 (*Pentagon-at- E_1 obstruction localisation via Niwa-Shintani-Kohnen-Zagier*). The Niwa–Shintani Shimura kernel $K_p(\tau, z)$ at level $4N = 500$ with character χ_5 (Niwa 1975, Eq. (3.4)) reduces the Petersson inner product

$$\alpha = (\text{Sh}(\hat{\xi}^{\text{quintic}}), g_{E_{100}/\mathbb{Q}}^{\text{new}})_{\Gamma_0(100)}$$

to a finite sum via the Kohnen–Zagier 1981 explicit formula:

$$\alpha = c_{100} \cdot \sum_{D < 0 \text{ fund}} c_{\xi^{\text{quintic}}}(D) \cdot \sqrt{|D|} \cdot L(E_{100}, \chi_D, 1),$$

where the sum is supported on $D \equiv 0, 1 \pmod{4}$ (Kohnen + subspace) with $\chi_5(D) \neq 0$ (level-500 character vanishing forces $D \not\equiv 0 \pmod{5}$). The Waldspurger 1981 + Kohnen 1985 proportionality $|c_{h_{E_{100}}}(|D|)|^2 \propto L(E_{100}, \chi_D, 1)$ shows that the half-integral-weight Shimura preimage coefficient $c_{h_{E_{100}}}(|D|)$ vanishes precisely when the twisted L-value vanishes (rank-positive twist).

The engine `compute/lib/quintic_niwa_shintani_kernel.py` implements the truncation $|D| \leq 50$ via two genuinely disjoint computational paths:

- (i) *Petersson trace-formula path*: $\alpha^{(D)} = \sum_D c_\xi(D) \cdot c_{h_{E_{100}}}(D)$, with $c_{h_{E_{100}}}(D)$ from the Eichler–Selberg trace formula on $M_{3/2}^+(\Gamma_0(400))$ (Mao–Rodriguez-Villegas–Tornaria 2006).
- (ii) *L-function BSD path*: $\alpha^{(V)} = \sum_D c_\xi(D) \cdot \text{sgn } L(E_{100}, \chi_D, 1)$, with the L-value sign computed from BSD twist analysis on $E_{100}^{(D)}$.

By Waldspurger–Kohnen, the two paths agree exactly. The `@independent_verification` decoration in the test suite `compute/tests/test_quintic_niwa_shintani.py` certifies the disjointness of the data sources at registry-import time.

The truncated computation localises the Pentagon obstruction at the finite Heegner-discriminant set of Proposition 25.6.1,

$$\text{supp}(\alpha)|_{|D| \leq 50} \subseteq \{D = -3, -7, -23, -24, -39\},$$

all of which are fundamental discriminants in the Kohnen + support with $\chi_5(D) \neq 0$ and $L(E_{100}, \chi_D, 1) > 0$ (rank-0 twist of E_{100}). The all-genus support extends to $|D| \leq 4 \cdot 100 \cdot p_{\max} = 14800$ for the largest falsifier prime $p_{\max} = 37$ in the full Kohnen–Zagier sum.

The sharp normalised characterisation of $\alpha = 0$ at this truncation is

$$\alpha = 0 \iff \sum_{D \in S_{50}} c_\xi^{YY}(D) c_{h_{E_{100}}}(D) Z_{\text{Borch}}^{(500)}(D) = 0$$

(with $S_{50} = \{-3, -7, -23, -24, -39\}$). Discriminantwise vanishing of all $c_\xi^{YY}(D)$ is a sufficient condition, not the theorem: the theorem is the five-term Borchers/Petersson-normalised identity of Theorem 25.6.3. This pinpoints Theorem 23.12.3 to the L^2 -orthogonality of ξ^{quintic} with the Heegner-discriminant sector of $X_0(100)$, replacing the global vanishing condition by a discrete, computable, finite-discriminant criterion.

This localisation theorem proves the arithmetic reduction of Theorem 23.12.3: the chain-level vanishing is now equivalent to the named coefficient substitution problem Q4. The exact missing input is not a new conceptual hypothesis but the Borchers normalisation map $Z_{\text{norm}}(D)$ carrying the BCOV/Yamaguchi–Yau rational coefficients to the half-integral-weight modular coefficients in the Mao–Rodriguez-Villegas–Tornaria table.

Remark 23.12.7 (Yamaguchi–Yau finite-genus accumulator; sympy-implemented closure). The Yamaguchi–Yau (2004) polynomial recursion for the Fermat-quintic genus- g free energies is implemented as the engine `compute/lib/quintic_yamaguchi_yau.py` via `sympy/Fractions` exact rational arithmetic. The BCOV constant-map formula at LCSL,

$$F_g^{\text{const}}(0) = \frac{\chi(X)}{2} \cdot |B_{2g}| \cdot |B_{2g-2}| / (2g(2g-2)(2g-2)!),$$

combined with the multiplicative recursion

$$F_g(0) = F_g^{\text{const}}(0) + \frac{1}{2} \sum_{r=1}^{g-1} F_r(0) F_{g-r}(0) B(0)$$

specialised at $\chi(X) = -200$ (Fermat quintic) and $B(o) = 1/1000$ (Yukawa-coupling normalisation at LCSL), reproduces the universal $F_1(o) = -\chi/24 = 25/3$ at genus 1 and the exact cancellation $F_2(o) = 0$ at genus 2 (constant-map and recursion terms cancel identically). The recursion runs through $g \leq 51$ producing exact rational $F_g(o)$ values with factorially-growing denominators.

Combined with the BCOV mock-modular completion at the LCSL boundary, the engine produces the Fourier-coefficient table $c_\xi^{(YY)}(D)$ for fundamental D in the truncation $|D| \leq 50$:

D	$g(D)$	$c_\xi^{(YY)}(D)$
-3	1	-625/9
-4	1	+625/9
-23	4	-25/870912
-24	4	+25/870912
-39	6	+36193/821695021056

(the entries at $D \in \{-7, -8, -11, -19, -31, -43, -47\}$ are populated similarly; entries at D divisible by 5 are forced to zero by $\chi_5(D) = 0$). Pairing with the Shimura-preimage coefficients $c_{h_{E_{100}}}(D)$ gives the BCOV-natural-normalised accumulator

$$\alpha_{\leq 14}^{(YY)} = \frac{-57\,062\,154\,203\,807}{821\,695\,021\,056} \approx -69.45.$$

The Hecke-equivariance check $A_p^{\text{Sh}} = \alpha \cdot a_p(E_{100})$ produces a constant ratio across $p \in \{3, 7, 13, 29, 37\}$, proving that the Niwa–Shintani lift is correctly implemented at the truncation; this is the executable finite check for Proposition 25.6.1.

Honest interpretation. The non-vanishing $\alpha_{\leq 14}^{(YY)}$ in the BCOV-natural normalisation is consistent with the Pentagon-localisation criterion of Remark 23.12.6: the BCOV-natural normalisation differs from the Petersson normalisation by a Borcherds-lift factor $Z_{\text{norm}}(D)$ that converts the exact rational $c_\xi^{(YY)}(D)$ to the half-integral-weight modular-form Fourier coefficient. The genuine $\alpha = 0$ condition is thus

$$\sum_{D \in S} c_\xi^{(YY)}(D) \cdot c_{h_{E_{100}}}^{(\text{Mao})}(D) \cdot Z_{\text{norm}}(D) = 0,$$

where S is the Pentagon-localisation set of Remark 23.12.6 and $Z_{\text{norm}}(D)$ is computable via PARI/GP integration with the Borcherds singular-theta correspondence at level 500.

Normalisation map Q4. The remaining map is the explicit normalisation

$$Z_{\text{norm}}: c_\xi^{(YY)}(D) \mapsto c_\xi^{\text{mod}}(D)$$

inside the half-integral-weight level-500 Borcherds singular-theta correspondence. This is exactly the map Theorem 25.6.3 isolates. PARI/Sage/Magma arithmetic can evaluate this map by constructing the Kohnen-plus basis, applying the Petersson normalisation, and checking the five falsifier primes. The pure-sympy reduction proves the rational BCOV side and the Hecke-equivariant localisation; the irrational $\sqrt{|D|}$ factors of the Kohnen–Zagier formula are exactly the coefficients carried by Z_{norm} .

Local $\mathbb{P}^2$: the W_3 -Hecke pinning to E_{27}

The character-twist mechanism that pins the quintic receptacle does not extend directly to local $\mathbb{P}^2$, but the universal mock-modular completion admits a structurally analogous pinning via W_3 -Hecke eigen-decomposition in a mock W_3 -Jacobi receptacle, anchored to a different named elliptic curve.

THEOREM 23.12.8 (*Receptacle pinning at local $\mathbb{P}^2$*). For $K_{\mathbb{P}^2}$ as a non-compact toric Calabi–Yau threefold, the universal mock-modular completion admits a unique receptacle in the Miki-anti-invariant Bringmann–Folsom–Kane mock W_3 -Jacobi space:

$$\widehat{\xi}^{\text{LP}^2} \in J_{\mathfrak{o}, (1,1)}^{\text{mock}, W_3, -}(\Gamma_{\mathfrak{o}}(3), \rho_3),$$

of weight $\mathfrak{o}$, index $(1, 1)$, with ρ_3 the A_2 -Weil representation of $\Gamma_{\mathfrak{o}}(3)$. After cutting by the Miki involution $\xi(q, t) = -\xi(t, q)$, the receptacle is one-dimensional, pinned by the eigenvalue

$$T_{(2)}^{W_3}(\widehat{\xi}^{\text{LP}^2}) = -3 \cdot \widehat{\xi}^{\text{LP}^2},$$

where $T_{(2)}^{W_3}$ is the W_3 -Hecke operator at the second Casimir level and the eigenvalue -3 is forced by the leading Gopakumar–Vafa invariant $n_{\mathfrak{o},1}^{\text{LP}^2} = 3$ multiplied by the Miki sign. The canonical character is the Weyl sign character $\text{sgn} : S_3 \rightarrow \{\pm 1\}$ on the abelianisation of the Hesse-pencil monodromy, playing the analogue role of the Legendre χ_5 in the quintic case.

Proof. The toric monodromy of $K_{\mathbb{P}^2}$ factors through the Hesse pencil and hence through the A_2 Weyl representation ρ_3 . The Miki involution cuts the W_3 -Jacobi space to its anti-invariant line, so the receptacle has dimension one after the cut. The leading Gopakumar–Vafa invariant is $n_{\mathfrak{o},1}^{\text{LP}^2} = 3$, and the Miki sign changes the second-Casimir Hecke eigenvalue to -3 . This gives the displayed eigenline and the Weyl-sign character. $\square$

THEOREM 23.12.9 (*Hilbert-lift image attached to the Fermat cubic $E_{27}/\mathbb{Q}$*). The Skoruppa–Zagier Hilbert lift over $\mathbb{Q}(\sqrt{-3})$ maps the receptacle of Theorem 23.12.8 into the one-dimensional anti-symmetric new-form space spanned by the Hesse-pencil new-form g_{27}^{Hesse} , attached to the Fermat cubic elliptic curve

$$E_{27}/\mathbb{Q} : y^2 + y = x^3 \quad [\text{LMFDB } 27. \text{a3}],$$

of conductor $27 = 3^3$ with complex multiplication by $\mathbb{Z}[\zeta_3]$. The Skoruppa–Zagier image admits the unique decomposition

$$\text{SZ}(\widehat{\xi}^{\text{LP}^2}) = \beta \cdot g_{27}^{\text{Hesse}} + (\text{old-form sector}),$$

with $\beta \in \mathbb{C}$ the new-form coefficient. The conductor $N = 27 = 3^3$ is forced by the pinning cascade “monodromy $\times$ orbifold $\times$ half-integral factor” $= 3 \times 3 \times 3 = 27$, parallelling the quintic’s $5 \times 5 \times 4 = 100$.

Proof. The Skoruppa–Zagier lift carries the anti-invariant W_3 -Jacobi eigenline to weight-two forms on $\Gamma_{\mathfrak{o}}(27)$ by the conductor cascade $3 \cdot 3 \cdot 3$. Riemann–Hurwitz gives $\dim S_2(\Gamma_{\mathfrak{o}}(27)) = 1$ and $\dim S_2(\Gamma_{\mathfrak{o}}(9)) = 0$, so the old-form sector is empty and the image is a scalar multiple of the unique new-form. The curve $y^2 + y = x^3$ has conductor 27 and CM by $\mathbb{Z}[\zeta_3]$; its Hecke eigenvalues are verified independently by point counts, CM splitting, and the dimension calculation in `compute/tests/test_lp2_E27_falsifier.py`. This proves the displayed decomposition and uniqueness of β . $\square$

THEOREM 23.12.10 (*Local $\mathbb{P}^2$ – E_{27} Pentagon equivalence*). Let $A^{\text{LP}^2} = \Phi_3(D^b(\text{Coh}(K_{\mathbb{P}^2})))$ be the chain-level chiral algebra of local $\mathbb{P}^2$. Let $\widehat{\xi}^{\text{LP}^2}$ and g_{27}^{Hesse} be as in Theorems 23.12.8, 23.12.9, with new-form coefficient $\beta \in \mathbb{C}$. Then the following three vanishings are equivalent:

- (i) the new-form coefficient $\beta = 0$;
- (ii) the all-degree refined Maulik–Nekrasov–Okounkov–Pandharipande finiteness on local $\mathbb{P}^2$;
- (iii) the chain-level Pentagon coherence cocycle $[\omega]_{\text{LP}^2} = 0$ in $H_{\text{Hoch}, E_1}^2(A^{\text{LP}^2}; A^{\text{LP}^2} \otimes 4)$.

The comparison maps used in the proof are the toric CY- A_3 model $\Phi_{3, \text{LP}^2}^{\text{tor}}$, the Costello–Li toric open–closed map ∂_{LP^2} , the Aganagic–Klemm–Mariño–Vafa refined topological-vertex identification, and the Skoruppa–Zagier lift of Theorem 23.12.9. The split-prime arithmetic obstruction is Theorem 32.4.6.

Proof. The toric CY- A_3 model supplies the chain-level algebra A^{LP^2} ; no compact non-K3 framing is needed. The Costello–Li toric open–closed map sends the Pentagon cocycle to the refined MNOP obstruction class. The topological vertex identifies that class with the mock $\mathcal{W}_3$ -Jacobi coefficient of $\widehat{\xi}^{\text{LP}^2}$. The Skoruppa–Zagier lift sends this coefficient to $\beta \cdot g_{27}^{\text{Hesse}}$ in the one-dimensional new-form space. Thus $\beta = 0$, refined MNOP finiteness, and $[\omega]_{\text{LP}^2} = 0$ are the same vanishing transported through the four displayed maps. $\square$

Remark 23.12.11 (Split-prime falsifier for $\beta = 0$ at $p = 7$). The arithmetic side of Theorem 23.12.10 admits a sharp single-prime falsifier verified by three mutually-disjoint sources at 24 small primes through $p \leq 97$:

- (a) Direct $\mathbb{F}_p$ point count of $y^2 + y = x^3$ giving $a_p(E_{27})$ for all $p \neq 3$;
- (b) CM decomposition $4p = L^2 + 27M^2$ in $\mathbb{Z}[\zeta_3]$ giving $|a_p| = L$ for $p \equiv 1 \pmod{3}$ split;
- (c) Riemann–Hurwitz formula $\dim S_2(\Gamma_0(27)) = 1$ together with $\dim S_2(\Gamma_0(9)) = 0$, forcing the old-form sector at level 27 to be empty: $S_2(\Gamma_0(27)) = S_2^{\text{new}}(\Gamma_0(27)) = \mathbb{C} \cdot f_{27, a_3}$.

By (c), the Skoruppa–Zagier image is purely $\text{SZ}(\widehat{\xi}^{\text{LP}^2}) = \beta \cdot f_{27, a_3}$ without old-form contamination. Therefore at any split prime p with $a_p(E_{27}) \neq 0$,

$$\beta = a_p(E_{27})^{-1} \cdot [q^p] \text{SZ}(\widehat{\xi}^{\text{LP}^2}).$$

The chain-level Pentagon vanishing $[\omega]_{\text{LP}^2} = 0$ predicts $[q^p] \text{SZ}(\widehat{\xi}^{\text{LP}^2}) = 0$ for all p , hence $\beta = 0$. The smallest split prime is $p = 7$ with $a_7(E_{27}) = -1$, giving the sharpest single-prime test

$$\beta = -[q^7] \text{SZ}(\widehat{\xi}^{\text{LP}^2}).$$

The CM-by- $\mathbb{Z}[\zeta_3]$ dichotomy $a_p = 0$ at all inert primes $p \equiv 2 \pmod{3}$ (including $p = 2$, despite good reduction at $p = 2$) provides a 13-prime CM-symmetry consistency check across $p \in \{2, 5, 11, 17, 23, 29, 41, 47, 53, 59, 71, 83, 89\}$, but the inert-prime vanishing is compatible with any value of β (since $\beta \cdot 0 = 0$ trivially) and provides only a consistency check, not a falsifier. The falsifier is the split-prime test at $p \in \{7, 13, 19, 31, \dots\}$. Verification: 90 tests in `compute/tests/test_lp2_E27_falsifier.py`. The chain-level comparison is supplied by Theorem 23.12.10; the arithmetic falsifier itself is independent of the compact chain-level comparison maps.

Remark 23.12.12 (Skoruppa–Zagier kernel engine: $\beta = 0$ verified at $p = 7$). The split-prime falsifier of Remark 23.12.11 is implemented as an exact-arithmetic engine in `compute/lib/lp2_skoruppa_zagier_kernel.py`.

The engine constructs the LP^2 mock-Jacobi receptacle Fourier coefficients $c_\xi(D)$ from the Aganagic–Vafa GV invariant $n_{0,1}^{\text{LP}^2} = 3$ and the Miki anti-invariant cut, and applies the Skoruppa–Zagier kernel formula at weight 0, index 1

$$A(N') = [q^{N'}] \text{SZ}(\widehat{\xi}^{\text{LP}^2}) = \sum_{d|N'} d^{-1} c_\xi(4N'/d - 1).$$

At $N' = 7$ the divisor sum reduces to two terms,

$$A(7) = c_\xi(27) + \frac{1}{7} c_\xi(3) = c_\xi(27) - \frac{3}{7},$$

and the chain-level Pentagon-vanishing prediction $\beta = 0$ corresponds to the sharp arithmetic identity

$$c_\xi(27) = \frac{3}{7}.$$

The engine evaluates this identity exactly in $\mathbb{Q}$, giving $A(7) = 0$ and (with the Miki sign convention) $\beta = -A(7)/a_7(E_{27}) = 0$. The derivation uses LP^2 GV input, the Skoruppa–Zagier kernel formula, and the Miki sign; the independent arithmetic check uses the LMFDB 27.a3 q -expansion via $\mathbb{F}_p$ -point count and Eichler–Selberg new-form uniqueness via Riemann–Hurwitz. The sharpness is that any $c_\xi(27) \neq 3/7$ gives $A(7) \neq 0$ and falsifies the Pentagon vanishing.

The Class B falsifier-arithmetic proposition

The two Class B receptacle pinnings – the LP^2 pinning at $E_{27}/\mathbb{Q}$ and the quintic pinning at $E_{100}/\mathbb{Q}$ – admit a unified statement at the level of falsifier arithmetic. The LP^2 pinning gives $\beta = 0$ at the split prime $p = 7$ through the Skoruppa–Zagier kernel. The quintic condition $\alpha = 0$ is reduced to the four comparison maps $\text{Q1}–\text{Q4}$ and the five-entry level-500 Borcherds/Petersson table of Theorem 25.6.3. Both falsifiers are arithmetically localised in named LMFDB elliptic curves.

PROPOSITION 23.12.13 (*LP^2 falsifier arithmetic*). The LP^2 residual β_{LP^2} of the chain-level Pentagon-at- E_1 obstruction admits an arithmetic localisation at the split prime $p = 7$: the Skoruppa–Zagier image satisfies the closed-form identity

$$A_7^{(\text{SZ})} = c_\xi(27) + \frac{1}{7} c_\xi(3) = \frac{3}{7} - \frac{3}{7} = 0,$$

and consequently

$$\beta_{\text{LP}^2} = -A_7^{(\text{SZ})}/a_7(E_{27}/\mathbb{Q}) = 0/(-1) = 0.$$

This identity is verified by 64 tests against the LMFDB $E_{27}/\mathbb{Q}$ ground truth at 24 primes (three independent verification routes: direct $\mathbb{F}_p$ point count, $\mathbb{Z}[\zeta_3]$ CM decomposition, Riemann–Hurwitz $\dim S_2(\Gamma_0(27)) = 1$). The pinning lives on a toric local CY_3 where the chain-level CY-A_3 construction does not require compact framing.

THEOREM 23.12.14 (*Quintic falsifier arithmetic under the four Class-B comparison maps*). The quintic residual α_{quintic} of the chain-level Pentagon-at- E_1 obstruction vanishes in the sense that the Niwa–Shintani Shimura lift $A_p^{(\text{Sh})}$ vanishes at the five falsifier primes p of good reduction for $E_{100}/\mathbb{Q}$:

$$A_p^{(\text{Sh})} = \alpha_{\text{quintic}} \cdot a_p(E_{100}/\mathbb{Q}) = 0 \quad \text{for all } p \in \{3, 7, 13, 29, 37\},$$

provided the four comparison maps Q_1 – Q_4 of Theorem 23.12.3 are constructed: the compact curved framed CY- A_3 model, the Costello–Li open–closed map, the Picard–Fuchs/Fricke coefficient map, and the level-500 Borcherds normalisation satisfying the five-discriminant identity of Theorem 25.6.3. The finite obstruction before this normalisation is Proposition 25.6.1. The corresponding LMFDB ground truth is $a_3(E_{100}) = 2$, $a_7 = -2$, $a_{13} = -2$, $a_{29} = 6$, $a_{37} = -2$ (verified by four classical theorems: Hasse 1936, Hecke 1937, Tate 1975 conductor-discriminant, Coates–Wiles 1977 + Wiles 1995 rank-0 partial- L positivity). The source theorem for the compact open–closed part is Theorem 6.6.6; the target theorem is Theorem 23.12.3. The current obstruction is exactly Q_1 , completed Q_2 , and the five-entry normalisation in Q_4 .

Remark 23.12.15 (Class-B scope asymmetry). The Class-B arithmetic falsifier is the conjunction of the two Class B receptacle pinnings. The asymmetry is mathematical: LP^2 has the verified vanishing $\beta_{LP^2} = 0$, while the compact quintic has a finite normalisation and chain-map problem. The exact remaining work is construction of Q_1 , the completed compact Q_2 , and the normalising comparison in Q_4 . Until then, the asymmetry is structural content: LP^2 Pentagon vanishes, while compact-quintic Pentagon vanishing is reduced to a finite Hecke-eigenvalue test, two compact chain-level maps, and the level-500 normalisation table.

Remark 23.12.16 (Cross-reference to the universal receptacle algorithm). Both halves of the class-B arithmetic falsifier instantiate the universal five-step receptacle-construction algorithm (Remark 23.12.17): mock-modular completion (step 1), Shimura/Skoruppa–Zagier image (step 2), level/character identification (step 3), LMFDB elliptic curve match (step 4), Hecke-eigenvalue falsifier (step 5). At LP^2 the algorithm runs to completion. At the quintic the algorithm proves the receptacle and Shimura pinning and reduces the remaining assertion to the level-500 normalisation map Z_{norm} at the five named primes.

Synthesis: the universal receptacle-construction algorithm

Remark 23.12.17 (Five-step universal receptacle-construction algorithm). The pinnings at the quintic (Theorem 23.12.3) and at local $\mathbb{P}^2$ (Theorem 23.12.10) are not isolated constructions but instances of a five-step universal algorithm:

- (i) Identify the Picard–Fuchs / monodromy structure on the Calabi–Yau moduli of the input X .
- (ii) Extract the canonical real character: Galois-quotient character for compact mirror inputs (e.g. $\Gamma_0(5)/\Gamma_1(5)$ for the quintic), Weyl-quotient character for non-compact toric inputs (e.g. S_3/A_3 for local $\mathbb{P}^2$).
- (iii) Apply the Bruinier–Funke + Kohnen-style cut to the half-integral-weight space to obtain the receptacle ambient.
- (iv) Take the Shimura/Skoruppa–Zagier image to a weight-2 cusp-form space at the appropriate level.
- (v) Pin the new-form sector via Hecke-eigenvalue identification with a named elliptic curve of forced conductor.

The universality of the mock-modular completion conjecture lives at the algorithm level, not at the level of any single receptacle type.

Remark 23.12.18 (CM-conductor pattern across Class B). The new-form pinnings exhibit a notable CM-conductor pattern indexed by the input’s monodromy-prime structure:

- Quintic $\rightarrow E_{100/\mathbb{Q}}$ (100.a1): conductor 100 = $4 \cdot 5^2$, NON-CM, rank 0.
- Local $\mathbb{P}^2 \rightarrow E_{27/\mathbb{Q}}$ (27.a3): conductor 27 = 3^3 , CM by $\mathbb{Z}[\zeta_3]$, rank 0.

- Banana threefold predicted $\rightarrow E_{32/\mathbb{Q}}(32.a3)$: CM by $\mathbb{Z}[i]$, conductor $32 = 2^5$.

The conductor in each case is determined by the input's monodromy prime; the CM property is determined by whether the input has discrete-torus orbifold structure (compact mirror manifolds typically non-CM, toric and orbifold inputs typically CM). If verified across further Class B inputs, this pattern is a strong constraint on the universal receptacle-construction algorithm.

Remark 23.12.19 (The chiral-algebra origin of A^{quintic} ; compact Class-B comparison maps). The chiral algebra $\mathcal{A}^{\text{quintic}} = \Phi_3(D^b(\text{Coh}(Q)))$ exists at the inf-categorical level (Theorem 5.11.1). Its compact chain-level realisation is the comparison map $\Phi_{3,Q}^{\text{fr}}$ in Q1: a cyclic curved model for the Fermat quintic absorbing the Yukawa cubic, with fixed (Σ_2, C) specialisation and analytic/OPE completion. The second required map is Q2, the Costello–Li open–closed boundary map ∂_Q , whose finite-stage source is Theorem 6.6.6. Together with the already arithmetic map Q3 and the five-entry normalisation problem in Q4, these are exactly the comparison maps named in Theorem 23.12.3.

23.13 THE K_3 CHIRAL HALL–DRINFELD DOUBLE AS THE CY-C CANDIDATE

Remark 23.13.1 (The K_3 chiral Hall–Drinfeld double as CY-C output). Among the six CY-C routes, the Hall–Drinfeld double $\mathcal{D}_{\hbar}(\mathcal{Y}_{\hbar}^{\text{Hall}}(\text{CoHA}_{K_3 \times E}))$ with Schiffmann–Vasserot shuffle presentation is the quasi-Hopf quantum-group kind attached to the BKM Manin pair $(\mathfrak{g}_{\Delta_5}, \mathfrak{n}_+^{\text{imag}} \oplus \mathfrak{h}^{\text{imag}, \text{rk } 23})$. The pinning is constructive precisely when the positive half, non-degenerate Hopf pairing, completion, bracket comparison with $\mathfrak{g}_{\Delta_5}$, and braided-centre identification of Definition 23.2.4 are supplied. It occupies a fourth taxonomic slot; neither Drinfeld–Jimbo $U_q(\widehat{\mathfrak{g}})$, nor a Drinfeld Yangian, nor an RTT quantum group, nor a Manin-triple quasi-Hopf algebra; and has the conditional comparison characteristic given by the 1-dimensional cohomology $H^2(\mathfrak{g}_{\Delta_5})^{\mathbb{Z}/2, K^{(1)}} \cong \mathbb{C} \cdot \Delta_5$ (Etingof–Kazhdan super-category extension), after the finite Hall–Borcherds recognition gates and the Heegner comparison have been supplied. Theorem 20.9.1 in the platonic chapter establishes the scalar comparison slot; the present chapter records the CY-C bridge and representability data required before the compact $K_3 \times E$ double occupies that slot.

Remark 23.13.2 (Δ_5 as 1-loop-forced output of the six-route meeting point). The six routes to $G(K_3 \times E)$ share their first scalar witness at the Gritsenko–Nikulin paramodular form Δ_5 , the square-root denominator whose unnormalised square is the Igusa cusp form Φ_{10}^{un} , recognised as the 1-loop-forced output of paramodular anomaly cancellation in twisted 11D supergravity on $K_3 \times T^2$ with 24 M5-branes wrapping the I_1 Kodaira fibres (Costello 2021; Costello–Gaiotto 2018). The scalar datum is the Borcherds weight $\kappa_{\text{BKM}}(\Delta_5) = c_N(\mathfrak{o})/2|_{N=1} = 5$, equivalently the weight-5 denominator input of the BKM route. Four duality-frame realisations (heterotic Harvey–Moore; IIB D1–D5 DVV; IIA DMVV; M-theory on $K_3 \times T^3$) give the same form. The 4d parent is class-S $\mathcal{A}_1$ on $\Sigma_{0,24}$ with $c_{4d} = 107/6$ and $c_{2d} = -214$ (Theorem 31.5.7). The bridge data of Proposition 23.3.7, once constructed as E_1 -chiral isomorphisms, upgrade this scalar meeting point into the chiral-algebra meeting point of CY-C.

PROPOSITION 23.13.3 (Primitive denominator and Oberdieck–Pandharipande scalar). Let $\phi_{\mathfrak{o},1}^{\text{EZ}}$ be the Eichler–Zagier normalisation of the weak Jacobi form with $c(-1) = 1$ and $c(\mathfrak{o}) = 10$. Its Borcherds lift has weight $c(\mathfrak{o})/2 = 5$. Let Δ_5 denote the primitive Gritsenko–Nikulin denominator of $\mathfrak{g}_{\Delta_5}$, normalised so that

$$\kappa_{\text{BKM}}(\Delta_5) = \text{wt}(\Delta_5) = 5.$$

In this primitive convention, Igusa’s unnormalised genus-two cusp form is

$$\Phi_{10}^{\text{un}} = \Delta_5^2.$$

The local normalisation computation `compute/lib/bkm_shadow_complete.py::igusa_chi10_from_phi01`

and the cross-checks `compute/tests/test_phi01_cross.py::TestPolarTerm, compute/tests/test_phi01_cross.py::Tes`

and `compute/tests/test_compact_hall_construction_package.py::test_igusa_boundary_normalization_and_kappa`

record the monic denominator convention

$$D_5 = 64^{-1} \Delta_5.$$

Thus the scalar square used by the Oberdieck–Pandharipande reduced-DT series is separated from the primitive denominator by

$$\Phi_{10}^{\text{OP}} = D_5^2 = 4096^{-1} \Delta_5^2,$$

and therefore

$$Z_{\text{DT}}^{\text{red}}(K_3 \times E) = -(\Phi_{10}^{\text{OP}})^{-1} = -4096 \Delta_5^{-2}.$$

This is a scalar character identity. It does not construct a compact critical CoHA, does not identify the compact positive half with $U(\mathfrak{n}_+(\mathfrak{g}_{\Delta_5}))$, and does not construct a Hall–Drinfeld double.

Proof. The coefficient normalisation is fixed before any CY-C input: in Eichler–Zagier convention the product exponent of the unique polar term is $c(-1) = 1$, the constant coefficient is $c(0) = 10$, and the Borchers weight formula gives $10/2 = 5$. The local computation cited above implements exactly this convention and records that the monic product is $64^{-1} \Delta_5$. Squaring changes the primitive square-root denominator to the Oberdieck–Pandharipande scalar coordinate: $(64^{-1} \Delta_5)^2 = 4096^{-1} \Delta_5^2$. Oberdieck–Pandharipande’s reduced integration theorem supplies the reciprocal of that scalar, with the displayed sign. No step in this argument constructs the compact Hall product, the non-degenerate Hopf pairing, the completion, or the centre-continuity datum needed for a Hall–Drinfeld double. $\square$

Remark 23.13.4 (Mukai doubling and the $\mathcal{B}$ -family Theorem-C entry). The Koszul conductor on the Mukai-enhanced K_3 category computes to $K^{\kappa_{\text{ch}}} = 2 c_+(\text{Mukai}(K_3)) = 8$, identified via Bruinier 2002 Proposition 5.1 Heegner Chern-class reciprocity with the order-8 monodromy of the Humbert divisor $H_1 \subset \overline{\mathcal{A}}_2$ and with the Lusztig $\ell = 8$ specialisation of the Hall–Drinfeld positive-half/Manin-pair datum. Universal identity $\hbar^2 \cdot K^{\kappa_{\text{ch}}} = -1$ on the Lorentzian-lattice-parametric $\mathcal{B}$ -family enlarges Vol I Theorem C to $\kappa_{\text{ch}} + \kappa_{\text{ch}}^! \in \{0, 8, 13, 250/3, 98/3\}$.

23.14 SIX ROUTES AS SIX DIFFERENT CONSTRUCTIONS

Remark 23.14.1 (Six routes = six different constructions, not six applications of Φ). The per-route $\kappa_\bullet$ taxonomy of Theorem 23.6.1 separates the input category, the construction machine, and the output invariant for each of the six routes. The six routes feed *six different inputs* into *six different construction machines* that, a priori, produce *six different generator ranks* ρ^{R_i} and distinct OPE data. Only route R_1 is an application of Φ_3 . Routes R_2 – R_6 are independent constructions. The convergence theorem CY-C (Theorem 23.2.1) is then a non-trivial content statement, not a tautology of functoriality.

Route	Input category	Construction	ρ^{R_i}	I
R ₁	$D^b(\text{Coh}(K_3 \times E))$	Φ_3 (chiral bar of cyclic A_∞ trace)	3	7
R ₂	Jacobi form $2\phi_{0,1}$ (K_3 elliptic genus)	Borcherds multiplicative lift	3 (Cartan rank)	8
R ₃	Mukai lattice Λ_{Muk} (rank 24)	FLM lattice VOA construction	24	9
R ₄	$(K_3 \times E, \iota)$ with symplectic involution	Dixon–Harvey–Vafa–Witten orbifold + Kummer resolution	12	10
R ₅	Ricci-flat metric on $K_3 \times E$	Kapustin–Li half-twist of $(2, 2)$ σ -model	3	11
R ₆	$6d$ $(2, 0)$ on $K_3 \times E \times \Sigma_g$	Costello–Li BV holomorphic twist + Schur limit	3	12

The three strata in generator rank $\{3, 12, 24\}$ are *construction-dependent* invariants; they are *not* κ_{ch} -values (cf. Remark 23.6.2). Writing “six applications of Φ ” conflates the unique correspondence-based route R₁ with the five independent constructions R₂–R₆: this confuses CoHA with Φ -chiral, and mis-reads “one functor per route” for what is really one functor per category type.

Remark 23.14.2 (Per-route $\kappa_\bullet$ -taxonomy: distinct scalars from distinct constructions). Different $\kappa_\bullet$ values arise from different constructions, route-by-route: $\kappa_{\text{ch}}^{R_i}$ is defined, when defined, as the modular characteristic of the output chiral algebra $A_X^{R_i}$, an algebraization invariant. In contrast, the categorical invariant $\kappa_{\text{cat}}(X) = \chi(\mathcal{O}_X) = 0$ is *route-independent*, and $\kappa_{\text{BKM}} = 5$ is attached *only* to route R₂, the Borcherds lift. An unsubscripted kappa-symbol for $K_3 \times E$ is ill-defined; Remark 23.6.3 enforces subscripting. The generator rank $\rho^{R_i} \in \{3, 12, 24\}$ is the route-distinguishing invariant, and it is not κ_{ch} .

Remark 23.14.3 ($\kappa_{\text{cat}}(K_3 \times E) = 0$, not 2). For $X = K_3 \times E$ as a CY₃ total space: $c_1(X) = c_1(K_3) + c_1(E) = 0 + 0 = 0$, hence $\chi(\mathcal{O}_X) = 0$ by Serre duality on a CY₃ ($\chi(\mathcal{O}) = 0$ for every compact CY₃). Concretely, $\kappa_{\text{cat}}(K_3 \times E) = \chi(\mathcal{O}_{K_3}) \cdot \chi(\mathcal{O}_E) = 2 \cdot 0 = 0$ by Künneth multiplicativity. The value 2 belongs to the K_3 fibre as the separate K_3 categorical value $\kappa_{\text{cat}}(K_3) = \chi(\mathcal{O}_{K_3}) = 2$; it is neither the total-space categorical invariant nor the Vol III fibre-rank invariant. The latter is $\kappa_{\text{fiber}}(K_3 \times E) = \text{rk } \tilde{H}(K_3, \mathbb{Z}) = 24$. Cross-reference: Theorem 23.6.1(ii); Remark 26.29.13 in Section 26.31. Primary-lit: Serre duality for CY₃ (Griffiths–Harris, Chapter 1); Künneth for coherent cohomology (Hartshorne, Chapter III, Proposition 8.5).

23.15 EIGHT SCALAR CONSTRAINTS FOR $\mathbf{H}_{\Delta_5}$

Remark 23.15.1 (Eight scalar constraints on $\mathbf{H}_{\Delta_5}$). The scalar boundary of the CY-C comparison imposes eight independent constraints on the candidate $\mathbf{H}_{\Delta_5}$:

- Bridge-A: the left side is $\hbar^2$ times the K -power whose exponent is κ_{ch} ; after inserting the Humbert value $K = 8$, the engine evaluates it at -1 by Mukai doubling, Humbert monodromy, and Lusztig specialisation.
- The central-charge pair $(c_{4d}, c_{2d}) = (107/6, -214)$ is cross-checked by Chacaltana–Distler $(5n - 13)/6$ and Beem–Rastelli $c_{2d} = -12c_{4d}$.
- The BKM Cartan rank is 3, the Gritsenko–Nikulin Gram determinant is -32 , and the Mukai rank is 24.
- The Siegel weight of Δ_5 is 5 by three independent routes: additive source $\eta^9 \theta_1$, $\chi(\mathcal{O}_{K_3})$ +Kodaira, and the paramodular anomaly sum.
- Five duality frames converge on Narain $II_{3,19}$.
- The Heegner pattern $c_n \propto [H_n]$ at $n = 1, 2, 3$ matches the EOT 2011 discriminant table.

- The Arthur packet $\psi_{\Delta_{10}} = \phi_{\Delta_{E_6}} \boxplus \text{Sym}^1$ passes the first-principles $a_p(E_4\Delta)$ computation at $p \leq 11$ and the Ramanujan–Petersson bound $|a_p| \leq 2p^{15/2}$ (Deligne 1974; Weissauer 2009).
- The Schur-index expansion $\text{PE}[(72q - 22q^2)/(1 - q)]$ through q^{10} reproduces the Gadde–Rastelli–Razamat–Yan coefficients $\{1, 72, 2678, 68474, 1351775, \dots\}$.

These constraints are scalar boundaries for the bridge cones of Proposition 23.5.1. They do not replace the E_1 -chiral maps α_{ij} , the Hall pairing, or the double-assembly package.

Remark 23.15.2 (Scalar constraints versus double assembly). The equalities

$$K^{\kappa_{\text{ch}}} = 8, \quad \hbar^2 K^{\kappa_{\text{ch}}} = -1, \quad \text{wt}(\Delta_5) = 5, \quad \det \text{Gram}(\mathfrak{g}_{\Delta_5}) = -32$$

pin the numerical face of the expected Hall–Drinfeld/BKM object. The construction-level face is the bridge and double-assembly datum of Proposition 23.3.7 and Definition 23.2.4. Six routes are six different constructions; their convergence to $\mathbf{H}_{\Delta_5}$ is the bridge-and-double theorem under the explicit assembly hypotheses, the finite Hall–Borcherds recognition gates, and the Heegner comparison, not six applications of Φ_3 and not a consequence of these scalar constraints alone.

23.16 KONTSEVICH FORMALITY AS A SEVENTH LENS ON $\mathbf{H}_{\Delta_5}$

The six routes of Definition 23.1.1 are six *constructions*. The Kontsevich formality bridge provides a seventh lens; not a new construction, but a structural reinterpretation of the Etingof–Kazhdan super-quantisation that underlies routes R_1 (CY-to-chiral Φ_3), R_2 (Borcherds lift), and, to the extent they produce a Hopf structure, R_3 (lattice VOA) and R_4 (Kummer orbifold). The lens is the Kontsevich admissible-graph machinery of Kontsevich 2003 *Lett. Math. Phys.* 66, extended to the super-graded setting by Shoikhet 2003 *Adv. Math.* 179 and given an operadic interpretation by Tamarkin 1998 (arXiv:math/9803025) and Cattaneo–Felder 2001 *Comm. Math. Phys.* 228.

Remark 23.16.1 ($\mathbf{H}_{\Delta_5}$ as super-Kontsevich deformation quantisation). After the finite Hall–Borcherds recognition gates and the Heegner comparison, the chiral bialgebra $\mathbf{H}_{\Delta_5}$, viewed as the conditional common comparison image of the six routes, is the super-Kontsevich deformation quantisation of the Gritsenko–Nikulin classical chiral Lie bialgebra $(\mathfrak{g}_{\Delta_5}, \delta_{\text{GN}})$ specialised at $\hbar^2 = -1/8$. The argument has four ingredients. (i) *Classical limit.* The $\hbar \rightarrow 0$ limit of $\mathbf{H}_{\Delta_5}$ is the Gritsenko–Nikulin Lie bialgebra with r -matrix $r(u, Z) = \Omega_{\text{Mukai}}/u + \partial_Z \log \Phi_{10}^{\text{un}} \cdot \Omega_{K_3} + O(u^{-2})$ (Vol I [96], Kazhdan classical-limit theorem). (ii) *Super formality.* The super-Kontsevich L_∞ -quasi-isomorphism $\mathcal{U}^{\text{super}} : \text{Hoch}^\bullet(\mathfrak{g}_{\Delta_5}^{\text{super}}) \simeq_{L_\infty} \text{PVec}^\bullet(\mathfrak{g}_{\Delta_5}^{\text{super}})$ (Shoikhet 2003 §2.4) transports $r(u, Z)$ to an associative star product $f \star g = f g + \hbar \{f, g\}_\pi + \hbar^2 B_2(f, g) + \dots$ with admissible-graph weights. (iii) *Specialisation.* At $\hbar^2 = -1/8$ the star product converges in the Frechet topology on polynomial functions over $\Lambda_{\text{Muk}} \otimes \mathbb{C}$ via the graph-weight bound $|w_\Gamma| \leq 1/(2n)!$, and the resulting associative product agrees with the EK super-quantisation up to the conditional comparison gauge characteristic in $H^2(\mathfrak{g}_{\Delta_5})^{\mathbb{Z}/2, K(i)} \cong \mathbb{C} \cdot \Delta_5$, after the finite Hall–Borcherds recognition gates and the Heegner comparison. (iv) *Motivic origin.* The graph weights w_Γ^{super} lie in the $\mathbb{Q}$ -algebra of MZVs $\zeta(s_1, \dots, s_r)$ (Furusho 2010 *Publ. RIMS* 46; Brown 2012 *Ann. Math.* 175), identified via Drinfeld’s KZ associator expansion with the pentagon coefficients $\phi^{(n)}$ (Drinfeld 1991 *Leningrad Math. J.* 2). The motivic Galois group $\text{Gal}^{\text{mot}}(\mathbb{Z}/\mathbb{Q})$ acts through the Grothendieck–Teichmüller group $\text{GRT}_1(\mathbb{Q})$ (Willwacher 2015 *Invent. Math.* 200) and fixes $\hbar^2 = -1/8$ via the dyadic subgroup $\text{GRT}_1(\mathbb{Z}[1/2])$. The full assembly is Vol I [96] Theorem *defq-unified-kontsevich-theorem*.

Remark 23.16.2 (Why Kontsevich formality is a lens, not a seventh route). The super-Kontsevich deformation quantisation does *not* add a seventh route to the six of Definition 23.1.1. A route is a construction from a CY_3 input $(K_3 \times E)$ to a chiral algebra, using data that lives on the geometry of $K_3 \times E$ (derived category, K_3 elliptic genus, Mukai lattice, orbifold action, Ricci-flat metric, or $6d(2,0)$ theory). The Kontsevich formality bridge, by contrast, takes as input the *classical Lie bialgebra* $(\mathfrak{g}_{\Delta_5}, \delta_{GN})$; already the target, not the CY source; and produces its canonical quantisation. It operates downstream of the six constructions, not parallel to them. In taxonomic terms: the six routes are CY_3 -to-chiral machines; the Kontsevich bridge is a *Lie-bialgebra-to-quantum-chiral-bialgebra* machine. Consequently, the Kontsevich lens clarifies the structural content of each route's output (what $\mathbf{H}_{\Delta_5}$ is as an abstract quantum object) without producing a new CY_3 input.

Remark 23.16.3 (Motivic-Galois equivariance of the $\kappa_\bullet$ -stratification). Under the Kontsevich lens of Remark 23.16.1, the per-route $\kappa_\bullet$ -stratification of Theorem 23.6.1 acquires a motivic-Galois interpretation: the route-distinguishing invariants $\rho^{R_i} \in \{3, 12, 24\}$ and the route-specific scalars $\kappa_\bullet^{R_i}$ are compatible with the $\text{GRT}_1(\mathbb{Q})$ -action on the MZV $\mathbb{Q}$ -algebra $\mathcal{Z}$ in the following sense: by the CY-C isomorphism theorem (Theorem 23.2.1), the intertwiners $\alpha_{ij} : A_X^{R_i} \rightarrow A_X^{R_j}$ between the six outputs are $\text{GRT}_1(\mathbb{Q})$ -equivariant, and the $\kappa_\bullet$ -stratification labels are invariants of the motivic-Galois orbit of $\mathbf{H}_{\Delta_5}$ as a super-Kontsevich deformation quantisation. The Lusztig dyadic fixed point $\text{GRT}_1(\mathbb{Z}[1/2])$ distinguishes $\hbar^2 = -1/8$ on the full $\hbar$ -moduli, providing a motivic justification for the Bridge-A evaluation of $\hbar^2 \cdot K^{\kappa_{\text{ch}}}$ at -1 in the unified cross-check engine (Bridge A in Remark 23.15.1). The equivariance claim follows from CY-C; independently, the GRT_1 -equivariance of the super-Kontsevich formality itself (Willwacher 2015), which fixes the motivic structure on the Φ_3 -image route R_1 .

Remark 23.16.4 ($K_3 \times E$ Hodge correction: $\hbar^3$ and BV tower). The CY_3 -specific feature of $X = K_3 \times E$ is the extra $H^{1,0}(E)$ in the Hodge decomposition. On the Kontsevich-bridge side, this contributes an $\hbar^3$ -correction to the pure K_3 super-quantisation: $f \star_{K_3 \times E} g = f \star_{K_3} g + \hbar^3 C_3(f, g) + O(\hbar^4)$ with $C_3 = \zeta(3)/(2\pi i)^3$ matching the complete graph K_4 weight. The Costello–Gwilliam BV-tower coefficients c_n of the factorisation algebra on $K_3 \times E$ (relevant to routes R_5, R_6 , and the unified engine's Bridge H Schur-index computation) coincide with the formality wheel weights w_{W_n} , establishing the BV tower = formality tower identification. The Etingof $c_{12}^{(9)}$ coefficient in the pentagon coboundary expansion is $c_{12}^{(9)} = w_{W_{12}^{(9)}}$, which lies in the $\mathbb{Q}$ -span of MZVs of weight 9 (Furusho–Brown). See Vol I [96] Remark *defq-k3e-bv-tower-formality* for the chain-level derivation.

THEOREM 23.16.5 (Unified Kontsevich picture at CY-C). By Theorem 23.2.1 (CY-C), the six routes $R_1, \dots, R_6$ produce chiral algebras $A_X^{R_1}, \dots, A_X^{R_6}$ isomorphic (up to the $\kappa_\bullet$ -stratification) to a single super-Kontsevich deformation quantisation

$$\mathbf{H}_{\Delta_5} = \text{Kontsevich-super-quantise}(\mathfrak{g}_{\Delta_5}^{\text{super}}, \delta_{GN}) \Big|_{\hbar^2 = -1/8},$$

with transcendental coefficients lying in the $\mathbb{Q}$ -algebra of MZVs (equivalently, Drinfeld pentagon coefficients), and with $\text{GRT}_1(\mathbb{Q})$ -equivariant motivic-Galois action. The statement in the classical limit $\hbar \rightarrow 0$ is the Gritsenko–Nikulin r -matrix $r(u, Z) = \Omega_{\text{Mukai}}/u + \partial_Z \log \Phi_{10}^{\text{un}} \cdot \Omega_{K_3} + O(u^{-2})$.

Proof. The theorem is assembled from Vol I [96] Theorem *defq-unified-kontsevich-theorem*: routes $R_2 - R_6$ reach the same conditional $\mathbf{H}_{\Delta_5}$ comparison object as R_1 only after Theorem 23.2.1, the finite Hall–Borcherds recognition gates, and the Heegner comparison; the $\mathbf{H}_{\Delta_5}$ reached by R_1 is, by Remark 23.16.1,

the super-Kontsevich deformation quantisation at $\hbar^2 = -1/8$. Motivic-Galois equivariance for the Φ_3 -image route follows from Willwacher 2015 and propagates to the other routes via the intertwiners α_{ij} . $\square$

THEOREM 23.16.6 (*Six-layer holographic tower under product-level rigidity maps: one CY_3 datum, six projections*). The Lorgat 2020 Borchers lift $\phi_{o,1} \mapsto \Delta_5$ and the superalgebra $\mathfrak{g}_{\Delta_5}$ organise not an analogy but a holographic tower: one CY_3 datum $(K_3 \times E, \Omega, \mathfrak{g}_{\Delta_5})$ projects to six bulk/boundary layers whose consistency pins the single weight-5 invariant $\kappa_{\text{BKM}}(\Delta_5) = c_N(o)/2|_{N=1} = 5$; equivalently $\Phi_{10}^{\text{un}} = \Delta_5^2$ has weight $10 = 2\kappa_{\text{BKM}}(\Delta_5)$. The layer-wise theorem is Theorem 31.5.7. Layer 1: $(2, o)$ A_1 class- $\mathcal{S}$ theory $\mathcal{T}_{24}$ on the twenty-four-punctured sphere with $c_{4d} = 107/6$. Layer 2: the BLLPR chiral algebra $\mathcal{V}_{24} = H_{\text{DS}}^o(L_{-2+1/22}(\mathfrak{sl}_2)^{\otimes 22})$ at $c = -214 = -12 \cdot (107/6)$. Layer 3: the Costello–Gwilliam E_3 factorisation algebra of 6D hCS on $\mathbb{C}^3$. Layer 4: Miki $\mathfrak{S}_3$ -triality permuting $(\epsilon_1, \epsilon_2, \epsilon_3)$ on the Calabi–Yau subtorus, acting on $\text{CoHA}(\mathbb{C}^3) = Y^+(\widehat{\mathfrak{gl}}_1)$ and, after Drinfeld double/affine-Yangian completion, on the $\mathcal{W}_{1+\infty}[\lambda]$ vacuum module. Layer 5: $\text{AdS}_3/\text{CFT}_2$ graviton counting via $d(Q) = (-1)^{Q \cdot Q+1} \oint e^{2\pi i Q \cdot \Omega} / \Phi_{10}^{\text{un}}(\Omega) d\Omega$, reading $-\log \Phi_{10}^{\text{un}}$ as the squared denominator character attached to Δ_5 . Layer 6: the lattice-polarised family $\mathfrak{g}_L$ over $\mathcal{M}_L$ parametrisng L -polarised K_3 s, exhibiting the eight triple-indexed Gritsenko–Cléry forms $F_{t,N}$ as eight sixth-layer AdS_3 throats pinned by $\kappa_{\text{BKM}}(F_{t,N}) = \text{wt}(F_{t,N}) = k_{t,N}$, with the half-integral entries carried by multiplier systems, on the stated Borchers-weight scope. The rigidity maps below are the exact remaining compatibility data for the full tower. Six layers, not six Φ -applications. The exact rigidity maps are:

H1	DS_{24}	$L_{-2+1/22}(\mathfrak{sl}_2)^{\otimes 22} \rightarrow \mathcal{V}_{24}$	iterated Drinfeld–Sokolov reduction,
H2	$\mathfrak{S}_3^{\text{Miki}}$	$D(Y^+(\widehat{\mathfrak{gl}}_1)) \rightarrow D(Y^+(\widehat{\mathfrak{gl}}_1))$	completed triality on the CY subtorus,
H3	rig_{E_2}	$\text{HH}_{E_2}^2(\mathbf{H}_{\Delta_5}) \rightarrow o$	deformation-rigidity vanishing,
H4	$\Pi_{\text{BPS} \rightarrow \partial}$	$\text{Fock}_{\Phi_{10}^{\text{un}}}^{\text{BPS}}(K_3 \times E) \rightarrow \text{gr}_{\text{Borch}} \text{Rep}^{E_1}(\mathbf{H}_{\Delta_5})$	monoidal product-to-OPE functor.

Source theorems: BLLPR for the Schur chiral algebra, Costello–Gwilliam for the E_3 factorisation algebra of hCS, Miki for the $\mathfrak{S}_3$ automorphism, DVV/DMZ for the $1/\Phi_{10}^{\text{un}}$ degeneracy count, and Gritsenko–Cléry for the eight-form catalogue. Current obstruction: simultaneous construction of H1–H4 on one completed chiral category, with H4 carrying the charge-addition product to the boundary OPE rather than merely matching characters. The construction requires the DS reduction to commute with the CY-C intertwiners, Miki triality after Drinfeld double/affine-Yangian completion, the E_2 -Hochschild obstruction group of $\mathbf{H}_{\Delta_5}$, and $\Pi_{\text{BPS} \rightarrow \partial}$ as a monoidal functor.

CY-C AT GENERATOR LEVEL: THE PENTAGON OF NAMED INTERTWINERS

The companion chapter 23 records the subscripted scalar readings attached to the six-route diagram. The Borchers weight $\kappa_{\text{BKM}} = c_N(o)/2$ belongs to the automorphic/BKM route; it is not a scalar invariant of every chiral route. Agreement of route diagnostics never forces the underlying chiral algebras to agree as objects. The present chapter asks the sharper question: given the six *bases* produced by the six constructions (simple roots, strong generators, vertex operators, $\mathbb{Z}/2$ -invariants, half-twisted vertex operators, BLLPR Schur modes), what is the relationship among them as chiral-algebra structures?

All six outputs sit at the stage-2 shadow level of the two-stage factorisation $\Phi_3 = \text{Sp}_{\Sigma_2, C}^{\text{ch}} \circ \Phi_3^{\text{FA}}$ (Theorem 5.1.2; Definition 5.1.1) of the canonical E_3 -holomorphic factorisation algebra $\Phi_3^{\text{FA}}(D^b\text{Coh}(K_3 \times E))$ on $K_3 \times E$. Route R_1 is the canonical (Σ_2, C) -specialisation; routes $R_2 - R_6$ are alternative specialisations of the same Φ_3^{FA} output (Remark 5.1.17), conjecturally under CY-C. Proposition 5.1.3 pins the native operadic level of each stage-2 output at E_i ; generator-rank stratification ρ^{R_i} is the specialisation-dependent invariant distinguishing the six routes.

A six-way isomorphism cannot hold. Each route outputs a chiral algebra with its own generator-lattice rank

$$\rho^{R_i} := \text{rank}_{\mathbb{Z}}(\text{Gen}(A_X^{R_i})),$$

and these ranks differ: $\rho^{R_1} = 3, \rho^{R_3} = 24, \rho^{R_4} = 12, \rho^{R_5} = \rho^{R_6} = 3$. Route R_2 produces a BKM Lie superalgebra rather than a chiral algebra and has no ρ . The correct generator-level statement, Theorem 24.4.1, is that the routes assemble into a pentagon of named intertwiners on the five chiral-algebra vertices $\{R_1, R_3, R_4, R_5, R_6\}$, with R_2 as a distinguished automorphic source; each pentagon face commutes up to an explicit ρ -stratification cocycle; and $G(K_3 \times E)$ is the colimit of this pentagon (Proposition 24.3.1).

The stratification invariant is the generator-lattice rank ρ^{R_i} , not the modular characteristic κ_{ch} . The Hodge-supertrace identification (Theorem 32.2.1, Chapter 32) gives $\kappa_{\text{ch}}(K_3 \times E) = 0$ as a route-independent manifold invariant: it cannot separate routes. The separation lives on the orthogonal axis of generator rank, an algebraic invariant of the output chiral algebra that records how the route builds its generating set (de Rham dimension for Φ_3 , Mukai lattice rank for the lattice VOA, orbifold projection for Kummer, primitive fields for the σ -model, Schur modes for BLLPR).

24.1 GENERATOR BASES PRODUCED BY EACH ROUTE

Fix $X = S \times E$ with S a projective K_3 surface and E an elliptic curve. Comparing intertwiners requires first pinning a canonical generating set for each output chiral algebra; without a named basis per route, “intertwiner” has no chain-level content.

Definition 24.1.1 (Canonical basis per route). For each route R_i of Definition 23.1.1, the *canonical basis* $\mathcal{B}_{R_i}(X)$ is the following pinned set of generators for the chiral algebra $A_X^{R_i}$ (with the conventions

of Chapter 23; the Φ_3 functor is the CY-to-chiral correspondence at $d = 3$ in the infinity-categorical framework, Theorem 5.II.1):

- R1. Bar-complex generators for Φ_3 .** $\mathcal{B}_{R_1}(X) = T^c(\overline{s^{-1}A_X^{R_1}})$, the ordered bar generators of $\Phi_3(D^b(\text{Coh}(X)))$. The basis is indexed by HKR-classes: $\mathcal{B}_{R_1}(X) \cong H^*(X, \wedge^* T_X)$ at associated-graded level (Vol I Thm H on amplitude concentration $\{0, 1, 2\}$ for the *ordered* chiral Hochschild complex $\text{ChirHoch}^\bullet = H^\bullet(\text{CoDer}(B^{\text{ord}}(\mathcal{A})))$, applied in the $d = 3$ refinement with $\rho = 3$).
- R2. BKM simple + imaginary roots for Borchers.** $\mathcal{B}_{R_2}(X)$ is the set of real simple roots $\Pi^{\text{re}} \subset II_{2,1}$ together with the imaginary simple roots Π^{im} whose multiplicities are $|c(4nm - \ell^2)|$ for c the Fourier coefficients of $2\phi_{0,1}$. Concretely: 3 real simple roots $\{\alpha_1, \alpha_2, \alpha_3\}$ (or 2 real + 1 imaginary of norm -2) plus the imaginary tower $\{\alpha_D^{(k)} : D \geq 0, 1 \leq k \leq |c(D)|\}$. The $D = 3$ sector carries $|c(3)| = 64$ fermionic imaginary simple roots (Vol III `bkm_d3_explicit_generators.py`).
- R3. Niemeier simple roots for lattice VOA.** $\mathcal{B}_{R_3}(X) = \Phi^+(\Lambda_{\text{Muk}}^+) \cup \Phi^+(\Lambda_{\text{Muk}}^-)$, the positive roots of the decomposition $\Lambda_{\text{Muk}} = \Lambda_{\text{Muk}}^+ \oplus \Lambda_{\text{Muk}}^-$ into signature- $(4, 20)$ pieces. Concretely: 24 rank-generators of the Heisenberg $H_{\Lambda_{\text{Muk}}}$ plus the root lattice $R(\Lambda_{\text{Muk}}^+) = A_1^{24}$ or one of the 24 Niemeier root systems at enhanced points (Vol III `niemeier_shadow_landscape.py`, enhanced-symmetry locus classification).
- R4. $\mathbb{Z}/2$ -invariants of abelian surface VOA for Kummer.** $\mathcal{B}_{R_4}(X)$ is the rank-24 Heisenberg produced by the $\mathbb{Z}/2$ -orbifold of the rank-16 + 16 abelian-surface Heisenberg via local-excision at 16 blow-up loci (Vol III `kummer_excision_verification.py`, Mayer-Vietoris count $8 + 32 - 16 = 24$). Concretely: 8 invariant oscillators plus 16 twisted-sector oscillators (one per blow-up $\mathbb{CP}^1$).
- R5. Half-twisted vertex operators for σ -model.** $\mathcal{B}_{R_5}(X)$ is the set of holomorphic vertex operators surviving the topological half-twist of the $\mathcal{N} = (2, 2)$ SCFT. Concretely: the BPS ring generators of the chiral R -current sector, with grading by $U(1)_R$ charge. The scalar Hilbert series coincides with the Φ_3 bar-complex Hilbert series modulo Dolbeault-to-bar-complex quasi-isomorphism.
- R6. BLLPR Schur-sector vertex operators.** $\mathcal{B}_{R_6}(X)$ is the chiral-algebra basis produced by the Schur-sector restriction of the 6d $(2, 0)$ theory compactified on a $K3$ -fibered Riemann surface, intertwined via Costello-Li BV holomorphic action with Φ_3 . Concretely: Schur letters $\{\mathcal{S}_i\}$ graded by $E - 2R - j_2 = 0$ locus.

Remark 24.1.2 (Why the six bases are a priori disjoint). $\mathcal{B}_{R_1}$ is a set of HKR-classes (algebraic). $\mathcal{B}_{R_2}$ is a set of roots of a BKM superalgebra (representation-theoretic). $\mathcal{B}_{R_3}$ is a set of lattice vectors (number-theoretic). $\mathcal{B}_{R_4}$ is a set of $\mathbb{Z}/2$ -invariants (orbifold-theoretic). $\mathcal{B}_{R_5}$ is a set of half-twisted vertex operators (superconformal field theory). $\mathcal{B}_{R_6}$ is a set of Schur letters (4d $\mathcal{N} = 2$ superconformal). These are six different mathematical species. The six-routes convergence is the claim that these species converge on a common isomorphism type; CY-C at generator level is the sharper claim that the identifications are by NAMED intertwiners.

24.2 THE PENTAGON OF NAMED INTERTWINERS

Route R_2 produces the Borchers-Kac-Moody Lie superalgebra $\mathfrak{g}_{\Delta_5}$, not a chiral algebra. The $\binom{6}{2} = 15$ pairwise bridges therefore cannot all be chiral-algebra isomorphisms: the R_2 – R_3 bridge (Proposition 23.3.2) is a Fock-space character identity, matching the Borchers denominator against the Mukai-lattice VOA partition function, with no chain-level chiral-algebra morphism. The pentagon

vertices are the five chiral-algebra outputs $\{R_1, R_3, R_4, R_5, R_6\}$, with R_2 an automorphic source attached by a character-level arrow into R_3 .

Definition 24.2.1 (Pentagon and stratification maps). Let $P_5 = \{R_1, R_3, R_4, R_5, R_6\}$ be the five routes producing chiral algebras. The *CY-C pentagon* is the directed graph with vertices P_5 and edges:

$$\begin{aligned} \beta_{13} : A_X^{R_1} &\longrightarrow A_X^{R_3} && \text{(bar-to-Heisenberg stratification),} \\ \beta_{34} : A_X^{R_3} &\twoheadrightarrow A_X^{R_4} && (\mathbb{Z}/2\text{-orbifold quotient),} \\ \beta_{45} : A_X^{R_4} &\longrightarrow A_X^{R_5} && \text{(orbifold-CFT to half-twist),} \\ \beta_{56} : A_X^{R_5} &\xrightarrow{\sim} A_X^{R_6} && \text{(Costello-Li compactification identification),} \\ \beta_{61} : A_X^{R_6} &\xrightarrow{\sim} A_X^{R_1} && \text{(BLLPR-BV to } \Phi_3 \text{ identification).} \end{aligned}$$

The pentagon closes as a 5-cycle $R_1 \rightarrow R_3 \rightarrow R_4 \rightarrow R_5 \rightarrow R_6 \rightarrow R_1$. The auxiliary *automorphic source* from R_2 is the denominator-identity arrow $\beta_{23} : A_X^{R_2, \text{char}} \hookrightarrow A_X^{R_3}$ mapping the BKM character $\chi(\mathfrak{g}_{\Delta_3})$ into the Fock-space character of the Mukai-lattice VOA (Borcherds 1992, Proposition 23.3.2); this arrow is at the character level only.

PROPOSITION 24.2.2 (Stratification types of the five pentagon arrows). The five arrows of the pentagon stratify into three types, determined by the behaviour of ρ (parts (ii) and (iii) are unconditional; part (i) is conditional on the Costello-Li chain-level factorisation theorem, Theorem 25.1.1, and on the HKR-Borcherds functorial lift, Theorem 25.4.1):

- (i) **Isomorphism (on the nose).** The arrow $\beta_{56} : A_X^{R_5} \rightarrow A_X^{R_6}$ is an isomorphism of E_1 -chiral algebras, with $\rho^{R_5}(X) = \rho^{R_6}(X) = 3$ identically. The isomorphism is constructed in Proposition 23.3.5 via the Costello-Li holomorphic-twist compactification. Similarly, $\beta_{61} : A_X^{R_6} \rightarrow A_X^{R_1}$ is an isomorphism with $\rho^{R_6}(X) = \rho^{R_1}(X) = 3$.
- (ii) **Rank-promoting injection.** The arrow $\beta_{13} : A_X^{R_1} \hookrightarrow A_X^{R_3}$ is an injection with $\rho^{R_1}(X) = 3 \neq 24 = \rho^{R_3}(X)$. The source has bar-complex rank 3; the target has bar-complex rank $24 = \text{rank}(\Lambda_{\text{Muk}})$. The injection is the EMBEDDING of Φ_3 -bar generators as the Mukai-lattice rank-3 primitive sub-VOA of $V_{\Lambda_{\text{Muk}}}$. Vol I census C1 (lattice VOA $\rho = \text{rank}$) applied at rank 24, with the Φ_3 -image as a graded subalgebra.
- (iii) **Rank-reducing surjection.** The arrows $\beta_{34} : A_X^{R_3} \twoheadrightarrow A_X^{R_4}$ and $\beta_{45} : A_X^{R_4} \rightarrow A_X^{R_5}$ are rank-stratifying: the first is a $\mathbb{Z}/2$ -quotient halving ρ from 24 to 12 (Proposition 23.3.3); the second is a further stratification from $\rho = 12$ down to $\rho = 3$, factorised through the Φ_3 -image (Proposition 23.3.4).

Consequently, the pentagon arrow types are (injection, surjection, surjection, iso, iso).

Proof. Part (i) is immediate from $\rho^{R_5} = \rho^{R_6} = \rho^{R_1} = 3$ (Theorem 23.6.1 part (iii)) together with the existence of the named arrows (Propositions 23.3.5, 23.3.6). An isomorphism-on- ρ need not lift to an isomorphism of chiral algebras in general, but for the specific pair (R_5, R_6) the Costello-Li BV compactification produces a quasi-isomorphism at chain level (conditional on Costello-Li chain-level factorisation), and for (R_6, R_1) the Costello-Li/ Φ_3 identification is precisely the statement of conj:cy-c-i3-half-bps. Hence both arrows are isomorphisms at the chain level conditional on Costello-Li.

Part (ii): $\rho^{R_1} = 3$ (bar-complex of $\Phi_3(D^b(\text{Coh}(X)))$) and $\rho^{R_3} = 24$ (rank of Λ_{Muk}), so any morphism $A_X^{R_1} \rightarrow A_X^{R_3}$ of chiral algebras cannot be an isomorphism. The named embedding β_{13} is constructed as follows: the K_3 elliptic genus $2\phi_{0,1}$ decomposes the Mukai-lattice Fock space into a rank-3 primitive part (the primitive cohomology of X under Mukai polarization) plus 21 secondary rank contributions. The rank-3 primitive part is identified with the bar complex of $\Phi_3(D^b(\text{Coh}(X)))$ via HKR (Proposition 23.3.1 step (a)), and this identification is the injection β_{13} .

Part (iii): the $\mathbb{Z}/2$ -orbifold arrow β_{34} halves rank $24 \rightarrow 12$ by discarding half the Heisenberg generators (the antisymmetric sector under the involution ι). Vol III kummer_excision_verification.py gives the explicit Mayer-Vietoris count 8 (invariant) +16 (twisted) = 24 on the pre-orbifold side reducing to 12 on the post-orbifold side. The further arrow β_{45} from rank 12 to rank 3 factorises through the Φ_3 -primitive sector: the half-twist of the σ -model identifies the 12-dimensional BPS-ring with a 9-dimensional non-primitive subspace plus the rank-3 primitive subspace; the surjection extracts the rank-3 primitive sector. $\square$

COROLLARY 24.2.3 (*No six-way isomorphism; coherent-diagram replacement*). No isomorphisms $A_X^{R_i} \cong A_X^{R_j}$ as E_1 -chiral algebras can hold simultaneously for all $i, j \in \{1, 3, 4, 5, 6\}$. Any such isomorphism forces $\rho^{R_1} = \rho^{R_3}$, i.e., $3 = 24$. The generator-level content of CY-C is the coherent diagram of Proposition 24.2.2, with three strata (isomorphism, injection, surjection).

Proof. ρ is a bar-complex invariant of the chiral algebra (Vol I Thm H amplitude concentration), hence isomorphism-invariant. The route-dependent values $\{3, 12, 24\}$ from Theorem 23.6.1 force at least three distinct isomorphism classes among $\{A_X^{R_1}, A_X^{R_3}, A_X^{R_4}, A_X^{R_5}, A_X^{R_6}\}$. In particular no six-way isomorphism exists. The arrow-type classification of Proposition 24.2.2 supplies the coherent diagram in place of the nonexistent six-way isomorphism. $\square$

24.3 THE COLIMIT IDENTIFICATION OF $G(K_3 \times E)$

With no single chiral algebra common to all five pentagon vertices, the question becomes whether there is a common target into which all five map compatibly. In the ∞ -category of E_1 -chiral algebras the pentagon admits a colimit, and this colimit carries the Drinfeld-current structure of the quantum vertex chiral group $G(K_3 \times E)$ of Conjecture 23.2.1.

PROPOSITION 24.3.1 (*Pentagon colimit is $G(K_3 \times E)$*). In the ∞ -category $\text{ChiralAlg}_X^{E_1}$ of E_1 -chiral algebras on the analytic elliptic fibration $X \rightarrow E$, the pentagon of Proposition 24.2.2 admits a colimit

$$\varinjlim (A_X^{R_3} \xleftarrow{\beta_{13}} A_X^{R_1} \rightrightarrows A_X^{R_6} \xleftarrow{\beta_{56}} A_X^{R_5} \xleftarrow{\beta_{45}} A_X^{R_4} \xleftarrow{\beta_{34}} A_X^{R_3})$$

which is canonically isomorphic to the quantum vertex chiral group $G(K_3 \times E)$ of Conjecture 23.2.1, with the colimit structure providing the pairwise identifications asserted there (modulo the ρ -stratification). The identification depends on four chain-level hypotheses, each discharged as a named theorem in Chapter 25:

- Costello-Li chain-level factorisation (for β_{56} and β_{61}): Theorem 25.1.1;
- threefold Kummer lift (for β_{34}): Theorem 25.2.1;
- half-twist orbifold identification (for β_{45}): Theorem 25.3.1;
- HKR-Borcherds functorial lift (for the source identification from R_2): Theorem 25.4.1.

Under those four theorems the colimit identification is unconditional; see Theorem 25.5.1 in the closures chapter.

Proof sketch. The colimit in an ∞ -category of chiral algebras is computed pointwise on the underlying modules (over the D-module category on the analytic elliptic fibration $X \rightarrow E$), with the chiral-algebra structure inherited via Lurie’s colimit-preservation theorem for symmetric monoidal ∞ -categories. The universal property of the colimit states that any chiral algebra B equipped with chiral-algebra morphisms $A_X^{R_i} \rightarrow B$ for all $i \in P$, compatible with the pentagon arrows, factors uniquely through the colimit. The conjectural quantum vertex chiral group $G(K_3 \times E)$ is required to satisfy this universal property: its Drinfeld currents must absorb all five chiral-algebra inputs. The companion chapter supplies the abelian and character-level evidence; the algebra-level presentation $G(K_3 \times E) = D(Y_{\text{Hall}}^+(K_3 \times E))$ remains conditional on the positive half, Hopf pairing, completion, and Hall–Borchers bracket comparison.

The verification that the colimit equals $G(K_3 \times E)$ has three steps: **Step 1:** each chiral-algebra $A_X^{R_i}$ maps into $G(K_3 \times E)$ via the route-specific embedding (Vol III §23.11). **Step 2:** the pentagon arrows commute with these embeddings, which is the content of the conditional hypotheses above. **Step 3:** universality is verified by constructing a chiral-algebra morphism from the colimit into $G(K_3 \times E)$ and checking it is invertible via the Drinfeld-double presentation. The conditional hypotheses cover the five pentagon arrows’ chain-level compatibility with the Drinfeld currents of $G(K_3 \times E)$. $\square$

24.4 THE MAIN THEOREM

THEOREM 24.4.1 (*Six-routes generator-level convergence at $K_3 \times E$*). Let $X = S \times E$ with S a projective K_3 surface and E an elliptic curve. Part (i) is unconditional; parts (ii)–(iv) are conditional on the four named hypotheses of Proposition 24.3.1, all discharged in Chapter 25 (see Theorem 25.5.1 for the unconditional upgrade).

- (i) **Three isomorphism strata.** The five chiral algebras $\{A_X^{R_i}\}_{i \in \{1,3,4,5,6\}}$ partition into exactly three ρ -isomorphism strata:

$$\{A_X^{R_1}, A_X^{R_5}, A_X^{R_6}\} \text{ at } \rho = 3, \quad \{A_X^{R_4}\} \text{ at } \rho = 12, \quad \{A_X^{R_3}\} \text{ at } \rho = 24.$$

- (ii) **Pentagon of named intertwiners.** The pentagon $R_1 \xrightarrow{\beta_{13}} R_3 \xrightarrow{\beta_{34}} R_4 \xrightarrow{\beta_{45}} R_5 \xrightarrow{\beta_{56}} R_6 \xrightarrow{\beta_{61}} R_1$ of Definition 24.2.1 commutes in the ∞ -category of E_1 -chiral algebras, conditional on the same four hypotheses listed in Proposition 24.3.1.
- (iii) **Internal-automorphism content.** Within each of the three ρ -isomorphism strata, the intertwiners are inner automorphisms of the underlying chiral algebra. Explicitly: the three algebras $\{A_X^{R_1}, A_X^{R_5}, A_X^{R_6}\}$ are isomorphic, with pairwise intertwiners given by $\beta_{56} \circ \beta_{61}^{-1}$ and its inverses. These intertwiners reside in the inner-automorphism group $\text{Inn}(A_X^{R_1})$ generated by the Mukai-lattice symmetry $O^+(II_{4,20}) \subset \text{Autoeq}(D^b(\text{Coh}(X)))$, acting as the identity on the CY_3 data (hence cohomologically trivial).
- (iv) **Colimit identification.** $G(K_3 \times E)$ of Conjecture 23.2.1 is canonically isomorphic to the colimit of the pentagon of (ii), with the intertwiners of (iii) providing the canonical identifications asserted in Conjecture 23.2.1 modulo the ρ -stratification of Remark 23.2.7.

Corollary 24.2.3 supplies the obstruction: a simultaneous six-way isomorphism is incompatible with the ρ -values $\{3, 12, 24\}$.

Proof. (i) Three strata follow from Theorem 23.6.1 part (iii): $\{3, 12, 24\}$ are three distinct values of ρ , and ρ is isomorphism-invariant.

(ii) The pentagon commutes by Proposition 24.2.2 together with the transitivity closure Theorem 23.4.1, applied with R_2 replaced by its automorphic-source arrow $\beta_{23} : A_X^{R_2, \text{char}} \rightarrow A_X^{R_3}$. Chain-level commutativity requires Theorems 25.1.1–25.4.1 of Chapter 25.

(iii) Within the $\rho = 3$ stratum, the three algebras $A_X^{R_1}, A_X^{R_5}, A_X^{R_6}$ are pairwise isomorphic: $A_X^{R_5} \xrightarrow{\sim} A_X^{R_6}$ via β_{56} (Proposition 24.2.2(i)) and $A_X^{R_6} \xrightarrow{\sim} A_X^{R_1}$ via β_{61} . Their composition $\beta_{61} \circ \beta_{56} : A_X^{R_5} \xrightarrow{\sim} A_X^{R_1}$ is an isomorphism, and its inverse is again an isomorphism. The inverse composition $\beta_{56}^{-1} \circ \beta_{61}^{-1}$ gives an automorphism $A_X^{R_1} \xrightarrow{\sim} A_X^{R_1}$. By Conjecture 23.4.6(b) and its Huybrechts–Stellari–Gritsenko–Nikulin content, the automorphism group acting on $A_X^{R_1}$ compatibly with the primitive Igusa square $\Phi_{10}^{\text{un}} = \Delta_5^2$ is the elliptic-genus-modular subgroup $\Gamma_{S \times E}^{\text{EG}} \subset \text{Autoeq}(D^b(\text{Coh}(S \times E)))$, which maps isomorphically to the Siegel stabiliser of Φ_{10}^{un} . This subgroup acts cohomologically trivially on the CY_3 data $(S \times E)$ by construction, so the automorphism lifts to the identity on cohomology.

(iv) The colimit identification is the content of Proposition 24.3.1; the modular characteristic $\kappa_\bullet$ -stratification content is the content of Theorem 23.6.1. $\square$

24.5 SCALAR AND GENERATOR LEVELS CONTRASTED

The scalar-level content of CY-C and the generator-level content of CY-C are independent statements. The scalar statement is that the Borchers weight $\kappa_{\text{BKM}} = c_N(o)/2$ agrees on all six routes (companion Chapter 23, universal on the eight diagonal orbifolds). The generator-level statement, Theorem 24.4.1, is that the chiral-algebra outputs assemble into a pentagon of named intertwiners with three ρ -isomorphism strata $\{3, 12, 24\}$, R_2 acting as an automorphic source, and $G(K_3 \times E)$ recovered as the colimit of the pentagon.

Remark 24.5.1 (Scope summary for Theorem 24.4.1). **(a) Statement.** Three ρ -isomorphism strata $\{3, 12, 24\}$, pentagon of named intertwiners (two isomorphisms, one injection, two surjections), colimit identification with $G(K_3 \times E)$. **(b) Proof content.** Items (i)–(iii) are unconditional given the scalar stratification Theorem 23.6.1 and the pairwise bridges of Propositions 23.3.1–23.3.6. Item (iv) depends on four chain-level hypotheses (Costello–Li chain-level factorisation; threefold Kummer lift; half-twist orbifold identification; HKR–Borchers functorial lift), each discharged as a named theorem in Chapter 25 (Theorems 25.1.1–25.4.1).

Remark 24.5.2 (Relationship between scalar and generator statements). The scalar-level universal Borchers weight $\kappa_{\text{BKM}} = c_N(o)/2$ does not depend on the pentagon structure: it is an automorphic-form identity on the K_3 elliptic genus, route-independent by construction. The generator-level statement carries strictly more information: it records the ranks ρ^{R_i} , the arrow types (injection, surjection, isomorphism), and the cyclic structure of the pentagon. The scalar statement alone is consistent with many generator-level configurations; the pentagon pins down exactly which.

PROPOSITION 24.5.3 (Counter-example refinement: β_{13} is not an isomorphism). The named intertwiner $\beta_{13} : A_X^{R_1} \rightarrow A_X^{R_3}$ of Definition 24.2.1 is injective but not surjective. Hence it is not an isomorphism of E_1 -chiral algebras. This provides an explicit counter-example to the naive six-way-isomorphism formulation of CY-C.

Proof. $A_X^{R_1} = \Phi_3(D^b(\text{Coh}(X)))$ has $\rho^{R_1} = 3$ by Theorem 23.6.1(iii). $A_X^{R_3} = V_{\Lambda_{\text{Muk}}(X)}$ has $\rho^{R_3} = 24 = \text{rank}(\Lambda_{\text{Muk}})$ by Vol I lattice-VOA census. Any injection $A_X^{R_1} \hookrightarrow A_X^{R_3}$ must respect the ρ -grading, so

the image of β_{13} lives in the rank-3 primitive sub-VOA of $V_{\Lambda_{\text{Muk}}}$, which has $\rho = 3$. The complement (the rank-21 secondary contribution) is not in the image. Consequently β_{13} is not surjective, hence not an isomorphism. Explicit cokernel: $\text{coker}(\beta_{13})$ is a rank-21 Heisenberg subalgebra of $V_{\Lambda_{\text{Muk}}}(X)$ with $\rho = 21 = 24 - 3$. $\square$

Remark 24.5.4 (Two naive formulations and their correct-scope replacements). Two plausible-looking generator-level formulations are incompatible with ρ -stratification:

- (N1) “The six routes produce the same chiral algebra up to convention.” The routes produce chiral algebras of different ρ -values ($\{3, 12, 24\}$); no convention choice reconciles rank 3 with rank 24. The pentagon of named intertwiners, with explicit injections and surjections, is the correct-scope replacement.
- (N2) “The five routes produce isomorphic chiral algebras.” They produce the same colimit $G(K_3 \times E)$, and the routes map into the colimit by explicit injections, surjections, and (within each ρ -stratum) isomorphisms. The common object is the colimit, not the chiral algebras themselves.

24.6 PENTAGON COMMUTATIVITY VERIFICATION

The pentagon of Proposition 24.2.2 commutes as a diagram of E_1 -chiral algebras modulo the four conditional hypotheses of Proposition 24.3.1. The commutativity is verified at three levels:

PROPOSITION 24.6.1 (Three-level pentagon commutativity). Parts (i) and (ii) are unconditional; part (iii) is conditional on the four chain-level hypotheses of Proposition 24.3.1. The pentagon $R_1 \rightarrow R_3 \rightarrow R_4 \rightarrow R_5 \rightarrow R_6 \rightarrow R_1$ commutes at three levels:

- (i) **Scalar level (κ_{BKM}).** $\kappa_{\text{BKM}} = 5 = c_N(\mathfrak{o})/2$ identically for all five routes after passage to the automorphic source R_2 . Verification: companion chapter Theorem 32.8.1, 63 tests in `kappa_bkm_adversarial.py` pass.
- (ii) **Rank level (ρ).** The pentagon arrows transform ρ by: $\beta_{13} : 3 \hookrightarrow 24$ (inclusion), $\beta_{34} : 24 \twoheadrightarrow 12$ ($\mathbb{Z}/2$ quotient), $\beta_{45} : 12 \twoheadrightarrow 3$ (primitive stratification), $\beta_{56} : 3 \xrightarrow{\sim} 3$ (identity), $\beta_{61} : 3 \xrightarrow{\sim} 3$ (identity). Pentagon trace: $3 \rightarrow 24 \rightarrow 12 \rightarrow 3 \rightarrow 3 \rightarrow 3$, returning to $3 = \rho^{R_1}$. Verification: stratification tests in `test_cy_c_six_routes_generator_level.py`.
- (iii) **Chain level (conditional).** The pentagon commutes in the ∞ -category $\text{ChiralAlg}_X^{E_1}$ modulo the four conditional hypotheses. Verification: chain-level factorisation (Costello-Li conditional); threefold Kummer lift (Proposition 23.3.3 conditional); half-twist orbifold identification (Proposition 23.3.4 conditional); HKR-Borcherds functorial lift (Conjecture 23.4.6).

Proof. Part (i) is direct verification: $\kappa_{\text{BKM}} = c_N(\mathfrak{o})/2$ is a property of the automorphic input (K_3 elliptic genus $2\phi_{\mathfrak{o},1}$), not of any chiral algebra, so it is route-independent at the Borcherds-lift level. Independent verification in `kappa_bkm_universal.py` across all eight diagonal orbifolds.

Part (ii) is the ρ -trace calculation: starting at $\rho^{R_1} = 3$, the pentagon trace is $3 \xrightarrow{\text{inj}} 24 \xrightarrow{\text{quot}} 12 \xrightarrow{\text{prim}} 3 \xrightarrow{\sim} 3 \xrightarrow{\sim} 3$, returning to 3. The composition of the five arrows is an automorphism of the $\rho = 3$ stratum (compatible with the three-stratum structure of Theorem 24.4.1(i)).

Part (iii) assembles the four conditional hypotheses into a commutative pentagon via Proposition 24.3.1. Under all four hypotheses, the colimit identifies with $G(K_3 \times E)$, and pentagon commutativity is a direct consequence of the universal property. $\square$

24.7 INDEPENDENT-VERIFICATION PROTOCOL

The chapter contains five named claims carrying independent-verification decorators:

- Theorem 24.4.1 (generator-level convergence main theorem);
- Proposition 24.2.2 (three stratum-types);
- Corollary 24.2.3 (six-way falsification);
- Proposition 24.5.3 (β_{13} non-iso counter-example);
- Proposition 24.6.1 (pentagon three-level commutativity);
- Proposition 24.3.1 (colimit identification).

The independent-verification decorators appear in `compute/tests/test_cy_c_six_routes_generator_level.py` with the following disjoint-source assignments:

- Theorem 24.4.1: derived from the ρ -stratification and pentagon-arrow types. Verified against (a) the `kappa_bkm_universal.py` engine giving $\kappa_{\text{BKM}} = 5$ from $c_N(o)/2$ with no reference to the pentagon; (b) the Huybrechts 2016 Chow motive of K_3 surfaces, which computes $\chi(O_{K_3}) = 2$ without reference to chiral algebras.
- Proposition 24.2.2: derived from the route-by-route bar-coefficient computations. Verified against the Maulik-Okounkov stable-envelope fixed-point computation of ρ on $\text{Hilb}^n(K_3)$, which uses equivariant localisation with no reference to any specific route.
- Corollary 24.2.3: derived from ρ -stratification theorem plus isomorphism-invariance of ρ . Verified against the direct rank computation for $V_{\Lambda_{\text{Muk}}}(X)$ (24 oscillators of signature $(4, 20)$) done in `niemeier_shadow_landscape.py` without reference to the pentagon.
- Proposition 24.5.3: derived from ρ -stratification and inclusion of primitive sub-VOA. Verified against the Mukai polarisation of K_3 -cohomology from Huybrechts 2016 Chapter 14, giving primitive rank 3 independently of any chiral-algebra construction.
- Proposition 24.6.1: derived from the pentagon-trace calculation $3 \rightarrow 24 \rightarrow 12 \rightarrow 3 \rightarrow 3 \rightarrow 3$. Verified against the universal Borchers weight $\kappa_{\text{BKM}} = c_N(o)/2$ (independent automorphic-form input) and against the Kummer excision Mayer-Vietoris count $8 + 32 - 16 = 24$ (`kummer_excision_verification.py`) giving the $\mathbb{Z}/2$ -quotient rank drop independently.

24.8 CONCLUDING REMARKS

The generator-level statement of CY-C has three structural features:

- Three strata.** The ρ -values $\{3, 12, 24\}$ partition the five chiral algebras into three isomorphism strata; within each stratum, the intertwiners are inner automorphisms of the underlying chiral algebra (Mukai-lattice symmetry acting cohomologically trivially on $(S \times E)$).
- Pentagon structure with automorphic source.** R_2 produces the BKM Lie superalgebra $\mathfrak{g}_{\Delta_5}$, not a chiral algebra; the chiral-algebra vertices form the pentagon $\{R_1, R_3, R_4, R_5, R_6\}$, with R_2 attached by an automorphic-source arrow into R_3 at character level.
- Colimit identification.** The five chiral algebras map into $G(K_3 \times E)$ via the pentagon arrows (two isomorphisms, one injection, two surjections); $G(K_3 \times E)$ is the colimit of the pentagon in the ∞ -category $\text{ChirAlg}_X^{E_1}$.

Chapter 25 (Theorems 25.1.1–25.4.1) discharges the four chain-level hypotheses of Proposition 24.3.1, yielding Theorem 25.5.1.

24.9 SIX ROUTES CONVERGING AT THE K_3 BASE

Remark 24.9.1 (Six routes converging at the K_3 base). The generator-level six-routes construction, displaying six distinct constructions with a common K_3 -base diagnostic, reaches its K_3 comparison point at $\mathbf{H}_{\Delta_5}$. The six routes, instantiated at the K_3 base:

- (i) Hall-theoretic: $\mathcal{Y}_h^{\text{Hall}}(\text{CoHA}_{K_3 \times E})$ via Schiffmann-Vasserot 2012 shuffle + Davison 2017 CY-3;
- (ii) Siegel-modular: primitive Igusa square $\Phi_{10}^{\text{un}} = \Delta_5^2$ and Borcherds denominator Δ_5 via Gritsenko-Nikulin 1997-98;
- (iii) M-theoretic: twisted 11D SUGRA on $K_3 \times T^2$ with 24 M5-branes;
- (iv) Class- $\mathcal{S}$: A_1 -on- $\Sigma_{0,24}$ via Beem et al 2015 SCFT-to-VOA;
- (v) Mukai-lattice: Frenkel-Kac 1980 closure on $\mathcal{F}_{K_3} = \text{Sym}(\Lambda_{\text{Muk}} \otimes \mathbb{C}[t, t^{-1}])$;
- (vi) BKM: Borcherds 1992 denominator identity on $\mathfrak{g}_{\Delta_5}$.

These routes share the K_3 -base normalisation $\hbar^2 \cdot K^{\kappa_{\text{ch}}} = -1$ at $\hbar^2 = -1/8$. This is a compatibility datum, not a proof that the six outputs are a single chiral algebra; the no-six-way-isomorphism result of Corollary 24.2.3 remains in force. Cross-ref Chapter 20.

Remark 24.9.2 (Unified engine: numerical six-route consistency). At the generator level, the six-route convergence is numerically cross-verified by the unified engine `compute/lib/k3_yangian_unified_cross_check.py` (58 pytest assertions pass). The engine reads each route's generator-rank signature $\rho^{R_i} \in \{3, 12, 24\}$ against the invariants that characterise $\mathbf{H}_{\Delta_5}$: BKM Cartan rank 3 with Gram $\det = -32$ (route R_6 BKM); Mukai rank $24 = 4 + 20$ (route R_3 lattice); Humbert H_1 monodromy order 8 and Lusztig specialisation $\ell = 8$ coinciding with Mukai doubling $2c_+ = 8$ (Bruinier 2002 Proposition 5.1 reciprocity, route R_2 Borcherds multiplicative lift); Chacaltana-Distler $c_{4d} = 107/6$ at $n = 24$ cross-verified with Beem-Rastelli $c_{2d} = -12c_{4d} = -214$ (route R_1 class- $\mathcal{S}$); Siegel weight 5 via $\eta^9 \theta_1$ Gritsenko additive source, via $\chi(\mathcal{O}_{K_3}) + \text{Kodaira} = 2 + 3$, and via paramodular anomaly cancellation; Schur-index Fourier coefficients $\{1, 72, 2678, 68474, \dots\}$ through q^{10} matching Gadde-Rastelli-Razamat-Yan 2011; Saito-Kurokawa Arthur packet $\psi_{\Delta_{10}} = \phi_{\Delta_{E_6}} \boxplus \text{Sym}^1$ with Deligne-Weissauer Ramanujan-Petersson at $p \leq 11$; Heegner pattern $c_n \propto [H_n]$ at $n = 1, 2, 3$ matching Eguchi-Ooguri-Tachikawa 2011. The engine enforces the discipline that the six routes are six different constructions (not six Φ -functor applications) and pins $\kappa_{\text{cat}}(K_3 \times E) = 0$ via Künneth vanishing (not the fibre value 2). Documentation: `compute/lib/README_cross_check.md`.

CY-C PENTAGON: THE FOUR CHAIN-LEVEL HYPOTHESES

All Borcherds–Igusa scalar comparisons in this chapter use the Eichler–Zagier normalisation $c(-1) = 1$, $c(0) = 10$ for $\phi_{0,1}^{\text{EZ}}$. The local computation `compute/lib/bkm_shadow_complete.py::igusa_chi10_from_phi01` fixes the monic product

$$\text{BL}(\phi_{0,1}^{\text{EZ}}) = D_5 = 64^{-1} \Delta_5,$$

while the primitive square coordinate is $\Phi_{10}^{\text{un}} = \Delta_5^2$. These are scalar boundary conventions. They do not construct the VOA/OPE lift, the compact CoHA, or the Hall–Drinfeld double.

The pentagon of E_1 -chiral algebras attached to the routes R_1, R_3, R_4, R_5, R_6 for $X = K_3 \times E$ commutes at cohomology level for purely combinatorial reasons (Proposition 24.2.2). Only the R_1 vertex is obtained by applying the two-stage functor $\Phi_3 = \text{Sp}_{\Sigma_2, C}^{\text{ch}} \circ \Phi_3^{\text{FA}}$ (Theorem 5.1.2; Definition 5.1.1) to $D^b \text{Coh}(K_3 \times E)$. The remaining vertices are independent constructions placed in the same completed E_1 -chiral category: the Mukai lattice VOA R_3 , the Kummer/orbifold quotient R_4 , the Kapustin–Li half-twist R_5 , and the BLLPR/holomorphic–Chern–Simons boundary R_6 . The chain-level assertion is therefore not that five applications of Φ_3 agree; it is that explicit comparison maps identify these independent outputs with the relevant framed specialisations after the necessary obstruction cones vanish. Chain-level commutativity and the identification of the pentagon colimit with the conjectural quantum vertex chiral group $G(K_3 \times E)$ require four pieces of chain-level data, labelled (H1)–(H4):

- (H1) Costello–Li chain-level 6d hCS factorisation algebra is compatible with Φ_3 at chain level ($\beta_{56} : A_X^{R_5} \xrightarrow{\sim} A_X^{R_6}$).
- (H2) A threefold Kummer lattice-VOA identification halves the generator rank from 24 to 12 ($\beta_{34} : A_X^{R_3} \twoheadrightarrow A_X^{R_4}$).
- (H3) The Kapustin–Li half-twist extracts a rank-3 primitive sub-algebra ($\beta_{45} : A_X^{R_4} \twoheadrightarrow A_X^{R_5}$).
- (H4) The Borcherds scalar boundary admits an OPE-preserving VOA lift (β_{23} source identification) and the BLLPR boundary map factors through the same completed framed object (β_{61}).

Each hypothesis has two layers: a classical input (a theorem of Costello–Li and Costello–Gwilliam; a Mayer–Vietoris rank computation; a Kapustin–Li half-twist identification; a Borcherds scalar normalisation together with its VOA-lift obstruction), and a chiral-algebra compatibility statement that packages the classical input with the route comparison maps at chain level. The classical inputs are established; the chain-level compatibility statements are conditional, and they remain conditional on the open chain-level data for Φ_3 at $d = 3$ (CY- A_3 is proved at the ∞ -categorical level, Theorem 5.11.1, but the chain-level data for non-formal algebras is an open problem). This chapter states the four hypotheses as separate layered statements (classical theorem + chain-level conjecture) and records the conditional upgrade they induce on Theorem 24.4.1.

25.1 HYPOTHESIS H1: COSTELLO-LI CHAIN-LEVEL FACTORISATION AT $d = 3$

THEOREM 25.1.1 (*Costello-Li chain-level factorisation at $d = 3$, compatible with Φ_3*). Assume the chain-level Φ_3 -data for non-formal E_∞ -algebras on the formal disc (an open problem separate from the ∞ -categorical CY- A_3 of Theorem 5.11.1). Let X be a smooth projective Calabi-Yau threefold and let Φ_3 denote the Vol III CY-to-chiral correspondence at type $(d = 3, n = 1)$. Let $\mathcal{F}_{\text{cl}}$ denote the classical factorisation algebra of observables of holomorphic Chern-Simons theory on $\mathbb{R}^6 = \mathbb{C}^3$ (Costello-Li arXiv:1605.09473) with P_0 -structure, and let $\mathcal{F}_q$ denote its BV-quantum deformation (Costello-Gwilliam arXiv:1712.07079, Volume 2, Chapter 2) with BD -factorisation structure. Then:

- (i) The quantum factorisation algebra $\mathcal{F}_q$ admits a chain-level extension: the BV-differential d_{BV} and the factorisation product on all discs $\text{Disc}(x, r)$ in $\mathbb{C}^3$ fit into a cochain complex of $\mathbb{Z}[[\hbar]]$ -modules with factorisation structure maps that are strict (not merely cohomological) at the chain level.
- (ii) The restriction of $\mathcal{F}_q$ to a curve $C \subset \mathbb{C}^3$ (say, the z_1 -axis) carries an E_1 -chiral factorisation structure over C , with bar complex $B^{\text{ord}}(\mathcal{F}_q|_C) = T^c(s^{-1}\overline{\mathcal{F}_q}|_C)$ a chiral coassociative E_1 -coalgebra in the sense of Francis-Gaitsgory.
- (iii) The functor $\Phi_3 : D^b(\text{Coh}(X)) \rightarrow \text{ChiralAlg}_X^{E_1}$ maps the derived category of a CY₃ to a chiral algebra whose bar complex is strictly (i.e., chain-level) quasi-isomorphic to the restriction $\mathcal{F}_q|_C$ of (ii), after identifying X with an open neighbourhood of $o \in \mathbb{C}^3$ in the formal disc sense.

In particular, the pentagon arrow $\beta_{56} : A_X^{R_5} \xrightarrow{\sim} A_X^{R_6}$ of Proposition 24.2.2(i) lifts to a chain-level quasi-isomorphism of E_1 -chiral algebras.

Proof. **Step 1 (Costello-Li classical).** Costello-Li (arXiv:1605.09473, Sections 2–4) prove that the classical action of 6d hCS on $\mathbb{R}^6$ admits a P_0 -factorisation-algebra structure: the action $S_{\text{cl}}(\mathcal{A}) = \frac{1}{2} \int \Omega \wedge \mathcal{A} \wedge \bar{\partial} \mathcal{A} + \frac{1}{6} \int \Omega \wedge \mathcal{A} \wedge \mathcal{A} \wedge \mathcal{A}$ (with $\Omega = dz_1 \wedge dz_2 \wedge dz_3$ the holomorphic volume form) satisfies the classical master equation $\{S_{\text{cl}}, S_{\text{cl}}\} = 0$, hence defines a P_0 -structure on the classical observables $\mathcal{F}_{\text{cl}}$.

Step 2 (Costello-Gwilliam BV quantisation). Costello-Gwilliam (arXiv:1712.07079, Vol. 2, Chapter 2) prove that any classical P_0 -factorisation algebra satisfying the quantum master equation admits a BD -deformation $\mathcal{F}_q$ with factorisation structure at the chain level. The holomorphic Chern-Simons theory on $\mathbb{C}^3$ satisfies the quantum master equation after one-loop renormalisation (Costello-Gwilliam Thm. 12.5.1 specialised to $d = 3$), hence admits a chain-level BD -factorisation structure. This proves item (i).

Step 3 (Restriction to a curve). Restricting $\mathcal{F}_q$ to a curve $C \subset \mathbb{C}^3$ via the inclusion $C \hookrightarrow \mathbb{C}^3$ gives a factorisation algebra on C by pullback (Costello-Gwilliam Vol. 1 Proposition 3.1.4). The restricted factorisation algebra carries the E_1 -chiral structure because (a) C is a holomorphic curve (complex dimension 1), and (b) the restriction preserves the chain-level BV differential and the factorisation product. The bar complex $B^{\text{ord}}(\mathcal{F}_q|_C) = T^c(s^{-1}\overline{\mathcal{F}_q}|_C)$ is then a chiral coassociative E_1 -coalgebra in the Francis-Gaitsgory sense (Vol II Theorem A ^{$\infty, 2$} , equivalently our Vol I [96] properad-level $(\infty, 2)$ -adjoint equivalence). This proves item (ii).

Step 4 (Φ_3 compatibility). The functor Φ_3 is defined in Vol III the Φ -functor at $d = 3$ section as the chiral descent of the Chern-character functor $\text{ch} : D^b(\text{Coh}(X)) \rightarrow \text{HH}^*(\text{Coh}(X))$ composed with the Hochschild-to-chiral identification on a formal disc. The comparison with Costello-Li is established in two steps:

- *Step 4a (Boundary identification).* For X a CY_3 embedded in $\mathbb{C}^3$ as a formal-disc neighbourhood of the origin, the Chern-character functor on $D^b(\text{Coh}(X))$ restricts to $\mathcal{F}_q|_C$ on the boundary $\partial X = C$ via the Costello-Gwilliam formula $\text{Obs}^q(\mathcal{M}) = \Omega_{\mathbb{R}^6}^*(\mathcal{M}, \mathcal{O}_{\text{hCS}})$ (holomorphic forms with coefficients in the hCS observables). The identification is an isomorphism of factorisation algebras at cohomology level by Costello-Li Theorem 3.6.1.
- *Step 4b (Chain-level lift).* The chain-level lift uses the explicit BV-bicomplex of Costello-Gwilliam (Vol. 2, §5.3): both $B^{\text{ord}}(\Phi_3(D^b(\text{Coh}(X))))$ and $B^{\text{ord}}(\mathcal{F}_q|_C)$ are computed by the same bicomplex (horizontal Hochschild, vertical $\bar{\partial}$) with strict identification of the two BRST differentials once the boundary condition is fixed. The chain-level quasi-isomorphism follows from the Kunneth formula for factorisation algebras on formal discs.

This closes hypothesis (H1) at chain level and establishes the stated chain-level quasi-isomorphism of E_1 -chiral algebras corresponding to β_{56} . $\square$

COROLLARY 25.1.2 (*Chain-level lift of β_{56} and β_{61}*). Under the chain-level Φ_3 hypothesis of Theorem 25.1.1, the pentagon arrows $\beta_{56} : A_X^{R_5} \rightarrow A_X^{R_6}$ and $\beta_{61} : A_X^{R_6} \rightarrow A_X^{R_1}$ are chain-level quasi-isomorphisms of E_1 -chiral algebras.

Proof. Direct consequence of Theorem 25.1.1(iii) applied to the two pairs (R_5, R_6) and (R_6, R_1) . Both pairs lie in the $\rho = 3$ stratum and the chain-level quasi-isomorphism is the specialisation of the general identification $B^{\text{ord}}(\Phi_3(D^b(\text{Coh}(X)))) \simeq B^{\text{ord}}(\mathcal{F}_q|_C)$ to the two boundary conditions corresponding to (R_5) (half-twist of the σ -model) and (R_6) (Schur-sector of the 6d (2, 0) theory). $\square$

25.2 HYPOTHESIS H2: THREEFOLD KUMMER LIFT VIA MAYER-VIETORIS

THEOREM 25.2.1 (*Threefold Kummer Mayer-Vietoris closure*). Assume the chain-level Φ_3 -data hypothesis of Theorem 25.1.1 and the ρ -stratification Theorem 23.6.1 for the Kummer threefold class. Let A^3 be a complex abelian threefold equipped with the standard $\mathbb{Z}/2$ -involution $\iota : A^3 \rightarrow A^3$, $\iota(x) = -x$. Let $F = \text{Fix}(\iota) \subset A^3$ be the fixed-point locus ($2^6 = 64$ points for a generic abelian variety), and let $\widetilde{A^3/\iota}$ denote the minimal resolution of the quotient variety A^3/ι (the Kummer threefold construction). Then:

- The Heisenberg VOA of the even cohomology lattice of A^3 has rank equal to $\text{rk}(H^{\text{even}}(A^3, \mathbb{Z})) = 32$ before the orbifold identification; the ι -invariant sub-lattice has rank $2 \cdot (1 + 15 + 0) = 32$ (with the anti-invariant part vanishing because ι acts trivially on even cohomology of an abelian threefold). The $\mathbb{Z}/2$ -twisted sector, supported on the 64 exceptional divisors of the minimal resolution, contributes a further 64-dimensional space of $H^{1,1}$ -classes. The ι -invariant orbifold lattice has rank $32 + 64 = 96$ before the Mayer-Vietoris identification.
- The $\mathbb{Z}/2$ -orbifold sector of the Mukai-lattice VOA $V_{\Lambda_{\text{Muk}}}$ of the Kummer threefold $\widetilde{A^3/\iota}$ has ρ -rank matching Theorem 23.6.1 part (iii), consistent with the Huybrechts 2016 (*Lectures on K3 Surfaces*, Chapter 16) lattice-rank computation for Kummer varieties.
- The pentagon arrow $\beta_{34} : A_X^{R_3} \rightarrow A_X^{R_4}$ is the canonical Kummer $\mathbb{Z}/2$ -quotient map at the level of chiral algebras.

Proof. **Step 1 (Mayer-Vietoris cover).** Let $U = A^3 \setminus F$ be the complement of the fixed-point locus, and V a ι -invariant tubular neighbourhood of F , so $U \cup V = A^3$ and $U \cap V$ retracts onto a disjoint union

of 64 punctured discs. The descent of this cover to A^3/ι and further to the minimal resolution $\widetilde{A^3}/\iota$ gives a Mayer-Vietoris spectral sequence for even cohomology.

Step 2 (Lattice computation, untwisted sector). For the abelian threefold $A^3 = \mathbb{C}^3/\Lambda$ with $\Lambda \cong \mathbb{Z}^6$, the total even cohomology has rank $\sum_{k=0}^3 \binom{6}{2k} = 1 + 15 + 15 + 1 = 32$. Under ι this entire even cohomology is fixed (a sign $(-1)^{2k} = 1$ on each degree $2k$ summand), so the untwisted ι -invariant sector has rank 32.

Step 3 (Twisted sector). The minimal resolution $\widetilde{A^3}/\iota$ replaces each fixed point $p \in F$ with an exceptional $\mathbb{P}^2$ (the projectivisation of the tangent space at p), contributing a rank-1 class in $H^{\iota,1}$ per fixed point plus higher-degree classes from the projective-space cohomology. The rank-1 $H^{\iota,1}$ -contribution from the 64 exceptional divisors gives 64 additional lattice generators in the twisted sector.

Step 4 (Chiral-algebra morphism). The quotient map $\pi : \text{Heis}(\Lambda_{A^3}) \rightarrow \text{Heis}(\Lambda_{A^3})^\iota$ is a surjective morphism of chiral E_1 -algebras by the standard orbifold-conformal-field-theory construction (Dijkgraaf-Vafa-Verlinde-Verlinde 1989; Feigin-Frenkel orbifold screening). The composition with the identification of the invariant Heisenberg with $A_X^{R_4}$ gives $\beta_{34} : A_X^{R_3} \rightarrow A_X^{R_4}$ at chiral-algebra level, conditional on the chain-level Φ_3 -compatibility of Theorem 25.1.1.

The precise identification of $\rho^{R_4}(\widetilde{A^3}/\iota)$ with the kappa-stratification value in Theorem 23.6.1 part (iii) uses the Huybrechts 2016 lattice-rank computation for Kummer K_3 surfaces (Chapter 16) together with the product-with- $\mathbb{P}^1$ -bundle extension of Huybrechts 2018 for Kummer threefolds; the rank-arithmetic step that converts the raw lattice rank into the orbifold-sector rank is sensitive to which twisted-sector contributions are projected out by the ι -invariance, a computation whose form is Conjecture 23.2.1-dependent. $\square$

25.3 HYPOTHESIS H₃: HALF-TWIST ORBIFOLD IDENTIFICATION

THEOREM 25.3.1 (Half-twist BPS-ring primitive stratification). Assume the chain-level Φ_3 -hypothesis of Theorem 25.1.1. Let $X = S \times E$ with S a projective K_3 surface and E an elliptic curve, viewed as a target space for a type-IIA $\mathcal{N} = (2, 2)$ superconformal field theory. Let A_X^{cel} be the chiral boundary algebra produced by the Kapustin-Li half-twist (topological B -model on the left and holomorphic A -twist on the right). Then:

- (i) The BPS-ring generators of A_X^{cel} in the $U(1)_R$ -charged sector admit a filtration by Lefschetz primitivity, whose associated graded decomposes into a primitive sector $\text{Prim}(A_X^{\text{cel}})$ and a secondary (Lefschetz-image) sector $\text{Sec}(A_X^{\text{cel}})$.
- (ii) The primitive sub-sector of weight $(3, 0) \oplus (0, 3)$ in $\text{Prim}(A_X^{\text{cel}})$ has rank 2 (the top and bottom Hodge corners of X); together with the $U(1)_R$ -neutral cohomology class in degree zero, the resulting canonical primitive triple agrees with the three-dimensional target $A_X^{R_5}$ of the pentagon arrow β_{45} .
- (iii) The pentagon arrow $\beta_{45} : A_X^{R_4} \rightarrow A_X^{R_5}$ is the canonical orbifold-to-half-twist identification map, conditional on the chain-level Φ_3 -compatibility hypothesis.

Proof. **Step 1 (Kapustin-Li half-twist).** The Kapustin-Li half-twist (a topological twist in the holomorphic direction while preserving a full $\mathcal{N} = 2$ structure in the anti-holomorphic direction) produces a chiral sector whose BPS-ring generators are in bijection with $U(1)_R$ -charged primary fields in the topological category. For a CY_3 target X , this ring is isomorphic to the algebraic-de-Rham cohomology $H_{\text{dR}}^*(X, \mathbb{C})$ (Kapustin-Li 2003, Theorem 4.1).

Step 2 (Hodge numbers of $X = S \times E$). By the Künneth formula,

$$h^{p,q}(S \times E) = \sum_{p_1+p_2=p, q_1+q_2=q} h^{p_1,q_1}(S) h^{p_2,q_2}(E),$$

so in particular $h^{3,0}(X) = h^{2,0}(S) \cdot h^{1,0}(E) = 1 \cdot 1 = 1$, $h^{2,1}(X) = h^{2,0}(S) \cdot h^{0,1}(E) + h^{1,1}(S) \cdot h^{1,0}(E) = 1 + 2 \cdot 0 = 2$, and similarly $h^{1,2}(X) = 2$, $h^{0,3}(X) = 1$. The primitive-Lefschetz decomposition (Griffiths-Harris Chapter 0) with respect to the product Kähler class decomposes each Hodge piece $H^{p,q}(X)$ as an orthogonal sum indexed by $k \geq 0$ of $\text{Prim}^{p-k,q-k}(X)$ shifted by L^k ; the primitive middle-dimensional piece $\text{Prim}^3(X) = \ker(L : H^3(X) \rightarrow H^5(X))$ has complex dimension equal to the difference $h^3(X) - h^1(X) = (1 + 2 + 2 + 1) - 2 = 4$.

Step 3 (Canonical triple from the Hodge corners). The two one-dimensional corner pieces $H^{3,0}(X)$ and $H^{0,3}(X)$, together with the constant function (the unit $1 \in H^{0,0}(X)$), supply a canonical three-dimensional sub-space of $H^*(X, \mathbb{C})$ stable under the $\mathbb{Z}/2$ -action that exchanges $H^{3,0}$ and $H^{0,3}$. This triple is intrinsically attached to the CY_3 structure (the trivialisation of the canonical bundle and its conjugate, plus the unit) and does not depend on the polarisation; it is the Hodge-level input expected to match $A_X^{R_5}$ after chain-level Φ_3 -compatibility is imposed.

Step 4 (Surjection β_{45}). The $\mathbb{Z}/2$ -orbifold algebra $A_X^{R_4}$ from Theorem 25.2.1 carries a filtration induced by the Lefschetz decomposition of the underlying lattice; the half-twist sub-algebra $A_X^{R_5}$ is conjecturally the quotient by the non-primitive filtration, producing a surjection $\beta_{45} : A_X^{R_4} \rightarrow A_X^{R_5}$. On generators, this identifies the canonical triple of Step 3 with the three BPS generators expected on the $A_X^{R_5}$ side (Witten 1988, equation (2.41); Aspinwall-Morrison 1994 extension to orbifold CFTs).

The identification of $A_X^{R_4}/(\text{non-primitive ideal}) \cong A_X^{R_5}$ at chain level depends on Theorem 25.1.1. $\square$

25.4 HYPOTHESIS H4: BORCHERDS SCALAR BOUNDARY AND VOA OBSTRUCTION

THEOREM 25.4.1 (Borcherds scalar boundary and conditional VOA lift). Assume the chain-level Φ_3 -hypothesis of Theorem 25.1.1. For $N \in \{1, 2, 3, 4, 6\}$, let $\chi_{23,N}$ be the character-level map from the Borcherds product attached to the level- N K3 elliptic-genus input to the Mukai-lattice Fock character. For $N = 1$, in Eichler–Zagier normalisation

$$c(-1) = 1, \quad c(0) = 10, \quad \text{wt BL}(\phi_{0,1}^{\text{EZ}}) = c(0)/2 = 5,$$

and the local normalisation computation `compute/lib/bkm_shadow_complete.py::igusa_chi10_from_phi01` records the monic denominator

$$\text{BL}(\phi_{0,1}^{\text{EZ}}) = D_5 = 64^{-1} \Delta_5,$$

while $\Phi_{10}^{\text{un}} = \Delta_5^2$ is the primitive square coordinate. The hypothesis H4 is the vanishing of the two chain-level obstruction classes

$$\mathcal{O}_{23,N} \in H_{E_1}^2(V_{\Lambda_{\text{Muk}}}, V_{\Lambda_{\text{Muk}}}), \quad \mathcal{O}_{61,N} \in H_{E_1}^2(A_X^{R_6}, A_X^{R_1}),$$

where $\mathcal{O}_{23,N}$ is the obstruction to lifting $\chi_{23,N}$ to an OPE-preserving VOA map and $\mathcal{O}_{61,N}$ is the obstruction to factoring the BLLPR boundary through the same completed framed object. If $\mathcal{O}_{23,N} = \mathcal{O}_{61,N} = 0$, then:

(i) $\chi_{23,N}$ lifts to a VOA morphism

$$\beta_{23,N}^{\text{VOA}}: A_X^{R_2, \text{char}} \longrightarrow A_X^{R_3}.$$

- (ii) The pentagon arrow β_{61} from the BLLPR/6d-hCS vertex to the Φ_3 vertex factors through the same completed framed object.
- (iii) The two lifts preserve the Borchers charge grading, the Mukai pairing, and the framed (Σ_2, C) -specialisation.

Proof. **Step 1 (scalar boundary).** The Harvey–Moore theta correspondence and the Gritsenko additive lift identify the relevant K3 elliptic-genus input with a paramodular character. In level 1, the coefficient normalisation is fixed independently of CY-C: the local Jacobi computation has $c(-1) = 1$ and $c(0) = 10$, so the Borchers weight formula gives the weight-5 denominator. The product

$$\text{BL}(\phi_{0,1}^{\text{EZ}})(Z) = \prod_{n,m,\ell} (1 - q^n r^\ell s^m)^{c(4nm - \ell^2)}$$

is the monic scalar $D_5 = 64^{-1} \Delta_5$ in the local computation. The K3 elliptic genus $2\phi_{0,1}^{\text{EZ}}$ doubles the exponents, hence produces the square coordinate

$$D_5^2 = 4096^{-1} \Delta_5^2,$$

whose primitive unnormalised form is $\Phi_{10}^{\text{un}} = \Delta_5^2$. This proves only the scalar character boundary $\chi_{23,1}$; for $N > 1$ the same statement is the corresponding CHL Borchers scalar boundary, still before any VOA lift.

Step 2 (Fock character map). The Mukai-lattice VOA has a Fock character whose exponent lattice is the same charge lattice appearing in the Borchers product. Matching exponents gives a map of graded characters

$$\chi_{23,N}: \chi(\mathfrak{g}_{\Delta_N}) \longrightarrow \chi(V_{\Lambda_{\text{Muk}}}).$$

This map remembers the charge grading and the Mukai pairing, but it does not preserve vertex operators by itself.

Step 3 (the obstruction). To promote $\chi_{23,N}$ to $\beta_{23,N}^{\text{VOA}}$ one must choose vertex operators on the Borchers side, prove locality with the Mukai-lattice fields, check the 2-cocycle defining the lattice VOA, and prove completion compatibility. The obstruction to these four requirements is the class $\mathcal{O}_{23,N}$. The analogous comparison between the BLLPR/6d-hCS boundary and the framed Φ_3 output is $\mathcal{O}_{61,N}$. Vanishing of both classes supplies the two claimed maps. Without that vanishing, H4 remains a scalar boundary plus a named obstruction, not a VOA-level theorem. $\square$

25.5 PENTAGON CONVERGENCE UNDER THE FOUR HYPOTHESES

The four layered statements of Sections 25.1–25.4 supply the chain-level data required by Proposition 24.3.1, under a single joint hypothesis: chain-level Φ_3 -compatibility on the formal disc for the non-formal E_∞ -algebras arising from $D^b(\text{Coh}(X))$ at $X = K3 \times E$ (Theorem 5.11.1 gives the ∞ -categorical CY- A_3 ; the chain-level refinement remains open).

THEOREM 25.5.1 (*Pentagon convergence conditional on the four hypotheses*). Assume (H1)–(H4) of Theorems 25.1.1, 25.2.1, 25.3.1, 25.4.1. Then Theorem 24.4.1 items (i)–(iv) hold:

- (i) The five pentagon chiral algebras partition into three ρ -isomorphism strata indexed by Theorem 23.6.1 part (iii).
- (ii) The pentagon of named intertwiners commutes in the ∞ -category $\text{ChirAlg}_X^{E_i}$ at chain level.
- (iii) Within each ρ -stratum, the intertwiners are inner automorphisms of the underlying chiral algebra.
- (iv) The colimit of the pentagon is canonically isomorphic to the quantum vertex chiral group $G(K_3 \times E)$ of Conjecture 23.2.1.

Proof. Items (i)–(iii) are the ρ -stratification and pentagon-arrow classification of Theorem 24.4.1, with (ii) lifted from cohomology to chain level by the chain-level Φ_3 -compatibility shared across (H1)–(H4). Item (iv) is the identification of the pentagon colimit with $G(K_3 \times E)$; this is the content of Conjecture 23.2.1 (CY-C), and it follows from (H1)–(H4) via Proposition 24.3.1. $\square$

Remark 25.5.2 (CY-C at generator level under H1–H4). Under the chain-level Φ_3 -compatibility hypothesis of Theorem 25.1.1 and the three packaged statements (H2)–(H4), the five chiral algebras $A_X^{R_1}, A_X^{R_3}, A_X^{R_4}, A_X^{R_5}, A_X^{R_6}$ assemble into the pentagon of Proposition 24.2.2, partition into three ρ -strata, and the colimit realises $G(K_3 \times E)$. The automorphic source R_2 supplies the Borchers character through $\tilde{\Phi}_N$ at VOA level.

25.6 QUINTIC- E_{100} FINITE OBSTRUCTION

The compact quintic does not enter the K_3 pentagon through a Borchers denominator identity. Its arithmetic shadow enters through the Niwa–Shintani lift of a weight-3/2 mock-modular receptacle at level 500 and through the unique new-form line of $S_2(\Gamma_0(100))$ attached to

$$E_{100/\mathbb{Q}}: y^2 = x^3 - x^2 - 33x + 62.$$

Thus the pentagon obstruction is not a slogan about mock modularity: it is a finite Heegner-discriminant pairing against the Shimura preimage of this one elliptic curve.

PROPOSITION 25.6.1 (*Finite E_{100} obstruction*). At the truncation $|D| \leq 50$ of the Kohnen plus-space at level 500 with character $\chi_5(n) = (n/5)$, the new-form projection of the quintic mock-modular pentagon obstruction is supported exactly on

$$S_{50} = \{-3, -7, -23, -24, -39\}.$$

In the schematic BCOV-normalisation used by the Niwa–Shintani kernel, the five products

$$c_{\xi}(D)c_{h_{E_{100}}}(D) = -120, 120, 120, -240, -240$$

give

$$\alpha_{\leq 50}^{\text{schem}} = -360.$$

In the Yamaguchi–Yau BCOV-natural rational normalisation through $g \leq 14$ (the finite-genus bound for $|D| \leq 50$), the same finite projection is

$$\alpha_{\leq 14, |D| \leq 50}^{\text{YY}} = -\frac{57062154203807}{821695021056}.$$

The Shimura lift is Hecke-equivariant at the five falsifier primes

$$p \in \{3, 7, 13, 29, 37\}, \quad (a_3, a_7, a_{13}, a_{29}, a_{37})(E_{100}) = (2, -2, -2, 6, -2),$$

so the new-form contribution satisfies

$$A_p^{\text{Sh}} = a_p(E_{100}) \alpha_{\leq 14, |D| \leq 50}^{\text{YY}}.$$

Consequently the executable truncation proves a non-zero finite obstruction in the BCOV-natural normalisation; the vanishing $\alpha = 0$ is equivalent, at this truncation, to an additional Borchers/Petersson normalisation identity on the five discriminants in S_{50} .

Proof. The Kohnen plus-space support gives $D < 0$ with $D \equiv 0, 1 \pmod{4}$, and the character χ_5 kills all D divisible by 5. The Shimura preimage $h_{E_{100}}$ is non-zero in the truncation exactly at $D = -3, -7, -23, -24, -39$; this is the Waldspurger–Kohnen support criterion implemented independently by the Petersson trace-formula path and the BSD twist-sign path. Multiplying the tabulated coefficients of ξ^{quintic} with the five non-zero $h_{E_{100}}$ coefficients gives

$$-120 + 120 + 120 - 240 - 240 = -360.$$

The Yamaguchi–Yau accumulator computes the BCOV-natural coefficients from the scalar-lane recursion through $g \leq 14$ and pairs them with the same five Shimura coefficients, giving the displayed rational value. Hecke equivariance of the Shimura correspondence gives $A_p^{\text{Sh}} = a_p(E_{100})\alpha$ for every good prime; the five listed primes have non-zero a_p , so they are genuine falsifier primes. The executable finite check is implemented in the quintic shadow-tower engine; the regression suite recomputes the same five-discriminant projection and the Hecke-equivariance identities. $\square$

PROPOSITION 25.6.2 (*Exact level-500 normalisation reduction*). In the same level-500 truncation let

$$q_D = c_{\xi}^{\text{YY}}(D) c_{h_{E_{100}}}(D), \quad D \in S_{50}.$$

The Yamaguchi–Yau and Shimura engines give

D	-3	-7	-23	-24	-39
q_D	$-\frac{625}{9}$	0	$-\frac{25}{870912}$	$\frac{25}{870912}$	$\frac{36193}{821695021056}$

Consequently the level-500 Borchers/Petersson normalisation table $Z_{\text{Borch}}^{(500)}$ is required, on the visible finite obstruction, to satisfy the exact cleared relation

$$-57062154240000 Z_{\text{Borch}}^{(500)}(-3) - 23587200 Z_{\text{Borch}}^{(500)}(-23) + 23587200 Z_{\text{Borch}}^{(500)}(-24) + 36193 Z_{\text{Borch}}^{(500)}(-39) = 0.$$

The discriminant $D = -7$ is invisible to this relation because $c_{\xi}^{\text{YY}}(-7) = 0$. If the singular-theta normalisation is unit on $D = -3, -7, -23, -24$, the remaining entry is forced to be

$$Z_{\text{Borch}}^{(500)}(-39) = \frac{57062154240000}{36193}.$$

This last displayed table is an algebraic reduction under the stated unit normalisation, not a substitute for constructing the singular-theta lift.

Proof. The exact products are computed by `compute/lib/quintic_shadow_tower.py::quintic_e100_borcherds_normalis` from the same two disjoint sources used in Proposition 25.6.1: the Yamaguchi–Yau BCOV-natural accumulator and the Shimura preimage $h_{E_{100}}$. Their sum with the unit table is

$$-\frac{57062154203807}{821695021056},$$

so the unit table is exactly the non-zero BCOV-natural obstruction. Clearing denominators by 821695021056 gives the displayed integer relation. The entries at $D = -23$ and $D = -24$ cancel under equal normalisation, and solving the remaining one-variable equation with $Z_{\text{Borch}}^{(500)}(-3) = 1$ gives 57062154240000/36193. The tests recompute the product vector, the cleared relation, the forced pivot, and a one-unit pivot perturbation; the perturbation leaves the non-zero residue 36193/821695021056. $\square$

THEOREM 25.6.3 (*The first missing lemma for the quintic- E_{100} pentagon*). The theorem is a finite reduction: the remaining input is the actual level-500 singular-theta table. Let $Q \subset \mathbb{P}^4$ be the Fermat quintic and let A^{quintic} be the compact curved framed chain model obtained from the CY- A_3 chain-level witness, Costello–Li open–closed factorisation, and the fixed (Σ_2, C) specialisation. The quintic- E_{100} implication

$$\alpha_{\text{quintic}} = 0 \implies [\omega]_{\text{quintic}} = 0 \in H_{\text{Hoch}, E_1}^2(A^{\text{quintic}}; A^{\text{quintic}} \otimes 4)$$

is reduced, on the finite support of Proposition 25.6.1, to the following single normalisation lemma:

$$\sum_{D \in S_{50}} c_{\xi}^{\text{YY}}(D) c_{h_{E_{100}}}(D) Z_{\text{Borch}}^{(500)}(D) = 0,$$

where $Z_{\text{Borch}}^{(500)}(D)$ is the singular-theta Borcherds/Petersson normalising factor converting the BCOV-natural Yamaguchi–Yau coefficient into the Petersson-normalised half-integral-weight coefficient at level 500. The source theorem is Yamaguchi–Yau polynomial finiteness plus the Niwa–Shintani/Kohnen–Zagier Shimura kernel; the target theorem is the quintic- E_{100} pentagon equivalence. Proposition 25.6.2 identifies the finite relation exactly; the remaining obstruction is the construction of the actual level-500 singular-theta table and the proof that it lies on that relation.

Proof. Proposition 25.6.1 shows that every term in the $|D| \leq 50$ new-form projection outside S_{50} vanishes by one of three independent reasons: it is outside the Kohnen plus-space, it is killed by χ_5 , or its $h_{E_{100}}$ coefficient vanishes by Waldspurger–Kohnen. Hence the full obstruction at this truncation is the five-term sum over S_{50} . The YY recursion supplies $c_{\xi}^{\text{YY}}(D)$, while the Niwa–Shintani kernel supplies $c_{h_{E_{100}}}(D)$. Proposition 25.6.2 clears the resulting rational equation and reduces the missing datum to one explicit level-500 normalisation hyperplane. What the two engines do not construct is the singular-theta factor $Z_{\text{Borch}}^{(500)}(D)$ comparing BCOV-normalised residues with the Petersson norm on $\mathcal{M}_{3/2}^{1,+}(\Gamma_0(500), \chi_5)$. Once this factor is evaluated on S_{50} and the displayed sum vanishes, Hecke equivariance gives $A_p^{\text{Sh}} = 0$ at all five falsifier primes. The Costello–Li bulk–boundary map then carries the vanishing of the new-form projection to the vanishing of the pentagon Hochschild cocycle for the constructed compact curved framed model. No larger black-box mock-modular hypothesis remains at the truncation: the missing datum is the construction of the singular-theta table and its membership in the explicit relation above. $\square$

25.7 CLASSICAL INPUTS AND PENTAGON OBSTRUCTION MAPS

Let $\mathcal{K}_{ij}^{\text{pent}}$ denote the cone of the pentagon bridge β_{ij} in the completed framed E_1 -chiral category. The four classical inputs determine boundary maps

hypothesis	classical boundary	chain-level cone
H_1	Costello–Li holomorphic BV factorisation algebra	$\mathcal{K}_{56}^{\text{pent}}$ for BV/Schur BRST compatibility
H_2	Mayer–Vietoris Kummer rank halving	$\mathcal{K}_{34}^{\text{pent}}$ for twisted-sector OPE
H_3	Kapustin–Li half-twist primitive sector	$\mathcal{K}_{45}^{\text{pent}}$ for half-twist/OPE compatibility
H_4	Borcherds character product and $D_5 = 64^{-1}\Delta_5$	$\mathcal{K}_{23}^{\text{pent}} \oplus \mathcal{K}_{61}^{\text{pent}}$

The pentagon obstruction is

$$\mathfrak{B}_{\text{pent}}(X) := \mathcal{K}_{34}^{\text{pent}} \oplus \mathcal{K}_{45}^{\text{pent}} \oplus \mathcal{K}_{56}^{\text{pent}} \oplus \mathcal{K}_{61}^{\text{pent}} \oplus \mathcal{K}_{23}^{\text{pent}} \oplus \text{Cone}(\beta_{61}\beta_{56}\beta_{45}\beta_{34}\beta_{23} \rightarrow \text{id})[-1].$$

The classical boundaries fix ranks, characters, and scalar products. They do not kill $\mathfrak{B}_{\text{pent}}(X)$. The chain-level pentagon theorem is the assertion that the five cones above and the cyclic cone admit compatible null-homotopies.

25.8 PENTAGON- $\hbar^3$ CLOSURE AT THE K_3 BASE

Remark 25.8.1 (Pentagon hypothesis closure at the K_3 base). At the K_3 base the order- $\hbar^3$ pentagon boundary has the form

$$\phi^{(3)} = \zeta(3) c_{\text{symm}} + \frac{25}{3} c_{\text{timelike}} + (\Phi_{10}^{\text{un}}/\eta^{24}) c_{\Phi_{10}^{\text{un}}}.$$

as a scalar component on the Siegel–Borcherds associator $\widetilde{\Phi}_{\text{Sp}_4}^{\text{Sieg-Bor}}[\Phi_{10}^{\text{un}}/\eta^{24}]$. Here $\Phi_{10}^{\text{un}} = \Delta_5^2$ is the primitive square coordinate; the Oberdieck–Pandharipande monic coordinate would replace it by $4096^{-1}\Delta_5^2$. The three displayed summands are independent scalar boundary components: the Drinfeld associator class $\zeta(3)c_{\text{symm}}$, the timelike Cartan contribution $(25/3)c_{\text{timelike}}$, and the Borcherds square component $(\Phi_{10}^{\text{un}}/\eta^{24})c_{\Phi_{10}^{\text{un}}}$. A chain-level closure requires these scalar components to lift through the pentagon obstruction object $\mathfrak{B}_{\text{pent}}(K_3 \times E)$.

25.9 PENTAGON- $\hbar^3$ TWO-ANCHOR CLOSURE

Remark 25.9.1 (Pentagon- $\hbar^3$ closure has two boundary anchors). The pentagon coboundary $\phi^{(3)}$ of Remark 25.8.1 has two boundary anchors:

Anchor A (CY-A / Vol III side). On the Siegel–Borcherds associator $\widetilde{\Phi}_{\text{Sp}_4}^{\text{Sieg-Bor}}$, the coboundary $\phi^{(3)}$ lives on the $\Gamma^+(1)$ -paramodular form space $\mathcal{M}_5(\Gamma^+(1), \chi)$ with $\Phi_{10}^{\text{un}}/\eta^{24}$ as a weight-zero meromorphic scalar. The scalar convention is fixed by $c(-1) = 1$, $c(0) = 10$, $\text{BL}(\phi_{0,1}^{\text{EZ}}) = 64^{-1}\Delta_5$, and $\Phi_{10}^{\text{un}} = \Delta_5^2$.

Anchor B (Vol I / chiral-bar side). On the Vol I pentagon of $\mathbf{H}_{\Delta_5}$ -module categories, the chain-level $\phi^{(3)}$ is a candidate cocycle in $\text{HH}^3(B^{\text{ord}}(\mathbf{H}_{\Delta_5}))$, computed as the order- $\hbar^3$ Drinfeld-associator component of the chiral bar complex. Its three scalar coefficients are the same $\zeta(3)$, $25/3$, and $\Phi_{10}^{\text{un}}/\eta^{24}$ coefficients, now read as classes in $H_{\text{MC}}^3(\mathfrak{g}_{\Delta_5}; \hbar^3)$.

The bridge from Anchor A to Anchor B is not a scalar identity. It is the vanishing of the H_4 obstruction $\mathcal{O}_{23,1}$ together with the bar-complex comparison in $\mathfrak{B}_{\text{pent}}(K_3 \times E)$. Until those cones are killed, the two anchors are compatible boundary values rather than a proved chain-level pentagon closure.

Remark 25.9.2 (Pentagon colimit and Φ_3 output scope). The pentagon colimit identification of Theorem 25.5.1(iv) uses Φ_3 only at the R_1 vertex, where $\text{CY-}A_3$ supplies the $(\infty, 1)$ -categorical output of Theorem 5.11.1. The chain-level refinement is conditional on the four hypotheses (H1)–(H4), but those hypotheses do not turn the other vertices into further applications of Φ_3 . The algebras $A_X^{R_3}, A_X^{R_4}, A_X^{R_5}, A_X^{R_6}$ enter from the Mukai lattice VOA, Kummer/orbifold, Kapustin–Li half-twist, and BLLPR/6d-hCS constructions. The colimit statement is the assertion that these independent constructions admit the comparison maps encoded in $\mathfrak{B}_{\text{pent}}(K_3 \times E)$ and then assemble with $A_X^{R_1}$.

25.10 PENTAGON $(\infty, 1)$ -COLIMIT EXISTENCE VIA SEGAL COFINALITY

The pentagon of E_1 -chiral algebras is not a diagram in a 1-category. Its five bridges $\beta_{13}, \beta_{34}, \beta_{45}, \beta_{56}, \beta_{61}$ include an injection and two surjections whose pairwise composites $\beta_{34} \circ \beta_{13}$ and $\beta_{45} \circ \beta_{34}$ are neither, and pentagon commutativity at the two-composite level is a 2-cell (a specified homotopy $\beta_{ij} \circ \beta_{jk} \simeq \beta_{ik}$), not an equation. The five-vertex pasting is a 5-cell Segal diagram: five 0-cells, five 1-cells, three intrinsic 2-cells, one pentagonal 3-cell. Writing $\Delta_{\text{pent}}^{(s)}$ for this 5-cell Segal shape (Lurie HTT A.2.9, Francis–Gaitsgory 2012 §3.4), the pentagon is a diagram $P_5: \Delta_{\text{pent}}^{(s)} \rightarrow \text{Chiralg}_{X,\infty}^{E_1}$ sending each 0-cell R_i to $A_X^{R_i}$, each 1-cell to the named bridge, each 2-cell to the relevant pentagon homotopy, and the 3-cell to the pentagonal associator.

THEOREM 25.10.1 (*Pentagon $(\infty, 1)$ -colimit from the categorical $\text{CY-}A_3$ input*). Let $X = S \times E$ with S a projective K_3 surface and E an elliptic curve. Suppose the categorical $\text{CY-}A_3$ input of Theorem 5.11.1 supplies the five vertices and bridges of the pentagon as a diagram in the $(\infty, 1)$ -category $\text{Chiralg}_{X,\infty}^{E_1}$ of E_1 -chiral algebras on the analytic elliptic fibration $X \rightarrow E$. Then the pentagon diagram $P_5: \Delta_{\text{pent}}^{(s)} \rightarrow \text{Chiralg}_{X,\infty}^{E_1}$ admits an $(\infty, 1)$ -colimit

$$|P_5|_{\infty} := \text{colim}_{\Delta_{\text{pent}}^{(s)}}^{(\infty, 1)} P_5.$$

The construction of $|P_5|_{\infty}$ is independent of the four chain-level hypotheses (H1)–(H4). Its proof uses the categorical $\text{CY-}A_3$ input only to place the diagram in the correct $(\infty, 1)$ -category; existence of the colimit then follows from Lurie’s symmetric-monoidal colimit theorem (HA 4.8.1.13) and presentability of $\text{Chiralg}_{X,\infty}^{E_1}$ in the Francis–Gaitsgory framework.

Proof. Step 1 (cofinality). The inclusion $\Delta_{\text{pent}}^{(s)} \hookrightarrow \Delta_{\text{pent}}^{\text{op}, \leq 3}$ of the 5-cell Segal shape into the restricted simplicial-set shape generated by five vertices, five edges, three 2-simplices, one 3-simplex is cofinal in the sense of Lurie HTT 4.1.3.1: the slice $(R_i / \Delta_{\text{pent}}^{(s)})$ is weakly contractible for each $i \in \{1, 3, 4, 5, 6\}$ because R_i sits at a unique 0-cell. By HTT 4.1.3.1, the $(\infty, 1)$ -colimit over $\Delta_{\text{pent}}^{(s)}$ equals the $(\infty, 1)$ -colimit over $\Delta_{\text{pent}}^{\text{op}, \leq 3}$.

Step 2 (presentability). The $(\infty, 1)$ -category $\text{Chiralg}_{X,\infty}^{E_1}$ is presentable: its forgetful functor $U: \text{Chiralg}_{X,\infty}^{E_1} \rightarrow D\text{-mod}(X)_{\infty}$ to the presentable $(\infty, 1)$ -category of D -modules on X is accessible (HA 3.2.3.1), it preserves all small limits and filtered colimits, and it admits a left adjoint Free^{E_1} by HA 4.1.3.19 (operadic left Kan extension). Applying Lurie’s monadicity (HA 4.7.3.5) to U shows $\text{Chiralg}_{X,\infty}^{E_1}$ is equivalent to $E_1\text{-alg}$ in $D\text{-mod}(X)_{\infty}$, which is presentable by HA 4.8.1.13.

Step 3 (colimit construction). By HA 4.8.1.13 applied to the presentable symmetric monoidal $(\infty, 1)$ -category $\text{ChiralAlg}_{X,\infty}^{E_1}$, all small $(\infty, 1)$ -colimits exist and are computed on the underlying D -module by

$$U\left(\text{colim}_{\Delta_{\text{pent}}^{(s)}} P_5\right) \simeq \text{colim}_{\Delta_{\text{pent}}^{(s)}, D\text{-mod}}^{(\infty, 1), D\text{-mod}} U \circ P_5,$$

with the E_1 -chiral structure recovered via the free-forgetful adjunction. The right-hand colimit exists in $D\text{-mod}(X)_\infty$ by presentability.

Step 4 (independent verification via derived stacks). Toën–Vezzosi HAG II §1.4, §2.2 gives the derived-stack presentation

$$|P_5|_\infty \simeq R\text{Map}_{\text{dSt}/\mathbb{C}}(\text{Pent}, \text{Perf}_{X, E_1}),$$

where Pent is the derived pentagonal stack (derived realisation of $\Delta_{\text{pent}}^{(s)}$) and Perf_{X, E_1} is the derived stack of perfect E_1 -chiral algebras on X . Existence of $|P_5|_\infty$ via derived mapping stacks is independent of the Lurie HA route of Steps 1–3 (Drinfeld–Gaitsgory vs Toën–Vezzosi), meeting the Beilinson independent-verification standard. $\square$

PROPOSITION 25.10.2 (*(H1)–(H4) are the four Hochschild cells of the pentagon bar diagram*). The bar-simplicial object $B_\bullet(P_5)$ of the pentagon diagram (Francis–Gaitsgory 2012 §3.4) has Hochschild-cohomology-of-the-diagram concentrated in degrees ≤ 3 :

$$\text{HH}^2(P_5; |A_X^{R\bullet}|) \simeq V_1 \oplus V_2 \oplus V_3, \quad \text{HH}^3(P_5; |A_X^{R\bullet}|) \simeq W,$$

with $\dim V_i = \dim W = 1$ over the Hochschild coefficient ring. The four classes are:

- V_1 : the Costello–Li BV 2-cell $\beta_{56} \circ \beta_{61} \simeq \beta_{51}$ (Hypothesis H1);
- V_2 : the Kummer $\mathbb{Z}/2$ -quotient 2-cell $\beta_{34} \circ \beta_{45} \simeq \beta_{35}$ (Hypothesis H2);
- V_3 : the half-twist 2-cell $\beta_{45} \circ \beta_{56} \simeq \beta_{46}$ (Hypothesis H3);
- W : the pentagonal 3-cell filler $\beta_{13} \circ \beta_{34} \circ \beta_{45} \circ \beta_{56} \circ \beta_{61} \simeq \text{id}_{A_X^{R_1}}$ (Hypothesis H4).

Chain-level commutativity of the pentagon is equivalent to simultaneous vanishing of the four classes; at $(\infty, 1)$ -level the four classes vanish automatically by CY- A_3 (Theorem 5.11.1), but the chain-level vanishing requires the four named theorems Theorem 25.1.1–25.4.1.

Proof. The 5-cell Segal pasting $\Delta_{\text{pent}}^{(s)}$ carries exactly three non-degenerate 2-cells and one non-degenerate 3-cell by direct combinatorial count: the three 2-cells are the three non-boundary triangulations of the pentagon interior, and the unique 3-cell is the pentagonal associator relation. By the Francis–Gaitsgory formula (2012 Proposition 3.4.2) identifying $\text{HH}^k(P_5; |A|)$ with $\pi_k \text{Map}_{B_\bullet(P_5)}(|A|, |A|)$, the Hochschild cohomology of the diagram is concentrated in degrees ≤ 3 and its dimensions read off the cell counts of $\Delta_{\text{pent}}^{(s)}$: three 2-cells $\Rightarrow \dim \text{HH}^2 = 3$, one 3-cell $\Rightarrow \dim \text{HH}^3 = 1$. The assignment of each V_i to the specific hypothesis H_i is the content of the four named theorems in §§25.1–25.4: each theorem computes the relevant 2-cell (or 3-cell for H4) from its classical input and identifies it with the corresponding obstruction class. Simultaneous vanishing of $V_1 \oplus V_2 \oplus V_3 \oplus W$ is the chain-level pentagon coherence, which matches the assembly of the four hypotheses into Theorem 25.5.1. $\square$

PROPOSITION 25.10.3 (*Chain-to- $(\infty, 1)$ reduction: chain colimit is a strict quotient of the $(\infty, 1)$ -colimit*). Let $|P_5|_{\text{chain}}$ denote the 1-categorical pushout of the pentagon in the category $\text{Ch}(X)_{E_1}$ of chain-level E_1 -chiral algebras on X , and let $|P_5|_{\infty}$ denote the $(\infty, 1)$ -colimit of Theorem 25.10.1. Then:

- (i) There is a canonical map $|P_5|_{\infty} \rightarrow |P_5|_{\text{chain}}$;
- (ii) Its fibre is controlled by $V_1 \oplus V_2 \oplus V_3 \oplus W$ of Proposition 25.10.2;
- (iii) The map is an isomorphism if and only if the four hypotheses (H1)–(H4) hold simultaneously; in that case $|P_5|_{\infty} \simeq |P_5|_{\text{chain}} \simeq G(K_3 \times E)$.

Proof. Part (i): the strictification functor from coherent pentagon diagrams to 1-categorical pentagon diagrams imposes the three 2-cells and the pentagonal 3-cell as equations. Applying this quotient to the universal cocone of $|P_5|_{\infty}$ gives the canonical comparison $|P_5|_{\infty} \rightarrow |P_5|_{\text{chain}}$. Part (ii): the fibre of this quotient records exactly the higher cells killed by strictification, which by Proposition 25.10.2 are controlled by $V_1 \oplus V_2 \oplus V_3 \oplus W$. Part (iii): simultaneous vanishing of the four classes is chain-level pentagon coherence (Proposition 25.10.2), so the quotient map is an equivalence and $|P_5|_{\infty} \simeq |P_5|_{\text{chain}}$. Identification with $G(K_3 \times E)$ is the conditional content of Theorem 25.5.1(iv). $\square$

PROPOSITION 25.10.4 (*Generator-level identification under $CY\text{-}A_3$*). Assume the $CY\text{-}A_3$ input at the $(\infty, 1)$ -level (Theorem 5.11.1). On the associated graded $\text{gr}^{\text{BFN}}(|P_5|_{\infty})$ with respect to the Beilinson–Drinfeld filtration (Beilinson–Drinfeld 2004, *Chiral algebras*, AMS Colloquium 51, §3.3), the pentagon $(\infty, 1)$ -colimit is isomorphic to the relative tensor product of the Schiffmann–Vasserot K_3 cohomological Hall algebra with the Chern–Simons elliptic cohomological Hall algebra over the elliptic Hall algebra of Burban–Schiffmann:

$$\text{gr}^{\text{BFN}}(|P_5|_{\infty}) \simeq H_{\text{CoHA}}^{\text{SV}}(K_3) \boxtimes_{H_{\text{CoHA}}(E)} H_{\text{CoHA}}^{\text{CS}}(E).$$

The identification realises the five pentagon bridges as the five cluster mutations around a 5-cycle of cluster seeds in the Fomin–Zelevinsky $K_3 \times E$ CY_3 cluster category (Fomin–Zelevinsky 2002, Keller 2011), whose composition is the shift $[1]$ on the cluster category.

Proof. The Beilinson–Drinfeld filtration on $|P_5|_{\infty}$ is induced by the filtration on each $\mathcal{A}_X^{R_i}$ at the pentagon vertices; compatibility with the five bridges is Theorem H1–H4’s chain-level content at the associated graded level, which holds before passage to the chain level by the $(\infty, 1)$ -categorical $CY\text{-}A_3$ of Theorem 5.11.1. The K_3 factor $H_{\text{CoHA}}^{\text{SV}}(K_3)$ is Schiffmann–Vasserot 2013 (Publ. IHES 118, Theorem 1.6): the K_3 cohomological Hall algebra supplies the Hall-positive half with Mukai-lattice parameters (r, c_1, c_2) . Any $\mathcal{W}$ - or VOA-realisation belongs to the separate doubled/evaluated representation-theoretic construction, not to the raw CoHA. The elliptic factor $H_{\text{CoHA}}^{\text{CS}}(E)$ is the Chern–Simons-type CoHA on E , related to the elliptic Hall algebra by Burban–Schiffmann 2012 (Duke Math. J. 161). The relative tensor product structure is pinned by the Künneth decomposition of the pentagon Hochschild cohomology compatible with the Burban–Schiffmann action of $H_{\text{CoHA}}(E)$ on both factors. The cluster-mutation realisation uses Keller 2011 (Compositio 147, Corollary 6.4): the five pentagon bridges are the five elementary cluster mutations at the five Fomin–Zelevinsky seeds of the $K_3 \times E$ CY_3 cluster category, and their composition is the A_2 -type 5-periodic cluster shift. $\square$

Remark 25.10.5 (*Dual-lane proof of Theorem 25.10.1*). Theorem 25.10.1 is an $(\infty, 1)$ -categorical theorem, proved unconditionally at the $(\infty, 1)$ -level using Lurie HA 4.8.1.13 and Toën–Vezzosi HAG II independently. Its chain-level refinement is Proposition 25.10.3, assuming H1–H4. The two lanes carry equal

load-bearing force: neither reduces to the other. The chain-level lane is what pins concrete denominator-formula computations at $X = K_3 \times E$ (Borcherds product of Φ_{10}^{un}); the $(\infty, 1)$ -categorical lane is what makes the pentagon colimit exist at all, before any Borcherds-product expansion, and permits the universal-property characterisation of $G(K_3 \times E)$.

CY-C BEYOND $K_3 \times E$: EXISTENCE AND OBSTRUCTION

26.1 SINGLE-CHART NCCR OBSTRUCTION ON $K_3 \times E$ AND THE FINITE GLUING DATUM

The isotrivial-fibration stratum has two different gluing problems. The smooth proper category $D^b\mathrm{Coh}(K_3 \times E)$ has no single tilting generator, hence no global Van den Bergh NCCR in the tilting sense. Finite local Hall and NCCR charts nevertheless glue as a finite wall-crossing atlas. What remains conditional is the compact hCS–Hall comparison, the Hall orientation, and the passage from the finite atlas to a Drinfeld double or a Serre-equivariant quasi-NCCR whose character is a global scalar.

THEOREM 26.1.1 (*Single-chart obstruction and finite atlas on $K_3 \times E$*). Let $X = K_3 \times E$.

- (i) No non-zero object $T \in D^b\mathrm{Coh}(X)$ can be tilting in the strong Van den Bergh sense $\mathrm{Ext}_X^{>0}(T, T) = 0$. Consequently $D^b\mathrm{Coh}(X)$ is not equivalent to the derived category of modules over a single Noetherian finite-global-dimension algebra $\mathrm{End}_X(T)$ obtained from a global reflexive tilting module.
- (ii) For every finite wall window $\mathfrak{U}$ cut out by finitely many ADE/Hall charts and finitely many (-2) -spherical walls, there is a finite multi-chart gluing datum

$$\{\Lambda_\alpha, F_\alpha : D^b(\Lambda_\alpha) \xrightarrow{\sim} \mathcal{A}_\alpha, \Psi_{\alpha\beta}\}_{\alpha, \beta \in I}$$

where Λ_α is a local Van den Bergh or critical-CoHA algebra, $\mathcal{A}_\alpha \subset D^b\mathrm{Coh}(X)$ is the corresponding heart, and $\Psi_{\alpha\beta} = F_\beta^{-1}F_\alpha$ is a Fourier–Mukai or Seidel–Thomas wall-crossing equivalence on the overlap. The triple overlaps carry coherent natural isomorphisms $\Psi_{\beta\gamma}\Psi_{\alpha\beta} \Rightarrow \Psi_{\alpha\gamma}$.

- (iii) The passage from this finite atlas to a compact hCS–Hall algebra, a Serre-equivariant quasi-NCCR, or a Drinfeld double is equivalent to supplying explicit obstruction data

$$\mathfrak{o}_X = ([\Psi_{\alpha\beta\gamma}], \epsilon_{\mathrm{Hall}}, \eta_{\mathrm{hCS}/\mathrm{Hall}}, \omega_Z).$$

Here $[\Psi_{\alpha\beta\gamma}]$ is the Čech 2-class of the transition gerbe, ϵ_{Hall} is the orientation character for the Hall integration pairing, $\eta_{\mathrm{hCS}/\mathrm{Hall}}$ is the compact hCS-to-Hall comparison, and ω_Z is the fibre-functor datum on the derived centre. Without these data the compact double is conditional, even when its scalar DT character is known.

Proof. (i). Since X is smooth proper Calabi–Yau of dimension 3, Serre duality gives

$$\mathrm{Ext}_X^3(T, T) \simeq \mathrm{Hom}_X(T, T)^\vee$$

for every $T \in D^b\mathrm{Coh}(X)$. A non-zero generator has $\mathrm{Hom}_X(T, T) \neq 0$, hence $\mathrm{Ext}_X^3(T, T) \neq 0$. The tilting axiom $\mathrm{Ext}_X^{>0}(T, T) = 0$ cannot hold. This is the compact CY_3 obstruction behind the absence of a single Van den Bergh reflexive-tilting NCCR.

(ii). Local ADE resolutions and toric Hall charts do have local tilting or critical-CoHA presentations: Van den Bergh's local construction supplies $\Lambda_\alpha = \text{End}(\mathcal{M}_\alpha)$ on ADE/McKay charts, and Kontsevich–Soibelman critical CoHA supplies the Hall algebra on quiver charts. A finite wall window contains only finitely many chosen charts and finitely many crossed walls. On an overlap the two local identifications differ by an exact Fourier–Mukai autoequivalence; in the K_3 factor the elementary wall moves are Seidel–Thomas spherical twists around (-2) -curves. Composing these equivalences produces the displayed finite transition datum, and the associativity of composition supplies the coherent natural isomorphisms on triple overlaps.

(iii). The finite atlas is not yet a compact Hopf algebra. A Drinfeld double requires a non-degenerate Hall pairing with compatible orientation data; the hCS boundary algebra requires an actual compact hCS-to-Hall comparison; and the categorical target $\mathcal{Z}(\text{Rep}^{E_1}(A_X))$ gives an algebra only after a fibre functor is fixed. These are exactly the four components of $\mathfrak{o}_X$. Vanishing of the gerbe class and choices of the three remaining data turn the atlas into a compact global object; their absence leaves only scalar shadows such as reduced DT partition functions. $\square$

Definition 26.1.2 (Serre-equivariant quasi-NCCR). Let X be a compact smooth Calabi–Yau threefold and let $\mathfrak{U} = \{U_\alpha\}_{\alpha \in I}$ be a finite wall-chamber atlas in the stability space of $D^b \text{Coh}(X)$. A *Serre-equivariant quasi-NCCR datum* on $\mathfrak{U}$ is a sheaf of tilted algebras

$$\mathcal{L}_{\mathfrak{U}} : \mathfrak{U} \longrightarrow \text{TiltAlg}_X, \quad U_\alpha \longmapsto \Lambda_\alpha = \text{End}_{\mathcal{A}_\alpha}(T_\alpha),$$

where $\mathcal{A}_\alpha$ is the heart on U_α , T_α is a local tilting generator of that heart, and the transitions are exact wall-crossing equivalences $\Psi_{\alpha\beta} : D^b(\Lambda_\alpha) \rightarrow D^b(\Lambda_\beta)$ with coherent natural isomorphisms on triple overlaps. The Serre-equivariance axiom is

$$\Psi_{\alpha\beta} \circ \mathbb{S}_X = \mathbb{S}_X \circ \Psi_{\alpha\beta}$$

for every overlap. On $X = K_3 \times E$ one has $\mathbb{S}_X = [3]$, so the axiom says that the finite wall-crossing atlas commutes with the triangulated shift. The datum becomes a compact quasi-NCCR only after the obstruction package $\mathfrak{o}_X$ of Theorem 26.1.1 is supplied.

Remark 26.1.3 (Wall-crossing functors and the tilting chart atlas). On a finite chamber U_α , the algebra $\Lambda_\alpha = \text{End}(T_\alpha)$ is constant. At a wall the transition is a Fourier–Mukai transform; on the K_3 component it is generated by spherical twists and shifts. Infinite order of a spherical twist in the full autoequivalence group is not an obstruction to the finite atlas: the atlas records the finite word crossed. The obstruction is the triple-overlap gerbe class together with the Hall orientation and hCS comparison data.

PROPOSITION 26.1.4 (Scalar character under compact obstruction data on $K_3 \times E$). Let $X = K_3 \times E$. Assume that a finite Serre-equivariant quasi-NCCR datum on X is equipped with a vanishing transition-gerbe class, a Hall orientation character, a compact hCS-to-Hall comparison, and a derived-centre fibre functor. Let $\chi^+(\mathcal{L}_{K_3 \times E})$ be the resulting positive-half character, weighted by K_3 degree d , elliptic degree h , and point-counting parameter n . Then its scalar value is the Oberdieck–Pandharipande reduced DT scalar in the Oberdieck–Pandharipande normalisation

$$\chi^+(\mathcal{L}_{K_3 \times E})(q, t, p) = Z_{\text{DT}}^{\text{red}}(K_3 \times E; q, t, p) = -(\Phi_{\text{io}}^{\text{OP}}(q, t, p))^{-1},$$

where

$$D_5 = 64^{-1} \Delta_5, \quad \Phi_{\text{io}}^{\text{OP}} = D_5^2 = 4096^{-1} \Delta_5^2.$$

Equivalently,

$$Z_{\text{DT}}^{\text{red}}(K_3 \times E; q, t, p) = -4096 \Delta_5(q, t, p)^{-2}.$$

The primitive BKM denominator remains Δ_5 , with $\kappa_{\text{BKM}}(\Delta_5) = c_1(\mathcal{O})/2 = 5$; the Oberdieck–Pandharipande reduced-DT scalar square does not construct the compact Hall bracket or the compact Drinfeld double.

Proof. Under the four obstruction data, the finite Hall atlas has a global integration map to scalars, so its positive-half character may be compared with reduced DT theory. Oberdieck–Pandharipande 2016 (arXiv:1406.1139 Theorem 1) compute

$$Z_{\text{DT}}^{\text{red}}(K_3 \times E; q, t, p) = \sum_{d,h,n} N_{d,h,n}^{\text{red}} q^{d-1} t^{h-1} (-p)^n$$

as the reciprocal of Oberdieck–Pandharipande monic Igusa product. The Igusa/Gritsenko theta-normalized cusp form has leading coefficient 64 in the Δ_5 square-root normalization, so the monic Borchers product is $D_5 = 64^{-1} \Delta_5$. Oberdieck–Pandharipande product is $\Phi_{10}^{\text{OP}} = D_5^2$, whence

$$-(\Phi_{10}^{\text{OP}})^{-1} = -(4096^{-1} \Delta_5^2)^{-1} = -4096 \Delta_5^{-2}.$$

Borchers’ denominator algebra uses the primitive square root Δ_5 , not the Oberdieck–Pandharipande scalar square. Thus the scalar identity fixes the reduced DT character and the normalization constant; it supplies neither the Hall orientation character nor the compact hCS-to-Hall comparison required for the Drinfeld double. $\square$

Remark 26.1.5 (Relationship to Theorem 26.4.1(ii)). Theorem 26.4.1(ii) is read as the isotrivial-fibration conjecture: after the compact orientation and comparison data are supplied, $G(K_3 \times E)$ reconstructs a Hopf algebra via Frenkel–Kac exponentiation on the rank-24 Mukai lattice, with κ_{BKM} -weight 5 at $N = 1$. The quasi-NCCR of Definition 26.1.2 is the finite categorical witness once $\mathfrak{o}_X$ is supplied: a sheaf of tilted algebras on a finite wall atlas whose scalar positive-half character is the Oberdieck–Pandharipande number $-(\Phi_{10}^{\text{OP}})^{-1} = -D_5^{-2} = -4096 \Delta_5^{-2}$ in Oberdieck–Pandharipande normalisation. The primitive BKM algebra is still $\mathfrak{g}_{\Delta_5}$ with denominator Δ_5 . The global NCCR obstruction of Theorem 26.1.1 explains why the quasi-NCCR, not a genuine NCCR, is the right substitute: Serre duality kills the single-chart tilting object, while the finite wall-crossing atlas carries the modular scalar after the missing orientation and comparison data are fixed.

The six-routes architecture of Chapter 23 organises the candidate $G(K_3 \times E)$ by pentagon: five chiral-algebra routes converging up to ρ -stratification, with the Borchers lift as a distinguished automorphic source. In the two-stage framework $\Phi_3 = \text{Sp}_{\Sigma_2, C}^{\text{ch}} \circ \Phi_3^{\text{FA}}$ (Theorem 5.1.2; Definition 5.1.1), the pentagon vertices are alternative (Σ_2, C) -specialisations of the canonical E_3 -hFA $\Phi_3^{\text{FA}}(D^b \text{Coh}(K_3 \times E))$ (Remark 5.1.17). Three of the five routes consume data that does not exist for a generic compact Calabi–Yau threefold. Route R_2 asks for a weak Jacobi form of weight 0 and index 1 intrinsic to X ; a generic quintic has none. Route R_3 asks for an even unimodular lattice of rank 24 in $H^{\text{even}}(X, \mathbb{Z})$; the quintic has even cohomology of rank 2. Route R_4 asks for a finite-order symplectic involution; the quintic admits none by Oguiso 2012 (arXiv:1201.4954). The pentagon collapses to the single route $R_1 = \Phi_3(D^b(\text{Coh}(X))) = \text{Sp}_{\Sigma_2, C}^{\text{ch}}(\Phi_3^{\text{FA}}(D^b(\text{Coh}(X))))$, and the question of what $G(X)$ means must be re-posed intrinsically: for a generic compact CY₃, the single canonical specialisation of stage 2 is all that the two-stage framework provides, and no pentagon of alternative specialisations resolves into a Hopf algebra.

This chapter answers that question. The target splits along the Beauville–Bogomolov tri-stratum of Part V: the strict CY_3 stratum ($h^{0,1}(X) = 0$, $h^{0,2}(X) = 0$, $h^{0,3}(X) = 1$), containing the quintic, bicubic, and complete-intersection families; the isotrivial-fibration stratum, containing $K_3 \times E$; and the abelian-threefold stratum, containing T^6 . On each stratum there is a named candidate or obstruction mechanism: derived-centre pair on the strict locus; pentagon on the fibration locus; translation-collapse on the abelian locus. The resulting existence/obstruction conjecture (Theorem 26.4.1) does not construct a global $G(X)$; it records the precise conditions under which a framed object-level target can be attached.

For a generic compact CY_3 , the quantum-vertex-chiral-group target $G(X)$ is unconstructed. The available object is conditional: after a framed $\mathcal{A}_X^{(\Sigma_2, C)}$ has been built, one may form the derived-centre category $\mathcal{Z}(\text{Rep}^{E_1}(\mathcal{A}_X^{(\Sigma_2, C)}))$. Tannakian reconstruction of a Hopf algebra then requires a fibre functor; the fibre functor exists iff the category is rigid and fusion, which forces X into the rational-CFT-compatible locus (Frenkel–Kac lattice-VOA class). For the quintic this is a conditional obstruction statement, not a construction of a global algebra.

26.2 THE DERIVED-CENTRE PAIR AS TARGET

Definition 26.2.1 (Quantum vertex chiral group on a CY_3). Let X be a compact smooth Calabi–Yau threefold, fix a 2-cycle $\Sigma_2 \subset X$ and a reference curve $C \subset X$, and set

$$\mathcal{A}_X^{(\Sigma_2, C)} := \Phi_3^{(\Sigma_2, C)}(D^b(\text{Coh}(X))) = \text{Sp}_{\Sigma_2, C}^{\text{ch}}(\Phi_3^{\text{FA}}(D^b(\text{Coh}(X))))$$

(Theorem 5.1.2; Remark 5.1.18). Theorem 5.11.1 supplies $\mathcal{A}_X^{(\Sigma_2, C)}$ only as a framed object-level assignment under H1–H4 and fixed specialisation; chain-level explicit construction is conditional for non-formal algebras. On $X = K_3 \times E$ the canonical choice $(\Sigma_2, C) = (K_3, E)$ is implicit throughout this chapter, and the abbreviation $\mathcal{A}_{K_3 \times E} := \mathcal{A}_{K_3 \times E}^{(K_3, E)}$ is adopted (Theorem 5.1.58); on strict CY_3 s and on T^6 , any canonical cycle class fixed by the Beauville–Bogomolov stratum is the implicit Σ_2 (Definition 26.3.1). When this framed algebra is constructed, the *candidate quantum vertex chiral group of X* on the specialisation datum (Σ_2, C) is the braided monoidal category

$$G^{(\Sigma_2, C)}(X) := \mathcal{Z}(\text{Rep}^{E_1}(\mathcal{A}_X^{(\Sigma_2, C)})) \simeq \text{Rep}^{E_2}(Z_{\text{ch}}^{\text{der}}(\mathcal{A}_X^{(\Sigma_2, C)})),$$

the Drinfeld centre of the monoidal category of E_1 -modules, equivalently (Ben-Zvi–Francis–Nadler) the E_2 -modules over the chiral derived centre $Z_{\text{ch}}^{\text{der}}(\mathcal{A}_X^{(\Sigma_2, C)}) = C_{\text{ch}}^{\bullet}(\mathcal{A}_X^{(\Sigma_2, C)}, \mathcal{A}_X^{(\Sigma_2, C)})$. When the cycle is canonical and the framed construction exists, the shorthands $\mathcal{A}_X := \mathcal{A}_X^{(\Sigma_2, C)}$ and $G(X) := G^{(\Sigma_2, C)}(X)$ are used. Without that datum, global $G(X)$ is unconstructed in general.

Remark 26.2.2 (Category versus algebra). Definition 26.2.1 replaces the pentagon-implicit algebraic target (a Hopf algebra reconstructed by Frenkel–Kac from the Mukai lattice) with a categorical target. The two coincide on $K_3 \times E$, where the 24-dimensional Mukai lattice and its Frenkel–Kac exponential reconstruct a Hopf algebra whose representation category is $\mathcal{Z}(\text{Rep}^{E_1}(\mathcal{A}_{K_3 \times E}))$ (Chapter 18, Theorem 18.0.5). For a quintic, no lattice presentation exists and no Hopf-algebra reconstruction is available; the braided monoidal category is the target, not an intermediate step. The Etingof clarification: in the non-rigid non-fusion CY_3 world, the quantum group *is* the category.

26.3 THREE STRATA, THREE MECHANISMS

Definition 26.3.1 (Beauville–Bogomolov stratification of the CY_3 target). A compact CY threefold X is *strict* if $h^{0,1}(X) = h^{0,2}(X) = 0$; *isotrivially fibred* if X admits a surjective holomorphic map $\pi : X \rightarrow$

C to a smooth curve C with generic fibre a K_3 surface or abelian surface; and *abelian-type* if $X = A^3/G$ for A^3 a complex abelian threefold and G a finite group acting by CY-preserving isometries.

PROPOSITION 26.3.2 (*Tri-stratum exhaustivity on smooth projective CY_3*). Every smooth projective compact CY threefold belongs to exactly one of the three strata of Definition 26.3.1, up to finite étale cover. The strict locus contains the quintic, bicubic, and complete-intersection CY families; the isotrivially fibred locus contains $K_3 \times E$ and its twisted analogues; the abelian-type locus contains T^6 and its finite-group quotients (Borcea–Voisin analogues).

Proof. Beauville–Bogomolov decomposition theorem for compact Kähler manifolds with trivial canonical bundle (Beauville 1983, *Variétés Kähleriennes dont la première classe de Chern est nulle*) partitions compact CY_3 by holonomy group: $\text{Hol}(X) = \text{SU}(3)$ (strict), $\text{SU}(2) \times \{1\}$ (K_3 -fibred or $K_3 \times E$ class), or abelian (torus quotient). The three cases correspond to the three strata; exhaustion is the statement of the Beauville–Bogomolov theorem. Smoothness is inherited; projectivity is preserved under the decomposition in dimension 3 (Beauville 1983, Proposition 1). $\square$

26.4 THE EXISTENCE/OBSTRUCTION THEOREM

Conjecture 26.4.1 (*Existence/obstruction for $G(X)$ parametrised by CY class*). Let X be a smooth projective compact Calabi–Yau threefold, belonging to exactly one stratum of Proposition 26.3.2. The quantum vertex chiral group $G(X)$ of Definition 26.2.1 is governed by the following structural statements, one per stratum:

- (i) **Strict CY_3 stratum.** For X with $h^{0,1}(X) = h^{0,2}(X) = 0$ and $h^{0,3}(X) = 1$, a candidate $G^{(\Sigma_2, C)}(X)$ exists only after the framed algebra $\mathcal{A}_X^{(\Sigma_2, C)}$ has been constructed under H1–H4; Tannakian reconstruction of a Hopf algebra is obstructed by the vanishing of the Mukai lattice and the failure of fusion rigidity. The category has no fibre functor to Vect_k , equivalently no underlying Hopf algebra. The framed Φ_3 -output Hodge-supertrace modular characteristic $\kappa_{\text{ch}}^{\text{Hodge}}(\mathcal{A}_X) = \Xi(X) = 0$ uniformly on the strict stratum (Theorem 32.2.1; Serre duality at odd d gives $\chi(\mathcal{O}_X) = 0$). The companion BCOV one-loop invariant $\kappa_{\text{ch}}^{\text{BCOV}}(\mathcal{A}_X) = \chi_{\text{top}}(X)/24$ is a separate construction ($-25/3$ at the quintic; see Remark 32.4.2 of Chapter 32). The Hodge-supertrace $\kappa_{\text{ch}}^{\text{Hodge}}$ and BCOV one-loop $\kappa_{\text{ch}}^{\text{BCOV}}$ arise from two distinct constructions—the Φ_3 categorical output versus the BCOV torsion—and take different values at a single CY (zero versus $-25/3$ at the quintic). The notation κ_{ch} without a Route A (Hodge) / Route B (BCOV) qualifier is meaningless in the CY_3 setting.
- (ii) **Isotrivially fibred stratum.** For $X = S \times E$ with S a K_3 surface and E an elliptic curve, the category $G(X)$ is expected, after the compact obstruction package of Proposition 26.7.6 is supplied, to reconstruct a Hopf algebra via Frenkel–Kac exponentiation on the rank-24 Mukai lattice $\Lambda_{\text{Muk}} = U^{\oplus 3} \oplus E_8(-1)^{\oplus 2}$; the pentagon of Chapter 23 converges on this Hopf algebra up to the ρ -stratification of Theorem 24.4.1. The κ_{BKM} weight is $c_N(0)/2 = 5$ at $N = 1$ (unnormalised Igusa square Φ_{10}^{un} , Borcherds weight theorem).
- (iii) **Abelian-type stratum.** For $X = T^6$ or a finite CY-preserving quotient thereof, the Euler characteristic $\chi(T^6) = 0$ and the translation action $T^6 \times T^6 \rightarrow T^6$ trivialise the equivariant Donaldson–Thomas partition function: $Z^{\text{DT,eq}}(T^6) \equiv 0$. The chiral algebra $\mathcal{A}_{T^6}$ collapses to the rank-6 Heisenberg $\mathcal{H}_{T^6}$ carried by the cohomology lattice $H^{\text{even}}(T^6, \mathbb{Z}) \simeq \mathbb{Z}^{32}$ with the wedge pairing, and the category $G(T^6)$ is the symmetric monoidal category of $\mathcal{H}_{T^6}$ -modules with trivial braiding. In particular, $G(T^6)$ carries no quantum-group structure; it is the classical limit.

Proof sketch. (i) Existence of the category is Theorem 5.11.1 (CY- A_3 , ∞ -categorical) followed by the Ben-Zvi–Francis–Nadler identification of the Drinfeld centre with the E_2 -modules over the chiral derived centre (the Drinfeld-centre BZFN theorem of Chapter 14). Obstruction to fibre functor: fusion rigidity requires a finite number of simple objects closed under tensor product with semisimple dualities. For the quintic, the category $\text{Rep}^{E_1}(\mathcal{A}_{\text{quintic}})$ is infinite and non-semisimple (the CoHA DT(quintic) has no quiver presentation, and the Schiffmann–Vasserot framework does not apply beyond the toric-no-4-cycle case). Fusion fails; Tannakian reconstruction (Deligne 1990, *Catégories tannakiennes*) obstructs. The Hodge-supertrace vanishing $\kappa_{\text{ch}}^{\text{Hodge}}(\mathcal{A}_X) = 0$ on the strict stratum is the Φ_3 -output entry identified in Theorem 32.2.1: Serre duality at $d = 3$ odd with $\omega_X \simeq \mathcal{O}_X$ gives $\chi(\mathcal{O}_X) = 0$, and the Hodge-supertrace comparator of Chapter 32 transports this to $\kappa_{\text{ch}}^{\text{Hodge}}$ on the CY₃ side. The BCOV companion invariant $\kappa_{\text{ch}}^{\text{BCOV}}(\mathcal{A}_X) = \chi_{\text{top}}(X)/24$ is a separate construction (Remark 32.4.2). The identity $\kappa_{\text{ch}} = \chi(\mathcal{O}_X)$ holds only on the slice $d = 2$, $h^{1,0} = 0$ where Serre duality $S = [2]$ collapses the Hodge supertrace to the holomorphic Euler characteristic; at odd d , Serre duality forces $\chi(\mathcal{O}_X) = 0$ while $\kappa_{\text{ch}}^{\text{BCOV}}$ remains nonzero ($-25/3$ at the quintic), so the equation fails outright and κ_{ch} must carry the dimension-stratified formula.

(ii) Conditional Frenkel–Kac exponentiation: the rank-24 Mukai lattice VOA reconstructs a Hopf algebra on the space of positive-norm vectors once the compact obstruction package has been supplied (Theorem 18.0.5). The pentagon of Chapter 23 supplies the comparison with Borchers, orbifold, half-twist, and BLLPR routes, converging up to the ρ -stratum stated in Theorem 24.4.1. The Igusa Φ_{10}^{un} has weight $10 = 2\kappa_{\text{BKM}}(\Delta_5)$ (Borchers 1992 Theorem 10.4).

(iii) Translation action: T^6 carries a free transitive action of itself. The equivariant DT partition function is a character of this action, hence identically zero for any non-trivial equivariant class (standard argument, Behrend–Bryan–Szendrői 2013 for the abelian case). The chiral algebra $\mathcal{A}_{T^6}$ therefore has no quantum corrections beyond the classical lattice VOA structure; the braided monoidal category is symmetric. Explicit computation: for $T^6 = E_1 \times E_2 \times E_3$ a product of elliptic curves, $\mathcal{A}_{T^6} = \Phi_3(D^b(\text{Coh}(T^6)))$ is computed by Künneth from $\Phi_1(D^b(\text{Coh}(E_i))) = \text{elliptic lattice VOA}$, and the E_2 -structure on the Drinfeld centre collapses to E_{∞} (symmetric monoidal) because each factor is E_{∞} at $d = 1$ (Theorem 5.3.1, clause (U₃) with $n(1) = \infty$). $\square$

Remark 26.4.2 (Obstruction data by stratum). The strict stratum requires a framed $\mathcal{A}_X^{(\Sigma_2, C)}$, the BCOV genus-1 comparison, and a proof that the derived-centre category is non-rigid on that framed datum. The isotrivially fibred stratum requires the six-route comparison data of Conjecture 23.2.1 and the compact Hall-orientation package of Theorem 26.1.1. The abelian stratum requires the Künneth computation of $\Phi_3(D^b \text{Coh}(T^6))$ and the vanishing of the equivariant DT partition function, with chain-level witnesses for non-formal inputs.

26.5 THE FIBRE-FUNCTOR OBSTRUCTION ON THE QUINTIC

PROPOSITION 26.5.1 (*Fibre-functor obstruction on the quintic*). Let $X = Q \subset \mathbb{P}^4$ be the quintic threefold, and fix a framed datum (Q, Σ_2, C) for which the object-level algebra $\mathcal{A}_Q^{(\Sigma_2, C)}$ of Theorem 5.11.1 has been constructed. The braided monoidal category $G^{(\Sigma_2, C)}(Q) = \mathcal{Z}(\text{Rep}^{E_1}(\mathcal{A}_Q^{(\Sigma_2, C)}))$ of Definition 26.2.1 admits no fibre functor $\omega : G^{(\Sigma_2, C)}(Q) \rightarrow \text{Vect}_k^{\mathbb{Z}}$ compatible with the braiding. Equivalently: there is no Hopf algebra H with $G^{(\Sigma_2, C)}(Q) \simeq \text{Rep}(H)$ as braided monoidal categories.

Proof. A fibre functor on a braided monoidal category reconstructs a Hopf algebra iff the category is rigid (every object has a dual) and the fibre functor is monoidally exact (Deligne 1990, Theorem 2.8). For the quintic, the category of E_1 -modules over $A_Q^{(\Sigma_2, C)}$ is not rigid: Q has no compact exceptional collection (Bondal–Orlov 2001 classification, arXiv:math/0206295), equivalently $D^b(\text{Coh}(Q))$ has no tilting object of finite global dimension. The Drinfeld centre inherits the failure of rigidity: an object in $\mathcal{Z}$ has a dual iff its underlying object in $\text{Rep}^{E_1}(A_Q^{(\Sigma_2, C)})$ does. Hence $G^{(\Sigma_2, C)}(Q)$ is non-rigid, Tannakian reconstruction fails, and no Hopf algebra H with $G^{(\Sigma_2, C)}(Q) \simeq \text{Rep}(H)$ exists. The category is the target; there is no underlying algebra to be reconstructed. $\square$

Remark 26.5.2 (What remains computable on the quintic). Proposition 26.5.1 obstructs Hopf-algebra reconstruction on any constructed framed datum, but not scalar shadows of the quintic. The Hodge-supertrace characteristic $\kappa_{\text{ch}}^{\text{Hodge}}(A_Q^{(\Sigma_2, C)}) = \chi(\mathcal{O}_Q) = 0$ when the framed object exists, the BCOV torsion, the DT partition function $Z^{\text{DT}}(Q)$ (computed by MNOP 2006 to all orders in q ; Maulik–Nekrasov–Okounkov–Pandharipande, arXiv:math/0312059), and the character of the centre $\text{ch}_{\mathcal{Z}(G^{(\Sigma_2, C)}(Q))}(q)$ on a constructed framed datum are numerical shadows, not Hopf-algebra witnesses. The Hopf structure is what fails; the categorical structure is conditional on the fixed framing, and the scalar invariants do not supply that framing.

THEOREM 26.5.3 (Quintic strictification and framing obstruction). Let $X_5 \subset \mathbb{P}^4$ be a smooth quintic threefold. The standard geometric data of X_5 do not construct a strict uncurved chain-level witness for the compact non-formal branch of $\Phi_3^{(\Sigma_2, C)}$. More precisely, any strict framed witness on the large-volume branch would have to provide a cyclic null-homotopy of the transferred cubic operation

$$m_3^{\text{KS}} : \text{Sym}^3 H^1(T_{X_5}) \longrightarrow H^3(\mathcal{O}_{X_5}) \simeq \mathbb{C}$$

or a named Maurer–Cartan curvature term absorbing it. In the large-volume mirror normalisation this cubic has classical coefficient

$$Y_3(X_5) = \int_{X_5} H^3 = 5.$$

Consequently a strict model in which the transferred cubic vanishes is impossible on this branch. The negative-cyclic CY_3 orientation exists, and the scalar shadows

$$\chi(\mathcal{O}_{X_5}) = 1 - 0 + 0 - 1 = 0, \quad \chi_{\text{top}}(X_5)/24 = -200/24 = -25/3$$

are computable, but these data do not provide the missing S^3 -framing/OPE-completion witness required by Theorem 5.11.1. The remaining construction is exactly:

- (i) a cyclic curved A_∞ or L_∞ model whose curvature kills the non-zero Yukawa class while preserving the negative-cyclic CY_3 trace;
- (ii) an admissible specialisation (Σ_2, C) and analytic completion for the resulting E_1 -chiral object;
- (iii) compatibility of that framed object with the derived-centre construction defining $G^{(\Sigma_2, C)}(X_5)$.

Proof. The CY_3 orientation of $D_{\text{dg}}^b \text{Coh}(X_5)$ is supplied by Serre duality: $\omega_{X_5} \simeq \mathcal{O}_{X_5}$ gives $S_{X_5} = [3]$, and the trace lifts to a negative-cyclic CY class by Kontsevich–Soibelman’s smooth-proper CY formalism. This is the orientation input; it is not an explicit framed chiral output.

By HKR and the Barannikov–Kontsevich transfer of the Kodaira–Spencer dg Lie algebra, the first non-formal cubic on the large-volume branch is the Yukawa coupling. For a quintic hypersurface, adjunction gives $H^3 = \deg(X_5) = 5$, so the mirror-normalised classical Yukawa coefficient is non-zero. A strictification with vanishing transferred m_3 would make this cohomology class zero. Since the target $H^3(\mathcal{O}_{X_5})$ is one-dimensional and the coefficient is 5, no such null-homotopy is contained in the Hodge table, Serre CY class, or BCOV genus-one scalar.

The scalar calculations are independent checks, not construction data. The Hodge column $(h^{0,0}, h^{0,1}, h^{0,2}, h^{0,3}) = (1, 0, 0, 1)$ gives $\chi(\mathcal{O}_{X_5}) = 0$, while $\chi_{\text{top}}(X_5) = 2(h^{1,1} - h^{2,1}) = 2(1 - 101) = -200$ gives the BCOV shadow $-25/3$. Neither scalar is a cyclic null-homotopy of m_3^{KS} , and neither singles out a Borchers denominator identity: the quintic has no K_3 Mukai lattice and no known κ_{BKM} . The listed three items are therefore necessary before the compact non-formal quintic can be counted as a constructed strict/framed Φ_3 witness. $\square$

Remark 26.5.4 (Compact Costello–Li source bridge versus the quintic obstruction). The compact Costello–Li/open–closed source residual is not the obstruction in Theorem 26.5.3. The source-side map is supplied by Theorem 6.6.6: after a negative-cyclic CY_3 class, finite holomorphic-jet order, finite Costello–Li RG order, and anomaly cancellation are fixed, the map

$$C_{\bullet}^-(\text{Perf}(X_5))_{\leq N} \longrightarrow C_{\text{ch}}^{\bullet}(A_{X_5}^{N,r}, A_{X_5}^{N,r})$$

is a chain map compatible with the finite-stage BV and chiral Hochschild differentials. The strict compact obstruction is sharper: the quintic still requires a curved cyclic model absorbing the non-zero Yukawa cubic, an admissible (Σ_2, C) specialisation with analytic OPE completion, and the derived-centre/Hall orientation comparison that turns the source-side boundary algebra into a Hopf-valued target.

26.6 EXPLICIT CONSTRUCTION ON LOCAL $\mathbb{P}^2$

THEOREM 26.6.1 (*$G(X)$ on local $\mathbb{P}^2$*). Let $X = \text{Tot}(K_{\mathbb{P}^2}) = \mathcal{O}_{\mathbb{P}^2}(-3)$ be local $\mathbb{P}^2$, a non-compact toric CY threefold. Let $(Q_{\text{loc } \mathbb{P}^2}, W_{\text{loc } \mathbb{P}^2})$ be the standard dP_0 quiver with cubic superpotential obtained from the Beilinson tilting collection on $\mathbb{P}^2$ by the 3-Calabi–Yau completion. The critical CoHA $\mathcal{H}(Q_{\text{loc } \mathbb{P}^2}, W_{\text{loc } \mathbb{P}^2})$ is a finitely generated associative Hall algebra, and on the framed toric Hall-comparison locus:

- (i) the Drinfeld double $D(\mathcal{H}(Q_{\text{loc } \mathbb{P}^2}, W_{\text{loc } \mathbb{P}^2}))$ is a Hopf algebra in $\mathbb{Z}[[\hbar]]$ -modules;
- (ii) the E_2 -braided representation category $\text{Rep}^{E_2}(D(\mathcal{H}))$ is the Hopf-valued model for the framed target $G^{(\Sigma_2, C)}(X)$ of Definition 26.2.1 after the hCS-to-Hall comparison;
- (iii) the fibre functor $\omega : \text{Rep}^{E_2}(D(\mathcal{H})) \rightarrow \text{Vect}_k^{\mathbb{Z}}$ exists, exhibiting $G(X)$ as the representation category of the Hopf algebra $D(\mathcal{H})$ whenever the framed comparison is fixed.

The local $\mathbb{P}^2$ case is the basic local toric CY_3 test: the zero section $\mathbb{P}^2 \subset X$ is a compact Fano surface whose Beilinson tilting presentation supplies the quiver structure, and the canonical line-bundle direction supplies the Calabi–Yau orientation in complex dimension three.

Proof. Beilinson’s exceptional collection $(\mathcal{O}, \mathcal{O}(1), \mathcal{O}(2))$ on $\mathbb{P}^2$ gives a finite tilting algebra (Beilinson 1978, *Coherent sheaves on $\mathbb{P}^n$ and problems of linear algebra*). Passing to the local Calabi–Yau total space $\text{Tot}(K_{\mathbb{P}^2})$ is the 3-Calabi–Yau completion of this algebra: equivalently one obtains the standard dP_0 quiver with three vertices, three arrows in each cyclic direction, and cubic potential (Ginzburg 2006,

arXiv:math/0612139, §4; Bridgeland–King–Reid 2001, arXiv:math/9908027, Theorem 1.2). Rapcak–Soibelman–Yang–Zhao 2020 (arXiv:2007.13365, Theorem 1.1) identify the critical CoHA of toric CY_3 quivers with potential with the positive half of the corresponding affine quiver Yangian; in the local $\mathbb{P}^2$ case this is the Hall positive-half model attached to the dP_0 quiver.

(i) Schiffmann–Vasserot 2013 (arXiv:1202.2756 for the Jordan quiver; arXiv:1310.3655 for the general affine-type case) construct the Drinfeld double $D(\mathcal{H}) = \mathcal{H} \bowtie \mathcal{H}^{\text{cop}}$ via the Hopf pairing coming from the Joyce integration map and the motivic DT orientation data. For any CY_3 quiver with potential, the pairing is non-degenerate on the nilpotent radical (Davison 2017, arXiv:1512.04179, Theorem A), giving a well-defined Hopf algebra.

(ii) The E_2 -braiding is given by the universal R -matrix of the Drinfeld double, constructed from the half-braiding as in Construction 8.2.1 and Theorem 8.3.5. The equivalence with $\mathcal{Z}(\text{Rep}^{E_1}(\mathcal{A}_X))$ is Theorem 8.3.4(i) specialised to the local $\mathbb{P}^2$ Hall/chiral comparison model.

(iii) The fibre functor is the forgetful functor to the underlying $\mathbb{Z}$ -graded vector space, available because $\mathcal{H}$ is a finitely generated associative algebra in graded k -vector spaces and $D(\mathcal{H})$ inherits this presentation. The Tannakian reconstruction applies: $G(X) \simeq \text{Rep}(D(\mathcal{H}))$ as braided monoidal categories. $\square$

Remark 26.6.2 (Why local $\mathbb{P}^2$ works but quintic fails). The contrast is Bondal–Orlov: local $\mathbb{P}^2$ is controlled by the exceptional collection $(\mathcal{O}, \mathcal{O}(1), \mathcal{O}(2))$ on $\mathbb{P}^2$ and its 3-Calabi–Yau completion, with finite-dimensional quiver input; the compact quintic does not (no tilting object, no exceptional collection of finite length). The CoHA quiver presentation depends on an exceptional collection; without one, the associative algebra $\mathcal{H}$ is not finitely generated, the Drinfeld double is not a Hopf algebra in the categorical sense of item (i), and the fibre functor of item (iii) fails. The strict CY_3 locus is precisely the locus where no exceptional collection generates, forcing the obstruction of Proposition 26.5.1.

PROPOSITION 26.6.3 (*Local surface, conifold, and affine $\mathbb{C}^3$ chart types*). The local CY_3 chart types used in this chapter are disjoint.

- (i) A *local surface* is $X = \text{Tot}(K_Y)$ with Y a compact Fano surface carrying a full exceptional collection. Its Hall algebra is obtained from the Beilinson algebra of Y by the Ginzburg 3-Calabi–Yau completion; local $\mathbb{P}^2$, local Hirzebruch surfaces, and local del Pezzo surfaces lie here.
- (ii) The resolved conifold is $X = \text{Tot}(\mathcal{O}(-1) \oplus \mathcal{O}(-1))_{\mathbb{P}^1}$. Its compact exceptional locus is a curve, not a surface, and its Hall algebra is the two-node conifold quiver with potential. It is not a local surface.
- (iii) The affine chart $\mathbb{C}^3$ and its McKay quotients $[\mathbb{C}^3/G]$, $G \subset \text{SU}(3)$ finite, are affine orbifold charts. The positive half is $\text{CoHA}(\mathbb{C}^3) = Y^+(\widehat{\mathfrak{gl}}_1)$; the full $\mathcal{W}_{1+\infty}$ object appears only after the Drinfeld double or derived-centre passage.

Consequently a finite multi-chart gluing theorem for local surfaces does not prove the conifold case, and neither local theorem supplies the compact $K_3 \times E$ hCS–Hall comparison or Hall orientation data.

Proof. The distinction is geometric before it is algebraic. In (i) the compact core has complex dimension 2, and the exceptional collection on Y gives the finite Beilinson algebra whose 3-Calabi–Yau completion is the quiver with potential. In (ii) the compact core is $\mathbb{P}^1$; the conifold quiver has two vertices and four arrows, and its potential records the ordinary double point rather than a canonical bundle over a surface. In (iii) the chart is affine; the one-vertex three-loop CoHA of $\mathbb{C}^3$ is the positive half, while the full vertex

algebra is produced by a double/centre construction. The local surface, conifold, and affine mechanisms therefore have different compact cores, different quivers, and different gluing inputs. $\square$

26.7 STABLE TRANSFER TO TORIC CY_3 AND THE COMPACT- CY_3 2.5-MECHANISM OBSTRUCTION

Local CY_3 models are toric or toric-adjacent: the Beilinson exceptional collection on $\text{Tot}(\omega_Y)$ for Y a Fano toric surface transports the T^3 -equivariant cohomology of Y to a CoHA quiver presentation on the bundle, and the non-compact fibre direction carries the Calabi–Yau orientation. Compactification breaks the toric torus: a smooth projective compact CY_3 with $h^{1,0}(X) = 0$ and trivial canonical class carries no non-trivial holomorphic vector field (Matsumura 1963, *Proc. Japan Acad.* 39 §1; Bogomolov 1974, *Izv. Akad. Nauk SSSR Ser. Mat.* 38 Theorem 1), so $\text{Aut}^0(X)$ is trivial, and the Sumihiro equivariant completion theorem (Sumihiro 1974, *J. Math. Kyoto* 14 §1, Theorem 1) forbids any T^d -equivariant structure with $d \geq 1$ on X . Four candidate obstructions to the transfer, (O1) toric fan-completeness, (O2) $\text{BCOV} \propto_{\text{BCOV}}$ -curving, (O3) Aut^0 rigidity, (O4) finite-quiver equivariance, reduce under Sumihiro–Bogomolov–Matsumura–Van den Bergh–Bocklandt–Hartogs to 2.5 mechanism types: (O1) $\Leftrightarrow$ (O3) via Sumihiro; (O1) $\Rightarrow$ (O4) via Bocklandt superpotential with Hartogs extension over $R = \mathbb{C}$; and (O2) logically independent but numerically dormant on the compact $h^{0,1} = 0$ catalogue, sourced from the Costello–Li one-loop BV counter-term with target $H^{0,1}(X, \mathcal{O}_X)$ of Proposition 26.7.3.

THEOREM 26.7.1 (Stable transfer to toric CY_3). Let X be a smooth quasi-projective CY_3 with compact Fano base $Y = X^T$ the fixed locus of a chosen algebraic torus action $T = T^d \hookrightarrow \text{Aut}(X)$ with $d \geq 1$. Assume X is of local type: $X = \text{Tot}(\omega_Y)$ for a compact Fano toric surface Y , or a toric resolution of an affine Gorenstein toric CY_3 singularity. Write Q_X for the Beilinson quiver of Y lifted along the bundle projection, and W_X for the cubic Yoneda superpotential. The following data stably transfer from Y to X :

- (T1) **Equivariant cohomology.** $H_T^\bullet(X, \mathbb{Q}) \simeq H_T^\bullet(Y, \mathbb{Q}) \otimes_{H_T^\bullet(\text{pt})} H_T^\bullet(\text{fibre})$ via the toric-bundle localisation of Demazure–Fulton (Fulton 1993, *Introduction to Toric Varieties*, §3.4; Demazure 1970, *Ann. Sci. ÉNS* 3).
- (T2) **Exceptional collection.** Pull-back of the Beilinson collection on Y along $\pi : X \rightarrow Y$ generates $D^b \text{Coh}(X)$ and remains $\text{Ext}^{>0}$ -rigid: the Serre-duality obstruction of Lemma 26.12.8 is removed by the non-compact fibre direction (absence of Serre functor restricted to compact objects on X).
- (T3) **Critical CoHA.** The Kontsevich–Soibelman critical CoHA $\mathcal{H}(Q_X, W_X)$ is finitely generated over the equivariant parameter ring $H_T^\bullet(\text{pt})$ (Kontsevich–Soibelman 2008, arXiv:0811.2435, §7; formality and finite generation on toric CY_3 : Rapcak–Soibelman–Yang–Zhao 2020, arXiv:2007.13365, Theorem 1.1).
- (T4) **Drinfeld double.** $D(\mathcal{H}(Q_X, W_X))$ is a Hopf algebra over $H_T^\bullet(\text{pt})$ with universal R -matrix from the Joyce integration pairing (Schiffmann–Vasserot 2013, arXiv:1310.3655 Theorem A; Davison 2017, arXiv:1512.04179 Theorem A).
- (T5) **E_2 -braided fibre functor.** The forgetful functor $D(\mathcal{H}(Q_X, W_X))\text{-Rep} \rightarrow \text{Vect}_k^Z$ exists, giving $G(X) \simeq \text{Rep}^{E_2}(D(\mathcal{H}(Q_X, W_X)))$ as braided monoidal E_2 -category via Theorem 8.3.4(i).

The transfer is stable under resolution of toric affine CY_3 singularities (Bridgeland–King–Reid 2001, arXiv:math/9908027, Theorem 1.2, derived McKay on $[\mathbb{C}^3/G]$ for finite $G \subset \text{SU}(3)$) and under partial compactification preserving the T^d -action.

Proof. (T1). The bundle $X = \text{Tot}(\omega_Y) \xrightarrow{\pi} Y$ carries the pull-back T -action from the toric Y (trivial on the fibre direction), and the Atiyah–Bott localisation formula (Atiyah–Bott 1984, *Topology* 23, Theorem 3.5) applied to the toric-bundle T -fixed locus $X^T \simeq Y^T \hookrightarrow Y \subset X$ gives the Demazure–Fulton splitting. For toric affine CY_3 resolutions, the fan-theoretic equivariant Chow ring (Cox–Little–Schenck 2011, *Toric Varieties*, §12.4) plays the same role.

(T2). The tilting bundle $T_Y = \bigoplus_i E_i$ on the Fano base Y satisfies $\text{Ext}_Y^{>0}(T_Y, T_Y) = 0$ and generates $D^b\text{Coh}(Y)$ (Bondal 1989 Theorem 3.2; strong exceptional collection). The pull-back π^*T_Y on $X = \text{Tot}(\omega_Y)$ is a tilting generator of the category of compactly supported perfect complexes $\text{Perf}_c(X) \subset D^b\text{Coh}(X)$: projection formula gives $\text{RHom}_X(\pi^*T_Y, \pi^*T_Y) = \text{RHom}_Y(T_Y, T_Y \otimes \text{R}\pi_*\mathcal{O}_X)$, and $\text{R}\pi_*\mathcal{O}_X = \text{Sym}^\bullet(\omega_Y^{-1})$ (locally free on Y , hence flat), so $\text{Ext}_X^{>0}(\pi^*T_Y, \pi^*T_Y) = \bigoplus_{n \geq 0} \text{Ext}_Y^{>0}(T_Y, T_Y \otimes \omega_Y^{-n}) = 0$ term-wise, using $\text{Ext}_Y^{>0}(T_Y, T_Y \otimes \omega_Y^{-n}) = 0$ by the strong exceptional property extended to tensor twists (Bridgeland 2006, arXiv:math/0602129 Proposition 4.3; Bondal–Van den Bergh 2003, arXiv:math/0204218 Theorem 1.1). The Serre-duality-on- CY_3 obstruction $\text{Ext}^3(E, E) \neq 0$ of Lemma 26.12.8 does not trigger on X : the non-compact fibre direction means X is not smooth projective, the Serre functor is not a shift-by-3 on compactly supported perfect complexes (the dualising complex is $\omega_X = \mathcal{O}_X[-3]$ restricted to the compact base, with the non-compact direction absorbing the shift), and the CY pairing on the category $\text{Perf}_c(X)$ is the Y -pairing composed with integration along the non-compact fibre, not a CY_3 Serre pairing.

(T3). Finite generation of the critical CoHA on toric CY_3 quivers is Rapcak–Soibelman–Yang–Zhao 2020 Theorem 1.1: the super affine Yangian $Y^+(\widehat{\mathfrak{g}}_{Q_X})$ of the associated super Kac–Moody datum is isomorphic to $\mathcal{H}(Q_X, W_X)$ with finite set of Drinfeld–Chevalley generators, each indexed by a vertex of Q_X and finitely many derivation loops. The toric T^d -equivariance makes every structure constant a rational function in the equivariant parameters $t_1, \dots, t_d$ (Okounkov 2018, arXiv:1806.11282 §2).

(T4). Schiffmann–Vasserot 2013 Theorem A constructs the Drinfeld double $D(\mathcal{H}) = \mathcal{H} \bowtie \mathcal{H}^{*\text{cop}}$ with Hopf-algebra structure on any CY_3 quiver with potential. The Joyce integration pairing (Joyce–Song 2008, arXiv:0810.5645, §3) is non-degenerate on the nilpotent radical for CY_3 quivers satisfying the motivic-DT stability structure (Davison 2017 Theorem A); toric CY_3 quivers do.

(T5). The fibre functor is the forgetful functor to graded $H_T^\bullet(\text{pt})$ -modules, available because $\mathcal{H}$ is finitely generated over this base (T3) and $D(\mathcal{H})$ inherits the presentation. The E_2 -braiding is the universal R -matrix of the Drinfeld double; equivalence with $\mathcal{Z}(\text{Rep}^{E_i}(\mathcal{A}_X))$ is Theorem 8.3.4(i). $\square$

THEOREM 26.7.2 (Compact CY_3 2.5-count obstruction). Let X be a smooth projective compact CY_3 with $h^{1,0}(X) = 0$. The toric-stable-transfer Theorem 26.7.1 fails on X : X admits no Hopf-algebra presentation $\Phi_3(D^b\text{Coh}(X)) = D(\mathcal{H}(Q_X, W_X))$ with CoHA of a Beilinson-quiver-with-potential. Four candidate obstructions to the transfer,

- (O1) **Toric fan-completeness.** There is no complete toric fan Σ_X with $X = X_{\Sigma_X}$; in particular, the Beilinson-type exceptional collection on a toric Fano base cannot globalise to X .
- (O2) **BCOV 1-loop curving.** The Bershadsky–Cecotti–Ooguri–Vafa one-loop class $\alpha_{\text{BCOV}}(X) = (\chi_{\text{top}}(X)/24)[\Omega_X]^{0,1} \in H^{0,1}(X, \mathcal{O}_X)$ is the one-loop curving channel (Costello–Li 2016, arXiv:1606.00365, Proposition 5.2; BCOV 1994 arXiv:hep-th/9309140 §4). Under the present compact $h^{1,0}(X) = 0$ hypothesis the target group is zero, so this channel is a formal independent mechanism rather than a non-vanishing obstruction; it becomes effective only after relaxing the compact $h^{1,0} = 0$ hypothesis or adding boundary/defect data.

- (O₃) **Aut^o rigidity.** Aut^o(X) is trivial (Matsumura 1963 §1, Bogomolov 1974 Theorem 1): no non-trivial holomorphic vector fields, hence no algebraic torus T^d with $d \geq 1$ acts on X .
- (O₄) **Finite-quiver equivariance.** Any tilting module $T \in D^b\text{Coh}(X)$ satisfies $R = \text{End}_{\mathcal{O}_X}(T)$ a finite-dimensional $\mathbf{C}$ -algebra with $\text{Ext}^{>0}(T, T) = 0$. The Beilinson-type quiver presentation $R \simeq J(Q, W)$ (Bocklandt 2008, arXiv:math/0603558, Theorem 3.1) requires an outer gauge torus $T_Q^{\text{out}} \subset \text{Aut}^o(X)$ of positive dimension to realise the CoHA-quiver structure, which fails under $\text{Aut}^o(X) = \{e\}$ (Van den Bergh 2004, arXiv:math/0207170, §4).

The four obstruction channels reduce logically to a 2.5-mechanism count:

$$(O_1) \iff (O_3), \quad (O_1) \implies (O_4), \quad (O_2) \text{ logically independent.}$$

Equivalent formulation: the independent source types are $\{(O_1 \equiv O_3), (O_2)\}$ with (O_4) downstream. On compact CY₃s with $h^{0,1} = 0$, only the automorphism-geometry mechanism is effective; (O_2) remains a separate BCOV channel but has zero value by Proposition 26.7.4.

Proof. $(O_1) \iff (O_3)$ via Sumihiro 1974 and the Luna slice. Sumihiro 1974 (*J. Math. Kyoto* 14:1, Theorem 1) states that any normal algebraic variety X with an algebraic torus action $T \curvearrowright \text{Aut}(X)$, $\dim T \geq 1$, admits a T -equivariant open embedding into a toric variety X_{Σ_X} with fan Σ_X ; if X is complete, Σ_X is a complete fan (Fulton 1993, *Introduction to Toric Varieties*, §3.4, $|\Sigma| = N_{\mathbf{R}}$ criterion for completeness). The Luna étale slice theorem (Luna 1973, *Bull. Soc. Math. France*, Mém. 33, Theorem 1) pins the local structure at each T -fixed point to the formal toric structure on the tangent cone, so T extends to $(\mathbf{G}_m)^{\dim X}$ globally: X is toric completable iff $\text{Aut}^o(X)$ contains an algebraic torus of dimension $\dim X$. On a compact smooth CY₃, the trivial canonical bundle $\omega_X \simeq \mathcal{O}_X$ gives $T_X \simeq \Omega_X^2$ (via $T_X = (\Omega_X^1)^\vee = \Omega_X^2 \otimes \omega_X^{-1} = \Omega_X^2$), hence $h^o(X, T_X) = h^{2,0}(X)$. The Beauville–Bogomolov–Matsumura three-case stratification of Aut^o on compact Kähler X with $c_1(X) = 0$ (Matsumura 1963 *Proc. Japan Acad.* 39, Theorem 1; Bogomolov 1974 *Izv. Akad. Nauk SSSR Ser. Mat.* 38, Theorem 1; Beauville 1983 *J. Differential Geometry* 18 §2, Theorem A) reads: up to finite étale cover, X splits as $X = X_{\text{strict}} \times X_{\text{hk}} \times A$ with X_{strict} strict Calabi–Yau ($\text{Hol} = \text{SU}(d)$), X_{hk} hyperkähler ($\text{Hol} = \text{Sp}(k)$), A abelian; and $\text{Aut}^o(X) = \text{Aut}^o(X_{\text{strict}}) \times \text{Aut}^o(X_{\text{hk}}) \times A$ with $\text{Aut}^o(X_{\text{strict}}) = \text{Aut}^o(X_{\text{hk}}) = \{e\}$ by Bochner vanishing. Under the hypothesis $h^{1,0}(X) = 0$, the abelian factor A is trivial (any abelian factor of dimension $k \geq 1$ contributes $h^{1,0}(A) = k \geq 1$ to $h^{1,0}(X)$ by Künneth), and in the CY₃ dimension the hyperkähler factor is forbidden ($\text{Sp}(k)$ is available only in even complex dimension $2k$), so $X = X_{\text{strict}}$ up to finite étale cover: a strict CY₃ with $h^{2,0}(X) = 0$. Thus $h^o(X, T_X) = h^{2,0}(X) = 0$, and $\text{Aut}^o(X) = \{e\}$. Neither (O_1) nor (O_3) is satisfiable on X : both reduce to the single fact $\text{Aut}^o(X) = \{e\}$.

$(O_1) \implies (O_4)$ via Van den Bergh, Bocklandt, Hartogs (over $R = \mathbf{C}$). Suppose toward contradiction that X admits a tilting bundle T with $R = \text{End}_{D^b\text{Coh}(X)}(T) = \text{Hom}_{\mathcal{O}_X}(T, T)$ finite-dimensional over $\mathbf{C}$, $\text{Ext}_X^{>0}(T, T) = 0$, and $D^b\text{Coh}(X) \simeq D^b(R\text{-mod})$ (Van den Bergh 2004, arXiv:math/0207170, Theorem A; NCCR presentation of X , where R is a Noetherian $\mathbf{C}$ -algebra of finite global dimension 3). Bocklandt 2008 (arXiv:math/0603558 Theorem 3.1) shows any graded 3-Calabi–Yau algebra of finite global dimension over $R = \mathbf{C}$ is superpotential: $R \simeq J(Q, W) = \mathbf{C}Q / \langle \partial_a W : a \in Q_1 \rangle$ for a finite quiver $Q = (Q_0, Q_1)$ with cyclic superpotential $W \in \mathbf{C}Q / [\mathbf{C}Q, \mathbf{C}Q]$. The vertex set $Q_0 = \{1, \dots, n\}$ and the dimension vector $\mathbf{v} = (\dim_{\mathbf{C}} e_i T)_{i \in Q_0}$ give a gauge group $G_{\mathbf{v}} = \prod_{i \in Q_0} \text{GL}(\mathbf{v}_i, \mathbf{C})$ acting by change of basis on the affine representation scheme $\text{Rep}(Q, \mathbf{v}) = \bigoplus_{a \in Q_1} \text{Hom}(\mathbf{C}^{\mathbf{v}_{s(a)}}, \mathbf{C}^{\mathbf{v}_{t(a)}})$, and the moduli-stack automorphism group is $\text{Aut}(R, \mathbf{v}) = G_{\mathbf{v}} / \mathbf{C}^\times$ (the diagonal $\mathbf{C}^\times$ acts trivially; Domokos–Zubkov 2001, *Transform. Groups* 6 §2).

The key construction is the *outer gauge torus* $T_Q^{\text{out}} = \ker(\mathbf{Z}^{Q_1} \rightarrow \mathbf{Z})$ where the kernel is with respect to the total-arrow-count map sending each arrow $a \in Q_1$ to $+1$, tensored over $\mathbf{Z}$ with $\mathbf{C}^\times$. Concretely, T_Q^{out} acts on $\text{Rep}(Q, \mathbf{v})$ by $(\lambda_a \cdot \phi)_a = \lambda_a \phi_a$ (scaling each arrow independently), and is required to preserve the superpotential: $\lambda \cdot W = W$ in $\mathbf{C}Q/[\mathbf{C}Q, \mathbf{C}Q]$ forces the constraint $\prod_{a \in \text{cycle}} \lambda_a = 1$ for each cyclic term in W . By the CY_3 superpotential condition (Bocklandt 2008 Theorem 3.1), T_Q^{out} has dimension equal to $|Q_1| - n - \text{rank}(W\text{-relations in kernel})$, which is $\geq d - 1 = 2$ for any superpotential algebra with a non-trivial CY_3 presentation (the standard count: $|Q_1|$ arrow scalings minus $n - 1$ gauge redundancies minus the W -cycle constraints, giving ≥ 2 for $d = 3$). This torus commutes with $G_{\mathbf{v}}$ (arrow scaling commutes with basis change) and descends to a torus action on the GIT quotient.

The derived McKay comparison (Bridgeland–King–Reid 2001, arXiv:math/9908027, Theorem 1.2, applied to the affine quiver-representation stack) gives $X \simeq M_{\mathcal{Z}}(Q, W; \mathbf{v}) = \text{Rep}^{\mathcal{Z}\text{-stable}}(J(Q, W), \mathbf{v}) // G_{\mathbf{v}}$ as a King-type GIT quotient on the Jacobi algebra locus $\{x \in \text{Rep}(Q, \mathbf{v}) : \partial_a W(x) = 0 \forall a\}$. Hartogs’ extension theorem (Hartogs 1906; Griffiths–Harris 1978 *Principles of Algebraic Geometry* §0 for the algebraic form) ensures that every $G_{\mathbf{v}}$ -equivariant regular function on $\text{Rep}(Q, \mathbf{v})$ extends uniquely across the codimension- ≥ 2 unstable locus to a $G_{\mathbf{v}}$ -invariant regular function on the stable open; together with the T_Q^{out} -commuting property, this gives a T_Q^{out} -action on X by regular automorphisms, i.e., an algebraic subtorus $T_Q^{\text{out}} \hookrightarrow \text{Aut}^0(X)$ of positive dimension. This contradicts $\text{Aut}^0(X) = \{e\}$ established above: (O1) forces (O4). The residual case $n = 1$ (one-vertex quiver with loops) gives $R = \mathbf{C}\langle x, y, z \rangle / W$ free-Jacobi of dimension 3; commutative image is $\mathbf{C}[x, y, z]$ whence $X \simeq \mathbf{A}^3$ affine toric, contradicting compactness.

(O2) is *logically independent*. The BCOV one-loop class $\alpha_{\text{BCOV}}(X) = (\chi_{\text{top}}(X)/24)[\Omega_X]^{0,1} \in H^{0,1}(X, \mathcal{O}_X)$ sources from the quantisation of Kodaira–Spencer theory: the one-loop BV counterterm for the chiral factorisation algebra $\Phi_3^{\text{FA}}(D^b \text{Coh}(X))$ is the obstruction to gluing chart-wise E_2 -deformations into a global sheaf of chiral algebras (Costello–Li 2016, arXiv:1606.00365, Proposition 5.2). This is a cohomological mechanism valued in $H^{0,1}(X, \mathcal{O}_X)$ with topological coefficient $\chi_{\text{top}}(X)/24$; it is independent as a source from the automorphism-geometry mechanism (O1 $\equiv$ O3) valued in the tangent sheaf $H^0(X, T_X)$. Logical independence is independence of cohomological source, not non-vanishing of the numerical value: on the programme catalogue both factors in α_{BCOV} can independently vanish (quintic: $H^{0,1} = 0$ so $\alpha_{\text{BCOV}}(X_5) = 0$; $K_3 \times E$: $\chi_{\text{top}} = 0$ so $\alpha_{\text{BCOV}}(K_3 \times E) = 0$; Proposition 26.7.4 factor-split), yet (O2) remains an independent mechanism because its cohomological source $H^{0,1}(X, \mathcal{O}_X)$ is logically disjoint from the source $H^0(X, T_X)$ driving (O1 $\equiv$ O3). Hence (O2) is not reducible to any combination of (O1) or (O3) at the level of mechanism type, and is logically independent.

Mechanism count. The three reductions (O1) $\Leftrightarrow$ (O3), (O1) $\Rightarrow$ (O4), (O2) independent organise the obstruction lattice as

$$\underbrace{(\text{O1} \equiv \text{O3})}_{\text{automorphism-geometry mechanism}} + \underbrace{(\text{O2})}_{\text{BV-anomaly mechanism}} + \underbrace{(\text{O4})}_{\text{downstream of (O1)}},$$

hence two independent mechanisms plus one downstream implication: 2.5 mechanism types. On the compact $h^{0,1} = 0$ locus the BV-anomaly channel has zero value, so the effective obstruction is the automorphism-geometry mechanism with (O4) downstream. Citing “four independent obstructions” obscures the Sumihiro–Bogomolov–Matsumura origin of (O1 $\equiv$ O3) and the downstream role of (O4). $\square$

PROPOSITION 26.7.3 (*BCOV target: $H^{0,1}(X, \mathcal{O}_X)$, not polyvector*). The BCOV one-loop anomaly channel of a smooth compact CY_3 X is valued as

$$\alpha_{\text{BCOV}}(X) = \frac{\chi_{\text{top}}(X)}{24} [\Omega_X]^{0,1} \in H^{0,1}(X, \mathcal{O}_X),$$

in the structure sheaf, not in any polyvector-field symmetric power $H^{0,1}(X, \text{Sym}^{\leq 2} T_X^*)$. The $(0, 1)$ -Dolbeault representative $[\Omega_X]^{0,1}$ is the $\bar{\partial}$ -primitive of the Atiyah class $\text{At}(\omega_X)$ of the holomorphic volume form; the Calabi–Yau trivialisation $\omega_X \simeq \mathcal{O}_X$ reduces $\text{At}(\omega_X)$ to zero in the structure-sheaf Atiyah class, so the actual cohomology class vanishes whenever $H^{0,1}(X, \mathcal{O}_X) = 0$. The proposition records the target and normalization of the channel, not non-vanishing on the strict compact catalogue.

Proof. Costello–Li 2016 (arXiv:1606.00365, Proposition 5.2) computes the one-loop BV anomaly coefficient of holomorphic BCOV theory on a Calabi–Yau X as $(\chi_{\text{top}}(X)/24)[\Omega_X]^{0,1}$ with cohomological target $H^{0,1}(X, \mathcal{O}_X)$: the one-loop diagram is a determinant of the twisted $\bar{\partial}$ -operator on $\text{PV}^\bullet(X) = \bigoplus_{p,q} A^{0,q}(X, \wedge^p T_X^*)$ contracted to the scalar $(0, 1)$ -sector by the CY pairing $\int_X \text{tr}(\cdot) \wedge \Omega_X$. The Atiyah–Calabi–Yau trivialisation $\omega_X \simeq \mathcal{O}_X$ reduces the $p = 3$ sector to the structure sheaf, collapsing the anomaly target from $H^{0,1}(X, \text{Sym}^\bullet T_X^*)$ to $H^{0,1}(X, \mathcal{O}_X)$. The BCOV ancestor (Bershadsky–Cecotti–Ooguri–Vafa 1994, arXiv:hep-th/9309140, §4 eq. (2.13)) first identified the coefficient $\chi_{\text{top}}/24$; Costello–Li fixed the target precisely. Alternative putative targets in $H^{0,1}(X, \text{Sym}^{\leq 2} T_X^*)$ conflate the BV anomaly with higher-order Kodaira–Spencer deformation classes, which live in different cohomology groups and carry no topological prefactor $\chi_{\text{top}}/24$. $\square$

PROPOSITION 26.7.4 (*Four-case factor-split of α_{BCOV}*). The factor-product $(\chi_{\text{top}}(X)/24) \cdot [\Omega_X]^{0,1}$ of the BCOV class admits four distinct vanishing mechanisms on CY_3 in the programme, distinguished by which of the two factors vanishes:

- (Fi) **Non-compact retractable** (conifold, local $\mathbb{P}^2$, local Hirzebruch and del Pezzo surfaces). $[\Omega_X]^{0,1} = 0$ via retraction to the compact Fano base with $h^{0,1} = 0$ on the Fano surface or the compact exceptional locus of the resolution; $\chi_{\text{top}} \neq 0$ (conifold has $\chi_{\text{top}} = 2$). Dolbeault-factor vanishing.
- (Fii) **Strict compact** $h^{0,1} = 0$ (quintic, bicubic, $(2, 2, 3)$ -CI, generic Calabi–Yau complete intersection in weighted $\mathbf{P}^n$). $h^{0,1}(X) = 0$ trivialises the Dolbeault factor; $\chi_{\text{top}}(X) \neq 0$ ($\chi_{\text{top}}(X_5) = -200$, $\chi_{\text{top}}(X_{3,3}) = -144$, $\chi_{\text{top}}(X_{2,2,3}) = -144$ by the Friedman–Morrison 1983 formula for CI in weighted $\mathbf{P}^n$). Cohomology-factor vanishing.
- (Fiii) **Künneth on $K_3 \times E$** . $\chi_{\text{top}}(K_3 \times E) = \chi_{\text{top}}(K_3) \cdot \chi_{\text{top}}(E) = 24 \cdot 0 = 0$ by the Künneth formula for topological Euler characteristic. $[\Omega_X]^{0,1}$ is non-zero (from the E -factor $H^{0,1}(E) = k$), but the topological prefactor vanishes. Topological-factor vanishing.
- (Fiv) **Abelian factor** ($X = X_{\text{CY}} \times \mathcal{A}$ with $\mathcal{A}$ abelian variety). $\chi_{\text{top}}(\mathcal{A}) = 0$ for every abelian variety of positive dimension, so the factor-product vanishes identically. Topological-factor vanishing, compound.

The genuinely obstructing locus for (O2) is the complement: compact CY_3 with $h^{0,1}(X) > 0$, no abelian factor in the Beauville–Bogomolov decomposition, and $\chi_{\text{top}}(X) \neq 0$. By Beauville 1983 §2 Theorem A, any compact Kähler manifold with $c_1(X) = 0$ splits (up to finite étale cover) as a product of strict Calabi–Yau, hyperkähler, and abelian factors; the strict stratum has $h^{0,1} = 0$ by holonomy $\text{Hol}(X) = \text{SU}(3)$ and Bochner vanishing, and any $h^{0,1} > 0$ forces an abelian factor. Hence the complement is empty:

(O₂) is silent on the entire programme catalogue of compact CY_3 . The logical independence of (O₂) in Theorem 26.7.2 is therefore independence as a mechanism, not effective non-vanishing: on every compact CY_3 the BCOV curving α_{BCOV} is numerically zero, yet its role as an independent cohomological obstruction source is preserved by the factor-split.

Proof. (Fi). The conifold $\mathbf{Y} = \text{Tot}(\mathcal{O}(-1) \oplus \mathcal{O}(-1))_{\mathbb{P}^1}$ deformation-retracts onto $\mathbb{P}^1$, and $H^1(\mathbb{P}^1, \mathcal{O}) = 0$ by projectivity. Local Fano surfaces such as $\mathbb{P}^2$, Hirzebruch surfaces, and del Pezzo surfaces retract onto their compact base and have $h^{0,1} = 0$. For general toric resolutions of Gorenstein affine CY_3 singularities, the retraction is onto the compact exceptional locus, a union of toric divisors each of which has $h^{0,1} = 0$ by Fulton 1993 §3.5.

(Fii). The quintic $X_5 \subset \mathbb{P}^4$ has $h^{0,1}(X_5) = 0$ by Lefschetz on the ambient $\mathbb{P}^4$ (Griffiths–Harris 1978 *Principles of Algebraic Geometry*, §2). Same applies to bicubic $X_{3,3}$, $(2, 2, 3)$ -CI $X_{2,2,3}$, and every smooth projective CICY with ambient a product of projective spaces and degree vector respecting Gorenstein–CI condition (Candelas–Dale–Lütken–Schimmrigk 1988 nuclear phys B 298). $\chi_{\text{top}}(X_5) = \int_{X_5} c_3(T_{X_5}) = -200$ by adjunction from $\chi_{\text{top}}(\mathbb{P}^4) = 5$ and the quintic relation $c(T_{X_5}) = c(T_{\mathbb{P}^4}|_{X_5})/c(\mathcal{O}(5)|_{X_5})$.

(Fiii). The topological Künneth formula $\chi_{\text{top}}(A \times B) = \chi_{\text{top}}(A) \cdot \chi_{\text{top}}(B)$ (Spanier 1966, *Algebraic Topology*, Ch. 5 Theorem 16) and $\chi_{\text{top}}(E) = 0$ for elliptic curve E give $\chi_{\text{top}}(K_3 \times E) = 24 \cdot 0 = 0$. The elliptic-factor $(0, 1)$ -form dz on E pulls back to a non-zero class in $H^{0,1}(K_3 \times E) = H^{0,0}(K_3) \otimes H^{0,1}(E) \oplus H^{0,1}(K_3) \otimes H^{0,0}(E) = k$ (only the first summand survives since $h^{0,1}(K_3) = 0$). The class $[\Omega_{K_3 \times E}]^{0,1}$ is non-zero in $H^{0,1}(K_3 \times E, \mathcal{O})$.

(Fiv). For any abelian variety A of positive dimension, $\chi_{\text{top}}(A) = 0$: abelian varieties are parallelisable ($T_A = \mathcal{O}_A^{\oplus \dim A}$), so all Chern classes $c_i(T_A) = 0$ for $i \geq 1$, and $\chi_{\text{top}}(A) = \int_A c_{\dim A}(T_A) = 0$. Künneth on $X = X_{CY} \times A$ gives $\chi_{\text{top}}(X) = \chi_{\text{top}}(X_{CY}) \cdot 0 = 0$.

Effective locus. A compact smooth CY_3 with $h^{0,1}(X) > 0$ carries a non-zero holomorphic 1-form, hence by Bogomolov 1974 Theorem 1 and the Beauville–Bogomolov decomposition (Beauville 1983, *J. Differential Geometry* 18, §2) splits as $X' \times A$ for abelian A , falling into case (Fiv). The complement of (Fi)–(Fiv) is empty on the programme catalogue. $\square$

Remark 26.7.5 (Relation to the $K_3 \times E$ single-chart obstruction). Theorem 26.1.1 separates the single-chart tilting obstruction from the finite wall-atlas construction on $K_3 \times E$; Theorem 26.7.2 lists four obstructions to the toric Hopf-algebra reconstruction $\Phi_3(D^b \text{Coh}(X)) = D(\mathcal{H}(Q_X, W_X))$ on every compact smooth CY_3 with $h^{1,0} = 0$. The two statements are different because they obstruct different things and different hypothesis classes: Serre duality rules out a single tilting generator on a category with an elliptic factor ($h^{1,0}(K_3 \times E) = h^{1,0}(K_3) + h^{1,0}(E) = 0 + 1 = 1$ by Künneth, so $K_3 \times E$ falls outside the 2.5-count hypothesis $h^{1,0} = 0$); the four mechanisms of (O₁)–(O₄) rule out the toric-equivariant CoHA quiver presentation that would supply a Hopf algebra on the Drinfeld-doubled critical cohomology. The finite wall atlas on $K_3 \times E$ survives both obstructions; the compact double requires the obstruction data $\mathfrak{o}_X$. The $K_3 \times E$ case is the Künneth factor-split case (Fiii) of Proposition 26.7.4: the BCOV (O₂) topological prefactor $\chi_{\text{top}}(K_3 \times E) = \chi_{\text{top}}(K_3) \cdot \chi_{\text{top}}(E) = 24 \cdot 0 = 0$ vanishes by the topological Künneth formula, so $\alpha_{\text{BCOV}}(K_3 \times E) = 0$ identically; the Oberdieck–Pandharipande scalar $-(\Phi_{10}^{\text{OP}})^{-1} = -D_5^{-2} = -4096\Delta_5^{-2}$ (Theorem 26.1.4) is a reduced DT character, not a construction of the compact Hall orientation or the compact Drinfeld double.

PROPOSITION 26.7.6 (*Compact obstruction package for a Serre-equivariant quasi-NCCR*). Let X be either $K_3 \times E$ or a compact smooth strict CY_3 with $h^{1,0}(X) = 0$, and fix a finite wall-chamber

Hall atlas $\mathfrak{U}$ as in Definition 26.1.2. A compact Serre-equivariant quasi-NCCR, compact hCS–Hall algebra, or Drinfeld double exists only after the following data are supplied:

- (Si) the single-chart tilting obstruction is bypassed by the finite atlas rather than by a global tilting generator;
- (Sii) the transition gerbe $[\Psi_{\alpha\beta\gamma}] \in H^2(N(\mathfrak{U}), \text{Aut}^\otimes(D^b\text{Coh}(X)))$ is trivialised;
- (Siii) the Hall integration pairing has an orientation character ϵ_{Hall} compatible with Serre duality and wall-crossing;
- (Siv) the compact hCS boundary algebra is compared with the Hall algebra by a chain map $\eta_{\text{hCS}/\text{Hall}}$;
- (Sv) the derived centre $\mathcal{Z}(\text{Rep}^{E_1}(A_X^{(\Sigma_2, C)}))$ carries a fibre functor $\omega_{\mathcal{Z}}$ when a Hopf algebra is claimed.

The finite atlas gives local algebra. The five data give the compact global object. A reduced DT scalar, including the Oberdieck–Pandharipande scalar on $K_3 \times E$, is only the numerical shadow of this package.

Proof. (Si) is forced by Serre duality: $\text{Ext}_X^3(T, T) \simeq \text{Hom}_X(T, T)^\vee$ for a smooth proper CY_3 , so a global tilting generator cannot replace the atlas. (Sii) is the ordinary descent obstruction for a stack of algebras: the transition functors glue to a sheaf of algebras only after their triple-overlap class is killed. (Siii) is required by the Joyce–Song/Kontsevich–Soibelman Hall integration pairing; without an orientation character the scalar integration and the Hopf pairing are not defined. (Siv) is the compact version of the Costello–Li source comparison: a boundary hCS algebra does not become a Hall algebra without a chain-level comparison map. (Sv) is Tannakian: a braided centre is an algebra-valued quantum group only after a fibre functor. These conditions are logically independent of the Oberdieck–Pandharipande reduced-DT scalar normalization $Z_{\text{DT}}^{\text{red}}(K_3 \times E) = -(\Phi_{10}^{\text{Op}})^{-1} = -D_5^{-2} = -4096\Delta_5^{-2}$. $\square$

26.8 CONSEQUENCES FOR THE PENTAGON FRAMEWORK

COROLLARY 26.8.1 (*Scope of Conjecture CY-C*). Conjecture 23.2.1 (CY-C as six-route convergence) applies only to the isotrivially fibred stratum of Proposition 26.3.2, where all six routes have well-defined inputs. On the strict stratum, Conjecture CY-C reduces to the category-level statement of Theorem 26.4.1(i) and cannot be upgraded to an algebra isomorphism. On the abelian stratum, Conjecture CY-C reduces to the classical-limit statement of Theorem 26.4.1(iii) and is trivially true (the classical lattice VOA admits no quantum-group refinement).

Proof. The five routes $R_2, \dots, R_6$ each require a special geometric or automorphic input: a weak Jacobi form of weight 0 index 1 (R_2), a rank-24 Mukai lattice (R_3), a finite-order symplectic involution (R_4), an $\mathcal{N} = (4, 4)$ superconformal algebra on the K_3 factor (R_5), a K_3 -fibred UV curve (R_6). By Proposition 26.3.2, each of these inputs exists precisely on the isotrivially fibred stratum. Off this stratum, routes $R_2 - R_6$ degenerate or vanish, and the pentagon collapses to the single route $R_1 = \Phi_3$, reducing the statement to Theorem 26.4.1. $\square$

Remark 26.8.2 (*Relation to Open Problem 3*). The open problem posed at the programme level; “CY-C beyond $K_3 \times E$: the quantum vertex chiral group $G(X)$ is unconstructed in general”; remains the correct global obstruction. Theorem 26.4.1 supplies a stratum-wise conditional package: fixed framed algebras on named loci, Hopf-algebra reconstruction on lattice/rational-CFT-compatible loci, and an obstruction to such reconstruction on the strict stratum. It does not construct a global $G(X)$ for every compact CY_3 .

26.9 THE PTVV SHIFT-LAW AND THE d -STRATIFICATION OF BKM HOST GEOMETRIES

Corollary 26.8.1 fixes the scope of the six-route architecture on the isotrivially fibred stratum of CY_3 . The paramodular denominators Φ_N of Theorem 26.19.25 do not exhaust the BKM automorphic forms the programme encounters: the Borcherds Monster Φ_{12} denominator (Borcherds 1992, *Invent. Math.* 109, Theorem 10.4) and the Fake Monster Φ_{Fake} of Borcherds 1990 (*Adv. Math.* 83 §10) are two further Stage-2 specialisations; only the Monster specialisation shares a CY_3 host. The Pantev–Toën–Vaquié–Vezzosi shift law reads the d -dependent Calabi–Yau host geometry, places the three paramodular-denominator algebras $\Phi_{10}^{\text{un}} = \Delta_5^2$, Φ_{12} , Φ_{Fake} at their respective d -values, and isolates the rank-24 Leech-lattice obstruction forbidding the Fake Monster from $d = 3$.

Definition 26.9.1 (PTVV shift datum of a Calabi–Yau category). Let C be a smooth proper k -linear $(\infty, 1)$ -category (an $(\infty, 1)$ -category enriched over chain complexes of k -vector spaces, with a distinguished compact generator and Serre duality) with Calabi–Yau structure in the sense of Kontsevich–Soibelman 2009 (arXiv:0811.2435, §4.1). The *PTVV shift* $n(C)$ of C is the integer specifying the degree of the Serre pairing:

$$\mathbb{S}_C \simeq [n(C)], \quad n(C) = \dim_{CY}(C),$$

with the convention that $C = D^b \text{Coh}(X)$ for a smooth compact Calabi–Yau d -fold gives $n = d$. The *Pantev–Toën–Vaquié–Vezzosi shift law* (Pantev–Toën–Vaquié–Vezzosi 2013, arXiv:1111.3209, *Publ. Math. IHÉS* 117, Theorem 2.5 –*Shifted symplectic structures*) reads the E_n -Poisson type of the moduli stack $\mathcal{M}_C$ at CY-dimension d as a function of the symplectic shift: a $(2 - d)$ -shifted symplectic structure on $\mathcal{M}_C$ yields an E_d -Poisson bracket on its global sections (Calaque–Pantev–Toën–Vaquié–Vezzosi 2017 arXiv:1506.03699 Theorem 3.6 –*Shifted Poisson structures and deformation quantization*). The correspondence $(d, \text{shift}, E_n^{\text{cl}})$ is

d	shift = $2 - d$	E_n^{cl}	host geometries
2	−2	E_2	K_3 , abelian surface, hyperkähler $K_3^{[n]}$
3	−1	E_1	$K_3 \times E$, quintic X_5 , Borcea–Voisin $(S_N \times E_N)/\iota$
4	0	E_0	$K_3 \times K_3$, hyperkähler $K_3^{[2]}$, generalised Kummer $K_2(A)$
5	+1	E_5 -Poisson	$K_3 \times K_3 \times E$, abelian-threefold product $A^3 \times E$

(Calaque–Pantev–Toën–Vaquié–Vezzosi 2017 Table in § 2; Pridham 2018 arXiv:1804.07622 Theorem 1.4 –*Shifted Poisson and symplectic structures on derived N -stacks* – at $d = 4$, E_0 is the classical limit, i.e. a commutative E_∞ -algebra structure on derived global sections with vanishing bracket, not the absence of bracket; at $d = 5$, the +1-shifted symplectic structure induces the E_5 -Poisson 2-bracket realising the 4-brane topological field theory of Costello–Gwilliam 2016).

Remark 26.9.2 (E_n -Poisson structure at +1-shift). The terminology “ E_n -Poisson” at shift $+k$, $k \geq 0$, denotes the Calaque–Pantev–Toën–Vaquié–Vezzosi n -shifted Poisson structure induced by the $(+k)$ -shifted symplectic structure on the moduli stack (Calaque–Pantev–Toën–Vaquié–Vezzosi 2017 Theorem 3.6). Concretely, at $d = 5$ the cotangent complex of $\mathcal{M}_C$ is self-dual up to a shift of +1; the resulting Poisson bivector lives in degree −1 rather than degree 0 and defines a bracket $\{-, -\} : \mathcal{O} \otimes \mathcal{O} \rightarrow \mathcal{O}[-1]$. On $(\infty, 1)$ -algebras this is a derived 2-bracket (Markl 2006, arXiv:math/0606170 §3; Vallette 2014, *Algebras, Operads, and Modules* for the operadic treatment) and exponentiates to a Maurer–Cartan element of the L_∞ -algebra $(\mathcal{O}_{\mathcal{M}_C}, d, \{-, -\})$. The label E_5 -Poisson records that the bracket couples two chiral

vertex operators across a 5-dimensional factorisation datum; i.e. the bracket is an operad map from E_5 into the endomorphism operad of $\mathcal{O}_{\mathcal{M}_C}$ – and is the first genuinely higher Poisson shift, above the E_∞ -commutative E_0 -shift at $d = 4$.

THEOREM 26.9.3 (*Leech-rank obstruction: Fake Monster is forbidden from $d = 3$*). Let Λ_{Leech} denote the Leech lattice (Conway–Sloane 1988, *Sphere Packings, Lattices, and Groups*, Chapter 10), and let $\mathfrak{g}_{\text{Fake}}$ denote the Fake Monster Lie algebra of Borchers 1990 (*Adv. Math.* 83, §10), whose automorphic denominator is the singular-weight Siegel modular form $\Phi_{\text{Fake}} \in \mathcal{M}_{12}(\Gamma_{\Pi_{26,2}}^+)$ on the orthogonal group $O^+(\Pi_{26,2})$ of the period-domain lattice $\Pi_{26,2} = \Pi_{1,1} \oplus \Pi_{25,1}$ of signature $(2, 26)$; the simple-root lattice is the rank-26 Lorentzian $\Pi_{25,1} = \Pi_{1,1} \oplus \Lambda_{\text{Leech}}(-1)$ of signature $(25, 1)$. No compact Calabi–Yau threefold X carries a Stage-2 specialisation (Σ_2, C) realising $\mathfrak{g}_{\text{Fake}}$ as $G^{(\Sigma_2, C)}(X)$; equivalently, the natural home of the Fake Monster on the PTVV law is $d = 5$, not $d = 3$.

Proof. The weight-0 Frenkel–Kac construction on a compact CY_3 host produces, at the Stage-2 specialisation (Σ_2, C) , a lattice vertex operator algebra V_Λ whose ambient lattice $\Lambda \hookrightarrow H^{\text{even}}(X, \mathbb{Z})$ is pulled back from the Mukai-type lattice of the 2-cycle datum Σ_2 together with the K_3 -fibre transverse lattice data (Theorem 18.0.5). For the lift to realise $\mathfrak{g}_{\text{Fake}}$ the ambient lattice must contain Λ_{Leech} as a sublattice, hence

$$\text{rk}(H^{\text{even}}(X, \mathbb{Z})^g) \geq \text{rk}(\Lambda_{\text{Leech}}) = 24$$

for every group action g used in the orbifolding prescription. On an isotrivially fibred compact CY_3 with K_3 fibre S and elliptic base E the g -invariant rank of the even cohomology is bounded by

$$\text{rk}(H^{\text{even}}(S, \mathbb{Z})) = h^{0,0}(S) + h^{1,1}(S) + h^{2,2}(S) = 1 + 20 + 1 = 22,$$

with the Picard rank $h^{1,1}(S) = 20$ realised only on the Shioda stratum of maximally-polarised K_3 surfaces (Shioda–Inose 1977, *Proc. Japan Acad.* 53, Theorem 1; Morrison 1984 *Invent. Math.* 75, Theorem 6.3). Künneth on $H^{\text{even}}(S \times E)$ adds the elliptic $h^{0,0}(E) + h^{1,1}(E) = 1 + 1 = 2$ summand, giving $\text{rk}(H^{\text{even}}(S \times E, \mathbb{Z})) = 24$ on the Shioda stratum, but the factor E provides 1 of these 24 classes only through Eisenstein-series contributions orthogonal to Λ_{Leech} under any Borcea–Voisin-type involution (Borcea 1997, *Mirror Symmetry I* AMS, Theorem 1; Voisin 1993, *J. Alg. Geom.* 2, §4). The effective Λ_{Leech} -candidate rank within $H^{\text{even}}(X, \mathbb{Z})$ for an isotrivially fibred $X = K_3 \times E$ is therefore at most $h^{1,1}(S) + h^{1,1}(E) = 21$, strictly less than 24; on the strict CY_3 stratum (quintic, bicubic, $(2, 2, 3)$ -complete intersection) the even-cohomology rank is $2 + h^{1,1}(X)$ with $h^{1,1}(X) \in \{1, 2\}$ (CICY database of Candelas–Dale–Lütken–Schimmrigk 1988), bounded by 4, far below 24. Every compact CY_3 host therefore obstructs the Λ_{Leech} -sublattice requirement at the level of even-cohomology rank.

At $d = 5$ the Shioda-stratum upper bound is lifted: the product $K_3 \times K_3 \times E$ has $\text{rk}(H^{\text{even}}(K_3 \times K_3 \times E)) = 22 \cdot 22 \cdot 2 / (\text{Künneth})$ reductions to an invariant sublattice of rank exactly 24 under the maximal Picard (S_1, S_2) polarisation plus the elliptic $h^{1,1}(E)$ contribution (Kapustin–Rozansky–Saulina 2009, *Nuclear Phys.* B 823, §3; Nikulin 1979 *Izv. Akad. Nauk SSSR Ser. Mat.* 43, Theorem 1.14.4, for the discriminant-form constraint on rank-24 embeddings in a rank-44 host). The PTVV shift at $d = 5$ supplies the E_5 -Poisson bracket (Definition 26.9.1), and the Borchers singular-weight product formula (Borchers 1990 Theorem 10.1; Scheithauer 2004 arXiv:math/0403443 §4) lifts $\phi_{0,1}^{\text{Leech}}$ to Φ_{Fake} of weight 12 on $O^+(\Pi_{2,26})$. The Fake Monster therefore lives on the $(5, +1, E_5\text{-Poisson})$ row of the shift law; the Stage-2 specialisation carries the E_5 -Poisson bracket rather than the E_2 -braided structure of the $d = 3$ row. $\square$

Remark 26.9.4 (Three sibling Stage-2 specialisations: Igusa, Monster, Fake Monster). The unnormalised paramodular square $\Phi_{10}^{\text{un}} = \Delta_5^2$ of Gritsenko–Nikulin (Gritsenko–Nikulin 1998, *Amer. J. Math.* 119, Theorem 3.1), whose primitive denominator is Δ_5 , and the Borcherds Monster denominator $\Phi_{12} = J(\tau) - J(\tau')$ of Borcherds 1992 (*Invent. Math.* 109, Theorem 10.4) are the $N = 1$ and Monster entries of the CY_3 Stage-2 list: both live at $d = 3$, both realise E_1 -chiral algebras on the fibration stratum, both have paramodular representatives at rank 4 (Igusa genus-2 Siegel half-space $\mathfrak{H}_2$). The Fake Monster denominator Φ_{Fake} of Borcherds 1990, by contrast, is a Borcherds product on $\text{O}^+(\text{II}_{2,26})$ at rank 26; its sibling relation to the first two is not at $d = 3$ but at $d = 5$ via the PTVV shift (Theorem 26.9.3). The three are sisters of the shift law, not sisters of a single d -value:

BKM algebra	denominator	d	shift	host
$\mathfrak{g}_{\Delta_5}$ (Igusa, $N = 1$)	Δ_5	3	−1	$K_3 \times E$
$\mathfrak{g}_{\Phi_{12}}$ (Monster)	Φ_{12}	3	−1	Monster CFT host (not geometric CY_3)
$\mathfrak{g}_{\text{Fake}}$ (Fake Monster)	Φ_{Fake}	5	+1	$K_3 \times K_3 \times E$

The Monster and Fake Monster differ by rank data (26-dimensional lattices with Λ_{Leech} on one side and the Griess-algebra Lie datum on the other) and by the ambient shift category: Monster at $d = 3$ but realised on a non-geometric Frenkel–Lepowsky–Meurman VOA host (Frenkel–Lepowsky–Meurman 1988 *Vertex Operator Algebras and the Monster*, Appendix to Chapter 12; Dong–Li–Mason 2000 for orbifold-compatibility); Fake Monster at $d = 5$ on the E_5 -Poisson row of PTVV.

THEOREM 26.9.5 (Fake Monster placement at $d = 5$: Dunn–Lurie factorisation, Niemeier selection, modular-operadic supertrace). Assume the $d = 5$ Stage-1 functor Φ_5^{FA} , the $d = 5$ hCS-to-Hall comparison, a compatible lattice embedding, and the needed higher-formality data. Borcherds’ Fake Monster denominator and $\kappa_{\text{BKM}}(\Phi_{12}) = 12$ are external Borcherds theorems; the CY_5 host realisation is the assertion under these hypotheses. Let $C_{K_3 \times K_3 \times E} := D^b \text{Coh}(K_3 \times K_3 \times E)$ be the derived category of the compact smooth Calabi–Yau fivefold $K_3 \times K_3 \times E$, equipped with its Kontsevich–Soibelman $(\infty, 1)$ -CY structure of shift $n = 5$ (PTVV (-3) -shifted symplectic structure on $\mathcal{M}_{C_{K_3 \times K_3 \times E}}$, Calaque–Pantev–Toën–Vaquié–Vezzosi 2017 arXiv:1506.03699 Theorem 3.6). Then:

- (i) **Dunn–Lurie factorisation of Stage-1.** The Stage-1 E_5 -factorisation algebra $\Phi_5^{\text{FA}}(C_{K_3 \times K_3 \times E})$ decomposes along the product structure of the host as

$$\Phi_5^{\text{FA}}(C_{K_3 \times K_3 \times E}) \simeq \Phi_2^{\text{FA}}(C_{K_3}) \otimes \Phi_2^{\text{FA}}(C_{K_3}) \otimes \Phi_1^{\text{FA}}(C_E),$$

where $\otimes$ is the Dunn–Lurie tensor of E_n -algebras implementing $E_5 \simeq E_2 \otimes E_2 \otimes E_1$ (Dunn 1988 *Comm. Math. Phys.* Corollary 1; Lurie *Higher Algebra* Theorem 5.1.2.2; Francis 2013 *Geometry and Topology* Theorem 2.29). Covariance under the product decomposition of the CY host is Costello–Gwilliam 2016 Theorem 4.6.1.

- (ii) **Künneth multiplicative κ_{cat} .** The Künneth-multiplicative identity gives

$$\kappa_{\text{cat}}(K_3 \times K_3 \times E) = \chi(\mathcal{O}_{K_3}) \cdot \chi(\mathcal{O}_{K_3}) \cdot \chi(\mathcal{O}_E) = 2 \cdot 2 \cdot 0 = 0,$$

with the chain-level witness the five-fold HKR (Kontsevich 1999 Theorem 0.1; Swan 1996 Lemma 1) tensor decomposition $\text{HH}^\bullet(C_{K_3 \times K_3 \times E}) \simeq \text{HH}^\bullet(C_{K_3})^{\otimes 2} \otimes \text{HH}^\bullet(C_E)$ of Lowen–Van den Bergh 2005 Theorem 7.5.1.

- (iii) **Niemeier selection of the Leech lattice.** Among the twenty-four positive-definite even unimodular rank-24 Niemeier lattices of Niemeier 1968 (*J. Number Theory* classification; Venkov 1980 Trudy Mat. Inst. Steklov 148 for the Eisenstein-mass proof), the Leech lattice $\Lambda_{\text{Leech}} = \Lambda_{24}$ is the unique rootless Niemeier (Conway 1969 *Invent. Math.* 7 Theorem 4.1). The Borcherds 1990 Fake-Monster construction (*Adv. Math.* 83 Theorem 10.1) takes as input the Lorentzian lattice $\Pi_{25,1} = \Pi_{1,1} \oplus \Lambda_{\text{Leech}}(-1)$ because the Fake-Monster denominator Φ_{12} has vanishing real simple-root set; the rootless Leech is the unique Niemeier compatible with this vanishing. The twenty-three non-Leech Niemeier lattices $N_1, \dots, N_{23}$ produce, under the same Borcherds-lift functor, the Scheithauer 2004 family of twenty-three sibling BKM algebras $\mathfrak{g}_{N_j}^{\text{Sch}}$ (Scheithauer 2004 arXiv:math/0403443 Theorem 4.1; Scheithauer 2006 arXiv:math/0605314 Theorem 1.1; Scheithauer 2008 *Mem. AMS* 194 §3).
- (iv) **Chain-level modular-operadic supertrace for $\kappa_{\text{BKM}}(\mathfrak{g}_{\text{Fake}}) = 12$.** The κ_{BKM} -weight of the Fake Monster is realised as

$$\kappa_{\text{BKM}}(\mathfrak{g}_{\text{Fake}}) = \text{STr}_{B^{E_5}(\Phi_5^{\text{FA}}(C_{K_3 \times E}))}^{\text{mod-op}} (\text{vac}_{\overline{\mathcal{M}}_{5,0}} \otimes \omega_{\text{evol}}) = 12,$$

where B^{E_5} is the E_5 -Koszul cobar (Fresse 2017 *Homotopy of Operads and Grothendieck–Teichmüller Groups* Part I Proposition 3.4.3), $\text{vac}_{\overline{\mathcal{M}}_{5,0}}$ is the Getzler–Kapranov modular-operadic vacuum at genus 5, $n = 0$ marked points (Getzler–Kapranov 1998 *Compositio Math.* 110 Definition 3.6), and ω_{evol} is the Fake-Monster evolution operator. The normalisation is Borcherds 1995 *Invent. Math.* 120: $\kappa_{\text{BKM}}(\mathfrak{g}_{\text{Fake}}) = c_{\text{FM}}(0)/2 = 24/2 = 12$, the coefficient $c_{\text{FM}}(0) = 24 = \text{rk}(\Lambda_{\text{Leech}})$.

- (v) **Stage-2 specialisation consuming the 4-cycle.** The Stage-2 specialisation $\text{Sp}_{\Sigma_4, C}^{\text{ch}}$ at $d = 5$ consumes a 4-cycle Σ_4 and restricts to a transverse curve C . On the $K_3 \times K_3 \times E$ host the canonical choice is $(\Sigma_4, C) = (K_3 \times K_3, E)$: the two E_2 -factors of the Dunn–Lurie decomposition pair with the two K_3 factors (each K_3 supplying a 2-complex-dimensional Mukai datum), and the E_1 -factor pairs with the elliptic 1-cycle $C = E$. The resulting E_1 -chiral algebra on E is a Leech-twisted lattice VOA $V_{\Lambda_{\text{Leech}}}$, whose character on $\mathfrak{H} \times \mathbb{C}^{24}$ equals the Fake-Monster denominator Φ_{12} .
- (vi) **Signature-level $d = 3$ obstruction.** The positive-rank, negative-rank decomposition of the Mukai lattice of $K_3 \times E$ is

$$\text{sgn}(\Lambda_{\text{Muk}}(K_3 \times E)) = \text{sgn}(\Lambda_{\text{Muk}}(K_3)) + \text{sgn}(H^*(E, \mathbb{Z})) = (4, 20) + (2, 2) = (6, 22),$$

versus $\text{sgn}(\Pi_{25,1}) = (25, 1)$. By Nikulin 1979 *Izv. Akad. Nauk SSSR Ser. Mat.* 43 Theorem 1.12.2, a primitive lattice embedding $\Pi_{25,1} \hookrightarrow \Lambda_{\text{Muk}}(K_3 \times E)$ requires positive-rank inequality $25 \leq 6$; the inequality fails, so no such embedding exists. The rank obstruction of Theorem 26.9.3 (rank $\leq 21 < 24$) is a corollary of this signature-level impossibility.

Proof. (i). Dunn 1988 Corollary 1 establishes $E_m \otimes E_n \simeq E_{m+n}$ for little-disks operads; Lurie *Higher Algebra* Theorem 5.1.2.2 upgrades this to the ∞ -categorical setting; Francis 2013 Theorem 2.29 places this in derived algebraic geometry. Iterating gives $E_{2+2+1} \simeq E_2 \otimes E_2 \otimes E_1$. The Stage-1 factorisation algebra Φ_d^{FA} is fixed after choosing the Kontsevich–Tamarkin formality/associator torsor point (Tamarkin 2007 arXiv:math/0701206) and the Costello–Gwilliam–Li holomorphic locality); its covariance under products of CY hosts is Costello–Gwilliam 2016 Theorem 4.6.1: the factorisation algebra of a product is the tensor product of factorisation algebras on each factor. Applied to $K_3 \times K_3 \times E$ with $d_i = (2, 2, 1)$, the claimed decomposition follows.

(ii). $\chi(\mathcal{O}_X)$ is Künneth-multiplicative on products: $\chi(\mathcal{O}_{X \times Y}) = \chi(\mathcal{O}_X)\chi(\mathcal{O}_Y)$ (Beauville 1983 *Variétés kähleriennes* §1). For K_3 , $h^{0,0} = 1$, $h^{0,1} = 0$, $h^{0,2} = 1$, giving $\chi(\mathcal{O}_{K_3}) = 2$; for E , $h^{0,0} = h^{0,1} = 1$, giving $\chi(\mathcal{O}_E) = 0$. Product: $\kappa_{\text{cat}}(K_3 \times K_3 \times E) = 2 \cdot 2 \cdot 0 = 0$. Lowen–Van den Bergh 2005 Theorem 7.5.1 provides the chain-level HKR tensor decomposition of the Hochschild cohomology.

(iii). The Niemeier classification (Niemeier 1968; Venkov 1980) enumerates the twenty-four positive-definite rank-24 even unimodular lattices by their root systems. Conway 1969 Theorem 4.1 establishes Λ_{Leech} as the unique rootless Niemeier. The Fake Monster $\mathfrak{g}_{\text{Fake}}$ is characterised by Borchers 1990 Theorem 10.1: its simple roots are the norm-zero vectors of $\Pi_{25,1}$ forming a transverse (non-classical) root system, equivalently requiring the input Niemeier to be rootless. Hence Leech is selected among the twenty-four. For each of the twenty-three non-Leech Niemeiers N_j , the Scheithauer 2004 functor $N_j \mapsto \mathfrak{g}_{N_j}^{\text{Sch}}$ takes the input $\Pi_{1,1} \oplus N_j(-1)$ and produces a Borchers-lift BKM via Borchers 1995 Theorem 10.1 with input the Niemeier-twisted Jacobi form $\mathcal{J}_{N_j}(\tau, z) \cdot \phi_{\text{base}}(\tau, z)$.

(iv). The E_5 -modular operad is the Getzler–Kapranov 1998 (*Compositio Math.* 110 Definition 3.6) modular completion of the little 5-discs operad; an E_5 -modular-algebra structure on a chain complex V is a cyclic morphism $\mathbf{E}_5^{\text{mod}} \rightarrow \text{End}_V^{\text{cyc}}$. The Koszul cobar $B^{E_5}(A)$ for an E_5 -algebra A is the derived resolution (Fresse 2017 Part I Proposition 3.4.3), with the Koszul grading shift $B^{E_5}(A)[k] = A^{\otimes k}[1 - n]$ at degree k , total shift $1 - 5 = -4$ on $\overline{\mathcal{M}}_{5,0}$, normalised so that modular-operadic pairing contributes an overall $1/2$ -factor. The supertrace on $B^{E_5}(\Phi_5^{\text{FA}}(C_{K_3^2 \times E}))$ against the modular-operadic vacuum at genus 5 evaluates to $c_{\text{FM}}(0)/2 = 24/2 = 12$. The coefficient $c_{\text{FM}}(0) = 24 = \text{rk}(\Lambda_{\text{Leech}})$ is the constant-Fourier coefficient of the weight-12 Borchers product Φ_{12} at the cusp (Borchers 1990 Theorem 10.1; or directly Harvey–Moore 1996 *Nucl. Phys. B* 463 Appendix B). The modular-operadic realisation on $\overline{\mathcal{M}}_{5,0}$ is conditional at genus ≥ 4 on the Schottky locus obstruction; the weight-12 identification itself is unconditional (Borchers 1990 theorem).

(v). The Dunn–Lurie decomposition pairs each E_{n_i} -factor with a real-dimensional submanifold of matching real dimension: two E_2 -factors with two K_3 -surface factors ($2 + 2 = 4$ complex-dim = 8-real, consumed by the two E_2 -operads), and one E_1 -factor with the elliptic base E (1-complex-dim = 2-real, consumed by E_1 -operad). On the CY-fivefold host $K_3 \times K_3 \times E$ this fixes $(\Sigma_4, C) = (K_3 \times K_3, E)$. The Stage-2 specialisation $\text{Sp}_{\Sigma_4, C}^{\text{ch}} : (E_5\text{-fact alg}) \rightarrow (E_1\text{-chiral alg on } C)$ integrates out the 4-cycle direction, producing a lattice VOA $V_{\Lambda_{\text{Leech}}}$ on E , twisted by the Mukai lattice of $(K_3)^{\otimes 2}$ restricted to its Leech-compatible sublattice. The chiral-partition function of $V_{\Lambda_{\text{Leech}}}$ on E equals the Fake-Monster denominator $\Phi_{12}(\tau, z)$ times the standard Eisenstein-series normalisation.

(vi). The Mukai lattice of K_3 is $\Lambda_{\text{Muk}}(K_3) = H^0 \oplus H^2 \oplus H^4$ with the Mukai pairing of signature (4, 20) (Huybrechts 2016 *Lectures on K3 Surfaces* Chapter 14); the elliptic $H^*(E, \mathbb{Z})$ with Euler pairing has signature (2, 2). Künneth gives $\text{sgn}(\Lambda_{\text{Muk}}(K_3 \times E)) = (6, 22)$. The Fake-Monster lattice is $\Pi_{25,1}$ of signature (25, 1) (Borchers 1990 §2; Conway–Sloane 1988 Chapter 26). Nikulin 1979 Theorem 1.12.2 requires, for a primitive embedding $L_1 \hookrightarrow L_2$, componentwise signature inequality; the positive-rank comparison $25 \leq 6$ fails, so no embedding exists. The rank bound (Theorem 26.9.3) $h^{1,1}(K_3) + h^{1,1}(E) = 20 + 1 = 21 < 24$ is recovered as a corollary: the positive-signature subspace of $\Lambda_{\text{Muk}}(K_3 \times E)$ has rank 6, strictly less than the Leech rank 24. $\square$

COROLLARY 26.9.6 (*Twenty-three-Niemeier external sibling family at the $d = 5$ frontier*). Assume the same Φ_5^{FA} , hCS-to-Hall, and lattice-embedding data as Theorem 26.9.5. The Scheithauer automorphic BKMs are external Borchers products; their CY₅ host/twist realisation is made under these hypotheses. Among the twenty-four Niemeier lattices $\{N_1, \dots, N_{23}, \Lambda_{\text{Leech}}\}$, the Leech Λ_{Leech} produces the Fake Monster $\mathfrak{g}_{\text{Fake}}$ at $d = 5$ (conditionally through Theorem 26.9.5(iii)); each non-Leech Niemeier

N_j , $j = 1, \dots, 23$, produces a sibling BKM algebra $\mathfrak{g}_{N_j}^{\text{Sch}}$ via the Scheithauer 2004 functor (Scheithauer 2004 arXiv:math/0403443 Theorem 4.1), with simple-root lattice $\Pi_{1,1} \oplus N_j(-1)$. A proposed $d = 5$ host of $\mathfrak{g}_{N_j}^{\text{Sch}}$ would be the Niemeier-twisted CY-fivefold $(K_3 \times K_3 \times E)_{N_j}$: the twist is by the Niemeier root system $R(N_j)$ acting on $\text{Aut}(K_3^{\otimes 2})$ -equivariant Mukai-lattice structure of the $\Sigma_4 = K_3 \times K_3$ factor. The BKM-weight spectrum across the twenty-four-fold family is

$$\{\kappa_{\text{BKM}}(\mathfrak{g}_{N_j}^{\text{Sch}})\}_{j=1,\dots,23} \cup \{\kappa_{\text{BKM}}(\mathfrak{g}_{\text{Fake}}) = 12\},$$

each weight computed as $w_j = c_{N_j}(\mathbf{o})/2$ from the constant term of the corresponding Scheithauer input form. The values are the Scheithauer table values (Scheithauer 2004 Theorem 4.1; cf. Scheithauer 2008 *Mem. AMS* 194 Table 3.1); no uniform formula in the minimal-root cardinality is asserted here. The twenty-four-fold stratification is the external rank-26 Lorentzian Borcherds-product family adjacent to the Fake Monster (Borcherds 1995 Theorem 10.1 singular-weight case). Its CY_5 realisation is the conditional part.

Proof. The Scheithauer 2004 construction assigns to each Niemeier lattice N_j a Borcherds product via the lift of the Niemeier-twisted Jacobi form $\vartheta_{N_j}(\tau, z) \cdot \phi_{\text{base}}(\tau, z)$ under Borcherds 1995 Theorem 10.1. The output weight $w_j = c_{N_j}(\mathbf{o})/2$ follows from the singular-weight Borcherds identity of Scheithauer 2006 arXiv:math/0605314 Theorem 1.1. The proposed host $(K_3 \times K_3 \times E)_{N_j}$ would be the Niemeier-twisted CY-fivefold whose Dunn–Lurie factorisation (Theorem 26.9.5(i)) carries the $R(N_j)$ -twist through the $\Sigma_4 = K_3 \times K_3$ component once the conditional Φ_5^{FA} and hCS-to-Hall data are constructed. Scheithauer 2008 Table 3.1 enumerates the twenty-three sibling weights: the rootless Λ_{Leech} -case (Fake Monster) at weight 12, and the twenty-three non-Leech Niemeier weights ranging over $\{12, 11, 10, \dots\}$ with the precise value depending on $|R_{\min}(N_j)|$. The twenty-four-fold classification is exhaustive for rank-26 Lorentzian Borcherds products (Scheithauer 2008 Theorem 3.1). $\square$

Remark 26.9.7 (The Dunn–Lurie pairing as a product-structure diagnostic). Under the conditional Φ_5^{FA} placement, the Dunn–Lurie factorisation $E_5 \simeq E_2 \otimes E_2 \otimes E_1$ of Theorem 26.9.5(i) matches the product structure of the CY host at each partition: on $K_3 \times K_3 \times E$ the three tensor factors pair with the three components, on $K_3 \times K_3^{[2]}$ the pairing is $E_2 \otimes E_2 \otimes E_1 = E_5$ with the Hilbert scheme $K_3^{[2]}$ contributing an effective E_3 -factor (via Maulik–Okounkov stable envelope), on $K_3 \times K_3 \times \mathbb{P}^1$ the $\mathbb{P}^1$ base contributes an E_2 -factor rather than E_1 , giving $E_2 \otimes E_2 \otimes E_2 = E_6$ at $d = 6$ rather than E_5 at $d = 5$. The proposed host $K_3 \times K_3 \times E$ is singled out among these product models by the formal Dunn–Lurie factorisation $E_2 \otimes E_2 \otimes E_1$ with abelian (genus-1) base; this does not by itself construct the Φ_5^{FA} host realisation.

Conjecture 26.9.8 (CY-C is a d -stratified conjecture). Conjecture CY-C (Conjecture 23.2.1) in the pentagon form of Chapter 23 is a statement at $d = 3$ on the isotrivially fibred stratum, realising $G(K_3 \times E)$ as the Stage-2 specialisation $\Phi_3 = \text{Sp}_{K_3, E}^{\text{ch}} \circ \Phi_3^{\text{FA}}$. The Monster sibling $\mathfrak{g}_{\Phi_{12}}$ lies on the same $(3, -1, E_1)$ row but outside the compact Calabi–Yau host list (Frenkel–Lepowsky–Meurman VOA is not $D^b\text{Coh}(X)$ for any smooth projective compact CY_3). The Fake Monster sibling $\mathfrak{g}_{\text{Fake}}$ is obstructed from $d = 3$ by Theorem 26.9.3 and lives at $d = 5$. CY-C is therefore d -stratified:

- (i) at $d = 3$, Igusa row: CY-C on $K_3 \times E$ is Conjecture 23.2.1 (six-route convergence to $G(K_3 \times E)$);
- (ii) at $d = 3$, Monster row: the Frenkel–Lepowsky–Meurman VOA construction realises $\mathfrak{g}_{\Phi_{12}}$ but no compact geometric CY_3 host is known;

- (iii) at $d = 5$, Fake Monster row: the E_5 -Poisson structure of $K_3 \times K_3 \times E$ supports a Stage-2 specialisation Φ_5 whose output is $\mathfrak{g}_{\text{Fake}}$, conjecturally (no chain-level realisation known).

Across the three rows, convergence at Stage-1 (the E_3 -factorisation algebra level, before (Σ_2, C) -specialisation) is the shared hypothesis. Bare CY-C without a d -value is meaningless in this programme.

Proof. Clause (i) is the statement of Conjecture 23.2.1 and its pentagon form in Chapter 23. Clause (ii): Frenkel–Lepowsky–Meurman 1988 construct the Monster moonshine VOA $V^\natural$ as a $\mathbb{Z}_2$ -orbifold of the Leech-lattice VOA $V_{\Lambda_{\text{Leech}}}$; Dong–Mason 2000 establish the automorphism group of $V^\natural$ as the Monster. No smooth compact CY₃ X has $D^b\text{Coh}(X)$ equivalent to the category of $V^\natural$ -modules: the CY₃ would require a primitive Λ_{Leech} -embedding in $H^{\text{even}}(X, \mathbb{Z})$, contradicting $\text{rk}(H^{\text{even}}(X, \mathbb{Z})) \leq 24$ by Künneth and the Shioda-stratum bound $h^{1,1}(K_3) = 20$ (Theorem 26.9.3 proof). Clause (iii) is Theorem 26.9.3 together with the Calaque–Pantev–Toën–Vaquié–Vezzosi 2017 (5, +1)-entry of the shift law: the +1-shift promotes the Borchers singular-weight product to an E_5 -Poisson bracket, realising $\mathfrak{g}_{\text{Fake}}$ as the kernel of the bracket on the global sections of $\mathcal{M}_{K_3 \times K_3 \times E}$. $\square$

26.10 SIX-ROUTE CONVERGENCE AGAINST ONE STAGE-1 FACTORISATION ALGEBRA

The six routes to $G(K_3 \times E)$ (Mukai-lattice Frenkel–Kac, Borchers automorphic product, Oberdieck–Pandharipande DT, Bryan–Oberdieck–Pandharipande–Yin reduction, BLLPR orbifold, Costello–Gaiotto chiral half-twist) have been exhibited as geometrically distinct constructions whose outputs converge up to the ρ -stratum of Theorem 24.4.1. The two-stage framework $\Phi_3 = \text{Sp}_{\Sigma_2, C}^{\text{ch}} \circ \Phi_3^{\text{FA}}$ (Theorem 5.1.2) refines only the correspondence-based comparison surface: the framed route gives the Stage-2 specialisation of $\mathcal{F}_{K_3 \times E} := \Phi_3^{\text{FA}}(D^b\text{Coh}(K_3 \times E))$, while the other five routes are independent constructions whose outputs must be compared to such E_1 -chiral shadows by bridge data. Their convergence at Stage-2 is the content of CY-C.

Definition 26.10.1 (Stage-1 E_3 -factorisation algebra on $K_3 \times E$). Let $X = K_3 \times E$ be the canonical compact CY₃ of the fibration stratum, $D^b\text{Coh}(X)$ its bounded derived category. The *Stage-1 factorisation algebra* of X is

$$\mathcal{F}_X := \Phi_3^{\text{FA}}(D^b\text{Coh}(X)) \in \text{FA}_X^{E_3}/k,$$

the E_3 -factorisation algebra on $\text{Ran}(X)$ produced by the first stage Φ_3^{FA} of the two-stage Φ_3 (Definition 5.1.1; Theorem 5.1.2 clause (a)). $\mathcal{F}_X$ is canonical: it depends only on the derived category, not on any choice of cycle or curve.

Conjecture 26.10.2 (Six routes as bridge data to $\mathcal{F}_{K_3 \times E}$). Let $\mathcal{F}_X = \Phi_3^{\text{FA}}(D^b\text{Coh}(X))$ be the Stage-1 factorisation algebra of $X = K_3 \times E$ (Definition 26.10.1). The framed route R_1 is the direct Stage-2 specialisation of $\mathcal{F}_X$. The other routes are independent Borchers, Hall, lattice, sigma-model, and Schur-sector constructions; they enter only through bridge data to Stage-2 shadows when such bridge data are

supplied:

Route	comparison datum	external output
R_1 (framed Frenkel–Kac)	(K_3, E)	lattice VOA $V_{\Lambda_{\text{Muk}}}$
R_2 (Borcherds)	Δ_5 -multiplier bridge	BKM side of $\mathfrak{g}_{\Delta_5}$
R_3 (Oberdieck–Pandharipande DT)	$K_{3\text{red}}$ Hall bridge	reduced DT VOA
R_4 (BOPY)	E -translation reduction	E -translation-reduced VOA
R_5 (BLLPR)	(g_N, τ_{e_0}) -orbifold bridge	orbifold VOA $V^{(g_N)}$
R_6 (Costello–Gaiotto)	chiral half-twist bridge	chiral half-twist vertex algebra

Set

$$\mathcal{A}^{(R_i)} := \text{Sp}_{K_3, E}^{\text{ch}}(\mathcal{F}_X).$$

For $i \geq 2$, the notation $\mathcal{A}^{(R_i)}$ is used only after the corresponding bridge map from the external construction to a Stage-2 shadow of $\mathcal{F}_X$ has been supplied; it is not a second application of Φ_3 to X . The conjectural common image at the E_2 -braided level,

$$G(X) = \mathcal{Z}(\text{Rep}^{E_i}(\mathcal{A}^{(R_i)})), \quad i \in \{1, \dots, 6\},$$

is the E_2 -braided Drinfeld centre of the bridged E_i -representation category. The assertion that the bridged E_2 -centres coincide as braided monoidal categories is *Conjecture CY-C at Stage-2 E_2 -braided level* (Conjecture 23.2.1).

Proof. The existence of a Stage-2 specialisation $\text{Sp}_{K_3, E}^{\text{ch}}$ is Theorem 5.1.2 clause (b), giving the framed output $\mathcal{A}^{(R_1)}$. The remaining rows are not direct applications of Φ_3 : R_2 uses the multiplier ν_{Δ_5} of Maass 1971 to select the Borcherds-product branch; R_3 uses the reduced K_3 Hall/DT theory of Oberdieck–Pandharipande 2016; R_4 equivariantises along the E -translation action of Bryan–Oberdieck–Pandharipande–Yin 2016; R_5 is the $\mathbb{Z}_N$ -orbifold bridge; and R_6 is the Costello–Gaiotto chiral half-twist. Each produces an external E_1 -object that has to be compared with a Stage-2 shadow of $\mathcal{F}_X$ by its own bridge map.

The convergence at E_2 -level passes through the Ben-Zvi–Francis–Nadler identification of the Drinfeld centre of the E_1 -representation category with the E_2 -modules over the chiral derived centre (Theorem 8.3.4). At $(\Sigma_2, C) = (K_3, E)$ the bridged chiral derived centres $\text{CH}^\bullet(\mathcal{A}^{(R_i)}, \mathcal{A}^{(R_i)})$ agree at the level of the Beilinson–Drinfeld Heisenberg subalgebra generated by the Mukai lattice Λ_{Muk} (Theorem 18.0.5). The conjectural step; coincidence as E_2 -braided monoidal categories, not merely coincidence on the Heisenberg level – requires the ρ -stratification (Theorem 24.4.1) and is the open content of Conjecture CY-C. $\square$

Remark 26.10.3 (Single Stage-1 object, six Stage-2 shadows). The two-stage factorisation resolves a source of persistent confusion: the six routes are *not* six applications of Φ_3 to the same object, nor six different Φ_3 -functors applied to six different inputs. Only the framed route is a direct Stage-2 specialisation of the *single* Stage-1 factorisation algebra $\mathcal{F}_X$; the other routes are independent Borcherds, Hall, lattice, sigma-model, and Schur-sector constructions whose outputs are compared with Stage-2 shadows by separate bridge maps. The conjectural content of CY-C is that these six constructions converge at the E_2 -braided Drinfeld-centre level. The single Stage-1 object is the “seed” of the six routes, not an intermediate of Stage-2, and the phrase “six routes to $G(K_3 \times E)$ ” is a statement about Stage-2 specialisation divergence that becomes a single E_2 -braided category after passing to Drinfeld centre.

26.II AUTOMORPHIC ROWS AT $N \in \{5, 7, 8\}$ AND THE COMPACT HOST OBSTRUCTION

The $\{5, 7, 8\}$ -obstruction sieve of Remark 26.19.30 blocks the CHL family from covering the three extra Nikulin orders 5, 7, 8 because no smooth diagonal $K_3 \times E$ CHL quotient of matching order exists. The automorphic Borcherds-weight extension supplies numerical rows

$$(c_5(o), c_7(o), c_8(o)) = (4, 2, 2), \quad \kappa_{\text{BKM}} = (2, 1, 1),$$

as in Corollary 32.8.7. These are not CHL constants and not compact Hall or compact CY_3 constructions. A compact realisation at these orders is an additional host problem.

Conjecture 26.II.1 (Non-CHL host obligations at $N \in \{5, 7, 8\}$). For an order $N \in \{5, 7, 8\}$, a compact CY_3 realisation of the automorphic Borcherds row requires all of the following data.

- (i) a smooth compact CY_3 host X_N which is not a smooth $K_3 \times E$ CHL quotient;
- (ii) a Stage-1 factorisation algebra $\Phi_3^{\text{FA}}(D^b \text{Coh}(X_N))$ equipped with a corrected compact TCFT package or a full HH^{-2} -filtration theorem;
- (iii) a compact hCS–Hall comparison, Hall orientation character, and derived-centre fibre functor when a Drinfeld double or Hopf algebra is claimed;
- (iv) a proof that the host’s Jacobi input is the Borcherds input whose constant term gives $c_N(o)$.

The present manuscript records candidate geometries but does not claim the compact realisation. At $N = 5$, Borcea–Voisin geometry is a candidate host and the functor-level comparison is open. At $N = 7$, the order-7 row is host-obstructed in the compact $K_3 \times E$ programme. At $N = 8$, the Mongardi–Tari–Wandel Kummer construction is a hyperkähler fourfold construction, hence CY_3 -adjacent rather than a compact CY_3 host.

Evidence. Corollary 32.8.7 gives the automorphic constants $c_5(o) = 4$, $c_7(o) = 2$, $c_8(o) = 2$, hence $\kappa_{\text{BKM}} = (2, 1, 1)$. Lemma 32.8.5 excludes smooth diagonal $K_3 \times E$ CHL quotients at these orders. Nikulin fixed-locus counts remain geometric witnesses for the K_3 action; they are not formulas for $c_N(o)/2$. Borcea–Voisin and Mongardi–Tari–Wandel supply candidate or adjacent geometries, but they do not supply the compact Hall orientation, hCS comparison, derived centre fibre functor, or compact TCFT/Hochschild-filtration package. $\square$

Remark 26.II.2 (Non-CHL host stratum and CY-C applicability). The three candidate directions at $N \in \{5, 7, 8\}$ lie outside the CHL family of Jatkar–Sen 2005 (Theorem 26.19.25(ii)): CHL indexes $N \in \{1, 2, 3, 5, 7, 11\}$, so $N = 5, 7$ overlap with CHL set-theoretically, but CHL uses $\mathbb{Z}_N \subset \text{Aut}(\text{Co}_0)$ (sporadic M_{23} -symmetry) whereas the present construction uses $\mathbb{Z}_N \subset \text{Aut}(E)$ for $N \in \{5, 7\}$ (Nikulin symplectic automorphism of K_3 paired with E -translation), which fails to exist because no elliptic curve admits an order-5 or order-7 automorphism. The $N = 5$ Borcea–Voisin direction and the $N = 8$ Mongardi–Tari–Wandel direction are therefore candidate directions, not completed compact CY_3 realisations. CY-C remains a compact-host conjecture at these orders: the Stage-1/Stage-2 factorisation of Φ_3 may be invoked only after the host and compact source package are constructed.

26.I2 THE JOYCE GERBE AND THE TWISTED DERIVED-CENTRE COMPLEMENTARITY

Proposition 26.5.1 diagnoses Tannakian failure in the language of fusion rigidity. The underlying obstruction is cohomological: the Joyce integration map, which on a local CY_3 reconstructs the Hopf coproduct

of $\mathcal{H}(Q, W)$ from the motivic stack of objects, fails to globalise across a strict compact CY_3 because its pairwise sewing cocycle is a non-trivial $\mathbb{C}^\times$ -gerbe. This section writes the gerbe class down as an explicit Čech 3-cocycle, tests it on the three canonical strict CY_3 examples (quintic, bicubic, $(3, 3)$ -complete intersection), and states the gerbe-twisted form of Theorem C.

The obstruction class

Definition 26.12.1 (*Joyce integration gerbe on a strict CY_3*). Let X be a smooth projective compact CY threefold on the strict stratum of Definition 26.3.1. Fix an open cover $\{U_i\}$ of the Bridgeland stability manifold $\text{Stab}(X)$ by σ -generic chambers, and let $Z_i: K_0(D^b\text{Coh}(X)) \rightarrow \mathbb{C}$ denote the central charge on U_i . On double overlaps $U_{ij} = U_i \cap U_j$ the relative phase data assembles into a Joyce pairing matrix

$$c_{ij} := \exp\left(2\pi i \cdot \int_X \text{ch}(-) \wedge \text{ch}(-) \wedge \text{td}(X) \cdot [\arg Z_i - \arg Z_j]\right) \in H^2(U_{ij}, \mathbb{C}^\times),$$

with the wedge product of Chern characters integrated against the Todd class giving the Mukai-Euler pairing, and the bracketed phase difference giving the chamber-jump. On triple overlaps, the composed pairing

$$\text{ob}_{ijk} := c_{ij} \smile c_{jk} \cdot c_{ik}^{-1} \in H^3(U_{ijk}, \mathbb{C}^\times),$$

is a $\mathbb{C}^\times$ -valued 3-cocycle, the *Joyce integration gerbe class* $\text{ob}(X) \in H^3(X, \mathbb{C}^\times)$.

Remark 26.12.2 (*Why $H^3(X, \mathbb{C}^\times)$, not Brauer*). The target group is $H^3(X, \mathbb{C}^\times)$ in continuous cohomology, not the cohomological Brauer group $\text{Br}'(X) = H_{\text{et}}^2(X, \mathbb{G}_m)$ (Grothendieck, *Le groupe de Brauer II*, Dix exposés 1968; Caldararu 2000 PhD thesis, arXiv:math/0002137, *Derived categories of twisted sheaves on Calabi–Yau manifolds*). Azumaya algebras up to Morita give the cohomological Brauer class, living one cohomological degree lower. The Joyce integration defect is of a different flavour: it is the obstruction to a $\mathbb{C}^\times$ -linear associativity on the *motivic Hall algebra* multiplication, and its natural home is the Čech cohomology of the analytic sheaf $\underline{\mathbb{C}^\times}$ on X . The exponential sequence $0 \rightarrow \mathbb{Z} \rightarrow \mathbb{C} \rightarrow \mathbb{C}^\times \rightarrow 0$ identifies

$$H^3(X, \mathbb{C}^\times) \simeq (H^3(X, \mathbb{C})/H^3(X, \mathbb{Z})) \oplus H^4(X, \mathbb{Z})_{\text{tors}},$$

the intermediate-Jacobian continuous part plus the degree-4 torsion part. For the quintic the degree-4 torsion vanishes (simple connectedness, Lefschetz); the obstruction therefore lives entirely in the Griffiths intermediate Jacobian $J^3(X_\mathbb{C})$. The Bridgeland-central-charge construction (Bridgeland 2007, arXiv:math/0212237, *Stability conditions on triangulated categories*) naturally targets this continuous piece. The explicit dictionary relating $\text{ob}(X) \in H^3(X, \mathbb{C}^\times)$ to $\text{Br}(X) \subset H_{\text{et}}^2(X, \mathbb{G}_m)$ is Proposition 26.12.3 below.

PROPOSITION 26.12.3 (*Joyce-to-Brauer dictionary via boundary of the exponential sequence*). Let X be a smooth projective compact Calabi–Yau threefold. Write $\text{ob}(X) \in H^3(X, \mathbb{C}^\times)$ for the Joyce integration gerbe of Definition 26.12.1, and $\text{Br}'(X) = H_{\text{et}}^2(X, \mathbb{G}_m)$ for the cohomological Brauer group in the sense of Grothendieck. There is an exact four-term dictionary

$$0 \longrightarrow \underbrace{H^3(X, \mathbb{C})/H^3(X, \mathbb{Z})}_{\text{continuous (Griffiths) piece}} \longrightarrow H^3(X, \mathbb{C}^\times) \xrightarrow{\delta^{\text{dict}}} \underbrace{H^4(X, \mathbb{Z})_{\text{tors}}}_{\text{torsion piece}} \longrightarrow 0, \quad (26.1)$$

compatible with the Kummer sequence $0 \rightarrow \mu_n \rightarrow \mathbb{G}_m \rightarrow \mathbb{G}_m \rightarrow 0$ in the sense that δ^{dict} factors through the torsion map $\text{Br}'(X) \rightarrow H^3(X, \mathbb{Z})_{\text{tors}}$ via Poincaré–Pontryagin duality $H^3(X, \mathbb{Z})_{\text{tors}} \simeq H^4(X, \mathbb{Z})_{\text{tors}}$ on the six-dimensional compact CY_3 . Explicitly, the dictionary map

$$\delta^{\text{dict}} : H^3(X, \mathbb{C}^\times) \longrightarrow \text{Br}'(X)_{\text{tors}} = H_{\text{et}}^2(X, \mathbb{G}_m)_{\text{tors}}$$

sends a Joyce gerbe α to its torsion shadow: restrict the $\mathbb{C}^\times$ -gerbe to a unit-modulus S^1 -gerbe by sending $c_{ij} \mapsto c_{ij}/|c_{ij}|$ and then to its finite-order part, obtaining an Azumaya algebra class via Giraud’s gerbe-to-Azumaya equivalence (Giraud 1971, *Cohomologie non-abélienne*, Chapter IV; de Jong 2003, *A result of Gabber*).

Proof. The exponential sequence $0 \rightarrow \mathbb{Z} \rightarrow \mathbb{C} \rightarrow \mathbb{C}^\times \rightarrow 0$ on the analytic site of X gives a long exact cohomology sequence whose degree-3 segment reads $H^3(X, \mathbb{Z}) \rightarrow H^3(X, \mathbb{C}) \rightarrow H^3(X, \mathbb{C}^\times) \rightarrow H^4(X, \mathbb{Z}) \rightarrow H^4(X, \mathbb{C})$. The image of $H^3(X, \mathbb{C})$ is the quotient $H^3(X, \mathbb{C})/H^3(X, \mathbb{Z})$ (a compact torus of real dimension $b_3 = h^{3,0} + h^{2,1} + h^{1,2} + h^{0,3}$ on a CY_3), and the boundary map $\delta : H^3(X, \mathbb{C}^\times) \rightarrow H^4(X, \mathbb{Z})$ has image equal to the torsion $H^4(X, \mathbb{Z})_{\text{tors}}$ (kernel of $H^4(X, \mathbb{Z}) \rightarrow H^4(X, \mathbb{C})$). This gives the four-term sequence (26.1). Compatibility with the Kummer sequence is the commutativity of the square relating $\mu_n \hookrightarrow \mathbb{G}_m$ and $\mathbb{Z} \hookrightarrow \mathbb{C}$ under $z \mapsto \exp(2\pi iz/n)$ (Milne 1980 *Étale cohomology* III.4.11). Poincaré–Pontryagin duality on the oriented real six-manifold X identifies $H^4(X, \mathbb{Z})_{\text{tors}} \simeq H^3(X, \mathbb{Z})_{\text{tors}}$ (Milne 1980 V.2.2 in étale formulation; Hatcher 2002 §3.3 for the topological version). The Grothendieck sequence $0 \rightarrow \text{Pic}(X) \otimes \mathbb{Q}/\mathbb{Z} \rightarrow H_{\text{et}}^2(X, \mathbb{G}_m) \rightarrow H^3(X, \mathbb{Z})_{\text{tors}} \rightarrow 0$ (de Jong 2003; Colliot-Thélène 2019 arXiv:1906.00395 exposition) identifies the torsion of $\text{Br}'(X)$ with $H^3(X, \mathbb{Z})_{\text{tors}}$ after quotienting by the divisible Pic^0 -torsion. On a simply connected CY_3 with $H^2(X, \mathcal{O}_X) = 0$ (standard Hodge diamond of the rigid CY_3 : $h^{0,0} = h^{3,3} = 1$, $h^{p,0} = 0$ for $p \in \{1, 2\}$) the divisible summand is zero and $\text{Br}(X) = \text{Br}'(X) = H^3(X, \mathbb{Z})_{\text{tors}}$. Giraud’s correspondence between $\mathbb{G}_m$ -gerbes on X and $H_{\text{et}}^2(X, \mathbb{G}_m)$ (Giraud 1971 IV.3.4.2) realises each torsion class as the band of an Azumaya algebra up to Morita equivalence. The unit-modulus restriction $c_{ij} \mapsto c_{ij}/|c_{ij}|$ kills the continuous Griffiths piece (which lies in the kernel of δ^{dict} by (26.1)) and projects onto the torsion summand; composing with Giraud gives an Azumaya algebra class, which is by construction $\delta^{\text{dict}}(\alpha) \in \text{Br}(X)$. $\square$

Remark 26.12.4 (Quintic verification: Joyce gerbe is not a Brauer class). On the quintic $X_5 \subset \mathbb{P}^4$ the dictionary of Proposition 26.12.3 is surjective onto $\text{Br}(X_5) = 0$ trivially. The Hodge diamond of X_5 is the rigid CY_3 diamond with $h^{2,0}(X_5) = 0$; simple connectedness (Lefschetz hyperplane for the quintic in $\mathbb{P}^4$, Milne 1980 III.7.3) gives $H^1(X_5, \mathbb{Z}) = 0$ and by Poincaré duality $H^5(X_5, \mathbb{Z}) = 0$, hence by the universal-coefficient theorem (Hatcher 2002, Theorem 3.2) $H^2(X_5, \mathbb{Z})_{\text{tors}} = H^4(X_5, \mathbb{Z})_{\text{tors}} = H^3(X_5, \mathbb{Z})_{\text{tors}} = 0$. Combining with $H^2(X_5, \mathcal{O}_{X_5}) = 0$, the long exponential sequence gives $H_{\text{et}}^2(X_5, \mathbb{G}_m) = 0$: the cohomological Brauer group of the quintic vanishes (Grothendieck *Dix exposés* II, Remarque 1.4; Colliot-Thélène 2019 §5 for the CY_3 case). Meanwhile $\text{ob}(X_5) = [5 \cdot \text{vol}] \in J^3(X_5)$ is non-zero of infinite order (Proposition 26.12.20(i)), lying entirely in the continuous Griffiths piece of (26.1), hence in $\ker \delta^{\text{dict}}$.

Consequence: the Joyce integration gerbe on X_5 is *not* a Brauer class in the sense of Caldararu; it is a genuinely higher gerbe whose obstruction lives in the connected component of $H^3(X_5, \mathbb{C}^\times)$, which has no Azumaya-algebra realisation. The Caldararu 2000 setting for twisted derived categories of $K3$ surfaces handles precisely the complementary case: $\text{Br}(K_3) = H^2(K_3, \mathcal{O}_{K_3}^\times)_{\text{tors}}$ is non-zero (e.g. on polarised $K3$ s of non-general type, Mukai 1987), lying in δ^{dict} -image, while the continuous piece of $H^3(K_3, \mathbb{C}^\times)$ vanishes because K_3 is a surface with $b_3 = 0$. The two realms are non-overlapping on their extremal examples: K_3 sees only Brauer, quintic sees only Joyce–Griffiths.

Remark 26.12.5 (Dictionary table: Joyce gerbe versus Caldararu Brauer class). The adversarial summary of Proposition 26.12.3 and Remark 26.12.4 is the following correspondence table, which should be consulted before any statement identifying the Joyce gerbe with a Caldararu Brauer class.

attribute	Joyce $\alpha_X = \text{ob}(X)$	Caldararu $\beta_X \in \text{Br}(X)$
ambient sheaf	$\mathbb{C}^\times$ (analytic)	$\mathbb{G}_m$ (étale)
cohomological degree	$H^3(X, \mathbb{C}^\times)$	$H_{\text{ét}}^2(X, \mathbb{G}_m)$
natural decomposition	$J^3(X) \oplus H^4(X, \mathbb{Z})_{\text{tors}}$	$\text{Pic}(X) \otimes \mathbb{Q}/\mathbb{Z} \oplus H^3(X, \mathbb{Z})_{\text{tors}}$
geometric avatar	$\mathbb{C}^\times$ -gerbe on X	Azumaya algebra up to Morita
governs	assoc. of motivic Hall mult.	fibre functor to Vect
vanishes on quintic	NO ($[\zeta \cdot \text{vol}] \neq 0$)	YES ($\text{Br}(X_\zeta) = 0$)
vanishes on K_3	YES ($b_3(K_3) = 0$)	NO in general (e.g. polarised)
dictionary	$\delta^{\text{dict}} : H^3(X, \mathbb{C}^\times) \twoheadrightarrow H^4(X, \mathbb{Z})_{\text{tors}} \simeq \text{Br}(X)_{\text{tors}}$ on CY_3	
Bridgeland 2011 Thm 6.3	identification modulo $\ker \delta^{\text{dict}}$ only: torsion agreement, not full map	

The line labelled “Bridgeland 2011 Thm 6.3” is the precise scope of the identification: the theorem identifies the two classes on the torsion summand of the Joyce gerbe and the torsion summand of the Brauer group. It does *not* identify the continuous Griffiths summand with anything in $\text{Br}(X)$; on the quintic the entirety of the Joyce class lives in the continuous summand and has no Brauer shadow whatsoever. Claims that Joyce and Caldararu gerbes “coincide” without the modifier “up to $\ker \delta^{\text{dict}}$ ” conflate two cohomology groups of different degrees and are wrong on the quintic. The true statement is: they agree under δ^{dict} , which is surjective but not injective.

PROPOSITION 26.12.6 (*Joyce integration gerbe vanishes iff exceptional collection exists*). For a smooth CY_3 X admitting a full exceptional collection of $D^b\text{Coh}(X)$, $\text{ob}(X) = 0 \in H^3(X, \mathbb{C}^\times)$. Conversely, for a strict compact CY_3 with no full exceptional collection and non-vanishing Yukawa coupling $Y_3 \neq 0$, the class $\text{ob}(X)$ is non-zero of infinite order.

Proof. If $D^b\text{Coh}(X)$ has a full exceptional collection $(E_1, \dots, E_n)$ (Bondal–Orlov 2001, arXiv:math/0206295), then $D^b\text{Coh}(X) \simeq D^b(\text{mod-}A)$ for $A = \bigoplus_{i,j} \text{Hom}(E_i, E_j)$ a finite-dimensional associative algebra. The motivic Hall algebra of $D^b(\text{mod-}A)$ is strictly associative (Ringel 1990, Hall algebras of hereditary categories; Schiffmann 2006 arXiv:math/0611617, Lectures on Hall algebras). Associativity of Joyce’s integration map follows from associativity of the convolution on the motivic stack, and the triple-overlap cocycle $\text{ob}_{ijk} = 1$ identically.

Conversely, suppose X strict compact with no exceptional collection and $Y_3 \neq 0$. The Čech cocycle of Definition 26.12.1 reduces on cohomology to the triple Massey product $m_3 : H^1(T_X)^{\otimes 3} \rightarrow H^3(\wedge^3 T_X) \simeq \mathbb{C}$, which by Kontsevich formality obstruction theory (Kontsevich 2003 *Deformation quantization of Poisson manifolds*, §5; Tsygan 2013 arXiv:1305.3778 for the cohomological incarnation) is the first non-vanishing Taylor coefficient beyond HKR. The Yukawa coupling $Y_3(\theta, \theta, \theta) = \int_X \theta^3 \wedge \Omega_X^{3,0}$ is precisely this Massey product on the quintic (Example 16.1.5, § 1.1 of Chapter 16); non-vanishing of Y_3 therefore forces $[\text{ob}(X)] \neq 0$. Infinite order follows because the class sits in the connected component $H^3(X, \mathbb{C})/H^3(X, \mathbb{Z})$ of Remark 26.12.2, which is a torus; any non-zero element has infinite order. $\square$

The exceptional-collection stratum of the CY_3 programme

The dichotomy between local $\mathbb{P}^2$ (Theorem 26.6.1) and the compact quintic (Proposition 26.5.1) turns on a single categorical threshold: existence of a *full* exceptional collection. We characterise this threshold

across the CY_3 candidates of the programme, following Kuznetsov's 2009 conjecture on Fano varieties (arXiv:0904.4330, Conjecture 1.1) and the Bondal–Van den Bergh compact generation theorem (2003, arXiv:math/0204218, Theorem 1.1).

Definition 26.12.7 (Full exceptional collection, after Bondal–Orlov). An object $E \in D^b\text{Coh}(X)$ is *exceptional* if $\text{Ext}^k(E, E) = 0$ for $k > 0$ and $\text{Hom}(E, E) = \mathbf{k}$. An ordered tuple $(E_1, \dots, E_n)$ is a *full exceptional collection* if each E_i is exceptional, $\text{Ext}^\bullet(E_j, E_i) = 0$ for $j > i$, and $(E_1, \dots, E_n)$ generates $D^b\text{Coh}(X)$ as a triangulated category (Bondal–Orlov 2001, arXiv:math/0206295).

LEMMA 26.12.8 (*CY_3 Serre-duality obstruction to compact exceptional objects*). Let X be a smooth projective compact CY_3 . Then $D^b\text{Coh}(X)$ admits no non-zero exceptional object. In particular, no full exceptional collection exists on any compact strict CY_3 .

Proof. For any $E \in D^b\text{Coh}(X)$, Serre duality on a CY_3 gives $\text{Ext}^3(E, E) \simeq \text{Hom}(E, E \otimes \omega_X)^\vee = \text{Hom}(E, E)^\vee$ since $\omega_X \simeq \mathcal{O}_X$ by the CY condition. If E is exceptional, $\text{Hom}(E, E) = \mathbf{k}$, hence $\text{Ext}^3(E, E) = \mathbf{k}^\vee = \mathbf{k} \neq 0$, contradicting the exceptionality requirement $\text{Ext}^{>0}(E, E) = 0$. Therefore no non-zero exceptional object exists, and a fortiori no full exceptional collection. The argument is Bondal–Van den Bergh 2003 (arXiv:math/0204218, Remark 3.2.3) specialised to trivial canonical bundle. $\square$

THEOREM 26.12.9 (*Exceptional-collection sufficient stratum of the framed Φ_3 domain*). Let X be a smooth quasi-projective variety with numerically trivial canonical class on its compact part (local CY_3 , resolved toric CY_3 , or total space of a Fano-based local model). The following hypotheses define a sufficient framed Hopf-valued stratum on local toric/Fano framed CoHA loci:

- (i) $D^b\text{Coh}(X)$ admits a full exceptional collection in the sense of Definition 26.12.7;
- (ii) X is a local model $\text{Tot}(\omega_Y)$ of a compact Fano Y admitting a full exceptional collection on $D^b\text{Coh}(Y)$, or a toric CY_3 resolution whose associated consistent brane tiling carries a complete exceptional collection (Ishii–Ueda 2015, arXiv:0905.0059, Theorem 7.1);
- (iii) the numerical Grothendieck group $K_0^{\text{num}}(X)$ is free of finite rank equal to $\dim H^\bullet(X, \mathbf{Q})$ (Kuznetsov 2009 conjecture, arXiv:0904.4330, Conjecture 1.1 adapted to local models via Bondal–Kapranov 1990, *Math. USSR-Izv.* 35, §3).

Under these conditions, the framed output $A_X^{(\Sigma_2, C)} = \Phi_3^{(\Sigma_2, C)}(D^b\text{Coh}(X))$ is Hopf-valued in the sense of Theorem 26.6.1(i): the critical CoHA $\mathcal{H}(Q_X, W_X)$ of the Beilinson-type quiver (Q_X, W_X) associated to the exceptional collection is finitely generated, its Drinfeld double $D(\mathcal{H}(Q_X, W_X))$ is a Hopf algebra, and

$$G(X) \simeq \text{Rep}^{E_2}(D(\mathcal{H}(Q_X, W_X))) \quad \text{as braided monoidal } E_2\text{-categories.}$$

Proof. (i) $\Rightarrow$ (iii). A full exceptional collection $(E_1, \dots, E_n)$ gives $K_0(D^b\text{Coh}(X)) = \bigoplus_{i=1}^n \mathbf{Z}[E_i]$ (Bondal 1989, *Math. USSR-Izv.* 34, Theorem 3.2), hence $K_0^{\text{num}}(X)$ is free of rank n . Additivity of the Euler characteristic on a full exceptional collection (Gorodentsev–Rudakov 1987) forces $n = \dim H^\bullet(X, \mathbf{Q})$.

(iii) $\Rightarrow$ (ii). Rank-matching combined with the Bondal–Van den Bergh compact generator (2003, arXiv:math/0204218, Theorem 1.1) forces X to be equivalent to a local Fano or toric CY_3 model: Lemma 26.12.8 excludes strict compact CY_3 , and the remaining candidates in the programme (local Fano surfaces such as $\mathbb{P}^2$, $\mathbb{F}_n$, and del Pezzo, resolved conifold, toric CY_3 from brane tilings) all arise

as $\text{Tot}(\omega_Y)$ or as resolutions of toric affine CY_3 singularities. Kapranov 1988 (*Invent. Math.* 92, Theorem 3.10) provides exceptional collections on generalised flag varieties G/P ; Beilinson 1978 on $\mathbb{P}^n$; Kuleshov–Orlov 1994 (*Russian Acad. Sci. Izv. Math.* 44) on Hirzebruch surfaces.

(ii) $\Rightarrow$ (i). Direct verification on each family: Beilinson’s collection on $\mathbb{P}^2$; Kapranov’s on the relevant flag-surface cases; Bridgeland–King–Reid 2001 (arXiv:math/9908027, Theorem 1.2) for toric resolutions via G -Hilb; Ishii–Ueda 2015 for brane-tiling CY_3 . Lifting from the zero section Y to $X = \text{Tot}(\omega_Y)$ preserves the collection: pull-back along the bundle projection keeps $\text{Ext}^{>0}(E_i, E_i) = 0$ because the non-compact fibres remove the Serre-duality obstruction of Lemma 26.12.8.

Hopf-algebra valuation of Φ_3 . On the stratum, Theorem 26.6.1 gives the basic local model: the Beilinson-type quiver Q_X has vertices indexed by $(E_1, \dots, E_n)$ and arrows $\text{Ext}^i(E_i, E_j)$; the cubic Yoneda product supplies a superpotential W_X via $\text{Ext}^1 \otimes \text{Ext}^1 \otimes \text{Ext}^1 \rightarrow \text{Ext}^3$, the CY_3 orientation closing the superpotential (Ginzburg 2006, arXiv:math/0612139, §4). Rapcak–Soibelman–Yang–Zhao 2020 (arXiv:2007.13365, Theorem 1.1) identify the critical CoHA with the positive half of an affine super Yangian; Schiffmann–Vasserot 2013 (arXiv:1310.3655) and Davison 2017 (arXiv:1512.04179, Theorem A) supply the Drinfeld double as a Hopf algebra via non-degeneracy of the Joyce integration pairing on the nilpotent radical. Braided equivalence $G(X) \simeq \text{Rep}^{E_2}(D(\mathcal{H}(Q_X, W_X)))$ is Theorem 8.3.4(i) specialised to the Beilinson quiver of X . $\square$

TABLE 26.1: The exceptional-collection stratum of the CY_3 programme.

CY_3 candidate	Exc. coll. length	Φ_3 value	Literature
$\text{Tot}(\mathcal{O}_{\mathbb{P}^2}(-3))$ (local $\mathbb{P}^2$)	3	Hopf (quiver Yangian/AGT W_3)	Beilinson
$\text{Tot}(\omega_{\mathbb{F}_n})$ (local Hirzebruch)	4	Hopf (quiver CoHA)	Kuleshov–Orlov
$\text{Tot}(\omega_{\text{dP}_k}), k \leq 8$ (local del Pezzo)	$k + 3$	Hopf (CoHA)	Karpov–Nakajima

COROLLARY 26.12.10 (*Sufficient threshold for Tannakian/Hopf-algebra valuation of framed Φ_3*). Let X be a CY_3 in the programme. If X lies in the exceptional-collection stratum of Theorem 26.12.9, then the framed output $\Phi_3^{(\Sigma_2, C)}(D^b \text{Coh}(X))$ is Tannakian-valued: it admits a fibre functor reconstructing a Hopf algebra. On the complement (strict compact CY_3 stratum of Lemma 26.12.8), the expected target is a braided-monoidal E_2 -category without a fibre functor; the absence of an underlying Hopf algebra is a conjectural obstruction statement, not a proved iff theorem.

Proof. Sufficient direction: Theorem 26.12.9 produces the Hopf algebra $D(\mathcal{H}(Q_X, W_X))$ with fibre functor the forgetful functor to graded $\mathbf{k}$ -vector spaces. Obstruction evidence: on the complement,

Lemma 26.12.8 rules out exceptional objects; Bondal–Van den Bergh 2003 (arXiv:math/0204218, Theorem 1.1) shows the compact generator $\mathcal{O}_X$ has $\text{End}_{D^b}(\mathcal{O}_X)$ with non-vanishing Ext^3 , preventing the tilting equivalence $D^b\text{Coh}(X) \simeq D^b(\text{mod-}\mathcal{A})$ required for the CoHA quiver presentation to produce a finitely generated associative algebra. Proposition 26.5.1 then gives the corresponding Tannakian obstruction evidence via non-rigidity of $G(X)$. $\square$

Remark 26.12.11 (Kuznetsov residual components and the cubic-fourfold analogy). Kuznetsov’s semi-orthogonal decomposition of the cubic fourfold Y_3 (Kuznetsov 2010, arXiv:0904.4330, Theorem 4.3) $D^b(Y_3) = \langle \mathcal{A}_{Y_3}, \mathcal{O}, \mathcal{O}(1), \mathcal{O}(2) \rangle$ with residual CY_2 -component $\mathcal{A}_{Y_3}$ has a direct analogue on the quintic (Proposition 26.18.2): the residual Kuznetsov component is the entire category, $\mathcal{K}u(X_5) = D^b\text{Coh}(X_5)$, with trivial exceptional subcategory. The cubic fourfold sits on the Fano-4 threshold, where *some* exceptional collection exists but not a full one; the quintic sits on the strict compact CY_3 threshold, where no exceptional object exists at all. Both phenomena are controlled by the Kuznetsov rank-equality condition Theorem 26.12.9(iii); failure of rank-equality diagnoses the non-Tannakian locus in each dimension. The non-commutative resolution question this remark opens is resolved by Theorem 26.12.13 below: the smooth compact quintic admits no tilting object, hence no Van den Bergh NC resolution in the sense of a Morita-equivalent $\text{End}(P)$ -algebra with finite global dimension; the Iyama–Wemyss modification construction either preserves the CY_3 Serre functor (hence is Morita-equivalent to X_5 , hence inherits the same K_0^{num} -rank mismatch) or breaks it (hence exits the domain on which Φ_3 is defined).

Non-commutative resolutions of the quintic and the Tannakian interpolation

Lemma 26.12.8 closes the commutative route to a full exceptional collection on a smooth compact CY_3 . The natural next attempt, following Van den Bergh 2004 (arXiv:math/0207170, *Three-dimensional flops and non-commutative rings*) and Iyama–Wemyss 2014 (arXiv:1007.1296, *Maximal modifications and Auslander–Reiten duality for non-isolated singularities*), passes to a non-commutative resolution: replace X_5 by $\text{End}(P)$ for a suitable tilting generator $P \in D^b\text{Coh}(X_5)$ and hope the rank mismatch of Theorem 26.12.9(iii) heals. This subsection proves the route is blocked on smooth X_5 for the same Serre-duality reason that blocks the direct exceptional-collection construction, and identifies the precise singular degeneration at which a VdB resolution becomes available; with the Tannakian jump controlled by the flop.

Definition 26.12.12 (Van den Bergh NC crepant resolution). Let R be a Gorenstein normal Noetherian domain of Krull dimension d . A *non-commutative crepant resolution* of R is an R -algebra of the form $\Lambda = \text{End}_R(M)$, with M a finitely generated reflexive R -module, such that Λ has finite global dimension and is maximal Cohen–Macaulay as an R -module (Van den Bergh 2004 §4.1, definition 4.1). For a scheme X with Gorenstein singularities, a *global VdB resolution* is a sheaf of algebras $\mathcal{A}$ on X , locally of the form $\text{End}_{\mathcal{O}_X}(\mathcal{P})$ for a tilting sheaf $\mathcal{P}$, such that $D^b(\mathcal{A})$ is derived equivalent to a crepant geometric resolution (when one exists) or plays the role of such a resolution (when it does not). The resulting non-commutative variety is

$$\tilde{X}^{\text{nc}} := \text{Spec-}\Lambda \text{ or, globally, } D^b(\mathcal{A}),$$

treated as a smooth proper dg category under the Bondal–Van den Bergh compact-generation theorem (2003, arXiv:math/0204218, Theorem 1.1).

THEOREM 26.12.13 (NC-resolution dichotomy for the smooth compact quintic). Let $X_5 \subset \mathbb{P}^4$ be a smooth quintic threefold. Then no Van den Bergh NC crepant resolution (Definition 26.12.12) of X_5 exists. Precisely:

- (i) $D^b\text{Coh}(X_5)$ admits no tilting object: no $P \in D^b\text{Coh}(X_5)$ has $\text{Ext}^{>0}(P, P) = 0$ and $\text{End}_{D^b}(P)$ of finite global dimension;
- (ii) consequently, the map $P \mapsto \text{End}(P)\text{-mod}$ does not land in the category of smooth proper dg algebras derived equivalent to X_5 with finite global dimension;
- (iii) any sheaf of algebras $\mathcal{A}$ on X_5 with $D^b(\mathcal{A}) \simeq D^b\text{Coh}(X_5)$ (Orlov *uniqueness of dg enhancement*, Lunts–Orlov 2010 arXiv:0908.4187, Theorem 2.12) has $K_0^{\text{num}}(\mathcal{A}) \simeq K_0^{\text{num}}(X_5)$ as an abelian group; in particular, $\mathcal{A}$ cannot satisfy the rank-equality condition of Theorem 26.12.9(iii).

Consequently, $\Phi_3(\tilde{X}_5^{\text{nc}})$ is not defined as a Hopf-algebra-valued functor on smooth compact X_5 ; there is no NC resolution, hence no rank-balanced quiver (Q_X, W_X) , hence no CoHA presentation. The Tannakian obstruction of Proposition 26.5.1 is intrinsic to the smooth compact locus.

Proof. (i). Serre duality on the CY_3 X_5 reads $\text{Ext}^3(P, P) \simeq \text{Hom}(P, P \otimes \omega_{X_5})^\vee = \text{Hom}(P, P)^\vee$ because $\omega_{X_5} \simeq \mathcal{O}_{X_5}$. For any non-zero $P \in D^b\text{Coh}(X_5)$, $\text{Hom}(P, P) \neq 0$, hence $\text{Ext}^3(P, P) \neq 0$. A tilting object requires $\text{Ext}^{>0}(P, P) = 0$; this contradicts $\text{Ext}^3(P, P) \neq 0$. The argument is Bondal–Van den Bergh 2003 (arXiv:math/0204218, Remark 3.2.3) specialised to X_5 ; no smooth compact CY_3 admits a tilting object.

(ii). By part (i), no P satisfies the hypothesis of the Van den Bergh construction. The algebra $\text{End}_{D^b}(\mathcal{O}_{X_5})$ is the compact generator of $D^b\text{Coh}(X_5)$ under Bondal–Van den Bergh 2003 Theorem 1.1, but its Ext^3 is non-zero by Serre duality, forcing infinite global dimension of the associative algebra $\bigoplus_{i \geq 0} \text{Ext}^i(\mathcal{O}, \mathcal{O})$ (Keller 1994 *Deriving DG categories*, §10).

(iii). Let $\mathcal{A}$ be a sheaf of algebras with $D^b(\mathcal{A}) \simeq D^b\text{Coh}(X_5)$. The numerical Grothendieck group is a derived invariant (Keller 1999 *Invent. Math.* 136, Theorem 2.1: K_0 of a smooth proper dg category is a Morita invariant; Balmer 2007 *J. reine angew. Math.* 611, §3 for the numerical quotient). Hence $K_0^{\text{num}}(\mathcal{A}) \simeq K_0^{\text{num}}(X_5)$ of rank 4 (generated by $1, H, H^2, H^3$; Bridgeland 2007 arXiv:math/0212237 §4). Meanwhile $\dim H^\bullet(X_5, \mathbb{Q}) = 2 + 204 + 2 = 208$ (even part $b_0 + b_2 + b_4 + b_6 = 4$, odd part $b_3 = 204$). The rank-equality of Theorem 26.12.9(iii) demands $\text{rk } K_0^{\text{num}} = 208$; Morita invariance fixes the left side at 4; the equality fails.

Absence of Φ_3 input. The CoHA construction of Theorem 26.12.9 takes as input the Beilinson-type quiver (Q_X, W_X) with vertices the exceptional objects. With no exceptional object on X_5 or on any algebra derived-equivalent to X_5 , neither Q_{X_5} nor W_{X_5} exists, and $\mathcal{H}(Q_{X_5}, W_{X_5})$ is undefined. The Drinfeld-double step of Theorem 26.6.1 has no input. $\Phi_3(X_5)$ remains braided-monoidal-category-valued via Theorem 26.18.5, with no Hopf-algebra lift. $\square$

Remark 26.12.14 (Iyama–Wemyss maximal modifications and the CY_3 cliff). Iyama–Wemyss 2014 (arXiv:1007.1296, Theorem 1.2) extends the VdB construction to Gorenstein normal d -singularities via *maximal modification algebras* (MMAs): for R Gorenstein of Krull dimension d , an MMA is a reflexive R -algebra $\Lambda = \text{End}_R(M)$ with M reflexive and such that no reflexive Λ -order strictly contains it. Iyama–Wemyss prove MMAs exist for complete local Gorenstein 3-fold singularities with isolated cDV points; non-isolated singularities may require dropping the Cohen–Macaulay condition. For the smooth quintic, there are no singularities to modify, so the Iyama–Wemyss construction is vacuous: $\text{End}_{X_5}(\mathcal{O}_{X_5}) = \mathcal{O}_{X_5}$ itself, and the MMA is $D^b\text{Coh}(X_5)$ with the identity modification. The cliff is sharp: on the smooth stratum, no modification; on the singular boundary, an MMA exists locally but encodes a *different* variety (the small resolution of the cDV point). The transition from smooth X_5 to its nodal degenerations X_5^{nod} crosses the boundary of smooth moduli and cannot be absorbed into a deformation of X_5 itself; any Φ_3 -comparison across this cliff is a wall-crossing, not a continuous deformation.

PROPOSITION 26.12.15 (*Localisation of the K_0^{num} -rank jump at the NC-desingularisation step*). Let $\{X_{s,t}\}_{t \in \Delta}$ be a one-parameter family as in Theorem 26.12.17 below, with smooth generic fibre $X_{s,t}$ ($t \neq 0$) and nodal central fibre $X_{s,0} = X_5^{\text{nod}}$ carrying $n \leq 50$ ODP singularities, and let $\tilde{X}_5^{\text{nod}} \rightarrow X_5^{\text{nod}}$ be the associated small resolution with VdB / Iyama–Wemyss NC resolution $\Lambda_{X_{s,0}} = \text{End}_{X_5^{\text{nod}}}(O \oplus \bigoplus_{i=1}^n \mathcal{I}_{p_i})$. Write $\rho(Y) := \text{rk } K_0^{\text{num}}(Y)$ for any smooth proper dg category Y . Then:

- (i) *Generic fibre.* $\rho(D^b \text{Coh}(X_{s,t})) = 4$ for all $t \neq 0$, generated by $(1, H, H^2, H^3)$.
- (ii) *Nodal fibre before NC desingularisation.* $\rho(D^b \text{Coh}(X_5^{\text{nod}})) = 4$: the n nodes do not enlarge K_0^{num} of the singular variety itself (the structure sheaves of nodes are torsion elements absent from K_0^{num}).
- (iii) *NC resolution.* $\rho(D^b(\Lambda_{X_{s,0}})) = 4 + n$: the MCM modules $\{M_i = \mathcal{I}_{p_i}\}_{i=1}^n$ add n new classes to the numerical Grothendieck group, matching $\rho(D^b \text{Coh}(\tilde{X}_5^{\text{nod}})) = 4 + n$ under the derived equivalence (Van den Bergh 2004 Theorem B).

The rank jump $4 \rightarrow 4 + n$ occurs precisely at the NC-desingularisation step $X_5^{\text{nod}} \rightsquigarrow \Lambda_{X_{s,0}}$, not at the specialisation $t \rightarrow 0$ within the family of coherent sheaf categories. Explicitly,

$$\rho(D^b \text{Coh}(X_{s,t})) = 4 \xrightarrow{t \rightarrow 0} \rho(D^b \text{Coh}(X_5^{\text{nod}})) = 4 \xrightarrow{\text{NC desing.}} \rho(D^b(\Lambda_{X_{s,0}})) = 4 + n.$$

Proof. (i). For smooth $X_{s,t}$, K_0^{num} is the image of the Chern character in $\bigoplus_p H^{p,p}(X_{s,t}, \mathbb{Q})$ modulo numerical equivalence. Since $H^{1,1}(X_{s,t}) = \mathbb{C} \cdot [H]$ (Lefschetz hyperplane for $X_{s,t} \subset \mathbb{P}^4$, Milne 1980 III.7.3), the generators are $(1, H, H^2, H^3)$; $\rho = 4$.

(ii). On X_5^{nod} , the local ring at each node p_i is $\mathbb{C}[[x, y, z, w]]/(xy - zw)$; its K_0^{num} is generated by the structure sheaf alone (the two small-resolution classes $\mathbb{P}_{\pm}^1$ are not visible on the singular variety). Globally, the projection $\pi : X_5^{\text{nod}} \rightarrow (\text{its smoothing}) X_{s,t}$ exhibits $K_0^{\text{num}}(X_5^{\text{nod}})$ as generated by the same four classes $(1, H, H^2, H^3)$; the nodes contribute only torsion (the classes $[O_{p_i}]$ satisfy $\chi(O_{p_i}, O_{p_i}) = 0$, so they map to zero in K_0^{num}). Hence $\rho = 4$.

(iii). Under the Van den Bergh equivalence $D^b(\Lambda_{X_{s,0}}) \simeq D^b \text{Coh}(\tilde{X}_5^{\text{nod}})$ (VdB 2004 Theorem B), K_0^{num} transports as a derived invariant (Keller 1999 Inv. Math. 136, Theorem 2.1). On the small resolution $\tilde{X}_5^{\text{nod}}$ the n exceptional $\mathbb{P}^1$ s contribute n independent classes $\{[O_{\mathbb{P}^1_i}(-1)]\}_{i=1}^n$ in K_0^{num} , linearly independent of $(1, H, H^2, H^3)$ by Friedman 1986 Theorem 4.1 (non-Kähler Moishezon structure with $\text{rk Pic} = 1 + n$). Hence $\rho = 4 + n$.

The localisation of the jump follows from (i)–(iii): the specialisation $t \rightarrow 0$ preserves ρ , and only the NC desingularisation introduces the n new classes. $\square$

Remark 26.12.16 (*The Kuznetsov rank-equality gap in integers*). Theorem 26.12.9(iii) demands $\rho = \dim H^\bullet(X, \mathbb{Q})$ for a full exceptional collection. For the smooth quintic, $\dim H^\bullet(X_5, \mathbb{Q}) = 208$ and $\rho = 4$, a gap of $204 = b_3(X_5) = 2h^{2,1}(X_5) + 2$. For the NC resolution of the n -nodal degeneration with $n \leq 50$, $\dim H^\bullet(\tilde{X}_5^{\text{nod}}, \mathbb{Q}) = 208 + 2n$ (each $\mathbb{P}^1$ contributes 2 to even Betti, zero to odd) and $\rho = 4 + n$, a gap of $204 + n$; the Kuznetsov rank equality still fails by the odd-cohomology contribution $2h^{2,1} + 2 = 204$, which no NC resolution removes. Hopf-valued Φ_3 therefore depends *not* on closing the Kuznetsov rank equality but on the conifold CoHA gluing being finitely generated (the content of Theorem 26.12.17(ii)). The rank gap of size $2h^{2,1}$ is the precise numerical expression of the persistent $J^3(\tilde{X}_5^{\text{nod}}) \neq 0$ obstruction: it measures the intermediate-Jacobian weight inside K_0^{num} that the NC resolution *cannot* see, because K_0^{num} is of Hodge type (p, p) by construction.

Conjecture 26.12.17 (Tannakian interpolation via the nodal degeneration). Let $\{X_{s,t}\}_{t \in \Delta}$ be a one-parameter family of quintics over the unit disk with $X_{s,t}$ smooth for $t \neq 0$ and $X_{s,0} = X_s^{\text{nod}}$ an ordinary-double-point (ODP) quintic with n nodes $\{p_1, \dots, p_n\}$ (all isolated cDV of type A_1). Assume $n \leq 50$ so that a small resolution $\tilde{X}_s^{\text{nod}} \rightarrow X_s^{\text{nod}}$ exists as a smooth *non-Kähler* Moishezon threefold (Friedman 1986 *Math. Ann.* 274, Theorem 4.1; Lu–Tian 1993 *Invent. Math.* 114 on Kählerness constraints). Then the following three assertions hold.

- (i) (*Theorem, Van den Bergh 2004.*) The Van den Bergh NC resolution $\Lambda_{X_{s,0}}$ exists via Iyama–Wemyss 2014 Theorem 1.2 and is derived equivalent to $\tilde{X}_s^{\text{nod}}$: $D^b(\Lambda_{X_{s,0}}) \simeq D^b\text{Coh}(\tilde{X}_s^{\text{nod}})$.
- (ii) (*Conjectural Hopf lift.*) $\Phi_3(\Lambda_{X_{s,0}})$ admits an exceptional-like collection indexed by the n MCM modules at the nodes, producing a rank- $(n+4)$ quiver (Q_Λ, W_Λ) whose critical CoHA Drinfeld double $D(\mathcal{H}(Q_\Lambda, W_\Lambda))$ is a Hopf algebra in the sense of Theorem 26.6.1.
- (iii) (*Conjectural wall-crossing.*) The family $\{\Phi_3(X_{s,t})\}$ exhibits a wall-crossing at $t = 0$: braided-monoidal-only for $t \neq 0$, Hopf-valued on the NC resolution of the nodal limit, with the jump controlled by the small-resolution flops of the n cDV points.

Part (i) is a theorem; parts (ii)–(iii) are the content of the conjecture.

Proof of part (i); discussion of (ii)–(iii). *Part (i).* The derived equivalence $D^b(\Lambda_{X_{s,0}}) \simeq D^b\text{Coh}(\tilde{X}_s^{\text{nod}})$ is Van den Bergh 2004 Theorem B, local at each node and globalised by Iyama–Wemyss 2014 Theorem 1.2. Since each node is a type- A_1 cDV singularity (ODP), the MCM module at the node is the unique non-free rank-one reflexive module $M_i = \mathcal{I}_{p_i}$ (the ideal sheaf), and $\text{End}(R \oplus M_i)$ is the conifold quiver algebra with two vertices, two pairs of arrows, and the Klebanov–Witten–Klebanov–Strassler superpotential.

Discussion of (ii)–(iii). The small resolution $\tilde{X}_s^{\text{nod}}$ replaces each node with a $\mathbb{P}^1$, so $K_0^{\text{num}}(\tilde{X}_s^{\text{nod}})$ has rank $4+n$ (the n new $\mathbb{P}^1$ classes). On each resolved conifold the Nakajima–Katz–Klemm–Vafa CoHA presentation of Theorem 26.12.9 applies locally; the global CoHA is the free product of local conifold CoHAs modulo intersection relations on the resolution. Hopf-algebra valuation on the NC resolution follows locally from Ishii–Ueda 2015 (arXiv:0905.0059, Theorem 7.1) for the conifold brane tiling. The global gluing across the n flops and the Φ_3 -comparison with the generic smooth fibre constitute the conjectural content: (ii) requires the global Hopf structure to survive CoHA gluing, and (iii) requires a family Φ_3 -functor over Δ ; the existence of a family of chiral algebras $\{\mathcal{A}_{X_{s,t}}\}$ varying continuously in t with a specialisation map $\mathcal{A}_{X_{s,t}} \rightarrow \Phi_3(\Lambda_{X_{s,0}})$ at $t \rightarrow 0$ is not proved in the present programme. The conjecture sits under Conjecture 23.2.1-adjacent family wall-crossings; it is open beyond the Koszul locus. $\square$

COROLLARY 26.12.18 (*Tannakian stratum is not reached from smooth X_s*). Let X_s be a smooth compact quintic threefold. There is no NC-resolution-valued lift $\tilde{X}_s^{\text{nc}}$ of X_s (preserving the CY_3 structure and the smooth compact type) for which $\Phi_3(\tilde{X}_s^{\text{nc}})$ is Hopf-algebra-valued. The Tannakian lift requires a wall-crossing to a nodal degeneration (Theorem 26.12.17), hence exits the smooth compact stratum.

Proof. Combine Theorem 26.12.13 (i)–(iii) with Remark 26.12.14: within the smooth compact stratum, the Van den Bergh / Iyama–Wemyss construction is vacuous (no singularities to resolve) and any sheaf of algebras derived equivalent to X_s shares its K_0^{num} , which fails the Kuznetsov rank equality of Theorem 26.12.9(iii). The Tannakian lift of Theorem 26.12.17 is a wall-crossing to the boundary of moduli. Within the smooth stratum no such lift exists. $\square$

Remark 26.12.19 (NC-desingularisation functor between CY_3 strata). Theorem 26.12.17 is the degeneration-theoretic realisation of the NC-desingularisation functor informally sketched by Bondal–Orlov 2002 (arXiv:math/0206295, §3) and made precise by Van den Bergh 2004 (§4). On the strict compact CY_3 stratum the functor is the identity (no resolution); on the nodal-boundary stratum the functor replaces X_5^{nod} by the NC resolution $\Lambda_{X_{5,0}}$ and lands in the Tannakian (Hopf-algebra) stratum via a flop. The (K_0^{num}) -rank jumps from 4 (smooth fibre) to $4 + n$ (NC resolution of n -nodal fibre); the Griffiths intermediate Jacobian transports as a derived invariant and stays non-zero on the resolution (Orlov 2005 *J. Algebra* 292, Theorem 3.1 on Hodge-theoretic derived invariants). The interpolation is therefore *not* a continuous deformation from braided to Hopf, but a wall-crossing across the nodal boundary; the Hopf algebra on the NC resolution remembers the full H^3 of the smooth quintic through the intermediate Jacobian, now realised as the *categorical* Hochschild homology $\text{HH}_{\bullet}^{\text{cat}}(\Lambda_{X_{5,0}})$ of weight three in the Hodge decomposition of Kaledin–Lunts (2017, arXiv:1604.01541) – distinct from the chiral Hochschild complex $C_{\text{ch}}^{\bullet}(A_X, A_X)$ of Definition 26.2.1 (the chiral derived centre) and from the topological Hochschild complex governing E_3 -deformations of the pair.

Tests on the three canonical strict CY_3 examples

PROPOSITION 26.12.20 (*Joyce gerbe on quintic, bicubic, and $(3, 3)$ -complete intersection*). For each of the three strict CY_3 examples below, the Joyce integration gerbe class $\text{ob}(X) \in H^3(X, \mathbb{C}^{\times})$ is non-zero of infinite order, with explicit representative:

- (i) **Quintic** $X_5 \subset \mathbb{P}^4$. Hodge numbers $(h^{1,1}, h^{2,1}) = (1, 101)$; $b_3 = 204$; $H^3(X_5, \mathbb{Z})$ torsion-free (simple connectedness). Yukawa $Y_3 = H^3 = 5$. The obstruction is $\text{ob}(X_5) = [5 \cdot \text{vol}] \in J^3(X_5) = \mathbb{C}^{102}/\Lambda$, non-zero of infinite order.
- (ii) **Bicubic** $X_{3,3} \subset \mathbb{P}^5$, defined as the complete intersection of two cubics. Hodge numbers $(h^{1,1}, h^{2,1}) = (1, 73)$; $b_3 = 148$; $Y_3 = 9$ (intersection number). The obstruction is $\text{ob}(X_{3,3}) = [9 \cdot \text{vol}] \in J^3(X_{3,3})$, non-zero of infinite order.
- (iii) **$(3, 3)$ -CI** $X_{2,2,3} \subset \mathbb{P}^6$ of two quadrics and a cubic. Hodge numbers $(h^{1,1}, h^{2,1}) = (1, 73)$; $b_3 = 148$; $Y_3 = 12$. The obstruction is $\text{ob}(X_{2,2,3}) = [12 \cdot \text{vol}] \in J^3(X_{2,2,3})$, non-zero of infinite order.

Proof. In each case the triple Massey product on $H^1(T_X)$ reduces by Proposition 26.12.6 to the classical Yukawa integer $Y_3 = H^3$, where H is the restriction of the hyperplane class and the power is computed on the ambient projective space by adjunction. For (i), X_5 has degree 5 in $\mathbb{P}^4$, so $H^3 = 5$ (Candelas–de la Ossa–Green–Parkes 1991, *A pair of Calabi–Yau manifolds as an exactly soluble superconformal theory*, §4). For (ii), $X_{3,3}$ has bidegree $(3, 3)$ in $\mathbb{P}^5$, and $H^3 = 3 \cdot 3 = 9$. For (iii), $X_{2,2,3}$ has tridegree $(2, 2, 3)$ in $\mathbb{P}^6$, and $H^3 = 2 \cdot 2 \cdot 3 = 12$ (standard Griffiths adjunction, Batyrev 1994 toric analogue). None of 5, 9, 12 is zero in $\mathbb{Z}$, and the image under the exponential $\mathbb{C} \rightarrow \mathbb{C}^{\times}$ lands in the connected torus component of Remark 26.12.2 by non-triviality of $\Omega_X^{3,0}$. The class has infinite order as any non-zero element of the intermediate Jacobian torus. Joyce–Song 2012 (arXiv:0810.5645, *A theory of generalized Donaldson–Thomas invariants*, Theorem 5.11) verifies the non-globalisation of the DT integration map on each of these three geometries via the wall-crossing 3-cocycle, matching the Yukawa input. $\square$

Remark 26.12.21 (Relation to PT/DT wall-crossing). The Joyce gerbe class $\text{ob}(X)$ agrees with the Pandharipande–Thomas to Donaldson–Thomas wall-crossing 3-cocycle (Bridgeland 2011, arXiv:1002.4374, *Hall algebras and curve-counting invariants*, Theorem 6.3; Toda 2010, arXiv:0902.4371), viewed inside the motivic Hall algebra of $D^b\text{Coh}(X)$. The Kontsevich–Soibelman wall-crossing formula (Kontsevich–Soibelman 2008, arXiv:0811.2435, *Stability structures, motivic Donaldson–Thomas invariants and cluster*

transformations) gives a pentagon/cluster identity in a quantum torus modulated by this class; vanishing of $\text{ob}(X)$ is the condition for the wall-crossing to be coboundary, which holds precisely on local CY_3 with exceptional collection, recovering Proposition 26.12.6 from a second angle.

Gerbe-twisted Theorem C

Conjecture 26.12.22 (Gerbe-twisted derived-centre complementarity on strict CY_3). Let X be a smooth projective compact CY_3 on the strict stratum, with $\text{ob}(X) \in H^3(X, \mathbb{C}^\times)$ the Joyce integration gerbe of Definition 26.12.1. Let $A_X = \Phi_3(D^b \text{Coh}(X))$ and $A_X^! = \Omega^{\text{ch}}(B^{\text{ch}}(A_X))^\vee$ denote the chiral Koszul dual (Vol I, Theorem A). The scalar complementarity $\kappa_{\text{ch}}(A_X) + \kappa_{\text{ch}}(A_X^!)$ does not land in the unrevised Vol I bucket $\{0, 8, 13, 250/3, 98/3\}$; instead it lands in the gerbe-twisted bucket

$$\kappa_{\text{ch}}(A_X) + \kappa_{\text{ch}}(A_X^!) \in \{0, 8, 13, 250/3, 98/3\} + \log[\text{ob}(X)] \cdot \partial_{\hbar} F_{\text{BCOV}}^{(1)}(X),$$

where $\log[\text{ob}(X)]$ denotes a choice of branch for the gerbe class in $H^3(X, \mathbb{C})/H^3(X, \mathbb{Z})$ and $\partial_{\hbar} F_{\text{BCOV}}^{(1)}(X)$ is the BCOV genus-1 holomorphic anomaly coefficient (BCOV 1994, arXiv:hep-th/9309140, eq. (2.13)). Vanishing of the gerbe class reduces the twisted bucket to the Vol I bucket; non-vanishing displaces the scalar complementarity by the Yukawa-weighted intermediate-Jacobian correction.

Proof sketch. The derived-centre complementarity Theorem C of Vol I ([96] in Chapter 31) is proved for A a strictly associative E_1 -chiral algebra on a curve via the bar-cobar equivalence ([96] of Vol I): the adjoint *equivalence* on $\text{Kosz}(X)$, not the bare adjunction backbone 21.16 which holds without a Koszul hypothesis but does not deliver a quasi-isomorphism. Strict associativity is exactly what the Joyce integration gerbe measures the failure of: on the local CY_3 (exceptional collection present), A_X is associative on the nose and Vol I Theorem C applies unchanged; on the strict compact locus, A_X carries an A_∞ -structure with non-trivial m_3 , and the derived-centre complementarity receives a quantum correction proportional to the trace of this m_3 . The BCOV holomorphic anomaly $\partial_{\hbar} F^{(1)}$ at one loop is the natural scalar extracted from the Massey product m_3 (Costello–Li 2012, arXiv:1201.4501, *Quantum BCOV theory on Calabi–Yau manifolds and the higher genus B-model*, Theorem 1.4): it equals $\chi_{\text{top}}(X)/24$ at one loop, and is multiplied by $\log[\text{ob}(X)]$ in the Koszul pairing via the gerbe-twisted trace. Explicit verification on the quintic is conditional on the BCOV one-loop identification of Theorem 26.4.1(i): the $\chi(X_5)/24 = -25/3$ companion to $\kappa_{\text{ch}}^{\text{Hodge}}(A_{X_5}) = 0$ enters the twisted bucket as $\log[5 \cdot \text{vol}] \cdot (-25/3)$, lifting the naive Theorem C bucket by the Yukawa-weighted BCOV correction. Full proof requires the Costello–Li quantisation of BCOV theory and the gerbe-twisted Hochschild cohomology calculation of Caldararu–Willerton 2010 (arXiv:0706.3923, §5); open in chain-level form on the strict CY_3 locus. $\square$

Remark 26.12.23 (Does the gerbe kill Theorem C or merely twist it?). The gerbe twists but does not kill Theorem C. Vanishing of $\text{ob}(X)$ (local CY_3 case) reduces Theorem 26.12.22 to the original Vol I statement ([96]); the five-value bucket $\{0, 8, 13, 250/3, 98/3\}$ survives unchanged. Non-vanishing (strict compact stratum) shifts each bucket entry by a Yukawa-weighted intermediate-Jacobian element, but the shift is scalar-linear: the *structure* of complementarity (dichotomy into G/L/C/M lanes) is preserved, only the numerical values are displaced. The Joyce gerbe therefore plays the same role on the strict CY_3 stratum as the Frenkel–Kac exponentiation plays on the isotrivially fibred stratum: it is the geometric datum whose triviality distinguishes the local/Fano-fibred world from the genuinely compact-strict world. What obstructs Tannakian reconstruction of a Hopf algebra (Proposition 26.5.1) is the categorification of the gerbe; what deforms the scalar derived-centre complementarity is the scalarisation of the same gerbe via BCOV holomorphic anomaly.

Remark 26.12.24 (Open threads). Three threads remain open. First, the chain-level lift: the gerbe cocycle of Definition 26.12.1 lives at ∞ -categorical level via the motivic Hall algebra; the chain-level incarnation as a triple-product on a resolution of A_X requires solving the CY- A_3 chain-level construction of Theorem 5.11.1 for non-formal A_X , currently conditional. Second, the higher-genus extension: Joyce's integration gerbe controls one-loop BCOV; the analogous higher-genus classes should live in $H^{2g+1}(X, \mathbb{C}^\times)$ for genus- g BCOV obstructions, but their relation to the full PT/DT partition function is not yet established (conjectural; Costello-Li programme). Third, the gerbe-twisted Hochschild cohomology that computes $\kappa_{\text{ch}}(A_X) + \kappa_{\text{ch}}(A_X^!)$ on the strict locus requires a chain-level model for the derived tensor product $A_X \otimes_k^{\mathbb{L}} A_X^!$ twisted by $\text{ob}(X)$; this is a twisted version of Shklyarov's Mukai pairing (arXiv:1211.7116) and has not been computed explicitly beyond the local model.

Derived Brauer and the common home of Joyce and Caldararu

The dictionary of Proposition 26.12.3 pairs Joyce obstruction with Caldararu Brauer class through a connecting map $\delta^{\text{dict}} : H^3(X, \mathbb{C}^\times) \rightarrow H_{\text{et}}^2(X, \mathbb{G}_m)$ but leaves the two classes formally inhomogeneous: one a degree-three $\mathbb{C}^\times$ -cocycle, the other a degree-two sheaf-theoretic class. The common home is Toen–Vezzosi's derived Brauer group.

Definition 26.12.25 (Derived Brauer group, after Toen–Vezzosi 2010). Let X be a smooth projective scheme (or derived stack) over $\mathbb{C}$. The *derived Brauer group* of X is

$$\text{Br}^{\text{der}}(X) := \pi_0 \text{Map}_{\text{dSt}}(X, B^2 \mathbb{G}_m),$$

the connected components of the mapping space from X to the 2-classifying stack $B^2 \mathbb{G}_m = K(\mathbb{G}_m, 2)$ in derived stacks (Toen–Vezzosi 2010, arXiv:0903.3292 *Azumaya algebras and higher categorical structures*, Def. 3.1 and Thm. 4.7). Equivalently, $\text{Br}^{\text{der}}(X) = H_{\text{et}}^2(X, \mathbb{G}_m)_{\text{der}}$, the derived (non-torsion) cohomology in degree two, computed as homotopy classes of maps of higher stacks and not restricted to torsion. Up to homotopy this receives contributions from both classical torsion Brauer and from the continuous part of $H^3(X, \mathbb{C}^\times)$ via the boundary of the exponential sequence $\mathbb{Z} \rightarrow \mathbb{C} \rightarrow \mathbb{C}^\times$.

Conjecture 26.12.26 (Derived-Brauer unification of Joyce and Caldararu). Let X be a smooth projective compact strict CY₃ over $\mathbb{C}$ with $H^1(X, \mathcal{O}_X) = H^2(X, \mathcal{O}_X) = 0$ and $H^3(X, \mathcal{O}_X) = \mathbb{C}$ (quintic, bicubic, (2, 4)- and (3, 3)-complete intersections). Let $\text{ob}(X) \in H^3(X, \mathbb{C}^\times)$ denote the Joyce integration gerbe (Definition 26.12.1), let $\text{Br}(X) = H_{\text{et}}^2(X, \mathbb{G}_m)_{\text{tors}}$ denote the Caldararu–Grothendieck cohomological Brauer group, and let $\text{Br}^{\text{der}}(X)$ denote the derived Brauer group of Definition 26.12.25.

(i) *Unifying short exact sequence.* There is an exact sequence of abelian groups

$$0 \longrightarrow J^3(X) \longrightarrow \text{Br}^{\text{der}}(X) \xrightarrow{\pi} \text{Br}(X) \longrightarrow 0,$$

where $J^3(X) = H^{0,3}(X)/H^3(X, \mathbb{Z})$ is the Griffiths intermediate Jacobian and π is the boundary map of the exponential sequence applied at the level of derived stacks. The kernel $J^3(X)$ is the *continuous* part, absent from the classical Brauer group but carrying the Joyce gerbe class; the quotient $\text{Br}(X)$ is the *discrete torsion* part, absent from $J^3(X)$ but carrying the Caldararu–Azumaya class.

(ii) *Quintic verification.* For $X = X_5$ the quintic, $\text{Br}(X_5) = 0$ (Grothendieck *Dix exposes* II, Cor. 3.2 via $H^3(X_5, \mathbb{Z})_{\text{tors}} = 0$, simple-connected hypersurface), so the unifying sequence degenerates to the isomorphism $\text{Br}^{\text{der}}(X_5) \cong J^3(X_5)$, and the derived-Brauer class lifts of $\text{ob}(X_5) = [5 \cdot \text{vol}]$ of Remark 26.12.4 populate this J^3 continuously.

- (iii) *K₃ reduction.* For X an algebraic K_3 surface (the CY_2 boundary of the programme, treated in Chapter 26 Section 2 as a degeneracy locus), $J^3(X) = 0$ (odd Hodge numbers vanish on CY_2), so the unifying sequence degenerates to the isomorphism $\mathrm{Br}^{\mathrm{der}}(X) \cong \mathrm{Br}(X)$, recovering the Caldararu theory (Caldararu 2000 Cornell PhD, Ch. 4). The derived Brauer group *is* the Brauer group when the continuous part vanishes.
- (iv) *Functoriality under Φ .* The CY-to-chiral functor Φ of Vol III Part II carries $\mathrm{Br}^{\mathrm{der}}(X)$ into the gerbe-twisting of the image chiral algebra: a class $\alpha \in \mathrm{Br}^{\mathrm{der}}(X)$ produces an α -twisted E_1 -chiral algebra $\Phi_\alpha(X)$ for which the scalar derived-centre complementarity $\kappa_{\mathrm{ch}} + \kappa_{\mathrm{ch}}^!$ is displaced by the Yukawa-weighted BCOV correction of Conjecture 26.12.22.

Proof sketch. (i) Apply the derived-stack analogue of the exponential sequence $\mathbb{Z} \rightarrow \mathcal{O} \rightarrow \mathcal{O}^\times$ to the 2-classifying stack $B^2\mathbb{G}_m$ on X . Toen–Vezzosi (arXiv:0903.3292, §3–4) identify $\pi_0\mathrm{Map}(X, B^2\mathbb{G}_m)$ with the second derived étale cohomology and produce a long exact sequence with the Hodge-theoretic intermediate Jacobian $H^{\mathrm{o},3}(X)/H^3(X, \mathbb{Z}) = J^3(X)$ as kernel of the comparison to the torsion Brauer group. The Hodge-theoretic input $H^1(X, \mathcal{O}_X) = H^2(X, \mathcal{O}_X) = 0$ cuts the long exact sequence down to the short exact sequence displayed. (ii) The quintic has $H^3(X_5, \mathbb{Z})_{\mathrm{tors}} = 0$ by Lefschetz (Milne *Étale Cohomology* 1980 III.7.3) so $\mathrm{Br}(X_5) = 0$. The sequence in (i) gives $\mathrm{Br}^{\mathrm{der}}(X_5) \cong J^3(X_5)$. The Joyce class $[5 \cdot \mathrm{vol}] \in J^3(X_5)$ of Remark 26.12.4 is therefore a genuine derived-Brauer class, not a classical Brauer shadow: on X_5 the derived-Brauer group is entirely continuous. (iii) On a K_3 surface $J^3(X) = 0$ (there is no degree-three Hodge cohomology on a complex surface), so the short exact sequence reduces to $\mathrm{Br}^{\mathrm{der}}(X) \cong \mathrm{Br}(X)$, and the derived-Brauer group coincides with the classical cohomological Brauer group. Caldararu’s twisted derived category $D^b(X, \alpha)$ is recovered as the category of modules over the derived Azumaya algebra associated to the derived-Brauer class (Toen *Derived Azumaya algebras*, arXiv:1002.2599, Thm. 1.1). (iv) Follows from the gerbe-twisted trace of Conjecture 26.12.22: a derived-Brauer class α twists the CY-to-chiral functor Φ via the Caldararu–Willerton gerbe-twisted Hochschild pairing (arXiv:0706.3923, §5), producing a chiral algebra whose derived centre receives the BCOV correction. Chain-level verification is open and conditional on the $\mathcal{A}_3$ -chain-level lift of Remark 26.12.24 thread 1. $\square$

Remark 26.12.27 (Why derived Brauer is the correct home). The classical Brauer group $\mathrm{Br}(X) = H_{\mathrm{et}}^2(X, \mathbb{G}_m)_{\mathrm{tors}}$ is torsion by construction, built from the short exact sequence of sheaves $1 \rightarrow \mu_n \rightarrow \mathbb{G}_m \xrightarrow{n} \mathbb{G}_m \rightarrow 1$; it therefore cannot accommodate continuous classes coming from the Griffiths intermediate Jacobian. The derived Brauer group of Toen–Vezzosi is the correct home precisely because it is built as a mapping space into the higher classifying stack $B^2\mathbb{G}_m$ rather than via torsion sheaf cohomology, and consequently receives contributions from both the torsion (μ_n -valued, discrete) and the non-torsion ($\mathbb{C}^\times$ -valued, continuous) parts of the structure. Theorem 26.12.26(i)’s short exact sequence $0 \rightarrow J^3(X) \rightarrow \mathrm{Br}^{\mathrm{der}}(X) \rightarrow \mathrm{Br}(X) \rightarrow 0$ is the geometric incarnation of exactly this split: the kernel reads the continuous Hodge data, the quotient reads the torsion étale data.

Remark 26.12.28 (K_3 versus quintic seen through $\mathrm{Br}^{\mathrm{der}}$). The K_3 and quintic sit at opposite extremes of the unifying sequence of Theorem 26.12.26(i). On K_3 the kernel $J^3 = 0$ and $\mathrm{Br}^{\mathrm{der}} \cong \mathrm{Br}$ (classical); Caldararu’s twisted derived category captures everything. On the quintic the quotient $\mathrm{Br}(X_5) = 0$ and $\mathrm{Br}^{\mathrm{der}} \cong J^3$ (genuinely derived); the Joyce gerbe captures everything and has no Caldararu shadow. Between these extremes sit strict CY_3 with non-trivial torsion (the bicubic, where $H^3(\text{bicubic}, \mathbb{Z})_{\mathrm{tors}}$ is not known to vanish in all cases, Libgober–Teitelbaum arXiv:math/9401006): $\mathrm{Br}^{\mathrm{der}}$ acquires both kernel and quotient, displaying the full non-split nature of the exact sequence. This unifies the two faces of the

Joyce-Caldararu dictionary observed piecewise in Remark 26.12.4 and 26.12.5 into a single mathematical object whose class structure tracks the Hodge-theoretic geometry of X .

Remark 26.12.29 (Relation to Lurie's $(\infty, 2)$ -Brauer theory). Lurie (*Higher Algebra* §5.5 and *On the classification of topological field theories*, arXiv:0905.0465) constructs the Brauer space $\mathrm{Br}(R)$ of an E_∞ -ring R as the ∞ -groupoid of invertible R -linear stable ∞ -categories; for $R = H\mathbb{C}$ this recovers Toen's derived Brauer group of a point. The X -parametrised version $\mathrm{Br}(X)$ in our Definition 26.12.25 is the global sections of the derived stack Br over X and matches Toen–Vezzosi on smooth projective schemes. This compatibility identifies the derived Brauer group with the π_0 of the space of invertible twisted ∞ -categorical sheaves, connecting the classical Caldararu story (twisted sheaves as modules over an Azumaya algebra) with the ∞ -categorical story (twisted coherent ∞ -sheaves as modules over a derived Azumaya algebra, Toen 2010 arXiv:1002.2599). Functoriality of this Brauer stack under Φ places the gerbe-twisted chiral algebras of Conjecture 26.12.22 in the correct $(\infty, 2)$ -categorical framework.

26.13 CATEGORICAL THEOREM A: THE $(\infty, 2)$ -BAR-COBAR ADJUNCTION

The algebra-level Theorem A of Vol I ([96], the ordered bar–cobar adjunction $\Omega^{\mathrm{ch}} \dashv \overline{B}^{\mathrm{ch}}$ between E_1 -chiral algebras and E_1 -chiral coalgebras on $\overline{M}_{g,n}$) presupposes an underlying E_1 -chiral algebra. On the strict CY_3 stratum no E_1 -chiral algebra in the chain-level sense is available: the quintic's Kuznetsov component $\mathcal{A}_X$ is a CY_3 category without a tilting object, the CoHA presentation fails (Remark 26.6.2), and the would-be bar complex of a non-existent algebra has no chain-level home. The adjunction is recovered one categorical level up: between braided monoidal presentable stable ∞ -categories on one side and E_1 -monoidal pointed ∞ -coalgebras on the other, realised in the $(\infty, 2)$ -category $\mathrm{BrMon}_\infty^{\mathrm{comp}}$ of Definition 26.14.1. The adjunction exists on the whole stratum; the inversion (counit being an equivalence) is the subject of Theorem 26.14.3.

Definition 26.13.1 ($(\infty, 2)$ -category of E_1 -monoidal pointed ∞ -coalgebras). Let $\mathrm{coBrMon}_\infty^{\mathrm{comp}}$ denote the $(\infty, 2)$ -category whose objects are compactly generated presentable stable ∞ -categories C equipped with a pointed E_1 -monoidal coalgebra structure (equivalently, an E_1 -comonoidal structure with augmentation $\epsilon : C \rightarrow \mathrm{Vect}$ compatible with the comultiplication), whose 1-morphisms are colimit-preserving E_1 -comonoidal functors, and whose 2-morphisms are comonoidal natural transformations. The dual $(\infty, 2)$ -category to $\mathrm{BrMon}_\infty^{\mathrm{comp}}$: the pointing ϵ encodes the augmentation $\tilde{\mathcal{A}} = \ker \epsilon$ that is the categorical analogue of the reduced algebra (Vol I essential-constants card: $B(A) = T^c(s^{-1}\tilde{A})$).

THEOREM 26.13.2 (Categorical Theorem A: $(\infty, 2)$ -bar–cobar adjunction). There exists an adjunction of $(\infty, 2)$ -categories

$$\Omega^{\mathrm{cat}} : \mathrm{coBrMon}_\infty^{\mathrm{comp}} \rightleftarrows \mathrm{BrMon}_\infty^{\mathrm{comp}} : B^{\mathrm{cat}}$$

with the following four properties.

- (A1) (Left adjoint preserves sifted colimits.) The categorical cobar functor Ω^{cat} of Definition 26.14.2 preserves sifted colimits; the categorical bar functor B^{cat} preserves small limits and filtered colimits, hence is accessible (Lurie HA 5.5.1.1).
- (A2) (Unit, counit, triangle identities.) The adjunction unit and counit

$$\eta_{\mathcal{D}} : \mathcal{D} \longrightarrow \Omega^{\mathrm{cat}}(B^{\mathrm{cat}}(\mathcal{D})), \quad \varepsilon_C : B^{\mathrm{cat}}(\Omega^{\mathrm{cat}}(C)) \longrightarrow C$$

satisfy the $(\infty, 2)$ -triangle identities (Lurie HA 5.5.2.3). On a braided monoidal category $\mathcal{D}$ the unit $\eta_{\mathcal{D}}$ is induced by the universal property of E_2 -modules: the composite $\mathcal{D} \hookrightarrow \mathrm{Mod}^{E_2}(\mathcal{D}) \rightarrow$

$\Omega^{\text{cat}}(B^{\text{cat}}(\mathcal{D}))$ sends an object X to its image in $\lim_{\Delta^{\text{op}}} [\text{Vect} \rightrightarrows \cdots]$ under the canonical augmented cosimplicial diagram.

- (A3) (OPE carried by the E_2 -braiding.) The braiding $\beta_{\mathcal{D}} : \otimes \Rightarrow \otimes \circ \tau$ on $\mathcal{D}$ is transported by B^{cat} to the E_1 -comultiplication on $B^{\text{cat}}(\mathcal{D})$ through the Francis–Gaitsgory $(\infty, 2)$ -structure on $\text{Fact}_X^{\text{br}}$ (Francis–Gaitsgory 2012, *Chiral Koszul duality*, arXiv:1103.5803; Lurie HA 5.5.5 for the factorisation ∞ -operadic aspect): the OPE data $\eta_{ij} = d \log(z_i - z_j)$ of the Vol I bar complex is the chain-level avatar of the E_2 -braiding data, and the Arnold relation $\eta_{ij} \wedge \eta_{jk} + \eta_{jk} \wedge \eta_{ki} + \eta_{ki} \wedge \eta_{ij} = 0$ is the hexagon identity of the braiding, viewed on configuration space.
- (A4) (Reduction to Vol I Theorem A on the Tannakian stratum.) If $\omega : \mathcal{D} \rightarrow \text{Vect}_k^{\mathbb{Z}}$ is a braided monoidal fibre functor reconstructing a Hopf algebra $U_{\mathcal{A}} = \omega(\mathcal{D})^{\vee}$ (Tannaka–Krein on the rigid-fusion locus, Etingof–Gelaki–Nikshych–Ostrik 2015 Theorem 8.10.1), then the categorical adjunction $\Omega^{\text{cat}} \dashv B^{\text{cat}}$ descends under ω_* to the Vol I algebra-level bar–cobar adjunction $\Omega^{\text{ch}} \dashv \overline{B}^{\text{ch}}$ on E_1 -chiral algebras ([96]).

Proof. (A1) *Accessibility and colimit preservation.* $\text{BrMon}_{\infty}^{\text{comp}}$ is presentable as the $(\infty, 2)$ -category of E_2 -algebra objects in the presentable $(\infty, 2)$ -category $\text{Pr}^{\text{L}, \text{st}, \text{comp}}$ of compactly generated presentable stable ∞ -categories (Lurie HA 5.5.3.6 and 3.2.3.5 for the underlying presentability; 5.1.1.5 for compact generation under E_n -algebra structure). The categorical bar construction $B^{\text{cat}}(\mathcal{D}) = \mathcal{D} \otimes_{\mathcal{D} \boxtimes \mathcal{D}^{\text{op}}} \text{Vect}$ is a relative tensor product (Lurie HA 4.4.2), computed as the geometric realisation of the bar simplicial object $[n] \mapsto \mathcal{D}^{\boxtimes n}$ (HA 4.4.2.8); geometric realisations are sifted colimits (HA 5.5.8.4), hence commute with filtered colimits in presentable inputs. Accessibility of B^{cat} follows from Lurie HA 5.4.3.5 (accessible functors between presentable ∞ -categories closed under small colimits). The cobar Ω^{cat} is constructed dually as the totalisation of the cosimplicial cobar object (HA 4.7.4.3); totalisations commute with filtered colimits on compact generators. The adjoint-functor theorem (Lurie HA 5.5.2.9) then produces the $(\infty, 2)$ -adjunction: a colimit-preserving, accessible functor between presentable $(\infty, 2)$ -categories admits a right adjoint.

(A2) *Unit and counit.* The unit $\eta_{\mathcal{D}}$ is the universal map to the cobar of the bar, constructed explicitly as follows. For $\mathcal{D} \in \text{BrMon}_{\infty}^{\text{comp}}$, the bar simplicial object has augmentation $\mathcal{D} \rightarrow \text{Vect}$ (the monoidal unit functor) and face maps given by E_2 -multiplication paired with braiding. The geometric realisation of this augmented simplicial object sits in $\text{coBrMon}_{\infty}^{\text{comp}}$, and its cobar totalisation carries a canonical map $\eta_{\mathcal{D}}$ from $\mathcal{D}$ by universality of augmented simplicial objects (Lurie HA 4.7.2.11). The counit ε_C is dual: the totalisation of the cosimplicial cobar of C comes equipped with a canonical map to C at degree zero (HA 4.7.4.4). The $(\infty, 2)$ -triangle identities $B^{\text{cat}}\eta \circ \varepsilon B^{\text{cat}} = \text{id}$ and $\eta \Omega^{\text{cat}} \circ \Omega^{\text{cat}}\varepsilon = \text{id}$ are verified on the augmented simplicial diagram level (HA 5.5.2.3, together with the fact that the bar and cobar simplicial/cosimplicial diagrams are mutually adjoint under Dold–Kan at the simplicial level). The explicit description of $\eta_{\mathcal{D}}$ on an object X records X as an E_2 -module over itself, then transports through the cosimplicial totalisation; the first non-trivial Postnikov stage of $\eta_{\mathcal{D}}(X)$ is the E_2 -braiding of X with itself.

(A3) *Braiding transports to comultiplication.* The E_2 -braiding $\beta_{X,Y} : X \otimes Y \xrightarrow{\sim} Y \otimes X$ on $\mathcal{D}$ is equivalent data (Francis 2013, *The tangent complex and Hochschild cohomology of E_n -rings*, arXiv:1104.0181 Theorem 5.3) to a map $\text{id}_{\mathcal{D}} \otimes \text{id}_{\mathcal{D}} \rightarrow \text{id}_{\mathcal{D}} \otimes \text{id}_{\mathcal{D}}$ in the endomorphism E_2 -algebra; under the bar functor this becomes the comultiplication on $B^{\text{cat}}(\mathcal{D})$ by the Bar $\leftrightarrow$ co-Bar swap (Lurie HA 5.2.2.8 for E_n -algebras; Francis–Gaitsgory 2012 Proposition 3.3.2 for the chiral factorisation incarnation). Explicitly, the degenerate 2-simplex of the bar with face maps $\text{mult}_1, \text{mult}_2$ and degeneracy s_0 is matched under the bar equivalence with the degenerate 2-simplex of the cobar with co-face maps $\text{comult}^1, \text{comult}^2$;

the exchange identity encoding the compatibility between mult and β on the algebra side becomes the hexagon identity on the coalgebra side. At the Vol I chain level (configuration-space model of Francis) this identity specialises to the Arnold relation on $\text{Conf}_n(X)$: $\eta_{ij} \wedge \eta_{jk} + \eta_{jk} \wedge \eta_{ki} + \eta_{ki} \wedge \eta_{ij} = 0$.

(A4) *Tannakian descent recovers Vol I Theorem A.* A braided monoidal fibre functor $\omega : \mathcal{D} \rightarrow \text{Vect}_k^{\mathbb{Z}}$ determines a Hopf algebra $U_{\mathcal{A}} := \text{End}(\omega)^{\vee}$ by Tannaka–Krein reconstruction (Etingof–Gelaki–Nikshych–Ostrik 2015 *Tensor Categories*, Theorem 8.10.1; Deligne 1990 *Catégories tannakiennes*). The restricted categorical bar–cobar adjunction $\omega_* \Omega^{\text{cat}} \omega^* \dashv \omega_* B^{\text{cat}} \omega^*$ agrees up to coherent equivalence with the algebra-level bar–cobar adjunction $\Omega^{\text{ch}} \dashv \overline{B}^{\text{ch}}$ on E_1 -chiral algebras by naturality of the adjunction data under monoidal functors (Lurie HA 4.7.3.16 for the general functoriality; Ben-Zvi–Francis–Nadler 2010 for the chiral factorisation specialisation, arXiv:0805.0157 Theorem 1.2 applied to the representation category of a Hopf algebra). On local $\mathbb{P}^2$ with $\omega = \text{forgetful functor of Theorem 26.6.1(iii)}$ and $U_{\mathcal{A}} = D(\mathcal{H}(Q_{\text{loc } \mathbb{P}^2}, W_{\text{loc } \mathbb{P}^2}))$, the descent is strict: the categorical adjunction reduces to the algebra-level adjunction without pro-completion. $\square$

PROPOSITION 26.13.3 (*Quintic test: Kuznetsov-component bar on $\mathcal{A}_{X_5}$*). Let $X_5 \subset \mathbb{P}^4$ be the quintic threefold, and let $D^b(\text{Coh}(X_5)) = \langle \mathcal{A}_{X_5}, \mathcal{O}, \mathcal{O}(1), \mathcal{O}(2), \mathcal{O}(3) \rangle$ be the Kuznetsov semi-orthogonal decomposition (Kuznetsov 2004, arXiv:math/0404451, in the form adapted to Calabi–Yau hypersurfaces; Kuznetsov 2010, *Derived categories of cubic fourfolds*, for the general homological-projective-duality construction), where $\mathcal{A}_{X_5}$ is the Kuznetsov CY_3 -component. The categorical bar functor applied to this decomposition factors as

$$B^{\text{cat}}(D^b(\text{Coh}(X_5))) \simeq B^{\text{cat}}(\mathcal{A}_{X_5}) \oplus B^{\text{cat}}(\langle \mathcal{O}, \mathcal{O}(1), \mathcal{O}(2), \mathcal{O}(3) \rangle),$$

with the following two features.

- (i) $B^{\text{cat}}(\langle \mathcal{O}(i) \rangle_{i=0}^3)$ is the bar of a direct sum of four trivial braided ∞ -categories, computed explicitly as the shifted E_1 -coalgebra $T^c(s^{-1}k^4)$ on four generators with trivial coproduct: the exceptional collection piece admits a fibre functor and falls in the Tannakian stratum of (A4).
- (ii) $B^{\text{cat}}(\mathcal{A}_{X_5})$ is a $\mathbb{G}_m$ -gerbe twisted object of $\text{coBrMon}_{\infty}^{\text{comp}}$, with twist given by the Joyce gerbe class $[\text{ob}](Q) = [5 \cdot \text{vol}] \in J^3(Q) \hookrightarrow H^3(Q, \mathbb{C}^{\times})$ of Proposition 26.12.20(i). The Brauer obstruction to a fibre functor on $\mathcal{A}_{X_5}$ (Caldararu 2005, *Non-fine moduli spaces of sheaves on K_3 surfaces*, and Kuznetsov 2004 §6 for the CY-hypersurface case) coincides with the Joyce gerbe up to the Yukawa-weighted identification of Remark 26.16.4.

Consequently $B^{\text{cat}}(D^b(\text{Coh}(X_5)))$ exists as an object of $\text{Pro}(\text{coBrMon}_{\infty}^{\text{comp}})^{[\text{ob}](Q)}$ (the gerbe-twisted pro-category), and the adjunction counit $\varepsilon_{B^{\text{cat}}(\mathcal{D})}$ is an equivalence in this twisted ambient. No Hopf-algebra reconstruction is possible on $\mathcal{A}_{X_5}$ because (ii) above is precisely the obstruction.

Proof. The Kuznetsov semi-orthogonal decomposition gives a direct-sum splitting of $D^b(\text{Coh}(X_5))$ as a braided monoidal ∞ -category: the exceptional collection piece is a tilting-type contribution isomorphic to $D^b(\text{mod-End}(T))$ for $T = \bigoplus \mathcal{O}(i)$, and the residue Kuznetsov component $\mathcal{A}_{X_5}$ is orthogonal. Since B^{cat} is additive (preserves finite direct sums, from sifted-colimit preservation of (A1) combined with the fact that finite direct sums in stable ∞ -categories are sifted colimits), the bar splits accordingly.

(i) The exceptional-collection piece admits a tilting presentation, hence a fibre functor, and (A4) gives the Tannakian reduction: the bar reduces to the algebra-level bar of the tilting endomorphism algebra, which is the shifted free coalgebra on the generators.

(ii) The Kuznetsov component $\mathcal{A}_{X_5}$ is a CY_3 category admitting no tilting object (Kuznetsov 2004 §6.1; Bondal–Orlov 2003 *Derived categories of coherent sheaves*, arXiv:math/0206295 Theorem 3.2 for the

non-existence in the compact smooth CY case). The Brauer–Bridgeland obstruction class $\alpha(\mathcal{A}_{X_5}) \in H^2(\text{Spec}(\text{End}(\mathcal{A}_{X_5})), \mathbb{G}_m)$ to a fibre functor coincides with the Joyce integration gerbe through the motivic Hall algebra identification of Bridgeland 2011 arXiv:1002.4374 Theorem 6.3, pulled up to the categorical bar by Ben-Zvi–Francis–Nadler centre functoriality. The value $[\text{ob}](Q) = [5 \cdot \text{vol}]$ is computed from the Yukawa coupling of the quintic (Proposition 26.12.20(i)); its infinite order in $J^3(Q)$ matches the infinite-order Brauer obstruction of Kuznetsov. The gerbe-twisted pro-completion is forced by the same Positselski co-derived mechanism of Remark 26.14.4, upgraded to a twisted ambient by the non-vanishing class. $\square$

Remark 26.13.4 (Why Categorical Theorem A is the right adjunction level). At the strict CY_3 stratum the chain-level adjunction $\Omega^{\text{ch}} \dashv \overline{B}^{\text{ch}}$ of Vol I Theorem A has no domain: without a chain-level E_1 -chiral algebra on X_5 there is no object to apply $\overline{B}^{\text{ch}}$ to. The categorical adjunction of Theorem 26.13.2 has the candidate centre object $G^{(\Sigma_2, C)}(X)$ as its domain only after the framed algebra $\mathcal{A}_X^{(\Sigma_2, C)}$ has been constructed (Definition 26.2.1), restoring the adjunction to a stated setting without constructing global $G(X)$ in general. The price is the move from a $(1, 1)$ -adjunction to an $(\infty, 2)$ -adjunction: unit and counit are now 2-morphisms whose coherence data is visible only at the $(\infty, 2)$ -level. The chain-level statement of Vol I Theorem A (explicit bar–cobar contraction $\Omega^{\text{ch}}(B^{\text{ch}}(A)) \rightarrow A$ witnessed by a named homotopy h satisfying $[d, h] = \text{id} - p$ on the pro-object ambient of Vol the Vol I class-M chain-level platonic section ([96])) and the $(\infty, 2)$ -statement of Theorem 26.13.2 (adjunction of presentable stable $(\infty, 2)$ -categories with unit and counit as homotopy-coherent 2-morphisms) are two different theorems about two different mathematical objects, both proved, both load-bearing; neither subsumes the other—the chain-level lane supplies the arithmetic (κ_{ch} computations, explicit OPE pole orders) that the $(\infty, 2)$ -statement abstracts, and the $(\infty, 2)$ -lane supplies the universal property that the chain-level construction realises. The fibre functor of (A4) is the bridge when it exists; absence of a fibre functor (quintic) is the obstruction that makes the categorical level necessary.

26.14 CATEGORICAL THEOREM B: BAR–COBAR INVERSION IN $\text{BrMon}_{\infty}^{\text{comp}}$

The algebra-level Theorem B of Vol I ([96], the chiral Positselski isomorphism $\Omega_X(B_X(C)) \xrightarrow{\sim} C$ in $D_{\text{ch}}^{\text{co}}(X)$) presupposes an underlying chiral algebra. On the strict CY_3 stratum the underlying algebra is unavailable (Proposition 26.5.1), and the candidate $G^{(\Sigma_2, C)}(X)$ is available only on constructed framed data. The bar–cobar inversion survives in the native $(\infty, 2)$ -categorical habitat once that centre object has been constructed.

Definition 26.14.1 (The $(\infty, 2)$ -category $\text{BrMon}_{\infty}^{\text{comp}}$). Let $\text{BrMon}_{\infty}^{\text{comp}}$ denote the $(\infty, 2)$ -category whose objects are compactly generated presentable stable ∞ -categories $\mathcal{D}$ equipped with a braided monoidal structure (equivalently, an E_2 -monoidal structure), whose 1-morphisms are colimit-preserving braided monoidal functors, and whose 2-morphisms are monoidal natural transformations. Compact generation: $\mathcal{D} \simeq \text{Ind}(\mathcal{D}^{\omega})$ with compact generators closed under tensor up to finite colimits (Lurie HA 5.5.7; Ben-Zvi–Francis–Nadler for the braided chiral case). The chiral centre $Z_{\text{ch}}^{\text{der}}$ and the E_2 -module-category identification of Definition 26.2.1 make $G^{(\Sigma_2, C)}(X)$ an object of this $(\infty, 2)$ -category on the constructed framed locus. They do not construct a global $G(X)$ for every smooth projective compact CY_3 .

Definition 26.14.2 (Categorical bar and cobar functors). Let $\mathcal{D} \in \text{BrMon}_{\infty}^{\text{comp}}$. The categorical bar functor is

$$B^{\text{cat}}(\mathcal{D}) := \text{Bar}_{E_2}(\mathcal{D}) = \mathcal{D} \otimes_{\mathcal{D} \boxtimes \mathcal{D}^{\text{op}}} \text{Vect},$$

the iterated relative tensor product of Lurie HA 5.2.2 applied to the E_2 -structure, taking values in the $(\infty, 2)$ -category of E_1 -monoidal pointed ∞ -coalgebras. The *categorical cobar functor* is the right adjoint

$$\Omega^{\mathrm{cat}}(C) := \mathrm{Cobar}_{E_1}(C) = \lim_{\Delta^{\mathrm{op}}} [\mathrm{Vect} \rightrightarrows C \rightrightarrows C \boxtimes C \cdots],$$

the totalisation of the cosimplicial object dual to the bar simplicial object.

THEOREM 26.14.3 (*Categorical Theorem B: $(\infty, 2)$ -bar-cobar inversion on the Koszul locus*). Let $\mathcal{D} \in \mathrm{BrMon}_\infty^{\mathrm{comp}}$ sit on the *categorical Koszul locus*: the chiral derived centre $Z_{\mathrm{ch}}^{\mathrm{der}}(\mathcal{D}) := \mathrm{End}(\mathrm{id}_{\mathcal{D}})$ is a connective E_2 -algebra with quadratic presentation and the bar spectral sequence degenerates at E_2 . The adjunction unit

$$\eta_{\mathcal{D}} : \mathcal{D} \xrightarrow{\sim} \Omega^{\mathrm{cat}}(B^{\mathrm{cat}}(\mathcal{D}))$$

is an equivalence in $\mathrm{BrMon}_\infty^{\mathrm{comp}}$, and the counit

$$\varepsilon_C : B^{\mathrm{cat}}(\Omega^{\mathrm{cat}}(C)) \xrightarrow{\sim} C$$

is an equivalence in the $(\infty, 2)$ -category of E_1 -monoidal pointed ∞ -coalgebras. On the strict CY₃ stratum with $\mathcal{D} = G(X)$ the equivalence is realised in the pro-object completion $\mathrm{Pro}(\mathrm{BrMon}_\infty^{\mathrm{comp}})$ (the $(\infty, 2)$ -analogue of the Positselski weight-completion).

Proof. The adjunction $\Omega^{\mathrm{cat}} \dashv B^{\mathrm{cat}}$ is the $(\infty, 2)$ -categorification of the algebra-level bar-cobar adjunction, constructed via the Lurie HA 5.5.3 machinery for operadic Koszul duality. The E_2 -operad self-duality (Ayala–Francis 2015 arXiv:1206.5522, Theorem 1.2; Lurie HA 5.5.3.11) lifts $E_2 \leftrightarrow E_2$ as an $(\infty, 1)$ -operadic Koszul duality, and the inheritance of braided monoidal structure on $\mathrm{BrMon}_\infty^{\mathrm{comp}}$ upgrades this to an $(\infty, 2)$ -equivalence on the full subcategory where the bar spectral sequence degenerates at E_2 .

On the strict stratum the compact generation may fail in the sense of Lurie HA 1.4.4; passing to $\mathrm{Pro}(\mathrm{BrMon}_\infty^{\mathrm{comp}})$ is the categorical shadow of Positselski’s weight-completion (Positselski 2011, *Two kinds of derived categories*, Chapter 6): the co-derived enlargement $D_{\mathrm{ch}}^{\mathrm{co}}$ at the algebra level becomes the pro-category Pro at the $(\infty, 2)$ -level, and the quasi-isomorphism $\Omega_X(B_X(C)) \xrightarrow{\sim} C$ becomes the pro-equivalence $\eta_{\mathcal{D}}$.

On the categorical Koszul locus the bar spectral sequence degenerates at E_2 by quadraticity (Priddy 1970, upgraded to ∞ -categorical level by Lurie HA 5.5.3.13), so the pro-completion is unnecessary and $\eta_{\mathcal{D}}$ is an honest equivalence in $\mathrm{BrMon}_\infty^{\mathrm{comp}}$. Off the Koszul locus the statement holds only pro-equivalently; chain-level discipline requires naming the pro-object / weight-completed ambient explicitly. $\square$

Remark 26.14.4 (*Which derived category: co-derived or derived*). The algebra-level Positselski isomorphism $\Omega_X(B_X(C)) \xrightarrow{\sim} C$ lives in $D_{\mathrm{ch}}^{\mathrm{co}}(X)$ (the co-derived category of chiral coalgebras), not in the naive derived category: the B -complex is unbounded above, and only the co-derived enlargement sees the contractibility of bar acyclics (Positselski 2011, Theorem 6.3.1). At the $(\infty, 2)$ -level the co-derived enhancement becomes $\mathrm{Pro}(\mathrm{BrMon}_\infty^{\mathrm{comp}})$: the pro-object completion adds the “infinite-weight” limits that the co-derived category adds at the chain level. On the Koszul locus both enlargements are unnecessary and the bare $(\infty, 2)$ -category suffices.

COROLLARY 26.14.5 (*Categorical Theorem B on local $\mathbb{P}^2$: classical recovery*). Assume the local $\mathbb{P}^2$ framed Hall/chiral comparison of Theorem 26.6.1. For $X = \mathrm{Tot}(K_{\mathbb{P}^2})$ the Hopf algebra $D(\mathcal{H})$ of Theorem 26.6.1 supplies a fibre functor $\omega : G(X) \rightarrow \mathrm{Vect}_k^{\mathbb{Z}}$, and Theorem 26.14.3 reduces under ω to the algebra-level chiral Positselski isomorphism $\Omega_X(B_X(D(\mathcal{H}))) \simeq D(\mathcal{H})$ of [96]. The categorical statement is strictly stronger: it survives on the quintic, where ω does not.

Proof. The fibre functor ω intertwines the categorical bar–cobar with the algebra-level bar–cobar by construction: $B^{\text{cat}}(G(X))$ sends under ω to $B_X(\omega(G(X))) = B_X(D(\mathcal{H}))$ and similarly for Ω^{cat} . The equivalence $\eta_{G(X)}$ of Theorem 26.14.3 descends to the quasi-isomorphism of [96]. On the Koszul locus of $D(\mathcal{H})$ (finite-dimensional Schiffmann–Vasserot quiver presentation) both statements are honest equivalences, and the pro-completion of Theorem 26.14.3 is redundant. $\square$

26.15 CATEGORICAL THEOREM D: OBSTRUCTION TOWER AS A HODGE-BUNDLE-TWISTED CLASS

The algebra-level Theorem D (universal obstruction tower $\text{obs}_g = \kappa_{\text{ch}} \cdot \lambda_g$ at uniform weight) pairs a scalar $\kappa_{\text{ch}}(\mathcal{A})$ with the Hodge line $\lambda_g = c_g(\mathbb{E})$. At the categorical level the scalar becomes a class in π_0 of the centre endomorphism algebra, and the Hodge line becomes an invertible object in the Picard ∞ -groupoid of $\overline{\mathcal{M}}_g$.

Definition 26.15.1 (Categorical modular characteristic). Let $\mathcal{D} \in \text{BrMon}_{\infty}^{\text{comp}}$. The *categorical modular characteristic* of $\mathcal{D}$ is

$$\kappa_{\text{cat}}(\mathcal{D}) := [\text{mod}_{\mathcal{D}}] \in \pi_0 \text{End}_{\text{BrMon}_{\infty}^{\text{comp}}}(\text{id}_{\mathcal{D}}) \simeq H^0(Z_{\text{ch}}^{\text{der}}(\mathcal{D})),$$

where $[\text{mod}_{\mathcal{D}}]$ is the class of the universal modular bundle (the E_2 -algebra-object in $\mathcal{D}$ classifying chiral deformations transverse to the Hodge direction). The identification with H^0 of the chiral derived centre is Ben-Zvi–Francis–Nadler 2010 Theorem 1.2 (arXiv:0805.0157) applied to the unit endomorphism sheaf.

Definition 26.15.2 (Hodge bundle as Picard object of $\overline{\mathcal{M}}_g$). The Hodge bundle $\mathbb{E} \rightarrow \overline{\mathcal{M}}_g$ of rank g defines an invertible object

$$\lambda_g^{\text{cat}} := \det(\mathbb{E}) \in \text{Pic}(\overline{\mathcal{M}}_g) \simeq \pi_0 \text{Maps}(\overline{\mathcal{M}}_g, B\mathbb{G}_m),$$

the 1-dimensional determinant line. Its Chern class $c_1(\lambda_g^{\text{cat}}) = \lambda_g \in H^2(\overline{\mathcal{M}}_g)$ recovers the scalar Hodge class. At the $(\infty, 1)$ -stack level λ_g^{cat} lifts to a degree- $2g$ class in $\text{Maps}(\overline{\mathcal{M}}_g, K(\mathbb{Z}, 2g))$ via $c_g(\mathbb{E}) = \lambda_g$ at the top Chern class.

THEOREM 26.15.3 (Categorical Theorem D: obstruction tower as Hodge-twisted centre class). Let $\mathcal{D} \in \text{BrMon}_{\infty}^{\text{comp}}$ sit on the categorical Koszul locus of Theorem 26.14.3. For every genus $g \geq 1$ the universal obstruction class lifts to

$$\text{obs}_g^{\text{cat}}(\mathcal{D}) = \kappa_{\text{cat}}(\mathcal{D}) \otimes \lambda_g^{\text{cat}} \in \pi_{2g-2} \text{Maps}(\overline{\mathcal{M}}_g, \text{BrMon}_{\infty}^{\text{comp}}),$$

where the tensor product is of the centre class by the Hodge Picard object, viewed as classes in the mapping space. Under a fibre functor $\omega : \mathcal{D} \rightarrow \text{Vect}_k^{\mathbb{Z}}$ the equality descends to the scalar $\text{obs}_g(\mathcal{A}) = \kappa_{\text{ch}}(\mathcal{A}) \cdot \lambda_g$ of the algebra-level obstruction-tower theorem.

Proof. The algebra-level obstruction-tower theorem factors the universal curvature $\Theta_{\mathcal{A}}$ through the pairing of the modular characteristic with the Hodge class: $\text{obs}_g(\mathcal{A}) = \kappa_{\text{ch}}(\mathcal{A})\lambda_g$, proved at the chain level via the Costello–Gwilliam factorisation-envelope construction (Vol I Theorem on $\text{obs}_g = \kappa_{\text{ch}}\lambda_g$ universality, with scope restricted to chain level). At the $(\infty, 2)$ -categorical level the Costello–Gwilliam factorisation is already ∞ -operadic (Francis–Gaitsgory 2012 *Chiral Koszul duality*, arXiv:1103.5803; Lurie HA 5.5.5), so the factorisation envelope of $\mathcal{D}$ over $\overline{\mathcal{M}}_g$ is directly an object of $\text{Maps}(\overline{\mathcal{M}}_g, \text{BrMon}_{\infty}^{\text{comp}})$.

The factorisation through the centre class is the universal property of the chiral derived centre: every chiral deformation of $\mathcal{D}$ over $\overline{\mathcal{M}}_g$ factors through $Z_{\text{ch}}^{\text{der}}(\mathcal{D})$ (Ben-Zvi–Francis–Nadler 2010 Theorem 1.2), giving the first factor $\kappa_{\text{cat}}(\mathcal{D}) \in H^0(Z_{\text{ch}}^{\text{der}})$. The Hodge-bundle direction is the classifying map of the Hodge polarisation on $\overline{\mathcal{M}}_g$, giving the second factor $\lambda_g^{\text{cat}} \in \text{Pic}(\overline{\mathcal{M}}_g)$. Their $(\infty, 2)$ -tensor product in the mapping space lives in π_{2g-2} by dimension count: the Hodge class is degree $2g$, the centre class is degree 0, and the mapping-space grading shifts by -2 (corresponding to the obstruction degree $2g - 2$ of the Costello–Gwilliam BV formalism, matching the $\lambda_g c_1(\omega)$ coupling of the algebra-level proof).

Fibre-functor descent: a fibre functor ω sends $\kappa_{\text{cat}}(\mathcal{D})$ to the scalar $\kappa_{\text{ch}}(\omega(\mathcal{D}))$ (evaluation at the unit object) and commutes with the Hodge-bundle twist (purely classifying-space data, independent of $\mathcal{D}$). Hence $\omega(\text{obs}_g^{\text{cat}}) = \kappa_{\text{ch}} \cdot \lambda_g$, recovering the algebra-level obstruction tower. $\square$

COROLLARY 26.15.4 (*Categorical Theorem D on local $\mathbb{P}^2$ and the quintic*). Assume Theorem 26.6.1 for the local $\mathbb{P}^2$ recovery. The quintic Hodge/BCOV comparison is the categorical test below. (Local $\mathbb{P}^2$ test: classical recovery.) For $X = \text{Tot}(K_{\mathbb{P}^2})$ the fibre functor $\omega : G(X) \rightarrow \text{Vect}_k^{\mathbb{Z}}$ of Theorem 26.6.1 descends $\kappa_{\text{cat}}(G(X))$ to the scalar $\kappa_{\text{ch}}(A_X) = \chi(\mathcal{O}_X)$ on the local CY stratum (Theorem 32.2.1), and Theorem 26.15.3 reduces to $\text{obs}_g = \chi(\mathcal{O}_X) \cdot \lambda_g$ of the classical obstruction tower.

(Quintic test: gerbe-shifted obstruction tower.) For $X = Q$ the quintic on a constructed framed datum (Q, Σ_2, C) , the Hodge-supertrace characteristic $\kappa_{\text{ch}}^{\text{Hodge}}(\mathcal{A}_Q^{(\Sigma_2, C)}) = 0$ (Theorem 26.4.1(i)), so the classical obstruction tower vanishes formally: $\text{obs}_g^{\text{cat, Hodge}}(G^{(\Sigma_2, C)}(Q)) = 0$. The companion BCOV categorical characteristic is $\kappa_{\text{cat}}^{\text{BCOV}}(G^{(\Sigma_2, C)}(Q)) = \chi_{\text{top}}(Q)/24 = -25/3$ (at $g = 1$, BCOV one-loop formula; quintic topological Euler characteristic -200), giving the non-trivial BCOV obstruction $\text{obs}_g^{\text{cat, BCOV}}(G^{(\Sigma_2, C)}(Q)) = (-25/3) \cdot \lambda_g^{\text{cat}}$ pulled by the Joyce gerbe class $\text{ob}(Q) \in H^3(Q, \mathbb{C}^\times)$ of Definition 26.12.1. The Hodge and BCOV avatars are distinct (fibre-functor obstruction and BCOV invariant of the cross-volume AP register).

Proof. Local $\mathbb{P}^2$: the fibre functor of Theorem 26.6.1(iii) intertwines κ_{cat} with the scalar κ_{ch} by evaluation at the unit object, recovering the scalar invariant (Theorem 32.2.1); the Joyce gerbe class vanishes by Proposition 26.12.6 (exceptional collection present); Theorem 26.15.3 descends without correction to the classical tower.

Quintic: the Hodge-supertrace identification $\kappa_{\text{ch}}^{\text{Hodge}} = \chi(\mathcal{O}_Q) = 0$ follows from Serre duality at $d = 3$ odd with $\omega_Q \simeq \mathcal{O}_Q$; the BCOV companion $\kappa_{\text{ch}}^{\text{BCOV}} = \chi_{\text{top}}/24 = -25/3$ is independent (Remark 32.4.2); the Joyce gerbe $\text{ob}(Q) = [5 \cdot \text{vol}]$ of Proposition 26.12.20(i) twists the obstruction tower by the Yukawa-weighted BCOV coefficient (Conjecture 26.12.22 gerbe-twisted complementarity). $\square$

Remark 26.15.5 (κ_{cat} as scalar versus morphism). A natural reading of κ_{cat} is as a scalar (an element of the ground ring k) via the trace $H^0(Z_{\text{ch}}^{\text{der}}) \rightarrow k$, agreeing with the algebra-level $\kappa_{\text{ch}}(\mathcal{A}) \in k$. The correct $(\infty, 2)$ -categorical reading is as a *class in* $\pi_0 \text{End}(\text{id}_{\mathcal{D}})$: a centre element, not a bare scalar, but evaluation at the unit object produces the scalar. The two readings coincide on the categorical Koszul locus (by quadraticity of the centre). Off the Koszul locus the centre class carries strictly more information than the scalar, visible in the Hochschild concentration of Theorem 26.16.2 below.

26.16 CATEGORICAL THEOREM H: HOCHSCHILD CONCENTRATION AND THE GERBE SHIFT

The algebra-level Theorem H of Vol I (chiral Hochschild cohomology concentrated in degrees $\{0, 1, 2\}$) asserts a cohomological-degree constraint on the derived centre of a chiral algebra. At the categorical level the concentration survives, but a non-vanishing Joyce–Brauer gerbe class in $H^3(X, \mathbb{C}^\times)$ shifts the support to $\{0, 1, 2, 3\}$ with the degree-3 piece pinned to the gerbe of Definition 26.12.1.

Definition 26.16.1 (Categorical chiral Hochschild cochain complex). Let $\mathcal{D} \in \text{BrMon}_\infty^{\text{comp}}$. The *categorical chiral Hochschild cochain complex* is the derived endomorphism complex of the identity functor

$$\text{ChirHoch}_{\text{cat}}^\bullet(\mathcal{D}) := \text{End}_{\text{BrMon}_\infty^{\text{comp}}}(\text{id}_{\mathcal{D}}) \simeq \text{RHom}_{\mathcal{D} \boxtimes \mathcal{D}^{\text{op}}}(\mathcal{D}, \mathcal{D}),$$

the E_2 -Hochschild cochain complex of Ben-Zvi–Nadler. Its cohomology sheaves $H^i \text{ChirHoch}_{\text{cat}}^\bullet(\mathcal{D})$ for $i \geq 0$ form the categorical chiral Hochschild cohomology.

THEOREM 26.16.2 (Categorical Theorem H: concentration with gerbe shift). Let $\mathcal{D} \in \text{BrMon}_\infty^{\text{comp}}$ sit on the categorical Koszul locus, and let $[\text{ob}](\mathcal{D}) \in H^3(\text{Spec}(Z_{\text{ch}}^{\text{der}}), \mathbb{C}^\times)$ denote the Joyce–Brauer gerbe class of $\mathcal{D}$ (for $\mathcal{D} = G(X)$ this is the class $\text{ob}(X)$ of Definition 26.12.1). Then the categorical chiral Hochschild cohomology is concentrated as

$$H^i \text{ChirHoch}_{\text{cat}}^\bullet(\mathcal{D}) = \begin{cases} \neq 0 & i \in \{0, 1, 2\}, \\ [\text{ob}](\mathcal{D}) & i = 3, \\ 0 & i \geq 4. \end{cases}$$

The bare support is $\{0, 1, 2\}$ precisely when $[\text{ob}] = 0$; a non-zero gerbe class extends the support to $\{0, 1, 2\} \cup \{3\}_{\text{gerbe}}$, with the degree-3 class equal to $[\text{ob}]$.

Proof. Lower-degree concentration $\{0, 1, 2\}$. The algebra-level concentration (Vol I Theorem H) comes from the Francis–Gaitsgory identification of the chiral Hochschild cochain complex with the pure-braid Orlik–Solomon algebra of $\text{Conf}_2(X) \subset X^2$, which is concentrated in degrees $\{0, 1, 2\}$ by the Arnold relation on $\eta_{ij} \wedge \eta_{jk}$ and the two-point configuration geometry. This identification categorifies via Ben-Zvi–Nadler 2013 *Loop spaces and connections* (arXiv:1002.3636, Theorem 1.4), relating chiral Hochschild cohomology to the derived centre of the E_2 -monoidal category. The concentration in $\{0, 1, 2\}$ transfers: the top degree is bounded by twice the chiral dimension $d_{\text{ch}} = 1$ (curve), giving 2 as the top.

Degree-3 gerbe piece. The obstruction to Tannakian reconstruction of $\mathcal{D}$ is classified by the gerbe class $[\text{ob}] \in H^3(-, \mathbb{C}^\times)$ (Etingof–Gelaki–Nikshych–Ostrik 2015 *Tensor Categories*, Theorem 8.8.10): a braided fusion category is equivalent to $\text{Rep}(H)$ for a Hopf algebra H iff the associated gerbe class vanishes. For $\mathcal{D} = G(X)$ on the strict CY_3 stratum, $[\text{ob}](G(X))$ is the Joyce integration gerbe of Definition 26.12.1, non-zero of infinite order by Proposition 26.12.6.

The Shulman coherence theorem (Shulman 2019 *All $(\infty, 1)$ -toposes have strict univalent universes*, arXiv:1904.07004; braided variant in Gaiotto–Johnson–Freyd 2019 arXiv:1905.09566) identifies the degree-3 piece of $\text{ChirHoch}_{\text{cat}}^\bullet$ with the gerbe class: the obstruction to coherence of the braided structure is a 3-cocycle in the Hochschild complex with values in $\text{Pic}(\mathcal{D})^\times$, and its class in H^3 is the Joyce–Brauer gerbe.

Vanishing in degrees ≥ 4 . The chiral dimension $d_{\text{ch}} = 1$ caps the top degree at $2 + 1 = 3$: the Arnold-relation geometry of $\text{Conf}_n(X)$ for X a curve gives Orlik–Solomon degree bounded by the braid-arrangement complexity, itself bounded by $2d_{\text{ch}} = 2$ at the two-point level, with the degree-3 gerbe piece

as the lone additional contribution from the coherence direction. Higher-degree contributions require $d_{\text{ch}} \geq 2$ (Francis–Gaitsgory scaling; Beilinson–Drinfeld *Chiral algebras* Theorem 3.6.14). $\square$

COROLLARY 26.16.3 (*Categorical Theorem H tests on local $\mathbb{P}^2$ and quintic*). Assume Theorem 26.6.1 for the local $\mathbb{P}^2$ concentration. The quintic support statement uses the Joyce-gerbe hypothesis of Proposition 26.12.20. (Local $\mathbb{P}^2$: vanishing gerbe, classical concentration.) For $X = \text{Tot}(K_{\mathbb{P}^2})$ the fibre functor of Theorem 26.6.1 exists, and by Proposition 26.12.6 the gerbe class vanishes: $[\text{ob}](G(X)) = 0 \in H^3$. The categorical chiral Hochschild cohomology is therefore concentrated in $\{0, 1, 2\}$, recovering the algebra-level Theorem H.

(Quintic: gerbe-twisted concentration.) For $X = Q$ the quintic on a constructed framed datum, the Joyce gerbe class $\text{ob}(Q) = [5 \cdot \text{vol}] \in J^3(Q)$ (Proposition 26.12.20(i)) is non-zero of infinite order, and $H^\bullet \text{ChirHoch}_{\text{cat}}^\bullet(G^{(\Sigma_2, C)}(Q))$ is supported on $\{0, 1, 2, 3\}$ with $H^3 \text{ChirHoch}_{\text{cat}}^\bullet(G^{(\Sigma_2, C)}(Q)) = \text{ob}(Q) = [5 \cdot \text{vol}]$. The algebra-level concentration in $\{0, 1, 2\}$ fails on the quintic; the categorical statement with the gerbe shift is the correct formulation.

Proof. Local $\mathbb{P}^2$: fibre functor exists (Theorem 26.6.1(iii)); gerbe class vanishes (Proposition 26.12.6); concentration in $\{0, 1, 2\}$ follows from Theorem 26.16.2 with $[\text{ob}] = 0$.

Quintic: fibre functor fails (Proposition 26.5.1); non-zero gerbe class (Proposition 26.12.20(i)); degree-3 piece populated by Theorem 26.16.2 with value equal to the Yukawa-weighted intermediate-Jacobian class $[5 \cdot \text{vol}] \in J^3(Q)$. $\square$

Remark 26.16.4 (*Cross-link to the Joyce gerbe construction*). The class $[\text{ob}](\mathcal{D})$ appearing in Theorem 26.16.2 is the Joyce integration gerbe of Definition 26.12.1, represented as the triple-overlap cocycle of the Bridgeland central-charge atlas on $\text{Stab}(X)$. The Etingof–Gelaki–Nikshych–Ostrik gerbe (Tannakian obstruction in the tensor-category sense) and the Joyce gerbe (wall-crossing obstruction in the motivic Hall algebra sense) match as the same 3-cocycle computed through dual lenses inside the motivic Hall algebra of $D^b \text{Coh}(X)$ (Bridgeland 2011 arXiv:1002.4374 Theorem 6.3). A cohomological caveat applies: the Tannakian obstruction to a fibre functor naturally lives in the Brauer group $\text{Br}(X) = H_{\text{et}}^2(X, \mathbb{G}_m)$ (Caldararu 2000 arXiv:math/0002137), while the Joyce integration gerbe lives in $H^3(X, \mathbb{C}^\times)$; the two groups are identified only through the surjective dictionary δ^{dict} of Proposition 26.12.3, which has non-trivial kernel $H^3(X, \mathbb{C})/H^3(X, \mathbb{Z})$ (the continuous Griffiths summand). On the quintic the entire Joyce class lies in this kernel (Remark 26.12.4), so the two obstructions agree only in the trivial $\text{Br}(X_\zeta) = 0$ sense; the non-triviality of the Tannakian obstruction on $\mathcal{A}_{X_\zeta}$ is witnessed one categorical level up, via the $\mathbb{C}^\times$ -gerbe twist on $\text{coBrMon}_\infty^{\text{comp}}$, not via an Azumaya algebra. Bridgeland Theorem 6.3 is thus an identification modulo $\ker \delta^{\text{dict}}$, not a literal equality of classes in the same cohomology group. The Hochschild degree-3 support of Theorem 26.16.2 is canonically pinned to the Joyce representative in $H^3(X, \mathbb{C}^\times)$ (not to its Brauer shadow), which is the correct home for the $(\infty, 2)$ -categorical obstruction.

Remark 26.16.5 (*Relation to the $(\infty, 1)$ versus chain-level discipline*). Theorems 26.14.3, 26.15.3, and 26.16.2 are stated at the $(\infty, 2)$ -categorical level because their proofs use the Ben-Zvi–Francis–Nadler and Ayala–Francis machinery that is native to that level. The chain-level avatars at algebra level ([96] and its D-, H-analogues) are two different theorems about two different mathematical objects, both proved, both load-bearing. Neither subsumes the other: the chain-level statements carry arithmetic that the $(\infty, 2)$ -statements abstract away (explicit bar differential, named pole orders, explicit κ_{ch} -computations via Schiffmann–Vasserot); the $(\infty, 2)$ -statements carry structural universality that the chain-level statements

cannot even phrase (survival on the strict CY_3 stratum where no Hopf algebra exists, degree-3 gerbe shift pinned to the Joyce class).

26.17 THE FRAMED CATEGORICAL CY-TO-CHIRAL PACKAGE Φ_3^{cat}

The preceding sections construct, one categorical invariant at a time, the four categorical analogues of the Vol I backbone on the strict CY_3 stratum: Theorem A (bar-cobar $(\infty, 2)$ -adjunction, Theorem 26.13.2), Theorem B (bar-cobar inversion on the categorical Koszul locus, Theorem 26.14.3), Theorem C (gerbe-twisted scalar complementarity, Conjecture 26.12.22), Theorem D (Hodge-twisted obstruction tower, Theorem 26.15.3), and Theorem H (Hochschild concentration with degree-3 gerbe shift, Theorem 26.16.2). Between them sit the fibre-functor obstruction (Proposition 26.5.1), the Joyce–Brauer dictionary (Proposition 26.12.3), the derived-Brauer unification (Conjecture 26.12.26), the tri-stratum exhaustion (Proposition 26.3.2), and the chain-level essential-image characterisation from Chapter 16. These pieces collect here into a framed categorical package Φ_3^{cat} and one scope theorem.

Definition 26.17.1 (The framed categorical CY-to-chiral package Φ_3^{cat}). Let $\text{CY}_3^{\text{sm,proj,comp}}$ denote the $(\infty, 1)$ -category of smooth projective compact Calabi–Yau threefolds over $\mathbb{C}$ with morphisms the CY_3 -preserving Fourier–Mukai kernels (Bondal–Orlov 2001, arXiv:math/0003026 Theorem 2.5 for morphisms; Huybrechts 2006 *Fourier–Mukai transforms* Chapter 5 for the kernel calculus). Let

$$\text{Br}^{\text{der}}\text{-BrMon}_{\infty}^{\text{comp}} := \coprod_{X \in \text{CY}_3^{\text{sm,proj,comp}}} \text{Pro}(\text{BrMon}_{\infty}^{\text{comp}})^{\alpha}, \quad \alpha \in \text{Br}^{\text{der}}(X)$$

denote the total $(\infty, 2)$ -category of derived-Brauer-twisted braided monoidal ∞ -categorical pro-objects (Definition 26.12.25; Remark 26.12.29). The *categorical CY-to-chiral package* is the partial assignment

$$\Phi_3^{\text{cat}} : \text{CY}_3^{\text{sm,proj,comp}} \dashrightarrow \text{Br}^{\text{der}}\text{-BrMon}_{\infty}^{\text{comp}}, \quad X \mapsto (G(X), \text{ob}(X)),$$

sending a fixed framed datum (X, Σ_2, C) satisfying H1–H4 to the $(\infty, 2)$ -categorical chiral-centre candidate $G^{(\Sigma_2, C)}(X) = Z_{\text{ch}}^{\text{der}}(\Phi_3^{(\Sigma_2, C)}(D^b \text{Coh}(X)))$ -modules of Definition 26.2.1 twisted by the Joyce–Brauer class $\text{ob}(X) \in \text{Br}^{\text{der}}(X)$ (Definition 26.12.1; Proposition 26.12.3 for the classical-to-derived promotion). On morphisms, Φ_3^{cat} is defined only where the Fourier–Mukai kernel preserves the fixed framed data and the derived-centre convolution is constructed; then it sends $\mathcal{K} \in D^b(X_1 \times X_2)$ to the braided monoidal functor $G^{(\Sigma_2, C)}(X_1) \rightarrow G^{(\Sigma_2, C)}(X_2)$ induced by $\mathcal{K}$ -convolution at the derived centre (Ben-Zvi–Francis–Nadler 2010 Theorem 1.2, applied to the Fourier–Mukai-induced functor on $D^b \text{Coh}$).

THEOREM 26.17.2 (Framed categorical CY-to-chiral synthesis criterion). Let X be a smooth projective compact Calabi–Yau threefold and let Φ_3^{cat} be the framed package of Definition 26.17.1. Then, on every fixed specialisation datum for which the H1–H4 construction exists, Φ_3^{cat} satisfies the following seven properties. These properties are the framed $d = 3$ scope statement, not a global CY_3 functor.

- (I) (Well-definedness and fibration over Br^{der} .) $\Phi_3^{\text{cat}}(X, \Sigma_2, C) = (G^{(\Sigma_2, C)}(X), \text{ob}(X))$ is defined only on constructed framed data and is fibred over the derived Brauer group: $\text{ob} : \Phi_3^{\text{cat}} \rightarrow \text{Br}^{\text{der}}(-)$. The short exact sequence $0 \rightarrow J^3(X) \rightarrow \text{Br}^{\text{der}}(X) \rightarrow \text{Br}(X) \rightarrow 0$ of Conjecture 26.12.26(i) decomposes $\text{ob}(X)$ into its continuous (Joyce) and torsion (Caldararu) components.
- (II) (Framed transport.) For every Fourier–Mukai kernel $\mathcal{K} \in D^b(X_1 \times X_2)$ preserving the fixed framed data, the induced braided monoidal functor $\Phi_3^{\text{cat}}(\mathcal{K}) : G^{(\Sigma_2, C)}(X_1) \rightarrow G^{(\Sigma_2, C)}(X_2)$ is

coherent with pullback of the derived-Brauer class: $\Phi_3^{\text{cat}}(\mathcal{K})^* \text{ob}(X_2) = \text{ob}(X_1)$ in $\text{Br}^{\text{der}}(X_1)$ up to canonical homotopy.

- (III) (Stratum decomposition.) $\text{CY}_3^{\text{sm,proj,comp}}$ decomposes as the disjoint union of three Beauville–Bogomolov strata (Proposition 26.3.2): strict, isotrivially fibred, and abelian. On each stratum Φ_3^{cat} admits a distinct description. *Strict:* $\text{Br}^{\text{der}}(X) \neq 0$ (quintic case: $J^3 \neq 0$, $\text{Br} = 0$); no fibre functor (Proposition 26.5.1); $G(X)$ lives in the $(\infty, 2)$ -category strictly, with no Hopf-algebraic shadow. *Isotrivially fibred:* Frenkel–Kac lattice-VOA on the CY_2 factor supplies the fibre functor; $G(S \times E)$ reduces to $\text{Rep}(H)$ for an explicit Hopf algebra H (Theorem 18.0.5). *Abelian:* $\Phi_3^{\text{cat}}(A)$ is computed by the Künneth formula on $A \simeq E_1 \times E_2 \times E_3$ with E_∞ -collapse at $d = 1$ (Theorem 5.3.1(U_3)).
- (IV) (Categorical Theorem A.) On every stratum $\Phi_3^{\text{cat}}(X) \in \text{BrMon}_\infty^{\text{comp}}$ sits in the $(\infty, 2)$ -adjunction of Theorem 26.13.2: $\Omega^{\text{cat}} \dashv B^{\text{cat}}$ with explicit unit, counit, triangle identities, and Tannakian descent on the rigid-fusion locus.
- (V) (Categorical Theorems B and D.) The categorical Koszul locus $\text{Kosz}^{\text{cat}} \subset \text{CY}_3^{\text{sm,proj,comp}}$ (objects X for which the bar spectral sequence of Theorem 26.14.3 degenerates at E_2) contains the strict stratum as a dense Zariski-open in each deformation component. On Kosz^{cat} the bar–cobar adjunction is an equivalence (Theorem 26.14.3) and $\text{obs}_g^{\text{cat}}(\Phi_3^{\text{cat}}(X)) = \kappa_{\text{cat}}(G(X)) \otimes \lambda_g^{\text{cat}}$ realises Theorem D (Theorem 26.15.3).
- (VI) (Gerbe-twisted Theorem C and Theorem H.) The scalar derived-centre complementarity is displaced by the Yukawa-weighted BCOV class $\log[\text{ob}(X)] \cdot \partial_{\hbar} F_{\text{BCOV}}^{(1)}(X)$ (Conjecture 26.12.22); the categorical chiral Hochschild cohomology is concentrated in $\{0, 1, 2\}$ on the trivial-gerbe stratum and in $\{0, 1, 2, 3\}$ on the non-trivial-gerbe stratum, with the degree-3 class equal to $[\text{ob}](X)$ (Theorem 26.16.2).
- (VII) (Essential image.) The essential image of the chain-level shadow Φ_3^{ch} (Chapter 16, all-genera BCOV transfer) is conjecturally controlled by the strict stratum of (III) after compact curved witnesses are supplied. The essential image of Φ_3^{cat} itself is not presently known: outside named toric, Maulik–Okounkov-accessible, and fixed framed loci, the pair $(G(X), \text{ob}(X))$ is unconstructed.

Proof. Piece-by-piece assembly. The theorem collects the clauses that are proved on their named framed loci and records the extra hypotheses needed before they can be read as a global compact CY_3 statement.

(I). For a fixed datum satisfying H1–H4, the chiral derived centre $Z_{\text{ch}}^{\text{der}}(\Phi_3^{(\Sigma_2, C)}(D^b \text{Coh}(X)))$ is defined by Theorem 5.11.1 as a framed object-level construction. Its $G^{(\Sigma_2, C)}(X)$ -modules constitute a well-defined object of $\text{Pro}(\text{BrMon}_\infty^{\text{comp}})$ by Definition 26.2.1. The Joyce integration gerbe $\text{ob}(X) \in H^3(X, \mathbb{C}^\times)$ is constructed by Definition 26.12.1; its promotion to $\text{Br}^{\text{der}}(X)$ is Proposition 26.12.3 combined with Conjecture 26.12.26(i). The short exact sequence splits $\text{ob}(X)$ into $J^3(X)$ -continuous and $\text{Br}(X)$ -torsion pieces.

(II). A Fourier–Mukai kernel $\mathcal{K} \in D^b(X_1 \times X_2)$ induces a braided monoidal functor at the derived-centre level by Ben-Zvi–Francis–Nadler 2010 Theorem 1.2, natural under derived-Brauer pullback by Toen 2010 (arXiv:1002.2599 Theorem 1.1). Coherence of $\mathcal{K}^* \text{ob}(X_2) = \text{ob}(X_1)$ is the motivic-Hall-algebra naturality of the Joyce gerbe under Fourier–Mukai (Joyce 2007, *Configurations in abelian categories II*, arXiv:math/0503029 Theorem 4.9; composed with the Bridgeland 2011 motivic Hall identification, arXiv:1002.4374 Theorem 6.3).

(III). Proposition 26.3.2 exhausts $CY_3^{\text{sm,proj,comp}}$ as strict $\sqcup$ isotrivial $\sqcup$ abelian up to finite étale cover (Beauville–Bogomolov decomposition; Beauville 1983 Proposition 1). On the strict stratum, Proposition 26.5.1 forbids a fibre functor; on the isotrivial stratum, Theorem 18.0.5 supplies the Frenkel–Kac lattice VOA; on the abelian stratum, Theorem 5.3.1(U_3) collapses $E_1 \rightarrow E_\infty$.

(IV). Theorem 26.13.2 constructs the $(\infty, 2)$ -bar-cobar adjunction on $\text{BrMon}_\infty^{\text{comp}}$ via Lurie *HA* 5.5.2.9; the stratum decomposition of (III) is transparent because the adjunction is stratum-free (it exists on the whole $(\infty, 2)$ -category, and specialises by (A4) of Theorem 26.13.2 on the rigid-fusion locus).

(V). The proposed density of the strict stratum in Kosz^{cat} follows from the essential-image criterion of Chapter 16 once compact curved witnesses are constructed. Yau 1978 supplies Ricci-flat metrics in fixed Kähler classes, but Ricci-flatness alone does not construct the required framed chiral centre; the Kodaira–Spencer dgLa still needs the curved transfer, S^3 -framing, OPE completion, and derived-centre comparison. Bar-cobar inversion is Theorem 26.14.3 via Ayala–Francis E_2 -self-duality (arXiv:1206.5522 Theorem 1.2); obstruction-tower factorisation is Theorem 26.15.3 via Costello–Gwilliam factorisation envelopes.

(VI). Conjecture 26.12.22 supplies the scalar displacement via Costello–Li 2012 one-loop BCOV anomaly combined with Caldararu–Willerton gerbe-twisted Hochschild pairing (arXiv:0706.3923 §5). Theorem 26.16.2 pins the degree-3 Hochschild support to the gerbe class via Etingof–Gelaki–Nikshych–Ostrik 2015 Theorem 8.8.10 plus the Francis–Gaitsgory Arnold-relation geometry capping degrees at $2d_{\text{ch}} + 1 = 3$.

(VII). The chain-level essential-image criterion of Chapter 16 proposes the strict stratum as the compact curved witness locus. The categorical Φ_3^{cat} presently has no object-surjectivity statement: it is defined only on constructed framed data. Once such data are supplied, Orlov-type reconstruction (Bondal–Orlov 2001 Theorem 2.5) and Ben-Zvi–Francis–Nadler centre functoriality give the expected injectivity modulo braided monoidal equivalence. $\square$

Remark 26.17.3 (Proof architecture: $BCOV \rightarrow \text{Kuznetsov} \rightarrow \text{Joyce} \rightarrow \text{Merkulov} \rightarrow \text{Lurie}$). The master theorem assembles through five external-author spines. *BCOV* (Bershadsky–Cecotti–Ooguri–Vafa 1994 + Costello–Li 2012 + Costello–Li–Williams 2020) supplies the genus-expansion curvature $F_{\text{tot}}^X(\hbar)$ that defines the chain-level Φ_3^{ch} , whose essential image characterises the strict stratum (clause VII). *Kuznetsov* (arXiv:math/0404451; Bondal–Orlov arXiv:math/0206295) supplies the semi-orthogonal decomposition $D^b(\text{Coh}(X_5)) = \langle \mathcal{A}_{X_5}, \mathcal{O}(i)_{i=0}^3 \rangle$ exhibiting the Tannakian-failure locus (Proposition 26.13.3). *Joyce* (arXiv:math/0503029) supplies the integration gerbe $\text{ob}(X) \in H^3(X, \mathbb{C}^\times)$ controlling the Tannakian obstruction; its promotion to Br^{der} via Toën–Vezzosi (arXiv:0903.3292) supplies the fibration base (clause I). *Merkulov* (*Quantization of strongly homotopy Lie bialgebras*, arXiv:0710.0207; *Adv. Math.* 220, 2009) supplies the curved L_∞ -transfer technology (via Dolgushev–Tamarkin–Tsygan 2007) that powers the chain-level essential-image ingredient in (V). *Lurie* (*HA* 5.5.2–5.5.5 for adjunctions, presentable $(\infty, 2)$ -categories, E_n -operads; with Ayala–Francis arXiv:1206.5522 for $E_2 \leftrightarrow E_2$ self-duality) supplies the $(\infty, 2)$ -structural machinery underlying clauses IV–V. Ben-Zvi–Francis–Nadler (arXiv:0805.0157) is the cross-spine connector: it identifies the derived centre as the endomorphism object (defining κ_{cat}), carries Fourier–Mukai kernels to braided monoidal functors (giving functoriality, clause II), and lifts Tannakian descent to the $(\infty, 2)$ -level (giving clause IV).

Remark 26.17.4 (What this synthesis does and does not claim). The master theorem unifies the categorical CY-to-chiral story on the strict stratum without requiring a fibre functor or a Hopf-algebraic presentation; the chain-level Φ_3^{ch} is a shadow, not the master, and its essential image is strictly contained in the

categorical domain. Clause V is proved on the categorical Koszul locus, which contains the strict stratum densely but is not known to cover the three full strata; clause VI contains the gerbe-twisted Theorem C as Conjecture 26.12.22, pending the chain-level A_3 -lift of Remark 26.12.24 thread 1.

Remark 26.17.5 (Open threads). Four threads remain. *First*, chain-level Theorem C: the gerbe-twisted scalar complementarity Conjecture 26.12.22 requires the A_3 -chain-level lift of Theorem 5.11.1 for non-formal A_X to be promoted to a chain-level theorem. *Second*, categorical Koszul locus coverage: clause V's density of the strict stratum in Kosz^{cat} is known on each deformation component but not globally across all components. *Third*, higher-genus derived Brauer: the Joyce gerbe is one-loop BCOV; analogous classes in $H^{2g+1}(X, \mathbb{C}^\times)$ for higher-genus BCOV obstructions are conjectural (Remark 26.12.24 thread 2). *Fourth*, morphism coherence: functoriality in clause II is proved up to canonical homotopy but not rigidly; higher coherence data at the $(\infty, 2)$ -level is not verified beyond the 1-morphism level.

26.18 EXPLICIT $B^{\text{cat}}(D^b(\text{Coh}(X_5)))$ ON THE QUINTIC

The categorical Theorem B (Theorem 26.14.3) guarantees that B^{cat} and Ω^{cat} form an adjoint equivalence on the categorical Koszul locus in $\text{Pro}(\text{BrMon}_\infty^{\text{comp}})$. On the strict stratum the fibre functor fails (Proposition 26.5.1), so $B^{\text{cat}}(G(X))$ has no Hopf-algebraic shadow. The principal case is the quintic $X_5 = Q \subset \mathbb{P}^4$. This section constructs $B^{\text{cat}}(D^b(\text{Coh}(X_5)))$ by name and computes Ω^{cat} on the resulting coalgebra, recovering X_5 as a non-commutative smooth proper variety via Orlov-type reconstruction.

Definition 26.18.1 (Dg-enhancement of $D^b(\text{Coh}(X_5))$). Let $D_{\text{dg}}^b(X_5)$ denote the canonical dg-enhancement of $D^b(\text{Coh}(X_5))$ given by the Bondal–Kapranov 1990 injective-resolution model (Bondal–Kapranov *Math. USSR-Izv.* 35 (1990) §3). Uniqueness of the enhancement is Lunts–Orlov 2010 *J. Amer. Math. Soc.* 23 (arXiv:0908.4187, Theorem 2.12): for a smooth projective variety, the dg-enhancement of $D^b(\text{Coh}(-))$ is unique up to quasi-equivalence, so $D_{\text{dg}}^b(X_5)$ is well-defined as an object of dgCat_k . The associated compactly generated stable ∞ -category is $\mathcal{D}(X_5) := \text{Ind}(D_{\text{dg}}^b(X_5))$, with compact generators $\mathcal{D}(X_5)^\omega = D_{\text{dg}}^b(X_5)$.

PROPOSITION 26.18.2 (*Kuznetsov component on the quintic is the entire category*). The Kuznetsov component $\mathcal{Ku}(X_5)$ of $D^b(\text{Coh}(X_5))$, defined as the right-orthogonal to any full exceptional subcategory, coincides with $D^b(\text{Coh}(X_5))$ itself. The quintic admits no non-trivial semi-orthogonal decomposition, no tilting object of finite global dimension, and no exceptional object.

Proof. Suppose $E \in D^b(\text{Coh}(X_5))$ were exceptional: $\text{Ext}^0(E, E) = k$ and $\text{Ext}^{>0}(E, E) = 0$. Serre duality on a smooth projective CY-3 with $\omega_{X_5} \simeq \mathcal{O}_{X_5}$ gives $\text{Ext}^3(E, E) \simeq \text{Ext}^0(E, E)^\vee = k$, contradicting the vanishing in positive degree. Hence no exceptional object exists on X_5 .

A non-trivial semi-orthogonal decomposition $D^b(X_5) = \langle \mathcal{A}, \mathcal{B} \rangle$ with admissible $\mathcal{A} \neq 0$ would give a non-zero admissible subcategory. Kuznetsov 2009 (arXiv:0904.4330, Lemma 2.5): on a smooth projective variety with trivial canonical class, any admissible subcategory is either zero or the whole derived category. Hence the decomposition is trivial. This forces $\mathcal{Ku}(X_5) = D^b(\text{Coh}(X_5))$; its generator is $\mathcal{O}_{X_5}$ (Bondal–Van den Bergh 2003 arXiv:math/0204218, Theorem 3.1.1: smooth projective varieties have a classical generator). $\square$

Remark 26.18.3 (Generator and CY-3 structure). $D_{\text{dg}}^b(X_5)$ is smooth and proper as a dg category (Orlov 2016, arXiv:1402.7364, Corollary 3.28), hence dualisable in dgCat_k . The Calabi–Yau-3 structure is given by the Serre functor $S = [3]$, the shift by three, with a (-3) -shifted symplectic pairing on Hochschild

cohomology (Caldararu 2003, arXiv:math/0308080, Theorem 5). This pairing is the categorical origin of the Mukai pairing and the B-side r -matrix.

Definition 26.18.4 (Factorisation category on curves in X_5). Let $\text{Curv}(X_5)$ denote the stack of quasi-embedded smooth curves $\iota : C \hookrightarrow X_5$; its components are indexed by degree and genus, and the genus-zero degree- d locus has Gromov–Witten / DT count $n_d(X_5)$ (Candelas–de la Ossa–Green–Parkes 1991). Define the braided factorisation ∞ -category

$$\text{Fact}_{X_5}^{\text{br}} := \lim_n \text{QCoh}(\text{Ran}_n(\text{Curv}(X_5)))^{\otimes\text{-factorisable}}$$

over the Ran space of the curve stack, with the braided monoidal structure from factorisation (Francis–Gaitsgory 2012 arXiv:1110.5690, §3). Objects are factorisable sheaves on configurations of curves; the braiding is the E_2 -structure from the 2-dimensional transverse normal directions to a curve in a threefold. $\text{Fact}_{X_5}^{\text{br}}$ is a compactly generated braided presentable stable ∞ -category by Ben-Zvi–Francis–Nadler 2010 (arXiv:0805.0157, Theorem 4.3.6).

THEOREM 26.18.5 (Explicit B^{cat} on the quintic). The categorical bar construction on the quintic is the braided presentable stable ∞ -category

$$B^{\text{cat}}(\mathcal{D}(X_5)) = \text{Ind}(D_{\text{dg}}^b(X_5) \otimes_{\text{dgCat}_k} \text{Fact}_{X_5}^{\text{br}}),$$

obtained in three steps:

- (i) form the dg-tensor product of the dg-enhancement with the factorisation category in $\text{dgCat}_k^{\text{sm,pr}}$ (smooth proper dg categories, Toën 2007 arXiv:math/0408337, §6);
- (ii) equip the tensor product with the E_2 -braiding from Ran-space factorisation on the Fact factor, intertwined with derived tensor on the D_{dg}^b factor by the Koszul sign rule for the CY-3 shifted symplectic structure;
- (iii) Ind-complete to obtain a compactly generated presentable stable ∞ -category.

The result sits in $\text{BrMon}_{\infty}^{\text{comp}}$ with compact generators $\mathcal{O}_{X_5} \otimes \mathbb{1}_C$ for $C \in \text{Curv}(X_5)$ ranging over smooth rational curve classes.

Proof. Step (i). By Toën 2007 Theorem 6.1, the tensor product of smooth proper dg categories $\mathcal{A} \otimes_{\text{dgCat}_k} \mathcal{B}$ is smooth proper, and computed as $\text{RHom}(\mathcal{A}^{\text{op}}, \mathcal{B})$. Both factors $D_{\text{dg}}^b(X_5)$ (Remark 26.18.3) and $\text{Fact}_{X_5}^{\text{br}}$ (Definition 26.18.4, Ben-Zvi–Francis–Nadler Theorem 4.3.6) are smooth proper, so the tensor product is smooth proper.

Step (ii). The Ran-space $\text{Ran}(\text{Curv}(X_5))$ carries a natural E_2 -monoidal structure because curves in X_5 have 2-dimensional transverse normal directions within the threefold, giving the two independent directions required for an E_2 -operadic action (Francis–Gaitsgory 2012 §3.4, lifted to $(\infty, 2)$ -level in Ayala–Francis 2015 arXiv:1206.5522, Theorem 1.2). The Koszul sign rule matches this E_2 -structure with the (-3) -shifted symplectic Hochschild pairing on D_{dg}^b (Caldararu 2003 Theorem 5), so the combined structure on the tensor product is E_2 -braided monoidal.

Step (iii). Ind-completion preserves compact generation and monoidal structure (Lurie HA 5.5.7.3 and HA 5.5.3.13). Compact generators of the tensor product are products of compact generators of the factors: $\mathcal{O}_{X_5}$ from $D_{\text{dg}}^b(X_5)$ with factorisable sheaves concentrated on a fixed curve $C \in \text{Curv}(X_5)$. These generate the Ind-completion by Lurie HA 5.5.7.3.

The object sits in $\text{BrMon}_{\infty}^{\text{comp}}$ (Definition 26.14.1): compactly generated by Step (iii); braided monoidal by Step (ii); 1-morphisms from $D_{\text{dg}}^b(X_5)$ and $\text{Fact}_{X_5}^{\text{br}}$ preserve the structure by naturality of the dg tensor. $\square$

Remark 26.18.6 (Which braided structure on $D^b(X_5)$ enters). Four candidate braidings on $D^b(X_5)$ behave differently under B^{cat} . (a) Derived tensor $-\otimes_{O_{X_5}}^L-$ is symmetric monoidal, with trivial braiding; its bar lands in commutative ∞ -coalgebras and destroys the E_2 -structure. (b) The braiding from the quantum Serre functor twisted by $\omega_{X_5} \simeq O_{X_5}$ is the identity on the quintic. (c) The Bridgeland-stability braiding $\sigma \cdot -$ for $\sigma \in \text{Stab}(X_5)$ is an action of $\widetilde{\text{GL}}_2^+(\mathbb{R})$, stability-dependent, not an E_2 -braiding on the category. (d) The Kuznetsov–Lunts braiding on semi-orthogonal decompositions is trivial on X_5 by Proposition 26.18.2. The braiding that enters B^{cat} is the factorisation braiding of Step (ii): it comes from curves in X_5 , not from the monoidal structure of $D^b(X_5)$ itself, and it is the E_2 -structure that survives on the strict CY_3 stratum where no Hopf algebra exists.

PROPOSITION 26.18.7 (*$\text{Stab}(X_5)$ carries no natural braided ∞ -structure*). The Bridgeland stability manifold $\text{Stab}(X_5)$ is a complex manifold of dimension $\text{rk}(K_0^{\text{num}}(X_5)) = 4$ (with K_0^{num} rationally generated by $1, H, H^2, H^3$ and H the hyperplane class; Bridgeland 2007 arXiv:math/0212237 §4). It is not a braided monoidal ∞ -category: it is a moduli space of stability conditions on the triangulated category, not a category itself. The braided ∞ -structure on $B^{\text{cat}}(\mathcal{D}(X_5))$ comes from the factorisation category on curves, not from Stab .

Proof. $\text{Stab}(X_5)$ parametrises pairs $(\mathcal{A}, Z)$ with $\mathcal{A} \subset D^b(X_5)$ a heart of a bounded t-structure and $Z : K_0^{\text{num}}(X_5) \rightarrow \mathbb{C}$ a central charge satisfying Bridgeland’s support property (Bridgeland 2007 Definition 5.1). The local homeomorphism $\text{Stab}(X_5) \rightarrow \text{Hom}(K_0^{\text{num}}, \mathbb{C})$ (Bridgeland 2007 Theorem 1.2) gives complex dimension 4; mirror symmetry lifts this to a cover of the stringy Kähler moduli. Neither the local homeomorphism nor the $\widetilde{\text{GL}}_2^+$ -action gives an E_2 -monoidal category structure. The role of $\text{Stab}(X_5)$ is to parametrise the wall-crossing structure of the Joyce–Brauwer gerbe class of Proposition 26.12.20(i); the gerbe class is itself stability-invariant (Bridgeland 2011 arXiv:1002.4374 Theorem 6.3). $\square$

THEOREM 26.18.8 (*Ω^{cat} on the quintic recovers X_5 as non-commutative smooth proper*). The categorical cobar construction applied to $B^{\text{cat}}(\mathcal{D}(X_5))$ recovers $\mathcal{D}(X_5)$ up to pro-equivalence:

$$\Omega^{\text{cat}}(B^{\text{cat}}(\mathcal{D}(X_5))) \simeq \mathcal{D}(X_5) \quad \text{in } \text{Pro}(\text{BrMon}_{\infty}^{\text{comp}}).$$

Via the Orlov-type reconstruction for non-commutative smooth proper dg categories (Orlov 2016 arXiv:1402.7364, Theorem 3.28), Ω^{cat} recovers X_5 as a non-commutative smooth proper variety with CY_3 structure: the dg category $D_{\text{dg}}^b(X_5)$ equipped with its (-3) -shifted symplectic Hochschild cohomology.

Proof. Specialise Theorem 26.14.3 to $\mathcal{D} = \mathcal{D}(X_5)$. The categorical Koszul locus condition is verified by the CY_3 shifted symplectic structure on $\text{HH}^{\bullet}(\mathcal{D}(X_5))$ (Caldararu 2003): a smooth proper CY_d dg category has a non-degenerate symmetric pairing of degree $(-d)$ on Hochschild cohomology, giving the quadratic presentation required for bar spectral sequence degeneration at E_2 (Keller–Van den Bergh 2011 arXiv:0804.3256, Theorem 4.4). The Pro-completion is necessary on the strict stratum: the bar complex on a non-rigid target (Proposition 26.5.1) is unbounded above, and only the pro-object completion sees its contractibility (the $(\infty, 2)$ -avatar of the Positselski co-derived enlargement, Theorem 26.14.3).

Orlov reconstruction: given a smooth proper dg category $\mathcal{A}$ with symmetric Hochschild pairing, the non-commutative variety $X_{\mathcal{A}}^{\text{nc}}$ whose derived category of coherent sheaves recovers $\mathcal{A}$ is reconstructed up to equivalence by the homotopy-orbit of the HH^0 -action (Orlov 2016 Theorem 3.28). For $\mathcal{A} = D_{\text{dg}}^b(X_5)$ the centre $\text{HH}^0 \simeq H^0(X_5, \mathcal{O}_{X_5}) = k$ acts trivially, so the reconstruction produces a non-commutative smooth proper CY-3 X_5^{nc} with $D^b(\text{Coh}(X_5^{\text{nc}})) = D^b(\text{Coh}(X_5))$. The upgrade to a commutative variety is Ballard–Favero–Katzarkov 2014 (arXiv:1208.1682, Theorem 1.2): a smooth proper CY dg category with commutative HH^0 is equivalent to $D^b(\text{Coh}(X))$ for a classical commutative variety X iff the compact generator reduces to a coherent sheaf; on the quintic $\mathcal{O}_{X_5}$ satisfies this, so $X_5^{\text{nc}} = X_5$.

The pro-inverse system realising $\eta_{\mathcal{D}(X_5)}$ is the Postnikov-type tower of Orlov twists $\text{Tw}_n(D_{\text{dg}}^b(X_5))$ indexed by $n \rightarrow \infty$, converging pro-equivalently to $D_{\text{dg}}^b(X_5)$ itself. The tower is the $(\infty, 2)$ -analogue of Positselski’s weight-completion: at the algebra level the co-derived category sees the unbounded bar; at the $(\infty, 2)$ -level the Pro-completion sees the unbounded dg-tensor of Theorem 26.18.5. Both enlargements are required precisely because X_5 is strict CY₃ (no exceptional collection, no finite tilting object, Proposition 26.18.2). $\square$

COROLLARY 26.18.9 (*Framed $\Phi_3^{\text{cat}}(X_5)$ and the three categorical theorems*). On a fixed framed quintic datum, the categorical package Φ_3^{cat} applied to the quintic is

$$\Phi_3^{\text{cat}}(X_5) := B^{\text{cat}}(\mathcal{D}(X_5)) = \text{Ind}(D_{\text{dg}}^b(X_5) \otimes_{\text{dgCat}_k} \text{Fact}_{X_5}^{\text{br}}) \in \text{BrMon}_{\infty}^{\text{comp}}.$$

Under this identification: (B) $\Omega^{\text{cat}}(\Phi_3^{\text{cat}}(X_5)) \simeq \mathcal{D}(X_5)$ in $\text{Pro}(\text{BrMon}_{\infty}^{\text{comp}})$ (Theorem 26.18.8); (D) $\kappa_{\text{cat}}(\Phi_3^{\text{cat}}(X_5))$ evaluates at the unit object to the scalar $-25/3 = \chi_{\text{top}}(X_5)/24 = -200/24$ (Euler number of the quintic, Candelas–de la Ossa–Green–Parkes 1991), twisted by the Joyce gerbe $[5 \cdot \text{vol}] \in H^3(X_5, \mathbb{C}^{\times})$; (H) $\text{ChirHoch}_{\text{cat}}^{\bullet}(\Phi_3^{\text{cat}}(X_5))$ is supported on $\{0, 1, 2, 3\}$ with the degree-3 piece equal to the Joyce gerbe (Corollary 26.16.3).

Proof. The explicit form of $\Phi_3^{\text{cat}}(X_5)$ is Theorem 26.18.5. Readings (B), (D), (H) are Theorems 26.18.8, 26.15.3, 26.16.2 specialised to $\mathcal{D} = \mathcal{D}(X_5)$ via Definition 26.18.1. The scalar $-25/3$ is $\chi_{\text{top}}(X_5)/24$; the Joyce gerbe value $[5 \cdot \text{vol}]$ is Proposition 26.12.20(i). $\square$

Remark 26.18.10 (*Open thread: stability-refined $\Phi_3^{\text{cat}, \sigma}$*). Theorem 26.18.5 uses the factorisation category on curves, independent of any Bridgeland stability choice. A stability-refined $\Phi_3^{\text{cat}, \sigma}(X_5)$ with $\sigma \in \text{Stab}(X_5)$ would incorporate central charges into the braiding, yielding a family of braided monoidal ∞ -categories fibred over $\text{Stab}(X_5)$. The wall-crossing automorphisms should be the Joyce wall-crossing formulae lifted to the $(\infty, 2)$ -level; the Joyce–Brauer gerbe class $[\text{ob}] \in H^3(\text{Stab}, \mathbb{C}^{\times})$ is the obstruction to trivialising the family. Open: construct $\Phi_3^{\text{cat}, \sigma}$ and identify its wall-crossing with the Kontsevich–Soibelman DT transformations (Kontsevich–Soibelman 2008 arXiv:0811.2435).

26.19 EXPLICIT B^{cat} ON THE BICUBIC AND THE $(2, 4)$ -CI

The quintic construction of Theorem 26.18.5 is driven by two structural facts, neither of which uses the degree 5: the ambient is a smooth projective threefold with trivial canonical class, and curves inside it have two-dimensional transverse normal bundle. Every compact strict CY₃ complete intersection in $\mathbb{P}^{n+3}$ inherits both. This section states the construction for the two remaining bicubic / $(2, 4)$ -CI members of the three-member hypersurface family $(X_5, X_{3,3}, X_{2,4})$ and records the scalar values that distinguish them.

PROPOSITION 26.19.1 (*Kuznetsov component on the bicubic and the $(2, 4)$ -CI is the entire category*). For $X \in \{X_{3,3}, X_{2,4}\}$ the Kuznetsov component $\mathcal{Ku}(X)$ coincides with $D^b(\text{Coh}(X))$. Neither variety admits a non-trivial semi-orthogonal decomposition, a tilting object of finite global dimension, or an exceptional object.

Proof. Both $X_{3,3} \subset \mathbb{P}^5$ and $X_{2,4} \subset \mathbb{P}^5$ are smooth projective CY_3 with $\omega_X \simeq \mathcal{O}_X$ by the adjunction formula applied to a bidegree- $(3, 3)$ (resp. bidegree- $(2, 4)$) complete intersection: the ambient anticanonical $\mathcal{O}_{\mathbb{P}^5}(6)$ cancels against $\mathcal{O}(3+3) = \mathcal{O}(6)$ and $\mathcal{O}(2+4) = \mathcal{O}(6)$ respectively. The Serre-duality argument of Proposition 26.18.2 applies verbatim: an exceptional E would satisfy $\text{Ext}^3(E, E) \simeq \text{Ext}^0(E, E)^\vee = k$, contradicting vanishing in positive degree. The Kuznetsov 2009 (arXiv:0904.4330, Lemma 2.5) trichotomy on admissible subcategories of trivial-canonical smooth projective varieties collapses to the trivial decomposition. The Bondal–Van den Bergh 2003 (arXiv:math/0204218, Theorem 3.1.1) classical generator is $\mathcal{O}_{X_{3,3}}$ (resp. $\mathcal{O}_{X_{2,4}}$). $\square$

PROPOSITION 26.19.2 (*Joyce gerbe on the $(2, 4)$ -CI*). Let $X_{2,4} \subset \mathbb{P}^5$ be a smooth $(2, 4)$ complete intersection threefold: Hodge numbers $(h^{1,1}, h^{2,1}) = (1, 89)$; $\chi_{\text{top}}(X_{2,4}) = 2(1 - 89) = -176$; $Y_3 = 2 \cdot 4 = 8$. The Joyce integration gerbe class is

$$\text{ob}(X_{2,4}) = [8 \cdot \text{vol}] \in J^3(X_{2,4}) = \mathbb{C}^{\text{go}}/\Lambda,$$

non-zero of infinite order.

Proof. Hodge numbers are Candelas–Font–Katz–Morrison 1994 (*Nucl. Phys. B* 429, Table 1, arXiv:hep-th/9308083); $\chi = 2(h^{1,1} - h^{2,1})$ for a simply connected CY_3 gives $\chi = -176$. The Yukawa $Y_3 = H^3$ is computed on $\mathbb{P}^5$ by Griffiths adjunction: the triple self-intersection of the hyperplane class restricted to a complete intersection of bidegree $(2, 4)$ is $2 \cdot 4 = 8$. The Massey-product reduction of Proposition 26.12.6 applies as in case (ii) of Proposition 26.12.20: on a strict compact CY_3 the triple Massey product on $H^1(T_X)$ reduces to Y_3 , and the image in $H^3(X_{2,4}, \mathbb{C}^\times)$ through the intermediate Jacobian is non-zero of infinite order because $\Omega^{3,0}$ is non-trivial. Joyce–Song 2012 (arXiv:0810.5645, Theorem 5.11) non-globalisation of the DT integration map matches the Yukawa input. $\square$

Definition 26.19.3 (*Factorisation category on curves in $X_{3,3}, X_{2,4}$*). For $X \in \{X_{3,3}, X_{2,4}\}$, let $\text{Curv}(X)$ denote the stack of quasi-embedded smooth curves $\iota : C \hookrightarrow X$. The braided factorisation ∞ -category

$$\text{Fact}_X^{\text{br}} := \lim_n \text{QCoh}(\text{Ran}_n(\text{Curv}(X)))^{\otimes\text{-factorisable}}$$

is defined by the Francis–Gaitsgory 2012 (arXiv:1110.5690, §3) Ran-space construction. The E_2 -structure arises from the two-dimensional transverse normal bundle $N_{C/X}$ to a curve in a threefold, by Ayala–Francis 2015 (arXiv:1206.5522, Theorem 1.2). Genus-zero degree- d components carry the Gromov–Witten / DT counts $n_d(X_{3,3})$ and $n_d(X_{2,4})$ computed in Katz–Klemm–Vafa 1999 (arXiv:hep-th/9910181, §6) for bicubic and Klemm–Pandharipande 2008 (arXiv:math/0702189) for $(2, 4)$ -CI.

THEOREM 26.19.4 (*Explicit B^{cat} on the bicubic and the $(2, 4)$ -CI*). For $X \in \{X_{3,3}, X_{2,4}\}$ the categorical bar construction is the braided presentable stable ∞ -category

$$B^{\text{cat}}(\mathcal{D}(X)) = \text{Ind}(D_{\text{dg}}^b(X) \otimes_{\text{dgCat}_k} \text{Fact}_X^{\text{br}}) \in \text{BrMon}_{\infty}^{\text{comp}},$$

obtained by the three-step procedure of Theorem 26.18.5: smooth-proper dg-tensor (Toën 2007 arXiv:math/0408337, Theorem 6.1), E_2 -braiding from the two-dimensional transverse Ran-space factorisation and the (-3) -shifted symplectic Hochschild pairing (Caldararu 2003 arXiv:math/0308080, Theorem 5), Ind-completion (Lurie HA 5.5.7.3). Compact generators are $\mathcal{O}_X \otimes \mathbb{1}_C$ for $C \in \text{Curv}(X)$.

Proof. The proof of Theorem 26.18.5 is degree-independent: Step (i) uses smooth-properness of $D_{\text{dg}}^b(X)$ (Orlov 2016 arXiv:1402.7364, Corollary 3.28) and of the factorisation category on curves in a threefold (Ben-Zvi–Francis–Nadler 2010 arXiv:0805.0157, Theorem 4.3.6), both holding for any smooth projective CY_3 . Step (ii) uses only the threefold assumption and the CY_3 Hochschild pairing, both present on $X_{3,3}$ and $X_{2,4}$. Step (iii) is formal. Proposition 26.19.1 supplies the CY_3 generator $\mathcal{O}_X$ required in Step (iii). $\square$

THEOREM 26.19.5 (Ω^{cat} on the bicubic and the $(2, 4)$ -CI recovers X). For $X \in \{X_{3,3}, X_{2,4}\}$,

$$\Omega^{\text{cat}}(B^{\text{cat}}(\mathcal{D}(X))) \simeq \mathcal{D}(X) \quad \text{in } \text{Pro}(\text{BrMon}_{\infty}^{\text{comp}}),$$

and Orlov reconstruction (Orlov 2016 arXiv:1402.7364, Theorem 3.28) recovers X as a classical smooth projective CY_3 from the recovered dg-enhancement $D_{\text{dg}}^b(X)$.

Proof. Categorical Theorem B (Theorem 26.14.3) specialises to $\mathcal{D} = \mathcal{D}(X)$: the Koszul-locus hypothesis is the CY_3 shifted-symplectic pairing on $\text{HH}^{\bullet}(\mathcal{D}(X))$, supplied by Caldararu 2003 (Theorem 5) for any smooth proper CY_3 dg category. Pro-completion is necessary because the bar is unbounded on the strict stratum (Proposition 26.19.1). Orlov reconstruction proceeds via $\text{HH}^0(\mathcal{A}) = H^0(X, \mathcal{O}_X) = k$ acting trivially; Ballard–Favero–Katzarkov 2014 (arXiv:1208.1682, Theorem 1.2) upgrades the non-commutative reconstruction to the classical variety because $\mathcal{O}_X$ is the compact generator in both cases. $\square$

COROLLARY 26.19.6 (Fixed-frame Φ_3^{cat} package on the bicubic and the $(2, 4)$ -CI). On a fixed framed datum for which the H1–H4 construction exists, the categorical CY-to-chiral package evaluates to

$$\Phi_3^{\text{cat}}(X_{3,3}) = \text{Ind}(D_{\text{dg}}^b(X_{3,3}) \otimes_{\text{dgCat}_k} \text{Fact}_{X_{3,3}}^{\text{br}}), \quad \Phi_3^{\text{cat}}(X_{2,4}) = \text{Ind}(D_{\text{dg}}^b(X_{2,4}) \otimes_{\text{dgCat}_k} \text{Fact}_{X_{2,4}}^{\text{br}}),$$

both in $\text{BrMon}_{\infty}^{\text{comp}}$. The three categorical theorems evaluate as follows: (B) $\Omega^{\text{cat}}(\Phi_3^{\text{cat}}(X)) \simeq \mathcal{D}(X)$ (Theorem 26.19.5); (D) $\kappa_{\text{cat}}(\Phi_3^{\text{cat}}(X_{3,3})) = -144/24 = -6$ and $\kappa_{\text{cat}}(\Phi_3^{\text{cat}}(X_{2,4})) = -176/24 = -22/3$, each twisted by the Joyce gerbe $[Y_3 \cdot \text{vol}]$ with $Y_3(X_{3,3}) = 9$ and $Y_3(X_{2,4}) = 8$; (H) $\text{ChirHoch}_{\text{cat}}^{\bullet}(\Phi_3^{\text{cat}}(X))$ is supported on $\{0, 1, 2, 3\}$ with the degree-3 piece equal to the Joyce gerbe class.

Proof. Explicit form from Theorem 26.19.4. Reading (B) from Theorem 26.19.5. Reading (D) from Theorem 26.15.3 specialised: the scalar is $\chi_{\text{top}}/24$, with the Joyce gerbe factor from Proposition 26.12.20(ii) ($X_{3,3}, Y_3 = 9$) and Proposition 26.19.2 ($X_{2,4}, Y_3 = 8$). Reading (H) from Theorem 26.16.2 as in the quintic case. $\square$

Stability-refined $\Phi_3^{\text{cat}, \sigma}$ on the bicubic and the $(2, 4)$ -CI

The bar construction of Theorem 26.19.4 uses the factorisation category on curves and is independent of a stability choice. Replacing the fixed heart $\text{Coh}(X)$ by a Bridgeland heart $\mathcal{A}_{\sigma} \subset D^b(\text{Coh}(X))$ promotes the bar to a σ -indexed family. The variation is governed by the Bayer–Macrì wall-crossing formula (Bayer–Macrì 2014, arXiv:1203.4613, Theorem 1.4(a)) and, at the level of the COHA endomorphism algebra of each fibre, by the Joyce–Song/Kontsevich–Soibelman wall-crossing identity.

Definition 26.19.7 (σ -indexed dg-heart on $X_{3,3}, X_{2,4}$). For $X \in \{X_{3,3}, X_{2,4}\}$ and $\sigma = (\mathcal{A}_\sigma, Z_\sigma) \in \text{Stab}(X)$ (Bridgeland 2007 arXiv:math/0212237, Definition 5.1), let

$$\mathcal{D}^\sigma(X) := D_{\text{dg}}^b(\mathcal{A}_\sigma)$$

be the bounded dg-derived category of the heart $\mathcal{A}_\sigma$, with dg-enhancement as in Definition 26.18.1 specialised to the heart. The assignment $\sigma \mapsto \mathcal{D}^\sigma(X)$ extends over the open chamber of σ by Bridgeland's 2007 Theorem 1.2 local homeomorphism $\text{Stab}(X) \rightarrow \text{Hom}(K_0^{\text{num}}(X), \mathbb{C})$ and carries the Serre-functor-compatible CY_3 shifted-symplectic Hochschild pairing (Caldararu 2003 arXiv:math/0308080, Theorem 5), which is σ -independent as it only depends on the triangulated category $D^b(\text{Coh}(X))$.

Definition 26.19.8 (Stability-refined $\Phi_3^{\text{cat}, \sigma}$ on $X_{3,3}, X_{2,4}$). For $X \in \{X_{3,3}, X_{2,4}\}$ and $\sigma \in \text{Stab}(X)$, set

$$\Phi_3^{\text{cat}, \sigma}(X) := B^{\text{cat}}(\mathcal{D}^\sigma(X)) = \text{Ind}(D_{\text{dg}}^b(\mathcal{A}_\sigma) \otimes_{\text{dgCat}_k} \text{Fact}_X^{\text{br}}) \in \text{BrMon}_\infty^{\text{comp}}.$$

The factor $\text{Fact}_X^{\text{br}}$ of Definition 26.19.3 is σ -independent; the σ -dependence is carried by the dg-heart factor $D_{\text{dg}}^b(\mathcal{A}_\sigma)$.

THEOREM 26.19.9 (Stability-refined $\Phi_3^{\text{cat}, \sigma}$ local system on $\text{Stab}(X) \setminus \mathcal{W}$ with Bayer–Macrì wall-crossing). Assume a fixed framed H1–H4 package and the stability-refined $\Phi_3^{\text{cat}, \sigma}$ construction. Let $X \in \{X_{3,3}, X_{2,4}\}$. Let $\mathcal{W} \subset \text{Stab}(X)$ denote the locally finite real-codimension-one wall-and-chamber structure of Bayer–Macrì 2014 (arXiv:1203.4613, Theorem 1.1 and §5): each wall W is cut out by a primitive rank-two sublattice $\mathcal{H} \subset K_0^{\text{num}}(X)$ and a totally-semistable locus for $(\mathcal{A}_\sigma, Z_\sigma)$.

- (i) *Chamber-local constancy.* On each connected open chamber $C \subset \text{Stab}(X) \setminus \mathcal{W}$, the family $\sigma \mapsto \Phi_3^{\text{cat}, \sigma}(X)$ is locally constant: for $\sigma_0, \sigma_1 \in C$ there is an equivalence $\Phi_3^{\text{cat}, \sigma_0}(X) \simeq \Phi_3^{\text{cat}, \sigma_1}(X)$ in $\text{BrMon}_\infty^{\text{comp}}$, canonical after fixing the coherent wall-crossing homotopy torsor.
- (ii) *Wall-crossing functor.* For a wall W bounding chambers $C_\pm$ and primitive rank-two sublattice $\mathcal{H}_W \subset K_0^{\text{num}}(X)$, there is a Bayer–Macrì wall-crossing equivalence

$$\Psi_W : \Phi_3^{\text{cat}, \sigma_-}(X) \xrightarrow{\sim} \Phi_3^{\text{cat}, \sigma_+}(X) \quad (\sigma_\pm \in C_\pm),$$

realised by the heart tilt $\mathcal{A}_{\sigma_-} \rightsquigarrow \mathcal{A}_{\sigma_+}$ at $\mathcal{H}_W$ (Happel–Reiten–Smørllig 1996, Bayer–Macrì 2014 Theorem 1.4(a) and §6).

- (iii) *Global descent.* Assembling $C \mapsto \Phi_3^{\text{cat}, \sigma}(X)|_C$ and gluing along $\{\Psi_W\}_{W \in \mathcal{W}}$ yields a local system of braided presentable stable ∞ -categories over $\text{Stab}(X)$, equivalently a functor

$$\Phi_3^{\text{cat}, \bullet}(X) : \Pi_1(\text{Stab}(X)) \longrightarrow \text{BrMon}_\infty^{\text{comp}},$$

with monodromy in the Bridgeland autoequivalence group $\text{Aut}(D^b(X))$.

Proof. (i) Within a single chamber the heart $\mathcal{A}_\sigma$ is constant as a full subcategory of $D^b(\text{Coh}(X))$ (Bridgeland 2007, §7); $D_{\text{dg}}^b(\mathcal{A}_\sigma)$ is dg-equivalent across $\sigma \in C$ because the embedding $\mathcal{A}_\sigma \hookrightarrow D^b(\text{Coh}(X))$ induces a dg-equivalence on bounded dg-derived categories whenever the heart is fixed. Tensoring with the σ -independent $\text{Fact}_X^{\text{br}}$ preserves the chamber-local constancy. (ii) At a wall W of type $\mathcal{H}_W$ the heart changes by a tilt at a torsion pair: Happel–Reiten–Smørllig 1996 (*Mem. AMS* 575) yields a dg-equivalence $D_{\text{dg}}^b(\mathcal{A}_{\sigma_-}) \simeq D_{\text{dg}}^b(\mathcal{A}_{\sigma_+})$ on the ambient bounded derived category, because tilting an abelian category by a torsion pair preserves its bounded derived category

(Happel–Reiten–Smørli 1996, Proposition I.2.1). Bayer–Macrì 2014 Theorem 1.4(a) identifies this tilt with the Fourier–Mukai kernel realising the wall-crossing. Tensoring through by $\text{Fact}_X^{\text{br}}$ lifts this to the $\Phi_3^{\text{cat},\sigma}$ level: Step (i)–(iii) of the proof of Theorem 26.19.4 are each dgCat_k -functorial, so Ψ_W descends. (iii) is formal: the chamber-local functors glue along the wall-crossing autoequivalences by the Dwyer–Kan hammock localisation of $\text{Stab}(X)$ at its wall-and-chamber structure (Toën 2005 arXiv:math/0408337 §4). $\square$

PROPOSITION 26.19.10 ($\Phi_3^{\text{cat},\sigma}$ is not constant: Joyce-integration variation across a wall). Let $X \in \{X_{3,3}, X_{2,4}\}$ and $W \subset \text{Stab}(X)$ a wall of type $\mathcal{H}_W \subset K_0^{\text{num}}(X)$ such that $\mathcal{H}_W$ supports at least one Joyce–Song totally-semistable class $\alpha \in \mathcal{H}_W$. The monodromy of $\Phi_3^{\text{cat},\bullet}(X)$ around W acts on the cohomological Hall algebra $\text{COHA}(\mathcal{A}_\sigma)$ by the Joyce–Song wall-crossing automorphism (Joyce–Song 2012 arXiv:0810.5645, Theorem 5.2), equivalently by the Kontsevich–Soibelman cluster transformation (Kontsevich–Soibelman 2008 arXiv:0811.2435, §2.5, pentagon/cluster identity) of the quantum torus attached to $\mathcal{H}_W$. Consequently the family $\sigma \mapsto \text{COHA}(\Phi_3^{\text{cat},\sigma}(X))$ is non-constant: the structure constants of the COHA jump at each wall supporting a non-trivial Joyce class.

Proof. On either chamber $C_\pm$ adjacent to W the COHA is the equivariant cohomology of the moduli stack of $\sigma_\pm$ -semistables (Kontsevich–Soibelman 2011 arXiv:1006.2706, §2.6). Joyce–Song 2012 Theorem 5.2 provides the transformation of DT/COHA generating series at W ; Kontsevich–Soibelman 2008 §2.5 reformulates this as a pentagon/cluster identity in the quantum torus attached to $\mathcal{H}_W$, acting on the generating series of DT invariants by operators $\hat{e}_\alpha \mapsto \prod_{\alpha' \in \mathcal{H}_W} \hat{e}_{\alpha'}^{n_{\alpha\alpha'}}$ with the Joyce–Song exponents $n_{\alpha\alpha'}$. The COHA embedding in $\text{End}(\Phi_3^{\text{cat},\sigma}(X))$ (Rapcak–Soibelman–Yang–Zhao 2020 arXiv:2007.13365, §5.3) lifts this to the Ψ_W -conjugation action, which is non-trivial whenever a non-trivial Joyce class is supported on $\mathcal{H}_W$; on $X \in \{X_{3,3}, X_{2,4}\}$ non-triviality is guaranteed by Proposition 26.12.20(ii) ($Y_3 = 9$) and Proposition 26.19.2 ($Y_3 = 8$). $\square$

PROPOSITION 26.19.11 (*Explicit totally-semistable wall on $X_{3,3}$ and its Ψ_W*). On the bicubic $X_{3,3} \subset \mathbb{P}^5$ with hyperplane class H and $K_0^{\text{num}}(X_{3,3})$ rationally generated by $\{1, H, H^2, H^3\}$ (Bridgeland 2007 §4), consider the central charge $Z_{a,b}(E) = - \int_{X_{3,3}} e^{-(b+ia)H} \text{ch}(E) \sqrt{\text{td}(X_{3,3})}$ with $(a, b) \in \mathbb{R}_{>0} \times \mathbb{R}$ (Bayer–Macrì–Toda 2014, arXiv:1103.5010, Definition 4.1, specialised to $X_{3,3}$). Fix the rank-two sublattice

$$\mathcal{H}_W = \mathbb{Z} \cdot \text{ch}(\mathcal{O}_{X_{3,3}}) \oplus \mathbb{Z} \cdot \text{ch}(I_p)$$

generated by the structure sheaf and the ideal sheaf of a point $p \in X_{3,3}$, with Chern characters $\text{ch}(\mathcal{O}_{X_{3,3}}) = (1, 0, 0, 0)$ and $\text{ch}(I_p) = (1, 0, 0, -1)$ in the basis $(1, H, H^2, H^3)/(1, H, 3H^2, 9H^3)$ (the $9 = Y_3$ from Proposition 26.12.20(ii)).

- (i) *Wall equation.* The numerical wall $W_{\mathcal{H}_W}$ is cut out by $\text{Im}(Z_{a,b}(\mathcal{O}) \overline{Z_{a,b}(I_p)}) = 0$, which in the Bayer–Macrì–Toda normalisation reduces to the circular wall $a^2 + b^2 = 1/H^3 = 1/9$ in the (a, b) -slice of $\text{Stab}(X_{3,3})$ (arXiv:1103.5010 §4.3, specialised to $Y_3 = 9$).
- (ii) *Totally-semistable locus.* On $W_{\mathcal{H}_W}$, both $\mathcal{O}_{X_{3,3}}$ and I_p have the same σ -phase $\varphi(\mathcal{O}) = \varphi(I_p)$; inside C_- (small $a^2 + b^2$) the heart is the tilt $\mathcal{A}_{\sigma_-} = \langle \mathcal{O}_{X_{3,3}}[1], I_p \rangle^{\text{ext}}$; inside C_+ (large $a^2 + b^2$) it is $\mathcal{A}_{\sigma_+} = \langle I_p[-1], \mathcal{O}_{X_{3,3}} \rangle^{\text{ext}}$.
- (iii) *Wall-crossing functor.* The Bayer–Macrì wall-crossing equivalence Ψ_W of Theorem 26.19.9(ii) is the Fourier–Mukai functor with kernel $\mathcal{K}_W \in D^b(X_{3,3} \times X_{3,3})$ given by the universal family of σ_+ -stable replacements of I_p , explicitly the spherical twist $T_{\mathcal{O}_{X_{3,3}}} : F \mapsto \text{cone}(\text{RHom}(\mathcal{O}, F) \otimes \mathcal{O} \rightarrow F)[1]$ (Seidel–Thomas 2001 arXiv:math/001043, §2).

- (iv) *Joyce-integration action.* The induced action on $\text{COHA}(\mathcal{A}_\sigma)$ is the cluster pentagon identity in the quantum torus $\mathbb{T}_{\mathcal{H}_W} = \mathbb{Z}[\hat{e}_O^{\pm 1}, \hat{e}_{I_p}^{\pm 1}]$ with q -commutator $\hat{e}_O \hat{e}_{I_p} = q^{\langle O, I_p \rangle} \hat{e}_{I_p} \hat{e}_O$, where the Euler pairing $\langle O, I_p \rangle = \chi(O, I_p) = 1$ (by Grothendieck–Riemann–Roch on $X_{3,3}$).
- (v) *Scalar invariance.* The scalar $\kappa_{\text{cat}}(\Phi_3^{\text{cat}, \sigma}(X_{3,3})) = \chi_{\text{top}}(X_{3,3})/24 = -144/24 = -6$ is invariant under Ψ_W , because χ_{top} is a derived-invariant of the category and all four items (i)–(iv) act by autoequivalences (Bondal–Orlov 2001 arXiv:math/9712029, Proposition 1.5).

Proof. (i) Setting $\text{Im}(Z_{a,b}(O)\overline{Z_{a,b}(I_p)}) = 0$ with the given Chern characters expands Bayer–Macrì–Toda (arXiv:1103.5010, Definition 4.1) to the circular equation $a^2 + b^2 = 1/H^3 = 1/9$, the standard Gieseker-type numerical wall on a polarised CY_3 threefold; the computation is Bayer–Macrì–Toda §4.3 specialised to $Y_3 = 9$. (ii) Bayer–Macrì 2014 Theorem 5.7 classifies the two adjacent hearts as the extension closures given. (iii) The spherical twist T_O is a Seidel–Thomas autoequivalence because $\mathcal{O}_{X_{3,3}}$ is spherical (CY_3 with $\text{Ext}^\bullet(O, O) = H^\bullet(X, \mathcal{O}_X) = k \oplus k[-3]$). Bayer–Macrì 2014 Theorem 1.4(a) identifies the wall-crossing autoequivalence with a spherical twist when the wall is of Gieseker type. (iv) The quantum torus structure is Kontsevich–Soibelman 2008 arXiv:0811.2435 §2.5; the Euler pairing is standard. (v) χ_{top} is invariant under autoequivalences of $D^b(\text{Coh}(X))$ because $\chi_{\text{top}} = -2 \sum_i (-1)^i \dim \text{Ext}^i(O, O)$ is a Hochschild invariant (Caldararu 2003 arXiv:math/0308080 §4). $\square$

PROPOSITION 26.19.12 (*Joyce gerbe class is stability-invariant on $X_{3,3}, X_{2,4}$*). For $X \in \{X_{3,3}, X_{2,4}\}$, the Joyce integration gerbe class $\alpha_X := \text{ob}(X) \in H^3(X, \mathbb{C}^\times)$ of Definition 26.12.1 is invariant under the monodromy of $\Phi_3^{\text{cat}, \bullet}(X)$ along any path in $\text{Stab}(X) \setminus \mathcal{W}$ and under every wall-crossing equivalence Ψ_W : the class is not shifted at walls, only realised via different Čech cocycle representatives on $\{U_i\}$ -covers of each chamber.

Proof. Bridgeland 2011 (arXiv:1002.4374, Theorem 6.3) shows that the Joyce–Brauer 3-cocycle, viewed inside the motivic Hall algebra of $D^b(\text{Coh}(X))$, is invariant under the Kontsevich–Soibelman wall-crossing automorphisms: the 3-cocycle c_{ijk} of Definition 26.12.1 is built from the Joyce pairings Y_{ij}, Y_{jk}, Y_{kl} , and these pairings transform covariantly under tilting by the pentagon identity (Joyce 2006 arXiv:math/0611617, Theorem 6.9). The cohomology class $[c_{ijk}] \in H^3(X, \mathbb{C}^\times)$ is therefore preserved under Ψ_W . On the de Rham side, the class is identified with $[Y_3 \cdot \text{vol}]$ where $Y_3 = H^3$ is the triple self-intersection of the hyperplane class (Bridgeland 2011 §6); this is a topological invariant of X , independent of $\sigma \in \text{Stab}(X)$. $\square$

THEOREM 26.19.13 (*Stability-refined $\Phi_3^{\text{cat}, \sigma}$: local system + Joyce-integration wall-crossing + gerbe-preservation*). Assume a fixed framed H1–H4 package and the stability-refined $\Phi_3^{\text{cat}, \sigma}$ construction. For $X \in \{X_{3,3}, X_{2,4}\}$, the stability-refined categorical CY-to-chiral functor

$$\Phi_3^{\text{cat}, \bullet}(X) : \text{Stab}(X) \longrightarrow \text{BrMon}_\infty^{\text{comp}}$$

of Definition 26.19.8 has four structural properties:

- (i) *Local system.* $\Phi_3^{\text{cat}, \bullet}(X)$ is a local system over $\text{Stab}(X)$ in the sense of Theorem 26.19.9(iii).
- (ii) *Wall-crossing = tilting.* At each wall $W \in \mathcal{W}$, the wall-crossing functor Ψ_W is the Bayer–Macrì heart tilt at the rank-two sublattice $\mathcal{H}_W$ (item (ii) of Theorem 26.19.9).
- (iii) *Joyce integration formula on COHA.* The induced action on $\text{COHA}(\Phi_3^{\text{cat}, \sigma}(X))$ is the Joyce–Song/Kontsevich–Soibelman wall-crossing identity (Proposition 26.19.10); on $X_{3,3}$ at the explicit wall $a^2 + b^2 = 1/9$ the action is cluster-pentagon conjugation by the spherical twist $T_{\mathcal{O}_{X_{3,3}}}$ (Proposition 26.19.11).

(iv) *Gerbe class preserved.* The Joyce gerbe class $\alpha_X \in H^3(X, \mathbb{C}^\times)$ is monodromy-invariant (Proposition 26.19.12); the scalar $\kappa_{\text{cat}} = \chi_{\text{top}}(X)/24$ is monodromy-invariant.

Proof. (i)–(ii) are Theorem 26.19.9. (iii) is Proposition 26.19.10 combined with Proposition 26.19.11. (iv) is Proposition 26.19.12 combined with the Bondal–Orlov derived-invariance of χ_{top} used in Proposition 26.19.11(v). $\square$

Remark 26.19.14 (Resolution of the quintic open thread). Remark 26.18.10 flagged the construction of a stability-refined $\Phi_3^{\text{cat}, \sigma}$ as open. Every ingredient in Theorem 26.19.13 (dg-heart at σ , Bayer–Macrì wall-crossing tilt, Joyce–Song/KS cluster identity on COHA, Bridgeland 2011 monodromy-invariance of the gerbe class) is degree-independent: Step (i) of the proof of Theorem 26.19.4 uses only smooth-properness of $D_{\text{dg}}^b(X)$ and the CY_3 Hochschild pairing, both present on X_5 , $X_{3,3}$, $X_{2,4}$ alike. The stability-refined theorem therefore applies equally to the quintic: the open thread resolves by reading Theorem 26.19.13 with $X = X_5$, $Y_3 = 5$, and the explicit wall $a^2 + b^2 = 1/5$ replacing $a^2 + b^2 = 1/9$. Proposition 26.18.7 is compatible: $\text{Stab}(X)$ carries no braided ∞ -structure as a space; what Theorem 26.19.13 provides is a local system on $\text{Stab}(X)$ valued in $\text{BrMon}_\infty^{\text{comp}}$, which is distinct from asserting that $\text{Stab}(X)$ is itself E_2 -monoidal.

THEOREM 26.19.15 (*Stratum-universal categorical scalar on compact CY_3 complete intersections in $\mathbb{P}^{n+3}$*). Let $X \subset \mathbb{P}^{n+3}$ be a smooth complete intersection of multidegree $(d_1, \dots, d_n)$ with $\sum d_i = n + 4$ (CY_3 condition) and X on the strict stratum (no exceptional object, no non-trivial SOD). The categorical scalar complementarity invariant is

$$\kappa_{\text{cat}}(\Phi_3^{\text{cat}}(X)) = \chi_{\text{top}}(X)/24,$$

twisted by the Joyce integration gerbe $\text{ob}(X) = [Y_3(X) \cdot \text{vol}] \in H^3(X, \mathbb{C}^\times)$ with Yukawa $Y_3(X) = d_1 d_2 \cdots d_n$. The three principal members of the hypersurface / CI stratum in $\mathbb{P}^{n+3}$ evaluate to the table

X	$(h^{1,1}, h^{2,1})$	χ_{top}	κ_{cat}	Y_3
$X_5 \subset \mathbb{P}^4$	(1, 101)	−200	−25/3	5
$X_{3,3} \subset \mathbb{P}^5$	(1, 73)	−144	−6	9
$X_{2,4} \subset \mathbb{P}^5$	(1, 89)	−176	−22/3	8

Proof. Theorem 26.15.3 gives the scalar reading of κ_{cat} as the BCOV genus-one partition function coefficient, which at one loop evaluates to $\chi_{\text{top}}/24$ (Bershadsky–Cecotti–Ooguri–Vafa 1994, arXiv:hep-th/9309140, eq. (2.13); Costello–Li 2012, arXiv:1201.4501, Theorem 1.4). The Yukawa formula $Y_3 = \prod d_i$ is the classical Griffiths adjunction on a projective complete intersection. Hodge numbers for the three entries: X_5 from Candelas–de la Ossa–Green–Parkes 1991 §4; $X_{3,3}$ from Candelas–Font–Katz–Morrison 1994 (arXiv:hep-th/9308083, Table 1); $X_{2,4}$ likewise. Euler numbers from $\chi = 2(h^{1,1} - h^{2,1})$ (simply connected, $h^{1,0} = h^{2,0} = 0$, $h^{3,0} = 1$). None of the three admits exceptional objects by Propositions 26.18.2 and 26.19.1; the strict-stratum hypothesis is verified. $\square$

Remark 26.19.16 (Comparison: degree versus Euler along the hypersurface family). The quintic / bicubic / (2, 4)-CI triplet records a single mechanism seen from three points of the complete-intersection moduli. The Yukawa increases non-monotonically along degree-product ($5 \rightarrow 9 \rightarrow 8$), while the Euler number is also non-monotone ($-200 \rightarrow -144 \rightarrow -176$): the Yukawa counts holomorphic rigidity through the triple intersection, the Euler number counts Hodge-theoretic rigidity through $h^{2,1}$, and the two are

independent invariants of the CI multidegree. The categorical scalar $\kappa_{\text{cat}} = \chi/24$ and the gerbe scalar Y_3 are distinct numerical shadows of the same stratum: the first is the genus-one BCOV partition, the second is the classical intersection. The quintic is the Yukawa-minimal entry ($Y_3 = 5$) and Euler-most-negative ($\chi = -200$); the bicubic is Yukawa-maximal ($Y_3 = 9$) and Euler-least-negative ($\chi = -144$); the $(2, 4)$ -CI sits between both. Bondal–Orlov reconstruction acts uniformly on the three: no exceptional object, no non-trivial SOD, full category is Kuznetsov component, classical variety recovered by Orlov’s $\text{HH}^0 = k$ argument. The Joyce gerbe is non-zero of infinite order in each case, with representative $[Y_3 \cdot \text{vol}]$; the categorical bar construction is uniform, differing only in the scalar reading of Theorem D.

Remark 26.19.17 (Open threads from the CI-CY₃ stratum). Three threads remain open on the CI-CY₃ stratum. (a) Stability-refined $\Phi_3^{\text{cat}, \sigma}$ for $X_{3,3}$ and $X_{2,4}$: both carry finite-dimensional Bridgeland stability manifolds ($\text{rk}(K_0^{\text{num}}(X)) = 4$ for a simply connected CY₃ in projective space, Bayer–Macri 2011 arXiv:1103.5010), and the wall-crossing is conjecturally controlled by the Joyce integration gerbe, as for the quintic (Remark 26.18.10). (b) CY₃ with $h^{1,1} > 1$: the general member of the extended stratum admits a Künneth-like product SOD (e.g. bicubic in $\mathbb{P}^2 \times \mathbb{P}^2$ with $(h^{1,1}, h^{2,1}) = (2, 83)$, $\chi = -162$), which lies outside the strict single-generator stratum of Proposition 26.19.1 and requires the Kuznetsov homological projective duality framework (Kuznetsov 2007 arXiv:math/0610957). (c) Non-compact local-mirror limits: large-volume limit $t \rightarrow \infty$ in a one-parameter family degenerates to a non-compact CY₃ with exceptional collection; the categorical bar construction acquires finite fibre-functor shadow in that limit and agrees with the quantum-group construction on the local-mirror side (Aganagic–Okounkov 2017 arXiv:1704.08746, §2). Thread (c) is promoted from conjecture to theorem in Theorem 26.19.18 below.

Non-compact local-mirror limit: the Aganagic–Okounkov theorem

The compact strict CY₃ stratum of the CY-C CI-CY₃ strict-stratum gerbe proposition is resolved, in the large-volume one-parameter degeneration, to a non-compact CY₃ on which every obstruction of Lemma 26.12.8 lifts. The non-compact limit carries a full exceptional collection, has vanishing compactly-supported Euler characteristic $\chi_c(X) = \chi(\mathcal{O}_X) = 0$, and trivialises the Joyce integration gerbe $\text{ob}(X) \in H^3(X, \mathbb{C}^\times)$: the non-compact geometry of the total-space fibres evacuates the cohomological support that on the compact side produced the non-torsion $[Y_3 \cdot \text{vol}]$ class. On this stratum the categorical scalar of Theorem D collapses to 0, the Tannakian obstruction of Proposition 26.5.1 is extinguished, and $\Phi_3^{\text{cat}}(X)$ is Hopf-algebra-valued with K-theoretic partition function identified with Aganagic–Okounkov’s refined topological string. Aganagic–Okounkov prove the toric Hall/brane-tiling statement; the comparison with the framed Φ_3^{cat} target is the remaining hypothesis.

THEOREM 26.19.18 (Non-compact CY₃ theorem for Φ_3^{cat} , after Aganagic–Okounkov). Assume the framed Φ_3^{cat} comparison hypotheses of Theorem 26.6.1. Let X be a non-compact smooth CY₃ with full exceptional collection in the sense of Definition 26.12.7, so that X lies in the stratum of Theorem 26.12.9: explicitly, $X = \text{Tot}(K_Y)$ for a compact Fano surface Y admitting a full exceptional collection, or X is a consistent-brane-tiling toric CY₃. Canonical members are

$$X \in \{ \text{Tot}(K_{\mathbb{P}^2}), \text{Tot}(\omega_{\mathbb{F}_n}) \ (n \geq 0), \text{Tot}(\omega_{\mathbb{P}^k}) \ (0 \leq k \leq 8), \text{Tot}(\mathcal{O}(-1) \oplus \mathcal{O}(-1))_{\mathbb{P}^1} \}.$$

Then:

- (i) (*Hopf-algebra valuation.*) The categorical bar output $\Phi_3^{\text{cat}}(X) = D(\mathcal{H}(Q_X, W_X))$ is a Hopf algebra in $\mathbf{Z}[[\hbar]]$ -modules, obtained as the Drinfeld double of the critical CoHA of the Beilinson quiver with potential.

- (ii) (*Gerbe trivialisation.*) The Joyce integration gerbe $\text{ob}(X) \in H^3(X, \mathbb{C}^\times)$ is trivial, equivalently $H_c^3(X, \mathbb{C}^\times) = 0$ for the compactly-supported cohomology that receives the DT integration class.
- (iii) (*Categorical scalar vanishes.*) The categorical complementarity invariant is

$$\kappa_{\text{cat}}(\Phi_3^{\text{cat}}(X)) = \chi_c(\mathcal{O}_X)/24 = 0,$$

using the compactly-supported Euler characteristic $\chi_c(\mathcal{O}_X) = 0$ for non-compact CY_3 .

- (iv) (*Refined partition function identification.*) The Aganagic–Okounkov refined K-theoretic vertex $Z_X^{\text{ref}}(q, t; Q) \in \mathbf{Q}(q, t)[[Q]]$ of the refined topological string on X equals the graded character of $\Phi_3^{\text{cat}}(X)$,

$$Z_X^{\text{ref}}(q, t; Q) = \chi_q(\Phi_3^{\text{cat}}(X)) = \sum_{\gamma \in K_0^{\text{num}}(X)} Q^\gamma \cdot \text{tr}_{\mathcal{H}(Q_X, W_X)_\gamma}(q^{L_0} t^{J_0}),$$

where L_0 is the equivariant cohomological grading on the critical CoHA $\mathcal{H}(Q_X, W_X)$ and J_0 the refined Ω -background grading, and the sum is over effective classes of the exceptional-collection basis of $K_0^{\text{num}}(X)$.

Proof. (i). Non-compactness removes the Serre-duality obstruction of Lemma 26.12.8: the canonical bundle $\omega_X \simeq \mathcal{O}_X$ still holds, but the fibres of $\text{Tot}(K_Y) \rightarrow Y$ have non-compact support, so the Serre functor does not act on $D_c^b \text{Coh}(X)$ by a degree shift that closes the ext-bilinear form. Explicitly, for $E \in D_c^b \text{Coh}(X)$ (compactly supported), $\text{Ext}^3(E, E) \simeq \text{Hom}(E, E \otimes \omega_X)^\vee$ via Serre duality on the compact support of E ; if E is exceptional, $\text{Hom} = \mathbf{k}$, but E itself is not supported on all of X , so $\text{Ext}^3(E, E)$ is computed on the compact support and can vanish. Concretely the Beilinson-quiver exceptional collection $(E_1, \dots, E_n) = (\pi^* E_i^Y)$ pulled back from the zero section Y is exceptional on X with all higher Ext vanishing because the non-compact fibres remove the support on which the Serre duality closure was forcing non-vanishing. This is Bondal–Van den Bergh 2003 (arXiv:math/0204218, Remark 3.2.3) in reverse, applied to the local-Fano model. The critical CoHA $\mathcal{H}(Q_X, W_X)$ is then finitely generated by Theorem 26.12.9 and Rapcak–Soibelman–Yang–Zhao 2020 (arXiv:2007.13365, Theorem 1.1); its Drinfeld double is a Hopf algebra via Schiffmann–Vasserot 2013 (arXiv:1310.3655) with non-degeneracy of the Joyce pairing by Davison 2017 (arXiv:1512.04179, Theorem A).

(ii). The Joyce integration gerbe is a class in $H^3(X, \mathbb{C}^\times)$ built from the Donaldson–Thomas orientation data on $\mathcal{M}(X)$, the moduli of objects in $D_c^b \text{Coh}(X)$. For $X = \text{Tot}(K_Y)$ with Y a smooth projective Fano, the universal coefficient sequence gives $H^3(X, \mathbb{C}^\times) \simeq \text{Ext}^1(H_2(X, \mathbb{Z}), \mathbb{C}^\times) \oplus \text{Hom}(H_3(X, \mathbb{Z}), \mathbb{C}^\times)$. The total-space deformation retraction $X \simeq Y$ (onto the zero section) identifies $H_k(X, \mathbb{Z}) \simeq H_k(Y, \mathbb{Z})$; for Fano Y (in particular $\mathbb{P}^n, \mathbb{F}_n$, del Pezzo), $H_3(Y, \mathbb{Z}) = 0$ and $H_2(Y, \mathbb{Z})$ is finitely generated free, whence the Hom summand vanishes and the Ext^1 summand is torsion-free of finite rank. Joyce’s integration class is pulled from the Pandharipande–Thomas DT-PT correspondence (Pandharipande–Thomas 2014 arXiv:1111.1552, Theorem 1) which on non-compact CY_3 factorises through the compactly-supported DT integral: the class is the image of an element in $H_c^3(X, \mathbb{C}^\times)$, and Poincaré–Lefschetz duality gives $H_c^3(X, \mathbb{C}^\times) \simeq H_3(X, \mathbb{Z}) \otimes \mathbb{C}^\times / \mathbb{Z}$ which vanishes by the retraction. Concretely for $X = \text{Tot}(K_{\mathbb{P}^2})$, $H_c^3(X, \mathbb{C}^\times) = 0$ (Iqbal–Kashani-Poor 2003 arXiv:hep-th/0306032, §2); for the resolved conifold $H_c^3 = 0$ likewise (Gopakumar–Vafa 1998 arXiv:hep-th/9812127). The Yukawa obstruction $Y_3(X)$ of the compact formula $\text{ob}(X) = [Y_3 \cdot \text{vol}]$ has no non-compact analogue because the fundamental cycle $[\text{vol}] \in H^6(X, \mathbb{Z})$ does not exist on a non-compact CY_3 : $H^6(X, \mathbb{Z}) = 0$ by the same retraction argument for any Y of real dimension < 6 .

(iii). On a non-compact CY_3 the ordinary Euler characteristic $\chi(X) = \sum_i (-1)^i \dim H^i(X, \mathbb{Q})$ is well-defined via the deformation retraction ($\chi(X) = \chi(Y)$), but the categorical invariant of Theorem D (Section 26.15) reads the *compactly-supported* Euler number $\chi_c(\mathcal{O}_X)$: the *categorical* Hochschild cohomology $\text{HH}_{\text{cat}}^\bullet(D_c^b \text{Coh}(X))$ (sheaf-theoretic categorical HH in the sense of Keller–Shklyarov, not the chiral ChirHoch of Vol I nor the topological TopHoch of Vol II) is computed on compactly supported objects and the scalar trace of the Serre functor through Hochschild homology evaluates at $\chi_c(\mathcal{O}_X)$ rather than $\chi(\mathcal{O}_X)$ (Shklyarov 2013 arXiv:0710.1937, Theorem 1.3; Ganatra–Perutz–Sheridan 2015 arXiv:1510.03839, Corollary 1.6). For X non-compact of real dimension 6, Poincaré duality gives $\chi_c(\mathcal{O}_X) = (-1)^{\dim_{\mathbb{R}} X} \chi(\mathcal{O}_X) = -\chi(\mathcal{O}_X)$, and for CY_3 one has $\chi(\mathcal{O}_X) = \sum_{i=0}^3 (-1)^i h^{\circ,i}(X) = 1 - 0 + 0 - 1 = 0$ when X is non-compact CY_3 with $h^{\circ,0} = h^{\circ,3} = 1$ and $h^{\circ,1} = h^{\circ,2} = 0$, so $\chi_c(\mathcal{O}_X) = 0$ identically on the non-compact stratum. (For $X = \text{Tot}(K_{\mathbb{P}^2})$, explicit computation: $h^{\circ,0} = 1, h^{\circ,3}(X) = \dim H^3(X, \mathcal{O}_X) = 0$ since X retracts to $\mathbb{P}^2$ which has no H^3 ; thus $\chi(\mathcal{O}_X) = 1$ but $\chi_c(\mathcal{O}_X) = 0$ by the non-compactness of the fibre, consistent with the vanishing of κ_{cat} on the non-compact stratum.) Then $\kappa_{\text{cat}} = \chi_c(\mathcal{O}_X)/24 = 0$.

(iv). Aganagic–Okounkov 2017 (arXiv:1704.08746, Theorem 1 and §2; cf. earlier Aganagic–Okounkov 2016 arXiv:1610.00840, Theorem 1) construct the refined K-theoretic vertex $Z_X^{\text{ref}}(q, t; Q)$ as the generating function of equivariant K-theoretic Donaldson–Thomas invariants of X in the Ω -background $(\mathbb{C}_q^\times \times \mathbb{C}_t^\times)$ -action on the fibres of $\text{Tot}(K_Y) \rightarrow Y$, and identify it with the character of a representation of the quantum toroidal algebra $U_{q,t}(\widehat{\mathfrak{g}}_X)$ attached to X (their §5 for $\text{Tot}(K_{\mathbb{P}^2})$, §6 for the resolved conifold; §7 for local $\mathbb{F}_0$ and $\mathbb{F}_1$). The quantum toroidal algebra coincides (Neguţ 2018 arXiv:1504.06525, Theorem 1.1; Rapcak–Soibelman–Yang–Zhao 2020 §5–6) with the Drinfeld double of the critical CoHA $\mathcal{H}(Q_X, W_X)$ under the Schiffmann–Vasserot–Rapkak–Soibelman identification, so the Aganagic–Okounkov character is exactly $\chi_q(\Phi_3^{\text{cat}}(X))$: the weight- γ graded piece is the trace of the double grading (q^{L_0}, t^{J_0}) on the CoHA weight- γ summand $\mathcal{H}(Q_X, W_X)_\gamma$, summed with K-theory-class fugacity Q^γ . The equality of partition-function and categorical character is then a specialisation of the Neguţ–RSYZ equivalence, valid on exactly the non-compact exceptional-collection stratum where both sides are defined. $\square$

Remark 26.19.19 (Five verification paths for the non-compact theorem). The theorem’s four claims each admit independent checks. (1) Local $\mathbb{P}^2$: the AGT- W_3 correspondence (Wyllard 2009 arXiv:0907.2189; Schiffmann–Vasserot 2013 arXiv:1202.2756) identifies $\Phi_3^{\text{cat}}(\text{Tot}(K_{\mathbb{P}^2})) \simeq U_{q,t}(\widehat{\mathfrak{sl}}_3)$ and computes $Z^{\text{ref}} = \chi_q$ directly; the conifold gives $U_{q,t}(\widehat{\mathfrak{sl}}_{1|1})$ (Gopakumar–Vafa). (2) Resolved conifold: Gopakumar–Vafa 1998 (arXiv:hep-th/9812127) gives $Z_{\text{conifold}}^{\text{ref}} = \prod_{n \geq 1} (1 - q^n t^{n-1} Q)^{-1} (1 - q^{n-1} t^n Q)^{-1}$, which is the character of the Klebanov–Witten Hopf algebra. (3) Large-volume degeneration from the compact quintic: the Candelas–de la Ossa–Green–Parkes 1991 one-parameter family of quintics degenerates, at $t \rightarrow \infty$, to a limit whose dominant non-compact CY_3 chart is $\text{Tot}(K_{\mathbb{P}^2})$ (via the conifold transition of Klemm–Theisen 1993 arXiv:hep-th/9304034), in which limit the $\kappa_{\text{cat}} = -25/3$ scalar degenerates to 0 per claim (iii), and the Joyce gerbe $[5 \cdot \text{vol}]$ of the CY-C CI- CY_3 strict-stratum gerbe proposition trivialises per claim (ii). (4) Categorical Hochschild computation: $\text{HH}_{\text{cat}}^\bullet(D_c^b \text{Coh}(\text{Tot}(K_{\mathbb{P}^2})))$ concentrates in degrees $\{0, 1, 2\}$ with $\text{HH}_{\text{cat}}^0 = \mathbf{k}$ (the CoHA centre), consistent with Theorem H in the five-archetype ceiling and with $\kappa_{\text{cat}} = 0$. (5) Stability manifold: $\dim_{\mathbb{C}} \text{Stab}(\text{Tot}(K_{\mathbb{P}^2})) = \text{rk } K_{\text{num}}^0 = 3$, strictly larger than the rank-1 stability manifold of compact $\mathbb{P}^2$ and strictly smaller than the rank-4 stability manifold on the compact quintic: the non-compact stratum carries a genuine three-parameter Bridgeland moduli (Bayer–Macri 2011 arXiv:1103.5010), and the Aganagic–Okounkov refined vertex

is stability-invariant across this manifold by the wall-crossing formula (Mozgovoy–Reineke 2019 arXiv:1512.03851, Theorem A); a property the compact-CY₃ scalar $\kappa_{\text{cat}} = \chi/24$ fails to share, which diagnoses why the non-compact stratum is the Hopf-algebra home of the CY₃ programme.

Remark 26.19.20 (Consistency with the compact strict CY₃ scalar). Theorem 26.19.18(iii) gives $\kappa_{\text{cat}} = 0$ on the non-compact stratum; the strict-compact formula of the CY-C CI-CY₃ strict-stratum gerbe proposition gives $\kappa_{\text{cat}} = \chi(X)/24 \neq 0$ on the compact CI stratum. The two are not contradictory: they are the scalar trace of Φ_3^{cat} on two disjoint strata of the CY₃ moduli, separated by a conifold transition (or by a large-volume degeneration), and the discontinuity of κ_{cat} across the transition is the genus-one wall-crossing jump $\chi/24 \mapsto 0$. The Joyce gerbe $\text{ob}(X)$ experiences the same jump: non-zero of infinite order on the compact stratum, trivial on the non-compact stratum; the common mechanism is the presence or absence of $H^6(X, \mathbb{Z})$, with compact CY₃ carrying a fundamental class and non-compact CY₃ lacking one. Theorem H concentration in $\{0, 1, 2\}$ survives the transition unchanged.

PROPOSITION 26.19.21 (*Humbert divisor $H_1 \subset \mathcal{A}_2$ and the Shioda–Inose partner of $K_3 \times E$*). Let $\mathcal{A}_2$ denote the moduli stack of principally polarised abelian surfaces. For a discriminant $\Delta \in \mathbb{Z}_{>0}$ with $\Delta \equiv 0, 1 \pmod{4}$, the Humbert surface $H_\Delta \subset \mathcal{A}_2$ is the locus of (A, Θ) whose endomorphism ring $\text{End}(A)$ contains a real-quadratic order of discriminant Δ ; at the boundary value $\Delta = 1$ the locus $H_1 \subset \mathcal{A}_2$ is the decomposable stratum

$$H_1 = \{ (A, \Theta) \in \mathcal{A}_2 : (A, \Theta) \simeq (E_1 \times E_2, \Theta_{E_1} \boxplus \Theta_{E_2}) \} \simeq \text{Sym}^2(\mathcal{A}_1),$$

with $\mathcal{A}_1 = \mathbb{H}/\text{SL}_2(\mathbb{Z})$ the modular curve. The Gritsenko weight-5 Siegel paramodular cusp form $\Delta_5 = \Phi_1$ (level 1, character the non-trivial quadratic character of the paramodular group Γ_1^{para}) has

$$\text{div}_{\mathcal{A}_2}(\Delta_5) = H_1, \quad \text{ord}_{H_1}(\Delta_5) = 1, \quad \text{div}_{\mathcal{A}_2}(\Delta_{10}) = 2H_1,$$

where $\Delta_{10} = \Delta_5^2$ is the Igusa weight-10 Siegel cusp form (Igusa 1962, *Amer. J. Math.* 84, Theorem 3). The Shioda–Inose correspondence assigns to a Kummer surface $\text{Kum}(A)$ (the crepant resolution of $A/\langle -1 \rangle$) a unique K3 surface $Y_{\text{SI}}(A)$ carrying a Nikulin involution ι_N with quotient K3 birational to $\text{Kum}(A)$; the Shioda–Inose partner of $A = E_1 \times E_2 \in H_1$ is

$$Y_{\text{SI}}(E_1 \times E_2) \dashrightarrow \text{Kum}(E_1 \times E_2)$$

and its transcendental lattice satisfies $T(Y_{\text{SI}}(E_1 \times E_2)) \simeq T(E_1 \times E_2)(2) = U^{\oplus 2}(2)$, a rank-4 even lattice of discriminant 16, Hodge-isometric to $T(\text{Kum}(E_1 \times E_2))$ via the Shioda–Inose Hodge isomorphism on transcendental cycles (Shioda–Inose 1977, *Complex Analysis and Algebraic Geometry*, Theorem 2; Morrison 1984, *Invent. Math.* 75, Corollary 6.4; the $T \mapsto T(2)$ rescaling by 2 records the degree-2 quotient $A \rightarrow \text{Kum}(A)$, consistent with [96] eq. $T_{\text{Kum}} \subset T_A(2)$). Consequently the compact threefold $K_3 \times E$ admits, along the one-parameter sub-locus where $K_3 = Y_{\text{SI}}(E \times E')$ for some auxiliary elliptic curve E' , a birational model $(Y_{\text{SI}}(E \times E')) \times E$ whose total cohomology decomposes via the Shioda–Inose involution as

$$H^*(Y_{\text{SI}} \times E) \simeq H^*(\text{Kum}(E \times E') \times E)^{\iota_N} \oplus H^*(E \times E')(2)^{-\iota_N}$$

where the second summand records the Kummer lattice correction.

Proof. The Humbert classification is Humbert 1899 as modernised by van der Geer 1988 (*Hilbert Modular Surfaces*, §IX.2): the locus of (A, Θ) with $\text{End}(A) \supset \mathcal{O}_\Delta = \mathbb{Z}[\frac{\Delta + \sqrt{\Delta}}{2}]$ is a non-empty divisor in $\mathcal{A}_2$

whenever $\Delta \equiv 0, 1 \pmod{4}$. For $\Delta = 1$, $\mathcal{O}_1 = \mathbb{Z}[1]$ is the trivial order, and $\text{End}(A) \supset \mathbb{Z}$ is automatic; the Humbert condition collapses to a codimension-1 *reducibility* condition on the polarisation, namely that Θ splits as a sum $\Theta = \Theta_1 \boxplus \Theta_2$ on a product factorisation $A \simeq E_1 \times E_2$ (van der Geer 1988, Theorem IX.2.4). The symmetric-square identification $H_1 \simeq \text{Sym}^2(\mathcal{A}_1)$ reflects the S_2 symmetry permuting the two elliptic factors.

The divisor identity $\text{div}(\Delta_5) = H_1$ with simple vanishing is the Gritsenko–Nikulin theorem (Gritsenko 1999, *Arithmetical lifting and its applications*, St. Petersburg Math. J. 11, Theorem 3; Gritsenko–Hulek–Sankaran *Moduli of K_3 Surfaces*, 2008, Proposition 4.4.3). The argument is: Δ_5 is constructed as the additive lift (exp-lift) of the weak Jacobi form $\phi_{0,1}$ of weight 0 and index 1, and the Borcherds product expansion exhibits Δ_5 as a product over positive roots of the Weyl chamber of the paramodular lattice Γ_1^{para} whose only simple real-root factor is the root defining H_1 (the Gritsenko–Nikulin $N = 1$ case of the eight-form list). The Igusa identity $\Delta_{10} = \Delta_5^2$ is classical (Igusa 1962, *Amer. J. Math.* 84, Theorem 3): the ring of Siegel modular forms of genus 2 and level 1 has Δ_5 as the unique paramodular cusp form of weight 5 (with non-trivial quadratic character), and Δ_5^2 is the unique Γ_2 -invariant cusp form of weight 10, normalised to equal Igusa’s product of ten even theta constants.

The Shioda–Inose correspondence is the statement that a K_3 surface Y with a symplectic involution ι_N fixing 8 isolated points and whose coinvariant lattice $(H^2(Y, \mathbb{Z})^{-\iota_N})_{H^2(Y, \mathbb{Z})}^\perp = E_8(-2)$ determines, and is determined by, an abelian surface A via $Y/\iota_N \dashrightarrow \text{Kum}(A)$ (Shioda–Inose 1977, Theorem 2; Morrison 1984, Corollary 6.4). For $A = E_1 \times E_2$ split, the partner $Y_{\text{SI}}(A)$ has transcendental lattice $T(Y_{\text{SI}}) \simeq T(A)(2)$ where $T(A) = \ker(H^2(A, \mathbb{Z}) \rightarrow \text{NS}(A))$. For a product of generic elliptic curves $T(E_1 \times E_2) = U^{\oplus 2}$ has rank 4 and discriminant 1, hence $T(Y_{\text{SI}}(E_1 \times E_2)) = U^{\oplus 2}(2)$ of rank 4 and discriminant 16. The doubling $T \mapsto T(2)$ comes from the degree-2 rational map $Y_{\text{SI}} \dashrightarrow \text{Kum}(A)$, equivalently the degree-2 quotient $A \rightarrow \text{Kum}(A) = \widetilde{A/\langle -1 \rangle}$ (Nikulin 1975, *Math. USSR-Izv.* 9, Theorem 1), where the sixteen (-2) -curves resolving the 2-torsion of A contribute the Kummer lattice $\Lambda_{\text{Kum}} \subset \text{NS}(\text{Kum}(A))$ orthogonal to $T(\text{Kum}(A))$ (consistent with the canonical Vol III lattice display [96] $\Lambda_{\text{Kum}} = E_8(-2)^{\oplus 2} \oplus \Pi_{1,1}(2) \oplus \langle -2 \rangle^{16}$).

The cohomological decomposition of $H^*(Y_{\text{SI}}(E \times E') \times E)$ follows by applying the Künneth formula to the Shioda–Inose factor and then decomposing $H^*(Y_{\text{SI}})$ into ι_N -invariant and ι_N -coinvariant parts: the invariant part coincides with $H^*(\text{Kum}(E \times E'))$ up to the Nikulin resolution divisor, and the coinvariant part is the $E_8(-2)$ lattice summand inside $H^2(Y_{\text{SI}}, \mathbb{Z})$ which carries the transcendental information of $E \times E'$ doubled (Nikulin 1979, *Trudy Moskov. Mat. Obsch.* 38, Theorem 4.5). The second summand of the stated decomposition is the Hodge realisation of this $E_8(-2)$ summand tensored with the elliptic curve factor. $\square$

Remark 26.19.22 (Humbert vanishing, paramodular divisor, and the existence-obstruction for CY_3 beyond $K_3 \times E$). The Humbert divisor $H_1 \subset \mathcal{A}_2$ is the geometric locus where the Gritsenko paramodular cusp form Δ_5 encodes the complementarity constraint of Theorem C: the Shioda–Inose correspondence on this locus is the mechanism by which $\kappa_{\text{BKM}}(\Delta_5) = c_1(0)/2 = 5$ is realised as a Borcherds weight on the K_3 side ([96] Theorem 32.8.1, $N = 1$). Three points crystallise the obstruction to extending the $K_3 \times E$ construction beyond the Shioda–Inose locus.

(i) The boundary $\mathcal{A}_2 \setminus H_1$ is the locus of *irreducible* principally polarised abelian surfaces, which is the Torelli image of Jacobians $\text{Jac} : \mathcal{M}_2 \hookrightarrow \mathcal{A}_2$ (Weil 1957, *Amer. J. Math.* 79; Oort–Ueno 1973). On this open locus Δ_5 is nowhere vanishing, and the paramodular Borcherds product expansion converges everywhere, giving the Gritsenko–Hulek denominator identity for the generic Jacobian. The Humbert divisor H_1 is thus the unique obstruction to global non-vanishing of Δ_5 , and correspondingly the unique

locus where the Shioda–Inose partner $Y_{SI}(A)$ degenerates from a transcendental-lattice rank-4 K_3 to a Kummer surface of an explicit product.

(ii) The Gritsenko–Cléry diagonal-divisor catalogue is not the CHL constant table. Its complete triple-indexed weight tuple is

$$(5, 2, 3, 1, 2, \frac{1}{2}, \frac{3}{2}, 1),$$

with twice-weight tuple $(10, 4, 6, 2, 4, 1, 3, 2)$; the CHL ladder uses $(10, 8, 6, 4, 2)$ as the constant terms for $N \in \{1, 2, 3, 4, 6\}$. The two automorphic scopes overlap only at Δ_5 . The existence obstruction beyond the $K_3 \times E$ host is therefore not a missing entry in one eight-term list, but the absence of a compact CY_3 host and compact source package realising the relevant automorphic row.

(iii) For the $K_3 \times E$ threefold specifically, the Shioda–Inose locus inside the relevant moduli substack of K_3 surfaces with a Nikulin involution is exactly the pull-back of $H_1 \subset \mathcal{A}_2$ under the Kuga–Satake map $KS : \mathcal{F}_{2d} \rightarrow \mathcal{A}_g$ for the polarised K_3 moduli $\mathcal{F}_{2d}$ of degree $2d$ (Kuga–Satake 1967, *Indag. Math.* 29; Deligne 1972, *Invent. Math.* 15). The corrected $K_3 \times E$ record is not a total-space spectrum with fibre value 2 inserted. It is the four-invariant package $\kappa_{ch}(K_3 \times E) = 0$ and $\kappa_{cat}(K_3 \times E) = 0$ on the compact product (Künneth-multiplicative: $\chi(\mathcal{O}_{K_3}) \cdot \chi(\mathcal{O}_E) = 2 \cdot 0 = 0$), $\kappa_{ch}^{Heis} = 3$ on the Heisenberg realisation, $\kappa_{BKM} = 5 = c_1(0)/2$ for Δ_5 on H_1 , and $\kappa_{fiber} = 24 = \chi_{top}(K_3)$. The auxiliary number $\chi(\mathcal{O}_{K_3}) = 2$ belongs to the K_3 fibre factor, not to the compact CY_3 total space; route sizes are generator ranks ρ^{R_i} , not route-dependent κ_{ch} values. The Shioda–Inose partner of the fibre Euler number (via $\text{Kum}(E \times E')$) carries the Niemeier-lattice enhancement of Mukai 1988 (*Invent. Math.* 94, §4) realising the Mathieu $\mathcal{M}_{23} \subset \mathcal{M}_{24}$ mock-modular shadow (Eguchi–Ooguri–Tachikawa 2010, arXiv:1004.0956).

The operating obstruction for CY_3 beyond $K_3 \times E$ is that only the H_1 -locus admits a Shioda–Inose partner with split Kummer origin; off H_1 , the Shioda–Inose K_3 has transcendental lattice $U^{\oplus 2} \oplus \langle -2\Delta \rangle$ with $\Delta > 1$ non-trivial, and the corresponding Borcherds product is not in the Gritsenko Φ_N -family. The existence of a CY_3 realising the BKM structure becomes a lattice-theoretic problem parametrised by $\Delta \in \mathbb{Z}_{>0}$; the Humbert discriminant; with the answer known only at $\Delta = 1$.

PROPOSITION 26.19.23 (*Reduced virtual class on $\text{Hilb}^n(S \times E, \beta_h)$ and the Δ_5^{-2} exponent lattice*). Let $\pi : S \rightarrow \mathbb{P}^1$ be a smooth elliptically fibered K_3 surface with zero-section $s \in \text{Pic}(S)$ and fibre class $F \in \text{Pic}(S)$ satisfying $s^2 = -2$, $s \cdot F = 1$, $F^2 = 0$ (Saint-Donat genus-0 normal form). Let E be an elliptic curve and $X = S \times E$ the compact Calabi–Yau threefold. For $h \geq 0$, $d \geq 1$, $n \in \mathbb{Z}$, set

$$\beta_{h,d} = (s + hF, d \cdot [E]) \in H_2(X; \mathbb{Z}) = \text{NS}(S) \oplus H_2(E; \mathbb{Z}),$$

and let $\text{Hilb}^n(X, \beta_{h,d})$ be the Hilbert scheme of one-dimensional subschemes $Z \subset X$ with $[Z] = \beta_{h,d}$ and $\chi(\mathcal{O}_Z) = n$. The following four statements hold, all at chain level.

- (i) *MNOP perfect obstruction theory, virtual dimension zero.* The tangent–obstruction complex $\mathbb{E}^\bullet = \text{RHom}(\mathbb{I}, \mathbb{I})_0[1]$, with $\mathbb{I}$ the universal ideal sheaf, is perfect of amplitude $[-1, 0]$ and virtual rank

$$\text{rk}(\mathbb{E}^\bullet) = -\chi(\mathbb{I}, \mathbb{I})_0 = \int_{\beta_{h,d}} c_1(T_X) = 0$$

on the CY_3 X (Maulik–Nekrasov–Okounkov–Pandharipande 2006a arXiv:math/0312059 §4; $c_1(T_X) = 0$ by Künneth $T_{S \times E} = \text{pr}_1^* T_S \oplus \text{pr}_2^* T_E$ with $c_1(T_S) = 0$ and $c_1(T_E) = 0$).

- (ii) *Reduction along the free E -translation.* The holomorphic symplectic 2-form on the smooth elliptic-curve factor produces a trivial line-bundle summand of $\mathbb{E}^\bullet$ corresponding to the moment-map

direction of the free $\mathbb{C}^\times$ -action on $\text{Hilb}^n(X, \beta_{h,d})$ by E -translation (free because $d \geq 1$). Quotienting by this summand gives a reduced perfect obstruction theory $\mathbb{E}_{\text{red}}^\bullet$ of virtual dimension

$$\text{vd}^{\text{red}}(\text{Hilb}^n(X, \beta_{h,d})) = \text{vd} + 1 = 1$$

(Bryan–Oberdieck–Pandharipande–Yin 2016 arXiv:1506.00841 Proposition 3; Oberdieck 2014 arXiv:1406.1139 §2).

(iii) *Behrend χ -weighted integration.*

$$\text{DT}_{n, \beta_{h,d}}^{X, \text{red}} := \int_{[\text{Hilb}^n(X, \beta_{h,d})]^{\text{vir, red}}/E} 1 = \sum_{k \in \mathbb{Z}} k \cdot \chi(\nu^{-1}(k)),$$

where $\nu : \text{Hilb}^n(X, \beta_{h,d}) \rightarrow \mathbb{Z}$ is Behrend’s constructible function and the quotient is by the free E -action (Behrend 2009, *Ann. Math.* 170, Theorem 4.18).

(iv) *Lattice self-pairing and the Δ_5^{-2} reciprocal.* On the K_3 Picard lattice, the self-pairing of the reduced curve class is

$$\langle \beta_h, \beta_h \rangle_{\text{NS}(S)} = s^2 + 2h(s \cdot F) + h^2 F^2 = -2 + 2h = 2(h - 1),$$

hence the t -exponent in the reciprocal-square generating series is $\frac{1}{2} \langle \beta_h, \beta_h \rangle = h - 1$, and the reduced DT generating series evaluates to

$$Z^{X, \text{red}}(q, t, p) = \sum_{h \geq 0} \sum_{d \geq 1} \sum_{n \in \mathbb{Z}} \text{DT}_{n, \beta_{h,d}}^{X, \text{red}} q^{d-1} t^{h-1} (-p)^n = -(\Phi_{10}^{\text{OP}}(q, t, p))^{-1} = -D_5(q, t, p)^{-2} = -4096 \Delta_5(q, t, p)^{-2}$$

in Oberdieck–Pandharipande normalisation:

$$D_5 = 64^{-1} \Delta_5, \quad \Phi_{10}^{\text{OP}} = D_5^2 = 4096^{-1} \Delta_5^2, \quad Z^{X, \text{red}} = -(\Phi_{10}^{\text{OP}})^{-1} = -D_5^{-2}.$$

Here Δ_5 is the primitive Igusa genus-2 cusp form of weight 5 and q, t, p are the Fourier–Jacobi variables on $\mathbb{H}_2$ associated to z_3 (E -fibre), z_0 (K_3 -base) and z_1 (Mukai–Heisenberg). The shifts q^{d-1} and t^{h-1} are the Gritsenko Weyl-vector shifts $\rho = f_2 - \frac{1}{2}f_3 + f_{-2}$ of the $\Lambda_{II}^{2,1}$ hyperbolic root datum (Gritsenko 1999 arXiv:math/9906190 Theorem 2.1; Oberdieck–Pandharipande 2016 arXiv:1406.1139 Theorem 1).

Proof. (1) For any projective CY_3 X , the trace-free derived endomorphism sheaf of the universal ideal is a perfect two-term obstruction theory; the virtual dimension equals $\int_\beta c_1(T_X)$, which vanishes on a CY_3 (MNOP 2006a Theorem 4.1). (2) The E -translation action is free on $\text{Hilb}^n(X, \beta_{h,d})$ whenever the E -component $d \cdot [E]$ is non-zero, enforced by $d \geq 1$. The holomorphic symplectic 2-form on E produces a trivial line-bundle summand of $\mathbb{E}^\bullet$ along the moment-map direction; quotienting by this summand is the reduction construction of Bryan–Oberdieck–Pandharipande–Yin 2016 (Proposition 3, adapted from K_3 to $K_3 \times E$ because the K_3 side is already reduced and the product structure commutes with reduction). The dimension increases by one because one obstruction has been eliminated. (3) Behrend’s theorem: for a scheme $\mathcal{M}$ admitting a symmetric perfect obstruction theory with virtual class integrating to a number, $\int_{[\mathcal{M}]^{\text{vir}}} 1 = \sum_k k \cdot \chi(\nu^{-1}(k))$. The reduced obstruction theory on $\text{Hilb}^n(X, \beta_{h,d})/E$ is symmetric (MNOP symmetry inherited from Serre duality on a CY_3 descends to the free quotient), so the identity applies. (4) The intersection numbers $s^2 = -2$, $s \cdot F = 1$, $F^2 = 0$ are the defining invariants of a smooth elliptic K_3 with section (s a (-2) -curve by Saint-Donat genus-0

adjunction). Expanding the bilinear form gives the stated $2(h-1)$. For the reciprocal-square identity: Oberdieck–Pandharipande 2016 prove the reduced DT partition function of $K_3 \times E$ as the reciprocal of the Oberdieck–Pandharipande monic Igusa product $\Phi_{10}^{\text{OP}} = D_5^2$, where $D_5 = 64^{-1}\Delta_5$ and hence $\Phi_{10}^{\text{OP}} = 4096^{-1}\Delta_5^2$. Therefore $Z^{X,\text{red}} = -(\Phi_{10}^{\text{OP}})^{-1} = -D_5^{-2} = -4096\Delta_5^{-2}$. The primitive automorphic correction algebra is still $\mathfrak{g}_{\Delta_5}$; the Oberdieck–Pandharipande scalar square is not the BKM denominator. The Weyl-vector shift $\rho = f_2 - \frac{1}{2}f_3 + f_{-2}$ of $\Lambda_{II}^{2,1}$ contributes a multiplicative $q^{-1}t^{-1}p^{-1}$ prefactor to the denominator product expansion (Gritsenko 1999 Theorem 2.1), recovering the $q^{d-1}t^{h-1}$ shifts. $\square$

Remark 26.19.24 (Arithmetic of β_h -conventions across BOPY, Oberdieck–Pandharipande, and $\mathfrak{g}_{\Delta_5}$). Three curve-class conventions populate the reduced-DT literature on $K_3 \times E$; they coincide as lattice classes and differ only in the integer shift chosen for the generating-series exponent. (a) Oberdieck–Pandharipande 2016 arXiv:1406.1139 index by $t^{\beta^2/2}$ with $\beta = s + hF$ and $\beta^2 = 2(h-1)$, hence t -exponent $h-1$ and a t^{-1} -prefactor absorbed into the Weyl-vector shift. (b) Bryan–Oberdieck–Pandharipande–Yin 2016 arXiv:1506.00841 index abelian CY_3 by $t^{\beta^2/2+1}$ with the Weyl shift absorbed, t -exponent h , no prefactor. (c) The automorphic-correction construction (the CY-C-beyond- $K_3 \times E$ existence-obstruction section above; cf. the $\Lambda^{3,2}$ -transfer of the CY-C-beyond-non- $K_3 \times E$ - CY_3 section) writes $t^{(1/2)\langle\beta_h, \beta_h\rangle}$ in the Oberdieck–Pandharipande convention. Conversion to BOPY is the substitution of t^{h-1} by t^h with a compensating t^{-1} in the scalar prefactor; the $\beta_h^2/2 = h-1$ identity is convention-independent, and the t -shift is a Weyl-vector normalisation choice at the $\Lambda_{II}^{2,1}$ root datum $\rho = f_2 - \frac{1}{2}f_3 + f_{-2}$. The fibre-degree shift q^{d-1} has the same origin: Gritsenko–Weyl-vector shift in the f_{-2} -component, equivalently the first Fourier–Jacobi coefficient $\phi_{5,1}(z_1, z_2)$ of Δ_5 being supported at $q^{1/2}$ rather than q^0 (Igusa 1972; Maass 1971 explicit multiplier formula ν_{Δ_5}). PT/DT stable-pairs correspondence (Pandharipande–Thomas 2009, *Invent. Math.* 178 §3) identifies $Z_{\text{PT}}^{X,\text{red}} = Z_{\text{DT}}^{X,\text{red}} / Z_{\text{DT}, \beta=0}^{X,\text{red}}$; on $X = S \times E$ the denominator is the constant-map contribution and the ratio evaluates in Oberdieck–Pandharipande normalisation to $-(\Phi_{10}^{\text{OP}})^{-1} = -D_5^{-2} = -4096\Delta_5^{-2}$ in the reduced theory (Oberdieck 2018 arXiv:1708.08485 Theorem 1). The reciprocal square is the Oberdieck–Pandharipande reduced-DT scalar. The primitive BKM denominator remains Δ_5 , with the 2-torsion multiplier ν_{Δ_5} of Maass 1971 controlling the square-root automorphic character.

THEOREM 26.19.25 (CHL vs programme N -list disjunction and the Jatkar–Sen/Gritsenko weight dichotomy). Let $N \in \mathbb{Z}_{\geq 1}$. Two distinct families of genus-2 Siegel modular forms Φ_N enter the $(K_3 \times E)$ -adjacent literature under identical notation; they are *not* the same automorphic datum and their weight laws do not coincide even on their common index set. (i) The programme family indexed by $N \in \{1, 2, 3, 4, 6\}$ is the set of Hodge–elliptic orders $|\text{Aut}(E)/\{\pm 1\}|$ admissible as a $\mathbb{Z}_N$ -action on the E -factor of $K_3 \times E$ preserving a holomorphic symplectic form. For this family the BKM denominator weight satisfies the Borcherds identity

$$\kappa_{\text{BKM}}(\Phi_N^{\text{prog}}) = c_N(0)/2 = (5, 4, 3, 2, 1)_{N=1,2,3,4,6},$$

where $c_N(0)$ is the constant term of the associated weak Jacobi form and Φ_N^{prog} is the paramodular Siegel cusp form of integer weight produced by Gritsenko–Nikulin’s exponential lift of $\phi_{0,1}^{(N)}$ (Gritsenko 1999, *St. Petersburg Math. J.* 11 §§2–3; Gritsenko–Nikulin 1997, *Duke Math. J.* 119). (ii) The CHL family of Jatkar–Sen (arXiv:hep-th/0510147 §2.3) indexed by $N \in \{1, 2, 3, 5, 7, 11\}$ is the set of orders of $\mathbb{Z}_N \subset \text{Aut}(\text{Co}_0)$ admitting a level-matching $(-1)^{F_L}$ shift on the T^2 of Type IIA on $(K_3 \times T^2)/\mathbb{Z}_N$. For this family

$$\text{wt}(\Phi_N^{\text{CHL}}) = \frac{24}{N+1} - 2 = (10, 6, 4, 2, 1, 0)_{N=1,2,3,5,7,11}.$$

(iii) The index sets intersect in $\{1, 2, 3\} \subsetneq \{1, 2, 3, 5, 7, 11\} \cap \{1, 2, 3, 4, 6\}$, and the programme weights $(5, 4, 3)$ and CHL weights $(10, 6, 4)$ at this intersection satisfy the weight-doubling identity $N = 1$, $\Phi_{10}^{\text{un, CHL}} = \Delta_5^2 = (\Phi_1^{\text{prog}})^2$, which fails strictly for $N = 2, 3$: the CHL and programme Φ_N are square-related only at $N = 1$; at $N = 2, 3$ they are distinct automorphic objects on different paramodular groups with $(6, 4) \neq 2 \cdot (4, 3)$. At $N = 11$ the CHL weight is 0, identifying Φ_{11}^{CHL} with a non-cuspidal weight-0 modular function (the level-11 Igusa cusp form degenerates to the cosmological-constant sector of the CHL BPS index).

Proof. (i) The Hodge-elliptic automorphisms $E \rightarrow E$ fixing a symplectic form form the cyclic group of order $|\text{Aut}(E)/\{\pm 1\}| \in \{1, 2, 3, 4, 6\}$ (Silverman, *Arithmetic of Elliptic Curves*, Appendix A § 1): orders 2, 4, 6 on the square and hexagonal CM lattices, order 3 at the equianharmonic point, order 1 generic. On each, Gritsenko's exponential lift $\text{Exp} : \phi_{0,1}^{(N)} \mapsto \Phi_N^{\text{prog}}$ from *weight 0 index 1* weak Jacobi forms produces a weight $c_N(0)/2$ Siegel cusp form on the paramodular group Γ_N^+ (Gritsenko 1999 Theorem 1.1; weight formula Theorem 2.1). Evaluation: $c_1(0) = 10, c_2(0) = 8, c_3(0) = 6, c_4(0) = 4, c_6(0) = 2$ read off $\phi_{0,1}^{(N)}$ from its Fourier expansion $\phi_{0,1}^{(N)}(\tau, z) = \sum_{n \geq 0} c_N(n) q^n \zeta^{\pm r(n)}$, tabulated in Eichler–Zagier 1985 *The Theory of Jacobi Forms* Table 1. (ii) The CHL orbifold $(K_3 \times T^2)/\mathbb{Z}_N$ (Jatkar–Sen 2005 arXiv:hep-th/0510147 § 2) selects N such that the associated conjugacy class in Co_0 has cycle shape admitting a level-matching $(-1)^{F_L}$ shift on T^2 ; the admissible orders are $\{1, 2, 3, 5, 7, 11\}$ (the *balanced* N_i -classes of M_{23} , see Chaudhuri–Hockney–Lykken 1995 *PRL* 75 2264, Table I; alternatively Mukai 1988 *Invent. Math.* 94 for the M_{23} connection to K_3 symplectic automorphisms). The BPS index on this orbifold is $1/\Phi_N^{\text{CHL}}$ with Φ_N^{CHL} a Siegel modular form of weight $24/(N+1) - 2$ on $\text{Sp}_4(\mathbb{Z}) \cap \Gamma_0(N)$ (Jatkar–Sen 2005 § 3, Theorem 1; David–Jatkar–Sen 2006 arXiv:hep-th/0603066 § 2.2 rederivation). Evaluation at $N = 1, 2, 3, 5, 7, 11$ gives 10, 6, 4, 2, 1, 0. (iii) Set-theoretically $\{1, 2, 3, 4, 6\} \cap \{1, 2, 3, 5, 7, 11\} = \{1, 2, 3\}$ because $4, 6 \notin \{1, 2, 3, 5, 7, 11\}$ and $5, 7, 11 \notin \{1, 2, 3, 4, 6\}$. The programme weights $(5, 4, 3)$ and CHL weights $(10, 6, 4)$ at $N = 1, 2, 3$ relate by doubling only at $N = 1$: the Igusa–Jatkar–Sen form $\Phi_{10}^{\text{un}} = \Delta_5^2$ (Igusa 1964 *Am. J. Math.* 86; the Δ_5 -square identity is the content of Gritsenko–Nikulin 1995 arXiv:alg-geom/9504006 Theorem 1.2), so $\Phi_1^{\text{CHL}} = (\Phi_1^{\text{prog}})^2$. At $N = 2$ one has Φ_2^{CHL} of weight 6 on Γ_2^+ while Φ_2^{prog} of weight 4 on Γ_2^+ ; their ratio $\Phi_2^{\text{CHL}}/(\Phi_2^{\text{prog}})^2$ has weight $6 - 8 = -2$ and is *not* a paramodular form, so $\Phi_2^{\text{CHL}} \neq (\Phi_2^{\text{prog}})^2$. Similarly Φ_3^{CHL} weight 4 versus $(\Phi_3^{\text{prog}})^2$ weight 6 fails. At $N = 11$ weight 0: Jatkar–Sen 2005 § 3.2 identifies Φ_{11}^{CHL} as a multiplicative eta-quotient of weight 0 on $\Gamma_0(11) \subset \text{Sp}_4$, the minimal extremal weight at which the Hodge-anomaly-free CHL partition function degenerates to a cosmological-constant contribution (David–Jatkar–Sen 2006 § 5 Cremmer–Julia dilaton asymptotics). $\square$

Remark 26.19.26 (Physical dichotomy and the weight-doubling obstruction). The programme Φ_N^{prog} is the BKM denominator of the automorphic correction algebra $\mathfrak{g}_{\Phi_N}$ governing reduced DT of $(K_3 \times E)/\mathbb{Z}_N$ with $\mathbb{Z}_N \subset \text{Aut}(E)$ a Hodge-elliptic translation-free action. The CHL Φ_N^{CHL} is the BPS index generating function of Type IIA on $(K_3 \times T^2)/\mathbb{Z}_N$ with $\mathbb{Z}_N \subset \text{Aut}(\text{Co}_0)$ a Mukai–Mathieu automorphism of K_3 combined with a $(-1)^{F_L}$ shift on T^2 . The physical setups are orthogonal: programme selects $\mathbb{Z}_N \subset \text{Aut}(E)$ (elliptic-curve symmetry, CM-type), CHL selects $\mathbb{Z}_N \subset \text{Aut}(\text{Co}_0)$ (sporadic-group symmetry of the Leech lattice via M_{23}). Their intersection $\{1, 2, 3\}$ is the set of N for which both $\text{Aut}(E)$ and Co_0 admit a cyclic subgroup of order N ; that two independent number-theoretic constraints intersect non-trivially is the arithmetic coincidence that made Jatkar–Sen's 2005 proposal recoverable from Ooguri–Vafa 2004 DT counts of $K_3 \times E$ at $N = 1$, the doubling $\Phi_{10}^{\text{un}} = \Delta_5^2$ incarnating the CHL-to-programme identification at the unorbifolded locus. The weight-doubling at $N = 1$ is *not* a universal

CHL-to-programme relation: the CHL weight formula $24/(N+1) - 2$ and the programme weight formula $c_N(o)/2$ agree at $N = 1$ because $24/2 - 2 = 10 = 2 \cdot 5 = 2 \cdot c_1(o)/2$, but the factor 2 is the $\Delta_5 \mapsto \Delta_5^2$ multiplier ν_{Δ_5} squaring to the trivial character on $\mathrm{Sp}_4(\mathbb{Z})$ (Maass 1971) and has *no* geometric counterpart at $N \geq 2$. At $N = 2, 3$ the CHL and programme paramodular groups $\Gamma_N^+ \cap \Gamma_o(N)$ vs Γ_N^+ differ, and the $(-1)^{F_L}$ shift on T^2 breaks the $\mathrm{Aut}(E)$ -compatible Hodge structure used by Gritsenko's exponential lift; the two Siegel forms are *different* automorphic objects on *different* discrete groups. Treating Φ_N^{CHL} and Φ_N^{prog} as the same datum under their common notation is an error of category, not of arithmetic; it conflates $\mathrm{Aut}(E)$ -elliptic symmetry with M_{23} -sporadic symmetry and produces weight predictions off by doubling factors and modular-group mismatches. The only safe policy is to index the programme construction by Hodge-elliptic orders $N \in \{1, 2, 3, 4, 6\}$, to index CHL by $N \in \{1, 2, 3, 5, 7, 11\}$, and to note that the two indexings agree only at $N = 1$ up to the Δ_5 square-root convention. The weight-0 CHL entry at $N = 11$, Φ_{11}^{CHL} , has no programme analogue: $11 \notin \{1, 2, 3, 4, 6\}$, no elliptic curve has an order-11 automorphism, and the weight-0 degeneration is the signature of a vanishing cosmological constant in the $N = 4$ CHL string (Sen 2007 arXiv:hep-th/0702141 § 4.3), not a BKM denominator in the Gritsenko–Borchers sense.

PROPOSITION 26.19.27 (*E-tangent reduction as $\mathbb{C}^\times$ -quotient and the $\frac{1}{2}\langle\beta_h, \beta_h\rangle = h - 1$ identification*). Let $X = S \times E$ with S a smooth elliptically fibered K_3 with zero-section s , fibre F , intersection invariants $s^2 = -2$, $s \cdot F = 1$, $F^2 = 0$, and let $\beta_{h,d} = (s + hF, d[E])$ with $h \geq 0$, $d \geq 1$. Write $M_{n,\beta_{h,d}} := \mathrm{Hilb}^n(X, \beta_{h,d})$ for the Hilbert scheme of 1-dimensional subschemes $Z \subset X$ with $[Z] = \beta_{h,d}$ and $\chi(O_Z) = n$. Then the four identifications

- (i) $\mathbb{C}^\times$ -reduction = *E-tangent reduction*. The free action of the 1-dimensional torus $E^\circ \simeq \mathbb{C}^\times$ by E -translation on $M_{n,\beta_{h,d}}$ (free because $d[E] \neq 0$) induces on the MNOP tangent–obstruction complex $\mathbb{E}^\bullet = \mathrm{R}\mathcal{H}om(\mathbb{L}, \mathbb{L})_o[1]$ a trivial rank-1 summand $\mathbb{L}$ along the moment-map direction of the E -translation; the quotient $\mathbb{E}_{\mathrm{red}}^\bullet := \mathbb{E}^\bullet/\mathbb{L}$ is perfect of amplitude $[-1, 0]$, symmetric under Serre duality on the free quotient $M_{n,\beta_{h,d}}/E$, and is the unique reduced perfect obstruction theory adapted to the $\mathbb{C}^\times$ -quotient (Oberdieck 2018 arXiv:1708.08485 §2.2; Maulik–Pandharipande 2013 arXiv:0710.3459 Proposition 3 on K_3 -reduction, transferred to $K_3 \times E$ along the E -factor because E -translation is a symplectomorphism of $\omega_E \wedge \omega_{K_3}$).
- (ii) *Virtual dimension and Behrend integration*. On the CY₃ X , $\mathrm{vd} = \int_{\beta_{h,d}} c_1(T_X) = 0$; removing the trivial rank-1 summand in (i) yields $\mathrm{vd}^{\mathrm{red}} = \mathrm{vd} + 1 = 1$, and

$$\mathrm{DT}_{n,\beta_{h,d}}^{X,\mathrm{red}} := \int_{[M_{n,\beta_{h,d}}]^{\mathrm{vir},\mathrm{red}}/E} 1 = \sum_{k \in \mathbb{Z}} k \cdot \chi(\nu^{-1}(k))$$

by Behrend's χ -weighted Euler-characteristic formula on the symmetric reduced theory (Behrend 2009 *Ann. Math.* 170 Theorem 4.18; symmetry descends to the free quotient because $\mathbb{C}^\times$ acts by symplectomorphisms).

- (iii) $\frac{1}{2}\langle\beta_h, \beta_h\rangle = h - 1$ and the Oberdieck slide convention. On $\mathrm{NS}(S)$ with the invariants $s^2 = -2$, $s \cdot F = 1$, $F^2 = 0$,

$$\langle\beta_h, \beta_h\rangle = (s + hF) \cdot (s + hF) = s^2 + 2h(s \cdot F) + h^2 F^2 = -2 + 2h,$$

so $\frac{1}{2}\langle\beta_h, \beta_h\rangle = h - 1$. The Oberdieck–Pandharipande 2016 convention (arXiv:1406.1139 Theorem 1) writes $t^{(1/2)\langle\beta_h, \beta_h\rangle} = t^{h-1}$ in the reduced DT partition function; the Gritsenko–Weyl-vector shift $\rho = f_2 - \frac{1}{2}f_3 + f_{-2}$ of $\Lambda_{II}^{2,1}$ contributes a t^{-1} -prefactor absorbed into the scalar normalisation; the displayed exponent $t^{(1/2)\langle\beta_h, \beta_h\rangle}$ is the Oberdieck convention.

(iv) *Evaluation to the Oberdieck–Pandharipande scalar.* Under the conventions of (3),

$$Z^{X, \text{red}}(q, t, p) = \sum_{h \geq 0} \sum_{d \geq 1} \sum_{n \in \mathbb{Z}} \text{DT}_{n, \beta_{h,d}}^{X, \text{red}} q^{d-1} t^{h-1} (-p)^n = -(\Phi_{10}^{\text{OP}}(q, t, p))^{-1} = -D_5(q, t, p)^{-2} = -4096 \Delta_5(q, t, p)^{-2}$$

where $D_5 = 64^{-1} \Delta_5$ and $\Phi_{10}^{\text{OP}} = D_5^2 = 4096^{-1} \Delta_5^2$ (Oberdieck 2018 Theorem 1; Igusa 1972 Corollary 7.2 normalisation $f_{\Delta_5}(1, 1, 1) = 64$). The primitive BKM denominator remains Δ_5 .

Proof. (1) Freedom of E -translation on $M_{n, \beta_{h,d}}$: if $\sigma_e Z = Z$ for $e \in E$, then e fixes the E -projection of $[Z] = d[E]$, which for $d \geq 1$ forces $e = 0$. The holomorphic $\omega_E \in H^0(E, \Omega_E^1)$ produces a trivial summand $\mathbb{L}$ of $\mathbb{E}^\bullet$ by cup-product with the universal ideal (Maulik–Pandharipande 2013 §2.2 on the E -factor; the construction mirrors K_3 -reduction because E -translation is a symplectomorphism of $\omega_E \wedge \omega_{K_3}$). Perfectness of amplitude $[-1, 0]$ and Serre-duality symmetry are preserved under removing a trivial summand on a free $\mathbb{C}^\times$ -quotient. (2) $c_1(T_X) = 0$ on the CY_3 gives $\text{vd} = 0$; removing $\mathbb{L}$ raises dimension by one. The reduced theory is symmetric because Serre duality on $X, R\mathcal{H}om(\mathbb{L}, \mathbb{L})_0[1] \simeq R\mathcal{H}om(\mathbb{L}, \mathbb{L})_0[2]^\vee$, descends to the free quotient (E -translation preserves ω_E). Behrend 2009 Theorem 4.18 then applies. (3) The invariants $s^2 = -2, s \cdot F = 1, F^2 = 0$ are forced by Saint-Donat genus-0 normal form on a smooth elliptic K_3 with section; bilinear expansion gives $-2 + 2h$. (4) Reduced DT on $K_3 \times E$ equals the inverse of the Oberdieck–Pandharipande monic product by Oberdieck–Pandharipande 2016 Theorem 1. With $D_5 = 64^{-1} \Delta_5$, one has $\Phi_{10}^{\text{OP}} = D_5^2 = 4096^{-1} \Delta_5^2$, hence $Z^{X, \text{red}} = -(\Phi_{10}^{\text{OP}})^{-1} = -D_5^{-2} = -4096 \Delta_5^{-2}$. The $(-p)^n$ sign is the Oberdieck–Pandharipande chamber sign; it does not alter the primitive denominator Δ_5 . $\square$

Remark 26.19.28 (The reduction as $\mathbb{C}^\times$ -quotient: three dictionary entries). The equivalence

$$\{E\text{-tangent reduction of } \mathbb{E}^\bullet\} \iff \{\text{free } \mathbb{C}^\times\text{-quotient by } E\text{-translation}\}$$

is the central technical mechanism of Oberdieck 2018 §2.2, and expresses a structural fact about reduced virtual classes on $K_3 \times E$ (and more generally on $\text{HK} \times E$ for HK hyperkähler): the holomorphic symplectic form on the E -factor is the source of the trivial summand $\mathbb{L}$ in $\mathbb{E}^\bullet$, and the corresponding flat direction of the moment map is the E -translation direction. Three dictionary entries anchor the convention landscape. (a) *Maulik–Pandharipande 2013 K_3 -reduction.* On S , the holomorphic symplectic 2-form produces a trivial summand of the Hilbert-scheme obstruction theory; reduction amounts to quotienting by the $\mathbb{C}^\times$ acting via the moment map. On $K_3 \times E$, the E -factor plays the rôle of the “extra” symplectic direction, mediated by the Shioda–Inose partner $\text{Kum}(E \times E')$ at discriminant $\Delta = 1$ (Mukai 1988 *Invent. Math.* 94 §4). (b) *BOPY 2016 abelian reduction.* For abelian CY_3 ’s $X = \text{Ab} \times E$, Bryan–Oberdieck–Pandharipande–Yin arXiv:1506.00841 Proposition 3 proves the analogous reduction with the trivial summand corresponding to the full translation action, raising virtual dimension by 3. The $K_3 \times E$ case here is the 1-dimensional specialization along the E -factor, with K_3 already internally reduced. (c) *Oberdieck–Pandharipande scalar versus primitive denominator.* Reduced DT on $K_3 \times E$ is the Oberdieck–Pandharipande scalar $-(\Phi_{10}^{\text{OP}})^{-1} = -D_5^{-2} = -4096 \Delta_5^{-2}$, where $\Phi_{10}^{\text{OP}} = D_5^2$ and $D_5 = 64^{-1} \Delta_5$. The BKM denominator of $\mathfrak{g}_{\Delta_5}$ is the primitive form Δ_5 , selected by the automorphic-correction construction with the ν_{Δ_5} -multiplier of Maass 1971 fixing the branch. The exponent $t^{(1/2)\langle \beta_h, \beta_h \rangle} = t^{h-1}$ is Oberdieck-convention and matches the Oberdieck exponent formula; the BOPY-convention t^h absorbs the Weyl-vector t^{-1} into a compensating prefactor. The verification is: (i) $\frac{1}{2}\langle \beta_h, \beta_h \rangle = h - 1$ by direct intersection on $\text{NS}(S)$ with $s^2 = -2, s \cdot F = 1, F^2 = 0$, matching the Oberdieck exponent; (ii) $\text{vd}^{\text{red}} = 1$ via $\mathbb{C}^\times$ -quotient of the MNOP virtual dimension 0; (iii) Behrend symmetry descending to

the free quotient because E -translation is a symplectomorphism; (iv) MNOP plus reduction evaluating to $-(\Phi_{10}^{\text{OP}})^{-1} = -D_5^{-2} = -4096\Delta_5^{-2}$ in Oberdieck–Pandharipande normalisation, consistent with Oberdieck 2018 Theorem 1; (v) the identification of E -tangent reduction with free $\mathbb{C}^\times$ -quotient by E -translation as the structural principle underneath Oberdieck’s reduction theorem; the “cosmological constant piece” of the partition function is precisely the E -translation moment-map direction factored out of the Hilbert-scheme obstruction theory.

PROPOSITION 26.19.29 (*The $\mathbb{Z}/N\mathbb{Z}$ -orbifold $CY_3 X = (S \times E)/\langle(g_N, \tau_{e_o})\rangle$, E -torsion section tower, and β_h as reduced curve class*). Fix $N \in \{1, 2, 3, 4, 5, 6, 7, 8\}$. Let (S, g_N) be a smooth K_3 surface with a symplectic automorphism of order N in the Nikulin list (Nikulin 1979, *Trudy Moskov. Mat. Obsch.* 38, Theorem 4.7; Mukai 1988, *Invent. Math.* 94, §1; the eight orders $N \leq 8$ are the only possible orders of a symplectic finite-order K_3 automorphism with non-empty Mukai-lattice fixed stratum), and let (E, e_o) be an elliptic curve with a primitive N -torsion point $e_o \in E[N]$. Let $\tau_{e_o} : E \rightarrow E$ denote translation by e_o . Let $\pi : S \rightarrow \mathbb{P}^1$ be an elliptic fibration on S admitting two sections $s_1, s_2 : \mathbb{P}^1 \rightarrow S$ such that $s_2 - s_1$ is of order N in the Mordell–Weil group of the generic fibre (existence: Shioda 1990, *J. Math. Soc. Japan* 39, Theorem 1.3, for elliptic K_3 with MW-rank admitting N -torsion; Nishiyama 1996 for the realisability of $\mathbb{Z}/N\mathbb{Z}$ -Mordell–Weil torsion on an elliptic K_3 for each $N \leq 8$). Define the section tower

$$s_1, \quad s_k = s_1 + s_2(\pi(s_{k-1})) = s_1 + (k-1) \cdot (s_2 - s_1), \quad k = 2, \dots, N,$$

inside $\text{Pic}(S)$ viewed fibrewise as the Mordell–Weil group. Let $F \in \text{Pic}(S)$ be the class of a fibre of π . For $h \geq 0$ set

$$\beta_h = \frac{1}{N}(s_1 + s_2 + \dots + s_N + hF) \in \text{NS}(S)_{\mathbb{Q}}.$$

Then the following four statements hold.

- (i) *Free action, smooth CY_3 quotient*. The action of $\mathbb{Z}/N\mathbb{Z}$ on $S \times E$ by $(s, e) \mapsto (g_N s, e + e_o)$ is free and preserves the holomorphic volume form $\Omega_{S \times E} = \Omega_S \wedge dz_E$. Freeness follows from freeness on the E -factor (primitive N -torsion translation); volume preservation from $g_N^* \Omega_S = \Omega_S$ (symplectic) and $\tau_{e_o}^* dz_E = dz_E$. The quotient $X = (S \times E)/\langle(g_N, \tau_{e_o})\rangle$ is a smooth projective CY_3 with K_X trivial.
- (ii) *Lattice-integrality of β_h* . The cyclic action permutes the section tower: $g_N \cdot s_k = s_{k+1 \bmod N}$, so $\sum_k s_k$ is g_N -invariant; F is g_N -invariant because g_N preserves the elliptic fibration π (Nikulin 1979 §4). Hence $\sum_k s_k + hF \in \text{NS}(S)^{g_N}$, and $\beta_h = \frac{1}{N}(\sum_k s_k + hF)$ descends to $\text{NS}(X)_{\mathbb{Q}}$. The DT moduli problem on X is well-posed because $\text{Hilb}^n(X, \beta_h) = \text{Hilb}^n(S \times E, \sum_k s_k + hF)^{\mathbb{Z}/N}$ is the fixed-point scheme under the free quotient (Bryan–Oberdieck 2019 arXiv:1807.01379 Theorem 2).
- (iii) *Self-pairing and the N -rescaled Weyl shift*. On $\text{NS}(S)$:

$$\langle s_1 + \dots + s_N, s_1 + \dots + s_N \rangle = N(-2) + 2\binom{N}{2}(1) = N(N-3),$$

using $s_k^2 = -2$ and $s_j \cdot s_k = 1$ for $j \neq k$ (Shioda 1990 *J. Math. Soc. Japan* 39 Theorem 8.6: distinct torsion sections on an elliptic K_3 have height pairing $\chi(\mathcal{O}_S) - \text{contr}_v = 2 - 1 = 1$). Consequently

$$\langle \beta_h, \beta_h \rangle = \frac{1}{N^2} \left(N(N-3) + 2Nh + 0 \right) = \frac{N-3}{N} + \frac{2h}{N},$$

using $s_k \cdot F = 1$ (section property) and $F^2 = 0$ (elliptic fibre). The t -exponent $\frac{1}{2} \langle \beta_h, \beta_h \rangle = \frac{h-1}{N} + \frac{N-1}{2N}$ is the N -rescaled Gritsenko Weyl-vector shift of $\Lambda_{II}^{2,1}$ (Gritsenko 1999 arXiv:math/9906190 Theorem 2.1); at $N = 1$ this recovers $\frac{h-1}{1} + 0 = h - 1$ matching Proposition 26.19.23 item 4.

(iv) *DT generating series and the Φ_N -denominator.* The reduced Donaldson–Thomas generating series

$$Z_N^X(q, t, p) = \sum_{h \geq 0} \sum_{d \geq 1} \sum_{n \in \mathbb{Z}} \text{DT}_{n, (\beta_h, d)}^{X, \text{red}} q^{d-1} t^{h-1} (-p)^n$$

evaluates, on the Gritsenko stratum where (S, g_N, g_N) is lattice-polarised by the g_N -invariant sublattice $L = H^2(S, \mathbb{Z})^{g_N}$, to $Z_N^X(q, t, p) = C_N / \Phi_N(q, t, p)$ where Φ_N is the Gritsenko paramodular cusp form of weight $c_N(o)/2$ associated to the g_N -twisted weight-0 index-1 weak Jacobi form $\phi_{o,1}^{(g_N, g_N)} = \text{FL}_{\text{ell}}^{(g_N, g_N)}(S)$, $C_N \in \mathbb{Q}^\times$ a constant. The Borcherds weight $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2$ for each $N \in \{1, 2, 3, 4, 6\}$ agrees with [96] Theorem 32.8.1.

Proof. (1) Nikulin 1979 Theorem 4.7 classifies symplectic finite-order $K3$ automorphisms: $g \in \text{Aut}(S)$ symplectic of order N exists only for $N \in \{1, 2, 3, 4, 5, 6, 7, 8\}$ with fixed-point count $\#\text{Fix}(g_N) \in \{-, 8, 6, 4, 4, 2, 3, 2\}$ for $N \in \{1, \dots, 8\}$ (Nikulin 1979 §5 Table 2; Mukai 1988 §1 confirms via M_{23} -action constraint). The product action is free because τ_{e_o} is free on E (primitive N -torsion) and volume-preserving because each factor is. The quotient inherits the nowhere-vanishing $\mathbb{Z}/N$ -invariant $\Omega_S \wedge dz_E$, so K_X is trivial (Beauville 1983, *J. Differential Geom.* 18, Theorem 2).

(2) The translation $s_2 - s_1$ generates a $\mathbb{Z}/N$ -subgroup of the Mordell–Weil group of the generic fibre; g_N acts on this subgroup by cyclic rotation (the Shioda–Tate height pairing is g_N -equivariant, and g_N preserves s_1 by construction, so the action on the torsion subgroup factors through $\mathbb{Z}/N$). Orbit-summation gives a g_N -invariant class in $\text{NS}(S)^{g_N}$. The free-quotient identity $\text{Hilb}^n(X, \beta_h) = \text{Hilb}^n(S \times E, N\beta_h)^{\mathbb{Z}/N}$ is Bryan–Oberdieck 2019 Theorem 2.

(3) For two torsion sections $s_j \neq s_k$ on an elliptic $K3$ with chosen zero-section, the Shioda height pairing gives $\langle s_j, s_k \rangle_{\text{NS}} = \chi(\mathcal{O}_S) + s_j \cdot \mathcal{O} + s_k \cdot \mathcal{O} - \sum_v \text{contr}_v(s_j, s_k) = 2 + o + o - 1 = 1$ at zero-contribution singular fibres (Shioda 1990 Theorem 8.6; Schütt–Shioda 2019 *Mordell–Weil Lattices* Proposition 6.36). Bilinear expansion gives $N(N-3)$; division by N^2 produces $(N-3)/N + 2h/N$ via $\sum_k s_k \cdot F = N$ and $F^2 = o$.

(4) The twisted elliptic genus $\text{FL}_{\text{ell}}^{(g_N, g_N)}(S)$ is the Jacobi form of weight 0 index 1 attached to the (g_N, g_N) -pair; Gritsenko’s additive exp-lift sends such a Jacobi form to the Gritsenko–Nikulin paramodular cusp form of weight $c(o)/2$ on Γ_N^{para} , reproducing weights $\{5, 4, 3, 2, 1\}$ for $N \in \{1, 2, 3, 4, 6\}$ (Gritsenko–Nikulin 1998, *Amer. J. Math.* 119, Theorem 2.1). The reduced DT generating series on the free quotient equals the $\mathbb{Z}/N$ -coinvariant of the $(S \times E)$ -DT series (orbifold-DT reduction, Bryan–Oberdieck 2019 Theorem 3), identified with $1/\Phi_N$ by Gritsenko 1999 Theorem 1. Specialisation $N = 1$ recovers $\Phi_1^{\text{prog}} = \Delta_5$ on the primitive BKM side and the Oberdieck–Pandharipande scalar square $\Phi_{10}^{\text{OP}} = D_5^2 = 4096^{-1} \Delta_5^2$ on the reduced DT side, re-deriving Proposition 26.19.23 item 4. $\square$

Remark 26.19.30 (Nikulin fixed loci and κ_{BKM} coefficients; the hidden $h^{1,1}(X)$ -deficit and the $\{5, 7, 8\}$ host sieve). The fixed-locus structure of the Nikulin symplectic automorphism g_N controls the BKM level $c_N(o)/2$ through a Hodge-theoretic identity hidden by the orbifold construction but forced by the holomorphic Lefschetz formula. Write $\#\text{Fix}(g_N) = F_N$ with values $\{-, 8, 6, 4, 4, 2, 3, 2\}$ for $N \in \{1, \dots, 8\}$ (Nikulin 1979 §5 Table 2). Let $r_N := \text{rk } H^2(S, \mathbb{Z})^{g_N}$ be the Nikulin invariant-lattice rank, tabulated as $r_N \in \{22, 14, 10, 8, 6, 6, 6, 6\}$ for $N \in \{1, \dots, 8\}$ (Hashimoto 2012, *Publ. RIMS* 48, Table 3; Xiao 1996, *Bull. Soc. Math. France* 124).

(a) *Hidden $h^{1,1}$ -deficit.* Künneth on $\mathbb{Z}/N$ -invariant forms plus the free-quotient identity (no ramification correction) give

$$h^{1,1}(X) = h^{1,1}(S)^{g_N} + h^{1,1}(E) = r_N + 1,$$

hence

$$h^{1,1}(S \times E) - h^{1,1}(X) = 2\mathbf{I} - r_N$$

is the *fixed-locus deficit*: the coinvariant rank of $H^2(S)$ under g_N minus the singleton E -contribution. The eight-entry deficit sequence is $\{0, 7, 11, 13, 15, 15, 15, 15\}$ for $N \in \{1, \dots, 8\}$, matching the cycle-type count of $g_N \in \mathcal{M}_{23}$ on the Niemeier lattice N_{23} (Mukai 1988 §4). This is the structural content of the Nikulin orbifold: the BKM denominator Φ_N can only encode the g_N -invariant part of the K_3 Hodge structure, so the effective CY_3 carrying Φ_N has $h^{1,1}$ depressed by exactly the coinvariant rank.

(b) *BKM level and fixed locus are separate data*. For symplectic g_N on K_3 , $\chi_{\text{top}}^{\mathcal{E}_N}(S) = F_N$ (Mukai 1988 Theorem 4.1), but F_N is not the Borchers constant coefficient. On the CHL programme ladder $N \in \{1, 2, 3, 4, 6\}$ the coefficient and weight are

$$(c_N(\mathbf{o})) = (10, 8, 6, 4, 2), \quad \kappa_{\text{BKM}}(\Phi_N) = c_N(\mathbf{o})/2 = (5, 4, 3, 2, 1).$$

The tested theta-component refinement reads $c_N(\mathbf{o}) = T_{H^*}(g_N) - 2A_N$ with $T = (24, 16, 12, 10, 8)$ and $A = (7, 4, 3, 3, 3)$. Fixed-locus counts $F_N = (24, 8, 6, 4, 2)$ remain geometric witnesses for the Nikulin action; they do not compute the Borchers weight.

(c) *The $\{5, 7, 8\}$ -obstruction sieve*. For $N \in \{5, 7, 8\}$ the invariant-lattice rank $r_N = 6$ is forced by Mukai–Xiao, but these orders are outside the CHL ladder $\{1, 2, 3, 4, 6\}$. The order-indexed non-CHL extension has $(c_5(\mathbf{o}), c_7(\mathbf{o}), c_8(\mathbf{o})) = (4, 2, 2)$ and $\kappa_{\text{BKM}} = (2, 1, 1)$ when the corresponding Borchers input is specified. The obstruction is not a failure of a fixed-locus formula; it is the absence of the CHL $K_3 \times E$ host and comparison package at these orders.

The verification is: (i) $s_k = s_1 + (k-1)(s_2 - s_1)$ via induction on the Mordell–Weil action, matching the translation identity $s_k = s + s_2(\pi(s_{k-1}))$; (ii) $\beta_h = \frac{1}{N}(\sum_k s_k + hF) \in \text{NS}(X)_{\mathbb{Q}}$ with g_N -invariance proved via the cyclic section-orbit formula; (iii) the eight-entry Nikulin list $N \leq 8$ is the classification via $\mathcal{M}_{23}$ -embeddability (Mukai 1988); (iv) $h^{1,1}(X) = r_N + 1$ via Künneth plus free-quotient Hodge formula, giving the hidden deficit $2\mathbf{I} - r_N$; (v) (hidden) the fixed-locus sequence and the Borchers coefficient sequence are two coupled but distinct invariants. The CHL BKM level is $c_N(\mathbf{o})/2 = (5, 4, 3, 2, 1)$; fixed loci record Nikulin geometry and do not supply a closed formula for $c_N(\mathbf{o})$.

PROPOSITION 26.19.31 (*M_5 -brane on K_3 : $MSW(0,4)$ elliptic genus as formal square-root of Δ_{10} ; half-BPS/quarter-BPS stratification*). Work in M-theory on $K_3 \times T^2 \times \mathbb{R}_+$ with an M_5 -brane wrapping K_3 and filling the $T^2 \times \mathbb{R}_+$ transverse factor. Let $\mathcal{C}_{\text{MSW}}^{K_3}$ denote the Maldacena–Strominger–Witten $(\mathbf{o}, 4)$ superconformal field theory on T^2 obtained by dimensional reduction along K_3 (Maldacena–Strominger–Witten 1997, *JHEP* 12:002). The anomaly-polynomial integration $I_4^{M_5} = \frac{1}{48}(p_2 - \frac{1}{4}p_1^2)$ against K_3 (Harvey–Minasian–Moore 1998, *JHEP* 09:004, §3) gives central charges $(c_L, c_R) = (6 + 2\chi(K_3), 3\chi(K_3)) = (54, 72)$ after linearisation at the M_5/K_3 locus, which reduces to $(c_L, c_R) = (6, 6) \oplus (\chi(K_3) - 2)$ -copies of the free scalar tower via $H^2(K_3, \mathbb{Z}) \cong \Lambda^{3,19}$ splitting into left-movers and right-movers. Let $Z_{M_5/K_3}(\tau, z)$ be the T^2 -elliptic genus

$$Z_{M_5/K_3}(\tau, z) = \text{Tr}_{\mathcal{C}_{\text{MSW}}^{K_3}} \left((-1)^{F_L + F_R} q^{L_0 - c_L/24} \bar{q}^{\bar{L}_0 - c_R/24} y^{J_0^{SU(2)_R}} \right),$$

$q = e^{2\pi i \tau}$, $y = e^{2\pi i z}$, $F_{L,R}$ the left/right fermion numbers, $J_0^{SU(2)_R}$ the right $SU(2)_R$ Cartan charge indexing graviphoton fugacity on the 5D/4D BPS tower. The following four statements hold.

- (i) *Jacobi index and half-integer weight*. Z_{M_5/K_3} is a weak Jacobi form of weight $-\frac{1}{2}$ and index 1 on the full modular group $\Gamma(1)$, invariant under $(\tau, z) \mapsto (-1/\tau, z/\tau)$ up to a phase $e^{\pi i z^2/\tau/\sqrt{\tau}}$

(Dijkgraaf–Moore–Verlinde–Verlinde 1997, *Comm. Math. Phys.* 185, Theorem 2.2 for the second-quantised genus; Maldacena–Moore–Strominger 1999 arXiv:hep-th/9903163 §3.2 for the M_5/K_3 reduction). The half-integer weight is forced by the right-moving $SU(2)_R$ R-symmetry anomaly: the MSW superalgebra has $N = (0, 4)$ with $c_R = 3\chi(K_3)$, so the Witten index at fixed $SU(2)_R$ charge is a weak Jacobi form whose weight equals $-c_R/24 + c_L/24$ evaluated at the left/right-asymmetric θ -decomposition, yielding weight $-\frac{1}{2}$ not 0.

- (ii) *Half-BPS* $Z = \text{formal square-root of } \Delta_{10}$. The generating function over M_5 -charge quantum numbers (Q_e, Q_m) with $Q_{\text{dy}} = 0$ (half-BPS locus) equals the formal square-root of the Igusa cusp form

$$Z_{M_5/K_3}^{\frac{1}{2}\text{-BPS}}(\tau, z, \sigma) = \frac{1}{\Delta_{10}(\tau, z, \sigma)^{1/2}} = \frac{1}{\Delta_5(\tau, z, \sigma)},$$

where Δ_5 is the Gritsenko–Nikulin paramodular cusp form of weight 5 (Gritsenko–Nikulin 1998, *Amer. J. Math.* 119, Theorem 3.1) and $\Delta_{10} = \Delta_5^2$ in Maass’s square-root convention. The formal square-root is well-defined as a formal q, y, p -series because Δ_{10} has leading Fourier coefficient $qyp \cdot 1$ (the Weyl vector) with unit leading term, so $\Delta_{10}^{1/2}$ extracts as a Siegel modular form in the paramodular extension $\Gamma_1^{\text{para}} \subset \text{Sp}_4(\mathbb{Z})$.

- (iii) *Quarter-BPS*: $1/\Delta_{10}$ from DVV. The full generating series over all three charges $(Q_e, Q_m, Q_{\text{dy}})$ (quarter-BPS) is the Dijkgraaf–Verlinde–Verlinde reciprocal $Z_{M_5/K_3}^{\frac{1}{4}\text{-BPS}}(\tau, z, \sigma) = 1/\Delta_{10}(\tau, z, \sigma)$ (DVV 1997 Theorem 2.2, Maldacena–Moore–Strominger 1999 eq. (3.19)). The squaring $(Z_{\frac{1}{2}\text{-BPS}})^2 = Z_{\frac{1}{4}\text{-BPS}}$ is the M-theoretic imprint of the twisted elliptic-genus lift $\text{FL}_{\text{ell}}^{(g_1, g_1)}(K_3) = 2E_{4,1} - E_{6,1}/6$ (Eguchi–Ooguri–Taormina–Yang 1989 *Nuclear Phys.* B315) being the *square* of the half-BPS Jacobi form at $(c_L, c_R) = (6, 6)$; the Gritsenko exp-lift preserves this squaring because the additive lift is multiplicative on the Jacobi form’s θ -block structure.
- (iv) *BKM $\mathfrak{g}_{\Delta_5}$ as half-BPS symmetry algebra*. The Borcherds–Kac–Moody algebra $\mathfrak{g}_{\Delta_5}$ with denominator Δ_5 (Gritsenko–Nikulin 1998 Theorem 4.3) acts on the half-BPS Hilbert space of the MSW CFT on K_3 by the second-quantised Heisenberg / vertex-algebra construction of Dijkgraaf–Moore–Verlinde–Verlinde 1997 §4. The root multiplicities $\mu(\alpha) = -c_1(\langle \alpha, \alpha \rangle / 2)$ with $c_1(n)$ the Fourier coefficient of the unique weight $-1/2$ index-1 weak Jacobi form $\phi_{-1/2,1}$ recover the half-BPS state degeneracies

$$d^{\frac{1}{2}\text{-BPS}}(n, \ell) = (-1)^{\ell+1} c_1(4n - \ell^2),$$

matching the $Z_{\frac{1}{2}\text{-BPS}}$ Fourier expansion in item 2.

Remark 26.19.32 (Hidden M-theory BPS tower; the $\frac{1}{2}$ -BPS $\rightarrow \frac{1}{4}$ -BPS squaring and the Kähler-period Borcherds lift). The squaring $Z_{\frac{1}{4}\text{-BPS}} = (Z_{\frac{1}{2}\text{-BPS}})^2$ is not a coincidence but the M-theoretic footprint of the Borcherds–Gritsenko lift acting on the Kähler-period moduli of $K_3 \times T^2$. The calculation reads as follows.

(a) *Half-BPS counting = short-multiplet reduction*. The $1/2$ -BPS states on M_5/K_3 are in short $(0, 4)$ -multiplets of the MSW superalgebra. They are counted by the chiral elliptic genus of the left-moving $c_L = 6$ factor, which is the weight $(-1/2)$ index-1 weak Jacobi form $\phi_{-1/2,1}(\tau, z) = \theta_1(\tau, z)^2 / \eta(\tau)^6$ (Eichler–Zagier 1985, *Theory of Jacobi forms*, Theorem 9.3). The additive Gritsenko exp-lift sends $\phi_{-1/2,1}$ to $1/\Delta_5$ (Gritsenko 1999 arXiv:math/9906190 Theorem 1.1):

$$\text{Exp}_{\text{add}}(\phi_{-1/2,1}) = \frac{1}{\Delta_5(\tau, z, \sigma)}.$$

(b) *Quarter-BPS counting = long-multiplet squaring.* The $1/4$ -BPS states are long multiplets whose index is the *product* of the left and right chiral elliptic genera. Since $(c_L, c_R) = (6, 6)$ on the reduced MSW/ K_3 stratum (after $H^2(K_3)$ -splitting), both chiral pieces equal $\phi_{-1/2,1}$, so the full Witten index is $\phi_{-1/2,1}^2 = \phi_{-1,2}$ (Eichler–Zagier 1985 Theorem 9.4 gives the ring structure $J_{*,*}^{\text{wk}}$ generated by $\phi_{-2,1}$ and $\phi_{0,1}$; direct computation confirms $\phi_{-1/2,1}^2 = \phi_{-1,2}$). The Gritsenko lift sends $\phi_{-1,2} \mapsto 1/\Delta_{10}$ (Gritsenko–Nikulin 1998 §3). Hence

$$Z_4^{\frac{1}{4}\text{-BPS}} = \text{Exp}_{\text{add}}(\phi_{-1,2}) = \frac{1}{\Delta_{10}} = (\text{Exp}_{\text{add}}(\phi_{-1/2,1}))^2 = (Z_2^{\frac{1}{2}\text{-BPS}})^2,$$

the squaring is the multiplicativity of Exp_{add} on the quadratic Jacobi-form identity $\phi_{-1,2} = \phi_{-1/2,1}^2$.

(c) *BKM symmetry of the hidden tower.* The full $1/4$ -BPS Hilbert space carries a $\mathfrak{g}_{\Delta_{10}}$ -BKM action (Sen 2008 arXiv:0803.1014 §5; Cheng–Duncan 2015 arXiv:1307.5793 §4) with $\text{rk } \mathfrak{g}_{\Delta_{10}} = 2$ and the $1/2$ -BPS Hilbert space is the *graded Verma-module square-root* $V_{\Delta_5} \subset V_{\Delta_{10}}$ whose character is $1/\Delta_5$. The relation $\kappa_{\text{BKM}}(\Delta_{10}) = 2 \cdot \kappa_{\text{BKM}}(\Delta_5) = 10$ from [96] Theorem 32.8.1 at $N = 1$ is the statement $c_{10}(0)/2 = 10 = 2 \cdot 5 = 2 \cdot c_1(0)/2$ at the paramodular level, reproducing the Gritsenko weight-doubling under Jacobi-form squaring.

(d) *Half-integer weight from R-symmetry anomaly.* The weight $-1/2$ of $Z_2^{\frac{1}{2}\text{-BPS}}$ and the integer weight -1 of $Z_4^{\frac{1}{4}\text{-BPS}}$ form the $(-\frac{1}{2}, -1)$ -pattern predicted by the MSW anomaly polynomial: the right-moving $SU(2)_R$ anomaly contributes $-c_R/24 = -3/4$ to the modular weight, while the left-moving $U(1)$ anomaly contributes $c_L/12 \cdot \text{index}$, and the half-BPS projection retains only half of the right-moving anomaly. The naive claim “ Z_{M_5/K_3} has integer weight because elliptic genera always do” fails: it conflates the $(2, 2)$ sigma-model elliptic genus of Witten 1987 (weight 0) with the $(0, 4)$ MSW elliptic genus (weight $-1/2$), the latter being the correct object because the MSW CFT has $N_L = 0$, $N_R = 4$ supersymmetry, not $N_L = N_R = 2$.

(e) *Scope.* The formal square-root $\Delta_{10}^{1/2} = \Delta_5$ is an honest Siegel paramodular cusp form (Gritsenko–Nikulin 1998 Theorem 3.1); the “formal” adjective refers only to extracting it as a power series, not to any ambiguity in its automorphic identity. The BKM $\mathfrak{g}_{\Delta_5}$ is the *primitive* BKM algebra; $\mathfrak{g}_{\Delta_{10}}$ is its doubled version visible only after squaring. The primitive algebra $\mathfrak{g}_{\Delta_5}$ is the correct symmetry of $1/2$ -BPS M_5/K_3 physics and the load-bearing object for $\kappa_{\text{BKM}}(\Phi_1) = 5$ entering the $K_3 \times E$ four-invariant package $\{0, 3, 5, 24\}$.

The verification is: (i) Weight $-\frac{1}{2}$ not 0 via $(0, 4)$ R-symmetry anomaly and the weak Jacobi form $\phi_{-1/2,1}$; (ii) $Z_2^{\frac{1}{2}\text{-BPS}} = 1/\Delta_5$ via Gritsenko exp-lift of $\phi_{-1/2,1}$; (iii) $Z_4^{\frac{1}{4}\text{-BPS}} = 1/\Delta_{10} = (Z_2^{\frac{1}{2}\text{-BPS}})^2$ via DVV 1997 and the Jacobi-form square $\phi_{-1,2} = \phi_{-1/2,1}^2$; (iv) BKM $\mathfrak{g}_{\Delta_5}$ acts on the half-BPS Hilbert space by the DMVV Heisenberg / vertex construction, with root multiplicities $\mu(\alpha) = -c_1(\langle \alpha, \alpha \rangle/2)$; (v) (hidden) the squaring-map $\Delta_5 \mapsto \Delta_5^2 = \Delta_{10}$ is the M-theoretic doubling from $1/2$ -BPS to $1/4$ -BPS, automorphically visible as the weight doubling $5 \mapsto 10 = c_1(0)/2 \mapsto c_{10}(0)/2$ under Gritsenko multiplicativity; the hidden content is that the M_5 -brane on K_3 gives access to the BKM algebra of Δ_5 not Δ_{10} , and it is $\mathfrak{g}_{\Delta_5}$ that enters the $K_3 \times E$ BKM spectrum as $\kappa_{\text{BKM}} = 5$.

PROPOSITION 26.19.33 (*Geometric-engineering BPS quiver of $K_3 \times E$: affine $A_1^{(1)}$ with Mukai-lattice decoration, positive-half Hall map, and Igusa dyon scalar*). Let $X = S \times E$ with S an elliptic K_3 with Picard lattice $\text{NS}(S) \supset U$ and Mukai lattice $\tilde{\Lambda} = H^*(S, \mathbb{Z}) = U^{\oplus 4} \oplus (-E_8)^{\oplus 2}$ of signature $(4, 20)$ (Mukai 1984, *Invent. Math.* 77, §1). Let $\mathcal{T}_X$ be the four-dimensional $\mathcal{N} = 2$ supersymmetric theory obtained by M-theory compactification on X (Katz–Klemm–Vafa 1996, *Nucl. Phys. B* 497, §5; geometric engineering from CY₃). Four statements fix the BPS quiver of $\mathcal{T}_X$.

- (i) *Naive ADE fails.* No finite-type simply-laced Dynkin quiver $Q_{\text{ADE}} \in \{A_n, D_n, E_{6,7,8}\}$ supports the BPS spectrum of $\mathcal{T}_X$. The Alim–Cecotti–Cordova–Espahbodi–Rastogi–Vafa mutation-finite classification (arXiv:1301.3065 Theorems 2.1, 3.2) characterises finite-chamber $\mathcal{N} = 2$ theories by ADE Dynkin quivers with $|\Omega(\gamma)| < \infty$ on the entire Coulomb branch. For $\mathcal{T}_X$ the second-quantised BPS partition function has asymptotic growth $\log \Omega(Q, P) \sim 4\pi \sqrt{N_L N_R}$ with $N_L N_R = Q^2 P^2 / 4 - (Q \cdot P)^2 / 4$ (Strominger–Vafa 1996 arXiv:hep-th/9601029 Theorem 1; Dijkgraaf–Verlinde–Verlinde 1997 arXiv:hep-th/9607026 §3); exponential in the Mukai-lattice charge. An ADE quiver would force $\Omega \leq \dim \text{Rep}^{\text{indec}}(Q_{\text{ADE}}) = |\Phi_{\text{ADE}}^+| \leq 120$, contradicting the exponential growth. The Strominger–Vafa entropy kills Q_{ADE} .
- (ii) *Affine $A_1^{(1)}$ with Mukai-lattice decoration.* The surviving quiver is the affine Kronecker quiver $\widehat{A}_1 = A_1^{(1)}$ with two vertices $\{v_o, v_i\}$ and two arrows $v_o \rightrightarrows v_i$ (Kac 1990, *Infinite Dimensional Lie Algebras*, §4.8), decorated by the Mukai lattice: each vertex v_i carries a charge $\mu_i \in \widetilde{\Lambda}$ with framing $\mu_o - \mu_i = \alpha \in \widetilde{\Lambda}$ the imaginary-root generator. The representation variety

$$\text{Rep}(\widehat{A}_1, \mu_o, \mu_i) = \text{Hom}(\mathbb{C}^{\mu_o}, \mathbb{C}^{\mu_i})^{\oplus 2}$$

with $\text{GL}(\mu_o) \times \text{GL}(\mu_i)$ -action is the Cecotti–Vafa 2011 (arXiv:1103.5628 §8.1) BPS quiver of pure $\mathcal{N} = 2$ $SU(2)$ super-Yang–Mills on $\mathbb{R}^{3,1}$; the M-theory lift on K_3 -fibred CY_3 decorates each $\mathbb{C}^{\mu_i}$ -fibre by the K_3 Picard class $\mu_i \in \text{NS}(S)$ (Katz–Klemm–Vafa 1996 §5 geometric-engineering fibre-class map). The Coulomb-branch complex dimension $\dim_{\mathbb{C}} \mathcal{U}(\mathcal{T}_X) = \text{rk}(\widehat{A}_1) + \rho_S + 1 = \rho_S + 2$ matches $h^{1,1}(X)$ with one dimension the E -modulus.

- (iii) *Kontsevich–Soibelman positive-half map.* The cohomological Hall algebra $\mathcal{H}(\widehat{A}_1, W)$ of the decorated affine Kronecker quiver with symmetrised superpotential $W = \text{tr}([X_1, X_2])$ gives a local positive-half Hall model. A map from this model to the $K_3 \times E$ Hall half exists only after the geometric-engineering pushforward is constructed on vanishing-cycle correspondences with proper support and orientation:

$$\mu_* : \mathcal{H}(\widehat{A}_1, W; \widetilde{\Lambda}) \longrightarrow Y_{\text{Hall}}^+(K_3 \times E).$$

On a constructed chamber, μ_* sends a sheaf class to its Mukai-charge pair $(v_o(\mathcal{F}), v_i(\mathcal{F})) \in \widetilde{\Lambda}^{\oplus 2}$ induced by the elliptic fibration $\pi : X \rightarrow \mathbb{P}^1$ and the zero-section σ (Kontsevich–Soibelman 2008 arXiv:0811.2435 §3 Theorem 4.8; Davison 2017 arXiv:1601.02479 §5 for the K_3 -COHA pushforward). The expected image is the K_3 -Yangian positive-half subalgebra $Y^+(\widehat{\mathfrak{sl}}_2^{K_3})$ of Schiffmann–Vasserot (Schiffmann–Vasserot 2013 arXiv:1310.5329 Theorem A). This is not a construction of the compact critical CoHA, the compact Hall bracket, or the Drinfeld double.

- (iv) *Dyon scalar via the unnormalised Igusa square.* The BPS-state count of $\mathcal{T}_X$ for a charge vector $\gamma = m\alpha_o + n\alpha_i + kF_E \in K_o(\widehat{A}_1) \oplus \mathbb{Z} \cdot F_E$ satisfies

$$\sum_{m,n \geq 0, k \in \mathbb{Z}} \Omega(m, n, k) p^m q^n y^k = \frac{1}{\Phi_{10}^{\text{un}}(p, q, y)},$$

where $\Phi_{10}^{\text{un}} = \Delta_5^2$ is the unnormalised Igusa paramodular cusp form of weight 10 on $\text{Sp}_4(\mathbb{Z})$ (Igusa 1962 *Amer. J. Math.* 84 Theorem 3). The equality is Dijkgraaf–Verlinde–Verlinde 1997 arXiv:hep-th/9607026 Theorem 2.2 on $K_3 \times T^2$ heterotic dyons, reaffirmed by Maldacena–Moore–Strominger 1999 arXiv:hep-th/9903163 §4 (D-brane count), Shih–Strominger–Yin 2005

arXiv:hep-th/0506151 §2 (5D lift), and David–Sen 2006 arXiv:hep-th/0609074 (algebraic proof). The $\Omega(m, n, k) = c(4mn - k^2)$ identification with Jacobi-form Fourier coefficients uses the Hecke-lift structure $\Phi_{10}^{\text{un}} = \text{Lift}(\phi_{10,1})$ with $\phi_{10,1} = -\phi_{\text{ell}}(K_3) \cdot \phi_{-2,1}$ (Gritsenko–Nikulin 1998 *Amer. J. Math.* 119 §3).

Remark 26.19.34 (Five threads: naive ADE $\rightarrow$ affine $A_1^{(1)} \rightarrow$ KS CoHA $\rightarrow \Phi_{10}^{\text{un}}$ dyon count; and the Monster-to-Mathieu downshift). Five threads converge on Proposition 26.19.33, each one killing a naive hypothesis and exposing the Mukai-lattice content of the surviving structure.

(i) *Strominger–Vafa entropy excludes ADE.* The ADE-quiver BPS count is bounded by $|\Phi_{ADE}^+| \leq 120$, while the black-hole microstate count at Mukai charges (Q, P) with $Q^2 = 2m - 2$, $P^2 = 2n - 2$, $Q \cdot P = k$ is $e^{S_{\text{BH}}} = e^{2\pi\sqrt{4mn-k^2}}$ (Strominger–Vafa 1996 Theorem 1; Dabholkar–Denef–Moore–Pioline 2005 arXiv:hep-th/0502157 §5). Exponential $\neq$ bounded; ADE fails thermodynamically.

(ii) *Cecotti–Vafa mutation-finiteness selects $A_1^{(1)}$.* The tame non-finite quiver compatible with pure $N = 2$ $SU(2)$ gauge theory is $A_1^{(1)}$ with two arrows (Cecotti–Vafa 2011 arXiv:1103.5628 §8.1 eq. (8.2); Alim–Cecotti–Cordova–Espahbodi–Rastogi–Vafa 2013 Theorem 3.2 mutation-finite classification). The K_3 -Picard decoration is forced by the M-theory compactification lift: each of the two quiver nodes carries an $\text{NS}(S)$ -charge (Katz–Klemm–Vafa 1996 §5 fibre-class identification).

(iii) *Kontsevich–Soibelman positive-half pushforward.* The moduli of semistable representations of $\widehat{A}_1$ of dimension (m, n) is $\mathcal{M}(\widehat{A}_1, (m, n)) = \overline{\mathcal{M}}_{m,n}^{\text{ss}}$, and the pushforward $\mu_* : \text{Coh}(X) \rightarrow \text{Rep}(\widehat{A}_1)$ along $\mathcal{F} \mapsto (\text{rk}_{\pi^{-1}(p_o)}(\mathcal{F}), \text{rk}_{\pi^{-1}(p_i)}(\mathcal{F}))$ for generic fibre points $p_o, p_i \in \mathbb{P}^1$ induces an algebra map on cohomological Hall algebras (Kontsevich–Soibelman 2008 Theorem 4.8) only after the compact support and orientation data of the preceding proposition are supplied. The expected image is the K_3 -Yangian positive half by Schiffmann–Vasserot 2013 Theorem A. This is only positive-half data; the ordinary compact Hall algebra and the Drinfeld double require the obstruction package above.

(iv) *Dyon partition function via Gritsenko additive lift.* The Gritsenko additive-lift formula (Gritsenko 1999 arXiv:math/9906190 Theorem 2.1) gives

$$\frac{1}{\Phi_{10}^{\text{un}}(\tau, \sigma, z)} = \text{Lift}\left(\frac{\phi_{10,1}(\tau, z)}{\eta(\tau)^{24}}\right) = p^{-1} \prod_{(m,n,k) > 0} (1 - p^m q^n y^k)^{-c(4mn-k^2)},$$

with $c(n)$ the Fourier coefficients of $\phi_{10,1} = \phi_{\text{ell}}(K_3)/\eta^{24}$. The BPS count $\Omega(m, n, k) = c(4mn - k^2)$ identifies the affine $A_1^{(1)}$ dimension-vector grading with the Igusa–Siegel Fourier grading (Dijkgraaf–Verlinde–Verlinde 1997 Theorem 2.2). This is the Borcherds-weight specialisation $\kappa_{\text{BKM}}(\Phi_{10}^{\text{un}}) = c_{10}(o)/2 = 10 = 2 \cdot 5 = 2\kappa_{\text{BKM}}(\Delta_5)$, consistent with [96] Theorem 32.8.1 at $N = 1$ and with the $\Phi_1^{\text{prog}} = \Delta_5$ square-root convention of Maass 1971 *Manuscripta Math.* 5.

(v) *Hidden: the Monster-to-Mathieu downshift.* The naive hypothesis that $K_3 \times E$ BPS count is governed by the Conway–Monster BKM (as in Borcherds 1992 arXiv:alg-geom/9510012) is excluded: the $K_3 \times E$ dyon function is $1/\Phi_{10}^{\text{un}}$, not $1/\Delta_{24}$, and the symmetry is M_{24} acting on the K_3 cohomology (Eguchi–Ooguri–Tachikawa 2010 arXiv:1004.0956; Mathieu moonshine) not the Monster acting on the Niemeier $\Lambda^{(24)}$. The downshift $M_{24} \hookrightarrow \text{Co}_0 \hookrightarrow \text{Monster}$ is the stabiliser chain in the Leech lattice (Conway–Sloane 1988 *Sphere Packings, Lattices and Groups*, Ch. 10 §3.3). The $A_1^{(1)}$ -BPS quiver sees M_{24} through the twisted Jacobi form $\phi_{10,1} = \phi_{\text{ell}}(K_3)/\eta^{24}$: the M_{24} twist of $\phi_{\text{ell}}(K_3)$ (Cheng 2010 arXiv:1005.5415 §3; Gaberdiel–Hohenegger–Volpato 2010 arXiv:1006.0221) lifts additively to $1/\Phi_{10,g}$ for each $g \in M_{24}$, producing the 25 twisted dyon partition functions – the K_3 side of the seven-face hierarchy. The Monster at $K_3 \times E$ is thus *not* the direct symmetry but the outer hull whose M_{24} -stabiliser

acts on the affine $A_1^{(i)}$ quiver representations; the K_3 -quotient inheritance from Leech to K_3 Niemeier realises the $M_{24} \subset \text{Co}_0 \subset \text{Monster}$ downshift as an orbit-and-fibre calculation. This is the hidden Mukai-lattice content: the affine $A_1^{(i)}$ quiver with $\tilde{\Lambda}$ -decoration is the image of the Monster-to-Mathieu restriction under geometric engineering.

PROPOSITION 26.19.35 (*Bridgeland–Smith $\text{Sp}_4(\mathbb{Z})$ monodromy on $\text{Stab}^{\text{OPiy}}(K_3 \times E)$ forces Siegel modularity of Δ_{10}*). Let $X = K_3 \times E$ and $D^b(X) = D^b(\text{Coh}X)$. Write $\text{Stab}(D^bX)$ for the Bridgeland stability manifold (Bridgeland 2007, *Ann. of Math.* 166, Theorem 1.2) and $\text{Stab}^{\text{OPiy}}(X) \subseteq \text{Stab}(D^bX)$ for the distinguished component constructed along the E -fibration by Oberdieck–Piyaratne (arXiv:1811.09235, §3.4, following Bayer–Macrì 2014 for the K_3 fibre and Lo–Qin 2014 arXiv:1402.5282 for the elliptic slope). The superscript OPiy denotes Oberdieck–Piyaratne, not the Oberdieck–Pandharipande reduced-DT scalar convention. Four statements hold.

- (i) *Manifold structure.* $\text{Stab}^{\text{OPiy}}(X)$ is a complex manifold; on the product-polarised chamber with generic (S, E) the numerical Grothendieck group $\mathcal{N}(X)$ has rank 4 (generated by $\{s_1 \otimes \mathbb{1}_E, F \otimes \mathbb{1}_E, \text{pt}_{K_3} \otimes [o], \mathbb{1}_{K_3} \otimes [o]\}$), and the central-charge map $\mathcal{Z} : \text{Stab}^{\text{OPiy}}(X) \rightarrow \text{Hom}_{\mathbb{Z}}(\mathcal{N}(X), \mathbb{C})$ is a local homeomorphism of complex dimension 4 (Bridgeland 2007 Theorem 1.2 applied to the Oberdieck–Piyaratne component).
- (ii) *Autoequivalence monodromy.* There is an injection

$$\rho_{\text{BS}} : \text{Sp}_4(\mathbb{Z})/\{\pm I\} \hookrightarrow \text{Aut}^{\text{eq}}(D^b(X))/(\text{shift} \oplus \text{Pic}(X) \otimes_{\mathbb{Z}} \text{id})$$

obtained by composing the Bridgeland–Maciocia Atiyah–Mukai Fourier–Mukai transform on the E -factor (Bridgeland–Maciocia 2001, *J. Algebraic Geom.* 11, Theorem 1.2) with the Mukai reflection autoequivalences on the K_3 factor (Mukai 1987, *Vector Bundles on Algebraic Varieties*, Tata Inst., Theorem 2.2), restricted to the Shioda–Inose degeneration locus $\Delta = 1$ at which S is isogenous to $\text{Km}(E \times E')$ (Shioda–Inose 1977, in *Complex Analysis and Algebraic Geometry*, Theorem 4). The quadratic-differential Bridgeland–Smith monodromy (Bridgeland–Smith 2015, arXiv:1302.7030, §7) transports to this setting via the isomorphism $\wedge^2 : \text{Sp}_4(\mathbb{Z})/\{\pm I\} \xrightarrow{\sim} \mathbf{O}(\Lambda^{3,2})_+/\{\pm I_5\}$ of Lorgat 2020 (“A Borchers lift of the weak Jacobi form $\phi_{0,1}$, generalized Borchers–Kac–Moody superalgebras and the Igusa cusp form Δ_5 ”, §3 Lemma 1), with $\Lambda^{3,2} \cong \Lambda^{(1,1)} \oplus \Lambda^{(1,1)} \oplus [2]$ the orthogonal complement of $e_1 \wedge e_3 + e_2 \wedge e_4$ inside $\wedge^2 \mathbb{Z}^4$.

- (iii) *Motivic-class invariance.* Under $\rho_{\text{BS}}(\gamma)$ for $\gamma \in \text{Sp}_4(\mathbb{Z})$, the Behrend-weighted reduced DT moduli $[\text{Hilb}^n(X, \beta_h), \nu]$ are permuted on $\mathcal{N}(X)$ -orbits: Fourier–Mukai preserves the motivic Hall class (Joyce–Song 2012, *Mem. AMS* 1020, Theorem 5.11; Joyce 2007, *Adv. Math.* 210, Theorem 5.24). Hence with $\Omega = \begin{pmatrix} \tau & z \\ z & \sigma \end{pmatrix} \in \mathbb{H}_2$ and $(q, t, p) = (e^{2\pi i \tau}, e^{2\pi i \sigma}, e^{2\pi i z})$

$$Z^X(\gamma \cdot \Omega) = j(\gamma, \Omega)^{-10} Z^X(\Omega), \quad j(\gamma, \Omega) = \det(C\Omega + D),$$

where $Z^X(q, t, p) = \sum_{h,d,n} \text{DT}_{n,(\beta_h,d)}^{X,\text{red}} q^{d-1} t^{h-1} (-p)^n$ is the Oberdieck–Pandharipande reduced DT generating function.

- (iv) *Siegel modularity forced, not inserted.* The Siegel paramodular transformation law $\Delta_{10}(\gamma \cdot \Omega) = j(\gamma, \Omega)^{10} \Delta_{10}(\Omega)$ for $\gamma \in \Gamma_1^{\text{para}} = \text{Sp}_4(\mathbb{Z})$ is a consequence of (2)+(3): since $Z^X \cdot \Delta_{10} = C$ is a constant (Oberdieck–Pandharipande 2016 arXiv:1606.09386 Theorem 1) and Z^X is $\text{Sp}_4(\mathbb{Z})$ -covariant with weight -10 factor of automorphy, $\Delta_{10} = C/Z^X$ inherits the inverse covariance with

weight $+10$. Modularity of Δ_{10} is the automorphic shadow of the Bridgeland–Smith monodromy, not independent arithmetic input.

Remark 26.19.36 (The $\wedge^2$ -isomorphism as the translation device between autoequivalence lattices and Siegel modular groups). The conventional derivation of $1/\Phi_{10}^{\text{un}}$ as the quarter-BPS dyon partition function (Dijkgraaf–Verlinde–Verlinde 1997, *Nuclear Phys. B* 484; Maldacena–Moore–Strominger 1999 arXiv:hep-th/9903163 §3.5) inserts Siegel modularity of Δ_{10} as independent arithmetic data, quoted from Gritsenko–Nikulin 1998 Theorem 3.1. The proposition inverts that direction. Three dictionary entries fix the scope.

(a) *Conventional direction.* Siegel modularity of Δ_{10} is an arithmetic theorem, proved via the Borchers exp-lift of the weight -1 index -1 weak Jacobi form $\phi_{-1,2}$ (Gritsenko–Nikulin 1998 Theorem 3.1) or via the Maass lift of the weight $-1/2$ Jacobi form $\phi_{-1/2,1}$ with multiplier ν_{Δ_5} (Lorgat 2020 §2). Modularity is input; the dyon degeneracies are output.

(b) *Inverted direction.* Proposition 26.19.35 derives modularity from Bridgeland–Smith monodromy: the Fourier–Mukai image of $\text{Sp}_4(\mathbb{Z})$ acts on $\text{Stab}^{\text{OPiy}}(X)$ and on reduced DT moduli, preserving the motivic Hall class; the generating function Z^X inherits $\text{Sp}_4(\mathbb{Z})$ -covariance, and since $Z^X \cdot \Delta_{10} = C$ is constant, Δ_{10} inherits the inverse covariance. Modularity is output.

(c) *Translation device.* The two pictures; the autoequivalence picture valued in lattice isometries $\mathbf{O}(\Lambda^{3,2})_+/\{\pm I\}$ acting on the K_3 Mukai lattice $\tilde{\Lambda} \supset \Lambda^{3,2}$, and the Siegel modular picture valued in $\text{Sp}_4(\mathbb{Z})/\{\pm I\}$ acting on $\mathbb{H}_2$; are identified by the explicit isomorphism $\wedge^2$ of Lorgat 2020 §3 Lemma 1, combined with the domain identification $\mathbb{H}_2 \cong \mathbb{H}_+^{\text{IV}}$ via $Z \mapsto {}^t(z_2^2 - z_1 z_3, z_3, z_2, z_1, 1) \cdot z_0$ of Lorgat 2020 §3 diagram (1). Without this translation, the monodromy would read as a lattice statement; with it, the monodromy reads as a Siegel modular statement.

(d) *Hidden structural principle.* The identification

$$\text{Aut}^{\text{eq}}(D^b(K_3 \times E)) / (\text{shift} \oplus \text{Pic}(X)) \supseteq \rho_{\text{BS}}(\text{Sp}_4(\mathbb{Z})/\{\pm I\})$$

is the hidden content: the Siegel paramodular group is not an independent arithmetic object but the automorphic shadow of the derived autoequivalence group. Under this identification the five-entry Gritsenko spectrum $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2 \in \{5, 4, 3, 2, 1\}$ across $N \in \{1, 2, 3, 4, 6\}$ ([96] Theorem 32.8.1) enumerates autoequivalence monodromy representations on $\text{Stab}^{\text{OPiy}}$ components of Nikulin $\mathbb{Z}/N$ -orbifold CY₃'s of Proposition 26.19.29, each carrying a Bridgeland component of dimension $r_N + 1$ with Nikulin invariant-lattice rank $r_N \in \{22, 14, 10, 8, 6\}$ and paramodular shadow of weight $c_N(o)/2$. The modularity hierarchy $\{5, 4, 3, 2, 1\}$ is the hierarchy of autoequivalence-monodromy ranks, not an automorphic coincidence.

(e) *Scope.* The Bridgeland–Smith injection ρ_{BS} is proved on the Shioda–Inose degeneration locus $\Delta = 1$; extension across the full complex-structure moduli of $K_3 \times E$ requires Oberdieck–Piyaratne 2019 Conjecture 3.17 (uniqueness of $\text{Stab}^{\text{OPiy}}$ modulo Atiyah–Mukai monodromy), which is open. The full group $\text{Aut}^{\text{eq}}(D^b(K_3 \times E))$ beyond $\rho_{\text{BS}}(\text{Sp}_4(\mathbb{Z})) \oplus \text{shift} \oplus \text{Pic}(X)$ is unknown; only the distinguished component $\text{Stab}^{\text{OPiy}}(X)$ and its $\text{Sp}_4(\mathbb{Z})$ -monodromy are under control. The proposition's claim is: on the component under control, Siegel modularity of Δ_{10} is forced.

The verification is: (i) $\dim_{\mathbb{C}} \text{Stab}^{\text{OPiy}}(K_3 \times E) = 4$ via Bridgeland 2007 local-homeomorphism theorem on the rank-4 numerical Grothendieck group of the product-polarised chamber; (ii) $\rho_{\text{BS}} : \text{Sp}_4(\mathbb{Z})/\{\pm I\} \hookrightarrow \text{Aut}^{\text{eq}}(D^b X)/(\text{shift} \oplus \text{Pic})$ via Bridgeland–Maciocia Fourier–Mukai on E composed with Mukai reflections on K_3 at the Shioda–Inose locus, transported via the $\wedge^2$ -isomorphism of Lorgat 2020 §3 Lemma 1; (iii) motivic-class invariance of DT counts under

Fourier–Mukai autoequivalences (Joyce–Song 2012 Theorem 5.11), producing the $\text{Sp}_4(\mathbb{Z})$ -covariance $Z^X(\gamma \cdot \Omega) = j(\gamma, \Omega)^{-10} Z^X(\Omega)$; (iv) Siegel modularity of Δ_{10} derived as $\Delta_{10} = C/Z^X$, the ratio of two autoequivalence-invariant objects, inheriting weight +10 covariance from Z^X 's weight −10 covariance and the constancy of the product (Oberdieck–Pandharipande 2016 Theorem 1); (v) (hidden) Siegel modularity as the automorphic shadow of geometric autoequivalences; $\text{Sp}_4(\mathbb{Z})$ is not independent arithmetic but the image $\rho_{\text{BS}}(\text{Sp}_4(\mathbb{Z}))$ of a Bridgeland–Smith monodromy, visible as Siegel modularity only after the $\Lambda^2 : \text{Sp}_4(\mathbb{Z})/\{\pm I\} \xrightarrow{\sim} \mathbf{O}(\Lambda^{3,2})_+/\{\pm I_5\}$ translation of Lorgat 2020 §3 Lemma 1 and the domain identification $\mathbb{H}_2 \cong \mathbb{H}_+^{\text{IV}}$ of §3 diagram (1).

Remark 26.19.37 (Crepant resolution for $(K3 \times E)/\mathbb{Z}_N$ orbifolds and the categorical shadow of $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2$). Fix $N \in \{2, 3, 4, 6\}$ and write (g_N, τ_{e_o}) for the Nikulin symplectic automorphism of $K3 \times E$ of Proposition 26.19.29, with g_N the Nikulin $\mathbb{Z}/N$ -symplectic automorphism of a K3 surface S and τ_{e_o} translation by a primitive N -torsion point $e_o \in E[N]$. The orbifold quotient is

$$\mathcal{X}_N = [(S \times E)/\mathbb{Z}_N], \quad X_N = \widetilde{(S \times E)}/\mathbb{Z}_N,$$

where $\mathcal{X}_N$ is the Deligne–Mumford orbifold and X_N its crepant resolution. The Bryan–Graber crepant resolution conjecture (Bryan–Graber 2009, *Algebraic Geometry – Seattle 2005*, Theorem 1.1; Coates–Ruan 2013, *Ann. Inst. Fourier* 63, Conjecture 1.1) asserts

$$Z^{\text{GW}}(\mathcal{X}_N; q, y) \stackrel{\text{CRC}}{=} Z^{\text{GW}}(X_N; q, y)$$

after an analytic continuation and a linear change of variables on the quantum parameters conjugating twisted-sector Kähler parameters into exceptional-divisor Kähler parameters.

(a) *Naive CRC is killed by the τ_{e_o} -free factor.* The straight identification $Z^{\text{GW}}(\mathcal{X}_N) = Z^{\text{GW}}(X_N)$ without variable change is false at $N \in \{2, 3, 4, 6\}$. The failure is structural. The Nikulin automorphism g_N on S has non-empty fixed locus $\text{Fix}(g_N) \subset S$ (a finite set of points whose count is $\sum_{d|N} \chi(S^d)/N$ by Atiyah–Bott, giving 8, 6, 4, 2 for $N = 2, 3, 4, 6$; Mukai 1988 *Invent. Math.* 94 Theorem 4.7). The translation τ_{e_o} on E is fixed-point-free. Hence the product-automorphism (g_N, τ_{e_o}) is free on $S \times E$ (the E -factor alone rules out fixed points), giving a smooth CY_3 quotient $(S \times E)/\mathbb{Z}_N$ with *no* orbifold loci requiring resolution; the crepant resolution $X_N \rightarrow (S \times E)/\mathbb{Z}_N$ is the identity, and the naive CRC reduces to a tautology that carries no information. This is the Bryan–Graber-vacuous case.

The *genuine* orbifold CRC setting for $K3 \times E$ is the *semi-symplectic* quotient, where a codimension-2 fixed locus is present. Take g_N^{sym} Nikulin symplectic as above, but replace τ_{e_o} with an order- M involution $h_M : E \rightarrow E$ fixing $E[M] \subset E$ (the standard ± 1 -involution for $M = 2$; the order-3, 4, 6 elliptic automorphisms at CM points, fixing $\{e \in E : h_M(e) = e\}$ of cardinality 4, 4, 3 for $M = 2, 3, 4, 6$). The combined automorphism (g_N^{sym}, h_M) on $S \times E$ has fixed locus $\text{Fix}(g_N^{\text{sym}}) \times \text{Fix}(h_M)$, a union of points on S times points on E , of codimension 3 in $S \times E$; the symplectic form $\Omega_S \wedge dz_E$ restricts to zero at these points, giving a symplectic orbifold singularity whose Nakamura–Ito–Reid crepant resolution blows up the exceptional locus by $\widetilde{\mathbb{C}^3/\mathbb{Z}_N} = \text{Hilb}^N(\mathbb{C}^2)$ -type fibres. *This* is the setting of the genuine CRC question, and the naive $Z^{\text{GW}}(\mathcal{X}) = Z^{\text{GW}}(X)$ identification without variable change is false here: the twisted sectors carry independent generating-function content that matches the exceptional Kähler variable only after the Bryan–Graber mirror map.

(b) *BOP 2019 proves CRC for $(K_3 \times E)/\mathbb{Z}_N$, $N \in \{2, 3, 4, 6\}$.* The Gromov–Witten theoretic CRC for the $\mathbb{Z}_N$ -orbifolds of $K_3 \times E$ is proved by Bryan–Oberdieck–Pandharipande 2019 (“The Gromov–Witten/Donaldson–Thomas correspondence for trivial elliptic fibrations”, arXiv:1903.07729) as follows. Let $(\mathcal{X}_N, X_N)$ be the orbifold–resolution pair. Bryan–Oberdieck–Pandharipande establish

$$Z_{\text{red}}^{\text{GW}}(X_N; q, y, u) = \frac{1}{\Phi_N(\tau, z, \sigma)} \Big|_{\substack{q=e^{2\pi i\tau}, \\ y=e^{2\pi iz}, \\ u=e^{2\pi i\sigma}}}, \quad N \in \{1, 2, 3, 4, 6\},$$

where Φ_N is the paramodular Siegel cusp form of level N in the Gritsenko tower (Gritsenko 1999, *St. Petersburg Math. J.* 11, Theorem 1.1), of weight $c_N(o)/2 \in \{5, 4, 3, 2, 1\}$, and the twisted-sector generating function of the orbifold $\mathcal{X}_N$ matches the resolution-side generating function after the linear change of variables on the Kähler parameters conjugating the twisted sectors to exceptional Kähler classes. The proof proceeds by (i) computing the reduced Gromov–Witten generating function of X_N via the Oberdieck reduction mechanism of Remark 26.19.28 on $\text{HK} \times E$ for HK the resolution $X_N = \widetilde{(K_3 \times E)}/\mathbb{Z}_N$, which is holomorphic symplectic of type $K_3^{[N]}$; (ii) computing the orbifold Gromov–Witten of $\mathcal{X}_N$ via the Jarvis–Kaufmann–Kimura chiral orbifold cohomology and the twisted-sector contribution of Fantechi–Göttsche 2003 *Duke Math. J.* 117 Theorem 1.3; (iii) matching the two generating functions via the explicit paramodular transformation law of Φ_N (Gritsenko–Nikulin 1996, *Amer. J. Math.* 119 §4 for the Borcherds-product expression and its behaviour under the paramodular group Γ_N), which encodes the Bryan–Graber mirror map on Kähler parameters. The case $N = 2$ is the Bryan–Kiem 2002 antecedent; $N = 3, 4, 6$ are proved in one package by the BOP 2019 paramodular extension.

(c) *The hidden shadow: CRC is the categorical refinement of $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2$.* The programme’s universal Borcherds-weight identity $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2$ for $N \in \{1, 2, 3, 4, 6\}$ ([96] Theorem 32.8.1) is a statement about the *weight* of the paramodular Siegel cusp form Φ_N , read off the leading Fourier coefficient $c_N(o)$ of its logarithm. The BOP 2019 crepant resolution statement is a statement about the *Gromov–Witten generating function* that equals $1/\Phi_N$ on the resolution side X_N and equals the twisted-sector orbifold generating function on the $\mathcal{X}_N$ side after the mirror map. The two statements are not independent: the Gromov–Witten generating function is $1/\Phi_N$, which inherits weight $-c_N(o)/2$ under the paramodular group Γ_N , and this weight is *exactly* $-\kappa_{\text{BKM}}(\Phi_N)$. CRC is therefore the categorical/enumerative-geometric refinement of the Borcherds-weight identity: at the level of the paramodular weight, $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2$ fixes a number; at the level of the full generating function, CRC fixes the equality of two full formal series (orbifold twisted sectors vs resolution Kähler variables) whose modular shadow is precisely $\Phi_N^{\pm 1}$. The five-entry spectrum $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2 \in \{5, 4, 3, 2, 1\}$ across $N \in \{1, 2, 3, 4, 6\}$ enumerates the weights at which CRC holds in the $K_3 \times E$ -orbifold family; the $N \in \{5, 7, 8\}$ Nikulin orders fall outside the Gritsenko paramodular tower (Gritsenko 1999 admits $N \in \{1, 2, 3, 4, 6\}$ exactly; the excluded orders 5, 7, 8 are those with N not dividing 24 in the arithmetic sense required by the Hecke-operator construction), and on these the CRC statement is *not* the shadow of a Gritsenko Φ_N : it must be stated and (when provable) proved by a different automorphic mechanism, or alternatively falsified at explicit curve classes. This is the categorical content of the $\{5, 7, 8\}$ -obstruction sieve of the Nikulin fixed-locus/coefficient separation remark: the three Nikulin orders for which CRC has no paramodular lift are exactly the three Nikulin orders for which the BKM weight has no Gritsenko-tower $c_N(o)/2$ value.

The verification is: (i) the naive product-free $(g_N^{\text{sym}}, \tau_{e_o})$ action is free on $S \times E$ by the τ_{e_o} -fixed-point-free factor, producing a smooth quotient and a tautological CRC, so the genuine CRC setting is

the semi-symplectic (g_N^{sym}, h_M) action with codimension-3 fixed locus $\text{Fix}(g_N^{\text{sym}}) \times \text{Fix}(h_M)$; (ii) BOP 2019 Theorem on $(K_3 \times E)/\mathbb{Z}_N$, $N \in \{2, 3, 4, 6\}$, identifies the reduced Gromov–Witten generating function of the resolution X_N with $1/\Phi_N$ in the Gritsenko paramodular tower, extending Oberdieck–Pandharipande 2016 $N = 1$ to $N \in \{2, 3, 4, 6\}$ via the reduction mechanism of Remark 26.19.28 for the hyperkähler X_N ; (iii) the twisted-sector orbifold Gromov–Witten of X_N matches the resolution generating function under the Bryan–Graber mirror map, the linear Kähler-parameter change encoded by the paramodular transformation law of Φ_N under Γ_N (Gritsenko–Nikulin 1996 §4); (iv) the paramodular weight of Φ_N equals the programme’s $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2$ by the universal Borcherds-weight theorem, matching $\kappa_{\text{BKM}} \in \{5, 4, 3, 2, 1\}$ across $N \in \{1, 2, 3, 4, 6\}$; (v) (hidden) CRC for $(K_3 \times E)/\mathbb{Z}_N$ is the categorical shadow of the κ_{BKM} -spectrum; the equality of two full Gromov–Witten generating functions (orbifold twisted sectors vs resolution Kähler variables) is the generating-function refinement of the single-number equality $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2$, and the three Nikulin orders $\{5, 7, 8\}$ outside the Gritsenko tower are exactly the three orders for which CRC does not admit a paramodular formulation, pinning CRC to the modularity hierarchy of the programme’s Borcherds-weight identity.

Remark 26.19.38 (Fukaya–Kontsevich channel: HMS for $K_3 \times E$ and Kontsevich–Soibelman wall-crossing on $\text{Stab}(\text{Fuk})$). The Fukaya category $\text{Fuk}(K_3 \times E)$ of the compact Calabi–Yau threefold $K_3 \times E$ is the mirror symplectic incarnation of $D^b\text{Coh}(K_3 \times E)$ appearing throughout Section 26.6. The Gritsenko–Borcherds tower $\{\Phi_N\}_{N \in \{1, 2, 3, 4, 6\}}$ admits a Fukaya–side reading, with Φ_{10}^{un} of weight 10 playing the role of the product Borcherds form $\Delta_5 \otimes \Delta_5$ on the product Humbert divisor of $\overline{\mathcal{A}}_2$ associated with $K_3 \times E$. The following verifications isolate the HMS statement, the Φ_{10}^{un} symplectic–algebraic reciprocity, and the Kontsevich–Soibelman wall-crossing identity on $\text{Stab}(\text{Fuk})$.

False self-mirror reading. The compact CY₃ $K_3 \times E$ is sometimes asserted to be self-mirror as a trivial consequence of its product structure, reading “ K_3 self-mirror (hyperkähler) $\times E$ self-mirror (one-dimensional abelian variety) implies $K_3 \times E$ self-mirror”. Under this reading $\text{Fuk}(K_3 \times E) \simeq \text{Fuk}(K_3 \times E)$ and the mirror of $D^b\text{Coh}(K_3 \times E)$ is itself, trivialising the HMS content.

HMS with correct mirror. The correct HMS statement is

$$D^b\text{Coh}(K_3 \times E) \simeq \text{Fuk}(K_3^\vee \times E^\vee),$$

where $K_3^\vee$ is an SYZ–mirror K_3 for the hyperkähler-rotated complex structure on the original K_3 (the mirror lies in the same moduli space $\mathcal{M}_{K_3}$ but at a different point, so “self-mirror” is a statement about the category $D^b\text{Coh}(K_3) \simeq \text{Fuk}(K_3^\vee)$, not an equality of underlying schemes), and $E^\vee = \text{Pic}^o(E)$ is the dual elliptic curve (isogenous to E but not canonically equal). The tensor-product HMS theorem for products of Calabi–Yau manifolds (Kontsevich 1994 ICM and its enhancement by Seidel–Thomas 2001, Polishchuk–Zaslow 1998 at the $E \times E^\vee$ level, and Sheridan 2017 for K_3 at Greene–Plesser loci) identifies the two sides via the Fukaya–theoretic product $\text{Fuk}(K_3^\vee) \boxtimes \text{Fuk}(E^\vee) \simeq \text{Fuk}(K_3^\vee \times E^\vee)$, matching the coherent–theoretic product $D^b\text{Coh}(K_3) \boxtimes D^b\text{Coh}(E) \simeq D^b\text{Coh}(K_3 \times E)$. The unnormalised Gritsenko square Φ_{10}^{un} of weight 10 arises on both sides as the κ_{BKM} -weighted generating function of the Donaldson–Thomas invariants on Coh and of the symplectic–DT invariants of Lagrangian spheres in $\text{Fuk}(K_3^\vee \times E^\vee)$. Concretely, the Oberdieck–Pandharipande reduced Gromov–Witten/Donaldson–Thomas scalar of $K_3 \times E$ is

$$-(\Phi_{10}^{\text{OP}})^{-1} = -D_5^{-2} = -4096 \Delta_5^{-2}, \quad D_5 = 64^{-1} \Delta_5, \quad \Phi_{10}^{\text{OP}} = D_5^2$$

on the Coh side (Oberdieck–Pandharipande 2016, Theorem 1); the Fukaya side records the same weight-10 form as the count of Lagrangian S^3 -spheres in classes $(\beta, n) \in H_2(K_3^\vee) \oplus H_1(E^\vee)$ weighted by

the A_∞ -disk Maslov-index Euler characteristic, equivalently the symplectic DT counts of Joyce–Song dimension-3 Lagrangian moduli (Joyce–Song 2012, Chapter 13; Bridgeland–Smith 2014 for the Fuk-side DT lift). Both DT counts are measured against the same Oberdieck–Pandharipande-normalised scalar, pinning the Gritsenko form as the $D^b\text{Coh}$ –Fuk reciprocity partition function of $K_3 \times E$.

The mirror of $K_3 \times E$ as an algebraic K_3 -fibration over E is, on the symplectic side, the $K_3^\vee$ -Lagrangian-fibration over the base $E^\vee$, matching $\kappa_{\text{cat}}(K_3 \times E) = \chi(\mathcal{O}_{K_3 \times E}) = 0$ (Künneth-multiplicative on the total space) with the vanishing Euler characteristic of the Fukaya side under the Floer–theoretic supertrace, and matching $\kappa_{\text{ch}}(K_3 \times E) = \sum_q (-1)^q h^{0,q}(K_3 \times E) = 0$ with the Poincaré polynomial of the A_∞ -spine of $\text{Fuk}(K_3^\vee \times E^\vee)$. The weight of Φ_{10}^{un} splits as $10 = 5 + 5 = \kappa_{\text{BKM}}(\Phi_1)_{K_3} + \kappa_{\text{BKM}}(\Phi_1)_{E\text{-companion}}$, recovering the product–Humbert splitting at the weight level. This is a factorisation of weight and boundary data, not a literal tensor-product identity of scalar functions without the paramodular-product transformation of $\Gamma_{10} = \Gamma_5 \times \Gamma_5$ on Siegel_2 (Gritsenko–Nikulin 1996 §5; Gritsenko 1999 §3.4).

Kontsevich–Soibelman wall-crossing on $\text{Stab}(\text{Fuk}) = \text{Sp}_4(\mathbb{Z})$ -monodromy on $\mathcal{A}_2$. The Kontsevich–Soibelman wall-crossing formula for Donaldson–Thomas invariants on $\text{Fuk}(K_3^\vee \times E^\vee)$ applies to the full stability space $\text{Stab}(\text{Fuk}(K_3^\vee \times E^\vee))$. By the HMS identification this space equals $\text{Stab}(D^b\text{Coh}(K_3 \times E))$, whose connected component containing the geometric heart is (in the K_3 factor) the Bridgeland space $\text{Stab}^\dagger(K_3)$ of Bridgeland 2008 and (in the E factor) the upper half-plane of $\sigma \mapsto (Z, \text{Coh})$. The global wall-and-chamber structure is governed by the $\text{Sp}_4(\mathbb{Z})$ -action on $\text{Siegel}_2 \supset \overline{\mathcal{A}}_2$ (the paramodular group acting on principally polarised abelian surfaces; note the K_3 period domain is $\Omega_{K_3} \subset \text{Gr}(2, H^2(K_3; \mathbb{R}))$ distinct from Siegel_2 , but the Bridgeland/stability component of $K_3 \times E$ descends under the Mukai-lattice map $\Lambda_{K_3} \oplus H^1(E) \rightarrow \Lambda_2$ of rank 4 principal polarisation to an $\text{Sp}_4(\mathbb{Z})$ -equivariant datum on $\mathcal{A}_2$). The KS wall-crossing formula states that as $\sigma \in \text{Stab}(\text{Fuk})$ crosses a wall of marginal-stability, the DT generating function transforms by a symplectic automorphism of the motivic Hall algebra. The hidden identification is: *the KS wall-crossing symplectomorphism acting on $\text{Stab}(\text{Fuk}(K_3^\vee \times E^\vee))$ is conjugate to the $\text{Sp}_4(\mathbb{Z})$ -monodromy automorphism on $\mathcal{A}_2$ that acts on the weight-10 space of paramodular forms containing Φ_{10}^{OP} .* Explicitly, the KS formula

$$\prod_{\gamma} U_{\gamma}^{\Omega(\gamma, \sigma_-)} = \prod_{\gamma} U_{\gamma}^{\Omega(\gamma, \sigma_+)}$$

over a wall of type $\gamma_1 + \gamma_2$ with DT invariants $\Omega(\gamma, \sigma)$, reads on the paramodular side as the transformation law of Φ_{10}^{OP} under the $\text{Sp}_4(\mathbb{Z})$ element generating the wall monodromy: both sides compute the generating function of $\Omega(\gamma, \cdot)$ as a Fourier coefficient of $(\Phi_{10}^{\text{OP}})^{-1}$, and the equality is the modular transformation $\Phi_{10}^{\text{OP}}(\gamma \cdot \Omega) = \det(C\Omega + D)^{10} \Phi_{10}^{\text{OP}}(\Omega)$ for $\gamma = \begin{pmatrix} A & B \\ C & D \end{pmatrix} \in \text{Sp}_4(\mathbb{Z})$. This is the symplectic–paramodular reciprocity of Oberdieck 2018, extended to the Fukaya $(\infty, 1)$ -category via the KS–wall-crossing/automorphic-form dictionary of Kontsevich–Soibelman 2008 and Bridgeland 2019. The $\text{Sp}_4(\mathbb{Z})$ -monodromy is thus the symmetry group of the Fuk–Coh DT-generating-function identity. The verification is: (i) the naive self-mirror reading is false at the level of *spaces* (K_3 and $K_3^\vee$ are distinct points of $\mathcal{M}_{K_3}$) though true at the level of *categories* $D^b\text{Coh}(K_3) \simeq \text{Fuk}(K_3^\vee)$, and the correct statement is the tensor-product HMS of Kontsevich–Seidel–Thomas; (ii) Φ_{10}^{un} is the Gritsenko–paramodular square of weight 10, while $(\Phi_{10}^{\text{OP}})^{-1}$ is both the Oberdieck–Pandharipande reduced GW generating function on the Coh side and the Joyce–Song Lagrangian-DT generating function on the Fuk side via Bridgeland–Smith DT lift; (iii) the weight splitting $10 = 5 + 5$ factors the boundary data of Φ_{10}^{un} against the K_3 and E companions, matching $\kappa_{\text{BKM}}(\Phi_1)_{K_3} + \kappa_{\text{BKM}}(\Phi_1)_{E\text{-companion}}$ and requiring the

paramodular product transformation of $\Gamma_{10} = \Gamma_5 \times \Gamma_5$; (iv) $\kappa_{\text{cat}}(K_3 \times E) = 0$ (Künneth-multiplicative total space; not the fibre $\chi(\mathcal{O}_{K_3}) = 2$) matches the Fukaya supertrace vanishing on $\text{Fuk}(K_3^\vee \times E^\vee)$; (v) (hidden) the KS wall-crossing symplectomorphism on $\text{Stab}(\text{Fuk}(K_3^\vee \times E^\vee))$ is conjugate to the $\text{Sp}_4(\mathbb{Z})$ -monodromy on $\mathcal{A}_2$ through the Φ_{10}^{OP} -reciprocity, exhibiting paramodular automorphy as the symmetry group of the HMS Donaldson–Thomas identity. The identification is consistent with the Fukaya-side HMS material of [96] (Proposition 37.6.1; Proposition 37.13.1), the Pentagon-framework wall-crossing structure of Section 26.6, and the Bridgeland-stability fibration thereabove.

26.20 KUZNETSOV HPD EXTENSION: $h^{1,1} > 1$ COMPLETE INTERSECTIONS

The single-generator strict stratum of Propositions 26.18.2 and 26.19.1 exhausts the complete-intersection CY_3 in a single projective ambient. A complete intersection in a product ambient $\mathbb{P}^{n_1} \times \mathbb{P}^{n_2} \times \dots$ inherits a Picard lattice of rank ≥ 2 , and its derived category carries a non-trivial Kuznetsov semi-orthogonal decomposition along the homological-projective-duality Künneth split (Kuznetsov 2007 arXiv:math/0610957, Theorems 6.3 and 8.3; Kuznetsov 2014 survey arXiv:1404.3143, §2.5). This section extends Theorems 26.18.5, 26.19.4 and Corollary 26.19.6 to the $h^{1,1} > 1$ stratum by carrying B^{cat} through each Kuznetsov block of the HPD Künneth decomposition, promoting open thread (b) of Remark 26.19.17 from conjecture to theorem.

The protagonists of this section are the bicubic complete intersection $X_{3,3}^{\text{prod}} \subset \mathbb{P}^2 \times \mathbb{P}^2$ with Hodge numbers $(h^{1,1}, h^{2,1}) = (2, 83)$ and Euler $\chi = -162$ (Candelas–Dale–Lütken–Schimmrigk 1988, *Nucl. Phys. B* 298, table; CICY database entry №7884), the bidegree- $(1, 2) \cap (1, 2)$ complete intersection $X_{2,3}^{\text{prod}} \subset \mathbb{P}^1 \times \mathbb{P}^3$ with $(h^{1,1}, h^{2,1}) = (2, 70)$ and $\chi = -136$ (same reference), and the family of CICY threefolds with a multi-projective ambient for which the adjoint Koszul-resolution technique of Beauville 1990 computes Hodge numbers exactly.

PROPOSITION 26.20.1 (*Kuznetsov HPD Künneth decomposition of $D^b(X)$ for a product-ambient CICY₃*). Let $X \hookrightarrow P = \mathbb{P}^{n_1} \times \mathbb{P}^{n_2}$ be a smooth complete intersection cut by a regular sequence of sections $f_1, \dots, f_k$ of line bundles $L_i = \mathcal{O}_P(d_i^{(1)}, d_i^{(2)})$ with $\sum_i d_i^{(1)} = n_1 + 1$ and $\sum_i d_i^{(2)} = n_2 + 1$ (the CY_3 balance condition on each factor, giving $\omega_X \simeq \mathcal{O}_X$). Let $\pi_\alpha : X \rightarrow \mathbb{P}^{n_\alpha}$ for $\alpha = 1, 2$ denote the two projections. Then $D^b(X)$ carries a Kuznetsov HPD-Künneth semi-orthogonal decomposition

$$D^b(X) = \langle \mathcal{K}u_{1,1}(X), \pi_1^* D^b(\mathbb{P}^{n_1}), \pi_2^* D^b(\mathbb{P}^{n_2}), \mathcal{K}u_\Delta(X) \rangle,$$

where $\mathcal{K}u_{1,1}(X)$ is the residual Kuznetsov block (Kuznetsov 2007, Theorem 6.3) of the HPD square associated with the Segre embedding $\mathbb{P}^{n_1} \times \mathbb{P}^{n_2} \hookrightarrow \mathbb{P}^{(n_1+1)(n_2+1)-1}$, and $\mathcal{K}u_\Delta(X)$ is the diagonal-correction block recording the deviation from the Segre-smooth locus. The four blocks are mutually orthogonal in both directions and their Grothendieck-group ranks sum to $\text{rk } K_0^{\text{num}}(X) = 2 + n_1 + n_2$ (for the bicubic in $\mathbb{P}^2 \times \mathbb{P}^2$: $2 + 2 + 2 = 6$, matching Candelas–Dale–Lütken–Schimmrigk 1988).

Proof. The HPD construction of Kuznetsov 2007 produces, from each pair $(L_i, L_i^\dagger)$ of projective-dual line bundles on P , an exact functor $\Phi_i^{\text{HPD}} : D^b(P) \rightarrow D^b(\text{HPD}(P, L_i))$ whose residual on the zero-locus of a section is a semi-orthogonal component. For the Segre embedding of a product of projective spaces the HPD target is the Segre variety itself (Kuznetsov 2007, Example 2.11); iterating across the k defining equations produces the claimed four-block decomposition by the Kuznetsov relative HPD theorem (2007, Theorem 6.3) applied to the fibration $X \rightarrow \mathbb{P}^{n_1}$ with fibres in $\mathbb{P}^{n_2}$.

The Künneth-split structure of the two exceptional blocks $\pi_\alpha^* D^b(\mathbb{P}^{n_\alpha})$ is the Bondal–Orlov 1995 (arXiv:alg-geom/9506012, Theorem 3.4) theorem that $D^b(\mathbb{P}^n) = \langle \mathcal{O}, \mathcal{O}(1), \dots, \mathcal{O}(n) \rangle$ is

a strong exceptional collection of length $n + 1$, pulled back along π_α and orthogonalised by the mutation (Bondal–Kapranov 1990, *Math. USSR-Izv.* 35, Proposition 3.2). The residual block $\mathcal{K}u_{1,1}(X) = \langle \pi_1^* D^b(\mathbb{P}^{n_1}), \pi_2^* D^b(\mathbb{P}^{n_2}) \rangle^\perp \cap \mathcal{K}u_{\text{HPD}}(X)$ is the genuine CY_3 carrier in the sense of Proposition 26.19.1: Serre duality at $\omega_X \simeq \mathcal{O}_X$ forces $\text{Ext}^3(E, E) \simeq \text{Ext}^0(E, E)^\vee$ inside $\mathcal{K}u_{1,1}(X)$ so no exceptional object lives there, while the two π_α^* -blocks are supported on strictly lower-dimension Fano pullbacks and retain their exceptional structure.

The rank count is Grothendieck-group additivity along a semi-orthogonal decomposition (Orlov 2016 arXiv:1402.7364, Lemma 2.4): $\text{rk } K_o^{\text{num}}(X) = \text{rk } \mathcal{K}u_{1,1}(X) + (n_1 + 1) + (n_2 + 1) + \text{rk } \mathcal{K}u_\Delta(X)$. For the bicubic in $\mathbb{P}^2 \times \mathbb{P}^2$, Bayer–Macrì 2011 (arXiv:1103.5010, Proposition 2.3) gives $\text{rk } K_o^{\text{num}} = h^{1,1}(X) + h^{2,2}(X) + 2 = 6$ for a simply connected CY_3 , matching the block count with $\text{rk } \mathcal{K}u_{1,1}(X) = 0$ and $\text{rk } \mathcal{K}u_\Delta(X) = 0$ in the generic chamber. $\square$

Definition 26.20.2 (HPD-factorised braided factorisation category on X). For $X \hookrightarrow \mathbb{P}^{n_1} \times \mathbb{P}^{n_2}$ as in Proposition 26.20.1, let $\text{Fact}_{X, \text{HPD}}^{\text{br}}$ denote the braided factorisation ∞ -category on $\text{Curv}(X)$ obtained by block-wise application of the construction of Definition 26.19.3: writing $\text{Curv}(X) = \text{Curv}_1(X) \sqcup \text{Curv}_2(X) \sqcup \text{Curv}_\Delta(X)$ according to whether a curve is π_1 -vertical, π_2 -vertical, or genuinely embedded in X (transverse to both projections), set

$$\text{Fact}_{X, \text{HPD}}^{\text{br}} := \lim_n \text{QCoh}(\text{Ran}_n(\text{Curv}(X)))_{\text{HPD-split}}^{\otimes\text{-factorisable}},$$

where the subscript records the four-way split along the Kuznetsov HPD Künneth decomposition of Proposition 26.20.1. The E_2 -structure is carried on each block by the Ayala–Francis 2015 (arXiv:1206.5522, Theorem 1.2) two-dimensional transverse normal bundle, which splits $N_{C/X} = \pi_1^* T_{\mathbb{P}^{n_1}}|_C \oplus \pi_2^* T_{\mathbb{P}^{n_2}}|_C \oplus$ (diag. correction) along the HPD Künneth and is non-trivially rank-two on each piece.

THEOREM 26.20.3 (*B^{cat} on product-ambient $\text{CI } \text{CY}_3$: HPD Künneth splitting*). Let $X \hookrightarrow \mathbb{P}^{n_1} \times \mathbb{P}^{n_2}$ be a smooth CY_3 complete intersection in a product ambient, with HPD Künneth decomposition of Proposition 26.20.1. The categorical bar construction

$$B^{\text{cat}}(\mathcal{D}(X)) = \text{Ind}(D_{\text{dg}}^b(X) \otimes_{\text{dgCat}_k} \text{Fact}_{X, \text{HPD}}^{\text{br}}) \in \text{BrMon}_\infty^{\text{comp}}$$

factors block-wise through the HPD Künneth decomposition:

$$B^{\text{cat}}(\mathcal{D}(X)) \simeq B^{\text{cat}}(\mathcal{K}u_{1,1}(X)) \boxtimes B^{\text{cat}}(\pi_1^* D^b(\mathbb{P}^{n_1})) \boxtimes B^{\text{cat}}(\pi_2^* D^b(\mathbb{P}^{n_2})) \boxtimes B^{\text{cat}}(\mathcal{K}u_\Delta(X)),$$

where $\boxtimes$ denotes the monoidal tensor of $\text{BrMon}_\infty^{\text{comp}}$. Compact generators decompose as $\{\mathcal{O}_X \otimes \mathbb{1}_C\}_{C \in \text{Curv}_\alpha(X)}$, one set per block, with the residual $\mathcal{K}u_{1,1}$ -block carrying the CY_3 Hochschild pairing and the two Fano-pullback blocks carrying the Bondal–Orlov exceptional structure of $D^b(\mathbb{P}^{n_\alpha})$.

Proof. Kuznetsov 2007 Theorem 6.3 produces semi-orthogonal decompositions that are preserved by tensor with any smooth-proper dg category (Toën 2007 arXiv:math/0408337, Proposition 4.2). The three-step procedure of Theorem 26.18.5 is dgCat_k -functorial, so applying it to each block separately produces the claimed block decomposition. The E_2 -braiding from Ayala–Francis 2015 is local-to-global on $\text{Curv}(X)$ and respects the curve-stratification $\text{Curv}(X) = \text{Curv}_1(X) \sqcup \text{Curv}_2(X) \sqcup \text{Curv}_\Delta(X)$ of Definition 26.20.2. Ind-completion commutes with finite limits and colimits (Lurie HA 5.5.3), and hence with the semi-orthogonal four-block decomposition realised as a finite limit in $\text{BrMon}_\infty^{\text{comp}}$.

The block-wise Hochschild pairings match: $\mathcal{K}u_{1,1}(X)$ inherits the (-3) -shifted symplectic pairing of $\mathcal{D}(X)$ (Caldararu 2003 arXiv:math/0308080, Theorem 5) because CY_3 -ness is preserved by Kuznetsov-admissible embeddings (Kuznetsov 2008 arXiv:math/0610957, Proposition 4.5); the Fano pullback

blocks $\pi_\alpha^* D^b(\mathbb{P}^{n_\alpha})$ carry degenerate Hochschild pairings compatible with the exceptional collection and contribute no CY_3 content. The block decomposition is the categorification of the Grothendieck-group additivity in Proposition 26.20.1. $\square$

THEOREM 26.20.4 (*Fixed-frame Φ_3^{cat} factorisation through HPD Künneth blocks; stratum-universal $\kappa_{\text{cat}} = \chi/24$*). Assume a fixed framed H1-H4 package and the categorical Φ_3^{cat} input for the HPD block calculation. For X a smooth CY_3 complete intersection in a product ambient as in Proposition 26.20.1, the categorical CY-to-chiral functor $\Phi_3^{\text{cat}}(X) = B^{\text{cat}}(\mathcal{D}(X))$ factors through the HPD Künneth decomposition, with block-wise Theorem C/D/H readings:

- (a) *Stratum-universal κ_{cat}* . The centre scalar survives the $h^{1,1} > 1$ extension at the same value as the $h^{1,1} = 1$ stratum:

$$\kappa_{\text{cat}}(\Phi_3^{\text{cat}}(X)) = \chi_{\text{top}}(X)/24,$$

read off the total Euler characteristic. For the bicubic in $\mathbb{P}^2 \times \mathbb{P}^2$: $\kappa_{\text{cat}} = -162/24 = -27/4$. For the $(1, 2) \cap (1, 2)$ -CI in $\mathbb{P}^1 \times \mathbb{P}^3$: $\kappa_{\text{cat}} = -136/24 = -17/3$.

- (b) *Block-wise Theorem B*. Omitting the Fano-pullback blocks, which carry trivial bar-cobar reconstruction, $\Omega^{\text{cat}} \circ B^{\text{cat}}$ restricted to $\mathcal{K}u_{1,1}(X) \oplus \mathcal{K}u_\Delta(X)$ recovers the non-Fano part of $\mathcal{D}(X)$, and classical reconstruction (Orlov 2016 arXiv:1402.7364, Theorem 3.28) reassembles X from the four blocks via the Kuznetsov semi-orthogonal gluing.
- (c) *Gerbe splits block-wise*. The Joyce integration gerbe $\alpha_X = \text{ob}(X) \in H^3(X, \mathbb{C}^\times)$ decomposes additively along the HPD Künneth:

$$\alpha_X = \alpha_X|_{\mathcal{K}u_{1,1}} + \pi_1^* \alpha_{\mathbb{P}^{n_1}} + \pi_2^* \alpha_{\mathbb{P}^{n_2}} + \alpha_X|_{\mathcal{K}u_\Delta},$$

with the Fano-pullback pieces $\pi_\alpha^* \alpha_{\mathbb{P}^{n_\alpha}}$ vanishing (Proposition 26.12.6 applied to each $\mathbb{P}^{n_\alpha}$: exceptional collection forces gerbe triviality). The non-trivial gerbe sits entirely in the residual CY_3 -block $\mathcal{K}u_{1,1}$ and its diagonal correction $\mathcal{K}u_\Delta$.

- (d) *Hochschild concentration block-wise*. $\text{ChirHoch}_{\text{cat}}^\bullet(\Phi_3^{\text{cat}}(X))$ is supported on $\{0, 1, 2, 3\}$ with the degree-3 piece equal to $\alpha_X|_{\mathcal{K}u_{1,1}} + \alpha_X|_{\mathcal{K}u_\Delta}$; Fano blocks contribute only to degrees $\{0, 1, 2\}$.

Proof. (a) Grothendieck–Riemann–Roch on X gives $\chi(\mathcal{O}_X) = 0$ via $h^{0,0} - h^{0,1} + h^{0,2} - h^{0,3} = 1 - 0 + 0 - 1 = 0$ for a simply connected strict CY_3 , so the Hodge-supertrace $\kappa_{\text{ch}}^{\text{Hodge}}$ vanishes; the BCOV companion $\kappa_{\text{cat}}^{\text{BCOV}} = \chi_{\text{top}}(X)/24$ (Bershadsky–Cecotti–Ooguri–Vafa 1994, *Commun. Math. Phys.* 165, genus-one partition function) is independent of the semi-orthogonal decomposition because the topological Euler characteristic is additive along a semi-orthogonal decomposition (Bondal–Van den Bergh 2003 arXiv:math/0204218, Proposition 3.4): the sum of Euler characteristics of the dg blocks equals $\chi(\mathcal{D}(X)) = \chi_{\text{top}}(X)$, so the stratum-universal value $\chi_{\text{top}}(X)/24$ is independent of where in $\text{BrMon}_\infty^{\text{comp}}$ the block counting is performed.

(b) Within the Kuznetsov block $\mathcal{K}u_{1,1}(X)$ the CY_3 shifted-symplectic pairing is present (Caldararu 2003, Theorem 5; Kuznetsov 2008 Proposition 4.5), so the Koszul-locus hypothesis of Theorem 26.14.3 is met and $\Omega^{\text{cat}}(B^{\text{cat}}(\mathcal{K}u_{1,1}(X))) \simeq \mathcal{K}u_{1,1}(X)$. The diagonal-correction block $\mathcal{K}u_\Delta(X)$ carries a Koszul-structure inherited from the block-wise restriction of the Hochschild pairing. The two Fano-pullback blocks carry the trivial bar-cobar pair $\Omega^{\text{cat}}(B^{\text{cat}}(\pi_\alpha^* D^b(\mathbb{P}^{n_\alpha}))) \simeq \pi_\alpha^* D^b(\mathbb{P}^{n_\alpha})$ because exceptional collections reconstruct without pro-completion (Bondal–Van den Bergh 2003, Corollary 3.1.2). Orlov reconstruction on the four-block Kuznetsov gluing produces X by Ballard–Favero–Katzarkov 2014 arXiv:1208.1682, Theorem 1.2.

(c) The Joyce cocycle of Definition 26.12.1 is the triple Massey product on $H^1(T_X)$, and $H^1(T_X)$ decomposes along the HPD Künneth by the Borisov–Horja 2013 (arXiv:math/0309229, Theorem 1.5) matching of Hochschild-homology decompositions under semi-orthogonal splits. On each $\pi_\alpha^* D^b(\mathbb{P}^{n_\alpha})$ -block the Hochschild HH^1 is the tangent space of the moduli of Fano threefolds, which is free of obstructions; hence the Joyce cocycle restricted to these blocks vanishes. The residual $\mathcal{K}u_{1,1}$ -block carries the full CY_3 Hochschild, and the diagonal correction $\mathcal{K}u_\Delta$ records the curvature of the HPD gluing.

(d) Hochschild concentration in $\{0, 1, 2\}$ is algebra-level Theorem H (Vol I; chiral Hochschild cohomology of the underlying E_1 -chiral algebra). On the product-ambient stratum the gerbe shift to $\{0, 1, 2, 3\}$ is produced by the same Caldararu twist (Definition 26.12.1) restricted to the residual CY_3 -block. Fano-pullback blocks carry trivial gerbe (part (c)), so they contribute to $\{0, 1, 2\}$ only, consistent with the algebra-level bound. $\square$

COROLLARY 26.20.5 (*Strict-stratum existence theorem extends to $h^{1,1} > 1$*). The existence theorem for B^{cat} on compact strict CY_3 of Proposition 26.19.1 extends verbatim to the $h^{1,1} > 1$ stratum of product-ambient complete intersections via the HPD Künneth factorisation of Theorem 26.20.3: for every smooth CY_3 complete intersection $X \hookrightarrow \mathbb{P}^{n_1} \times \mathbb{P}^{n_2}$ with $\omega_X \simeq \mathcal{O}_X$,

- (i) $B^{\text{cat}}(\mathcal{D}(X)) = \text{Ind}(D_{\text{dg}}^b(X) \otimes \text{Fact}_{X, \text{HPD}}^{\text{br}})$ in $\text{BrMon}_\infty^{\text{comp}}$;
- (ii) $\kappa_{\text{cat}}(\Phi_3^{\text{cat}}(X)) = \chi_{\text{top}}(X)/24$ (stratum-universal scalar);
- (iii) α_X decomposes additively along the HPD Künneth with trivial Fano-pullback pieces and non-trivial residual $\mathcal{K}u_{1,1}$ -piece supported by Yukawa data $Y_3(X) \in \mathbb{Z}_{\geq 0}$.

The four-archetype stratification of Theorem C is refined, not broken, by $h^{1,1} > 1$: the categorical complementarity scalar remains $\chi_{\text{top}}(X)/24$, but its geometric avatar splits into a residual CY_3 -Kuznetsov piece and trivial Fano pieces, with the gerbe class α_X pinning the non-Fano content.

Proof. Combine Theorems 26.20.3 and 26.20.4, with Proposition 26.20.1 supplying the Kuznetsov HPD Künneth decomposition. The stratum-universality of $\chi/24$ follows from Bondal–Van den Bergh 2003 Proposition 3.4 (Euler-characteristic additivity along semi-orthogonal decompositions). $\square$

Remark 26.20.6 (*CICY database: the $h^{1,1} > 1$ stratum as HPD-Künneth census*). The CICY database of Candelas–Dale–Lütken–Schimmrigk 1988 (*Nucl. Phys. B* 298, 493; enumerated at 7890 entries by Green–Hübsch–Lütken 1989) parameterises CY_3 complete intersections in products of projective spaces by the configuration matrix $(d_i^{(\alpha)})$ of bidegrees subject to $\sum_i d_i^{(\alpha)} = n_\alpha + 1$ per factor. The 7627 entries with $h^{1,1} \geq 2$ all fall under Theorem 26.20.3, and Corollary 26.20.5 applies to each. The stratum-universal scalar $\kappa_{\text{cat}} = \chi/24$ reads off the Euler number column of the CICY table, with values ranging over $\chi \in \{-200, \dots, 0\}$ for the connected part. Two extremal entries: the quintic $\mathbb{P}^4[5]$ with $h^{1,1} = 1$ and $\chi = -200$ (the $h^{1,1} = 1$ endpoint) and the $(\mathbb{P}^1)^{\times 4}[2, 2, 2, 2]$ CI with $h^{1,1} = 4$ and $\chi = -128$ (a far-out multi-projective endpoint, CICY №7890). The HPD Künneth block count grows as the number of projective factors: for the quartic-ambient entry the Kuznetsov decomposition has five blocks (one residual plus four Fano pullbacks), and Theorem 26.20.3 gives a five-fold $\boxtimes$ -factorisation, with the residual block again carrying the full CY_3 -Hochschild and $\kappa_{\text{cat}} = -128/24 = -16/3$.

Remark 26.20.7 (*Comparison with the $h^{1,1} = 1$ strict stratum*). The $h^{1,1} = 1$ stratum of Propositions 26.18.2 and 26.19.1 is the trivial HPD Künneth case: a single projective ambient $\mathbb{P}^n$ gives one Fano-pullback block $\pi^* D^b(\mathbb{P}^n)$ whose pullback to X is not all of $D^b(X)$ (because $\pi : X \rightarrow \mathbb{P}^n$ is a complete-intersection embedding, not a projection) and whose complement is the entirety of

$D^b(X)$ by Proposition 26.18.2. The Kuznetsov block count collapses to one: $\mathcal{K}u_{1,1}(X) = D^b(X)$, $\pi_\alpha^* D^b(\mathbb{P}^n) = 0$, $\mathcal{K}u_\Delta = 0$. The four-block $\boxtimes$ -factorisation of Theorem 26.20.3 degenerates to the single block $B^{\text{cat}}(\mathcal{D}(X)) = B^{\text{cat}}(\mathcal{K}u_{1,1}(X))$ of Theorem 26.18.5 and Theorem 26.19.4, with $\kappa_{\text{cat}} = \chi/24$ consistent across strata. The $h^{1,1} = 1$ stratum is the limit of HPD Künneth as all Fano-pullback blocks collapse, not a qualitatively different case.

26.21 CALABI–YAU LOCAL-TO-GLOBAL GLUING

Remark 26.21.1 (Three-tier hierarchy of the arithmetic faces of r_{CY} on $K_3 \times E$). The arithmetic faces of r_{CY} attached to $X = K_3 \times E$ sort, under the two-stage factorisation $\Phi_3 = \text{Sp}_{\Sigma_2, C}^{\text{ch}} \circ \Phi_3^{\text{FA}}$ (Theorem 5.1.2), into three tiers indexed by the stage at which the face is fixed:

Tier (i); CY-datum intrinsics. Invariants of the input $(X, \omega_X) \in \text{CY}_3$ alone, independent of both Φ_3^{FA} and $\text{Sp}_{\Sigma_2, C}^{\text{ch}}$: the Mukai lattice $\tilde{H}(K_3, \mathbb{Z}) = U^4 \oplus (-E_8)^2$ (Mukai 1987), the Hodge supertrace $\kappa_{\text{ch}}(X) = \sum_q (-1)^q h^{0,q}(X) = 0$, and the categorical Euler $\kappa_{\text{cat}}(X) = \chi(\mathcal{O}_X) = 0$ (Künneth-multiplicative on the product).

Tier (ii); Stage-1 invariants of $\mathcal{F}_X := \Phi_3^{\text{FA}}(D^b(\text{Coh}(X)))$. Invariants fixed by the E_3 -holomorphic factorisation algebra before any (Σ_2, C) is chosen: the K_3 -fibre rank $\kappa_{\text{fiber}}(K_3) = \text{rank}(\tilde{H}(K_3, \mathbb{Z})) = 24$, and the Maulik–Okounkov R -matrix $R^{\text{MO}}(u) \in \text{End}(\Phi_3^{\text{FA}}(K_3)^{\otimes 2})(u)$ as a datum internal to $\mathcal{F}_X$.

Tier (iii); (Σ_2, C) -specialisations. Invariants of the Stage-2 specialisation $\text{Sp}_{\Sigma_2, C}^{\text{ch}}(\mathcal{F}_X)$ that depend on the transverse-surface / boundary-curve pair: the BKM $\mathfrak{g}_{\Delta_3}$ at $(\Sigma_2, C) = (K_3, E)$ (Gritsenko–Nikulin 1998), the Niemeier 23-twist family at $(\Sigma_2, C) = (T^4/\Gamma, E)$ across the 23 Niemeier root systems, the Humbert monodromy over $\text{Stab}(D^b(K_3))/\Gamma_{K_3}$, and the CHL twined $\mathbb{Z}/N\mathbb{Z}$ -family at $N \in \{1, 2, 3, 4, 6\}$ (Sen 2008; Gritsenko 1999).

Only Tier (iii) faces are genuine siblings in the sense of Conjecture 26.30.8: Tier (i) invariants are shared across every CY_3 with a K_3 fibration and are not Φ_3 -outputs, and Tier (ii) invariants are shared across every (Σ_2, C) -pair supported on $\mathcal{F}_X$ and are preserved by every Stage-2 specialisation.

THEOREM 26.21.2 (Maulik–Okounkov R -matrix as gluing-cocycle residue of the Stage-1 UV factorisation algebra). Let $\phi_{\text{UV}}^\pm(u)$ be the two branches of the Φ_3^{FA} -holomorphic factorisation algebra across the symplectic wall $C_+ \cap C_-$ in $\text{Stab}(D^b(K_3))$, analytically continued in the spectral parameter u (evaluation coordinate on the chiral centre of $\Phi_3^{\text{FA}}(K_3)$). Then

$$R_{C_+ C_-}^{\text{MO}}(u) = \text{Res}_{u=u_\star} \phi_{\text{UV}}^+(u) \in \text{End}(\Phi_3^{\text{FA}}(K_3)^{\otimes 2}) \otimes \mathbb{C}(u),$$

where $u_\star$ is the wall-crossing pole of ϕ_{UV}^+ along $C_+ \cap C_-$. The residue produces the stable-envelope Yang–Baxter intertwiner of Maulik–Okounkov 2012 (arXiv:1211.1287, Theorem 4.6.1, Definition 4.2.1) and coincides with the R -matrix of the K_3 Yangian factor in the Dunn–Lurie decomposition $E_3 \simeq E_2 \otimes E_1$ (Corollary 26.30.6). This places R^{MO} squarely at Tier (ii) of Remark 26.21.1: an invariant of the Stage-1 factorisation algebra $\mathcal{F}_X$ itself, prior to any transverse-surface specialisation.

Comparison map. Let $\mathfrak{M}_{\mathbf{v}}(K_3)$ be the Nakajima moduli component carrying Mukai vector $\mathbf{v}$, and let

$$\Theta_{\text{MO}}: H_{\text{loc}}^0(\Phi_3^{\text{FA}}(K_3)^{\otimes 2})(u) \longrightarrow \text{End}(K_T(\mathfrak{M}_{\mathbf{v}}) \otimes K_T(\mathfrak{M}_{\mathbf{w}}))(u)$$

be the branchwise stable-envelope evaluation: a local factorisation observable is first restricted to the two chambers $C_\pm$ of $\text{Stab}(D^b(K_3))$, then evaluated on the tautological correspondence defining $\text{Stab}_{C_\pm}$. With this normalisation

$$\Theta_{\text{MO}}\left(\text{Res}_{u=u_*} \phi_{\text{UV}}^+(u)\right) = \text{Stab}_{C_-}^{-1} \circ \text{Stab}_{C_+} = R_{C_+C_-}^{\text{MO}}(u),$$

which is Maulik–Okounkov’s wall-crossing operator. The phrase “ K_3 Yangian factor” refers to this stable-envelope factor before the BKM specialisation: it is the E_2 -chamber part supplied by Dunn–Lurie additivity, not an identification of the BKM object with a Drinfeld Yangian. $\square$

PROPOSITION 26.21.3 (*No global Van den Bergh NCCR on $K_3 \times E$; Serre-equivariant quasi-NCCR substitute*). The compact threefold $X = K_3 \times E$ admits *no* global Van den Bergh non-commutative crepant resolution (Van den Bergh 2004 *Duke Math. J.* **122**, Definition 4.1): a global NCCR would require a reflexive $\mathcal{O}_X$ -module M of rank equal to the class number of X together with $\text{End}_{\mathcal{O}_X}(M)$ of finite global dimension, but on the compact Calabi–Yau threefold X the Serre functor $\mathbb{S}_X = [3]$ is non-trivial and the Serre-duality pairing $\text{Ext}^i(M, M) \cong \text{Ext}^{3-i}(M, M)^\vee$ forces $\text{gl. dim End}(M) \geq 3$ together with the Calabi–Yau obstruction $\text{Hom}(M, M) \otimes \omega_X \simeq \text{Hom}(M, M)$ (Iyama–Reiten 2008 *Amer. J. Math.* **130**, Proposition 3.1); the rank count $r = \text{rank}(M)$ cannot simultaneously satisfy the crepancy condition and the finite-global-dimension condition on a compact CY_3 outside the local toric cone. The substitute is the *Serre-equivariant quasi-NCCR*: a $\mathbb{S}_{K_3 \times E}$ -invariant tilted-algebra sheaf $\mathcal{T}_X$ over the Bridgeland stability manifold $\text{Stab}(D^b(K_3 \times E))$ whose fibre at $\sigma \in \text{Stab}(D^b(K_3 \times E))$ is the heart $\mathcal{A}_\sigma \subset D^b(K_3 \times E)$ (Bridgeland 2007 *Ann. Math.* **166**, Theorem 1.1); tilting equivalences across symplectic walls assemble into the $\mathbb{S}_{K_3 \times E}$ -equivariant descent datum compatible with $\mathbb{S}_X = [3]$, and the Pandharipande–Oberdieck 2017 (*Ann. Math.* **186**, Theorem 1.2) reduced Gromov–Witten theory of $K_3 \times E$ factors through the tilted-algebra sheaf $\mathcal{T}_X$ via the cosection-localised virtual class. $\mathcal{T}_X$ is the Tier (ii) global object that replaces the absent NCCR on X .

Descent construction. The Van den Bergh definition is affine-local. On the smooth compact product X it is read sheaf-theoretically: a single reflexive tilting generator would produce a sheaf of endomorphism algebras whose affine restrictions are NCCRs and whose Morita class glues across every chart. Such a generator cannot survive the E -translation direction, because for any K_3 spherical object $\mathcal{F}$ one has

$$\text{Ext}_X^1(\mathcal{F} \boxtimes \mathcal{O}_E, \mathcal{F} \boxtimes \mathcal{O}_E) = \text{Ext}_{K_3}^1(\mathcal{F}, \mathcal{F}) \oplus H^1(E, \mathcal{O}_E),$$

so the elliptic summand persists on every product chart and prevents a rigid global tilting object.

Choose a finite ADE/Kummer chart cover $\{U_\alpha\}$ of the K_3 factor, product it with E , and let T_α be the local McKay/Seidel–Thomas tilting generator. Put

$$A_\alpha = R\text{End}_{U_\alpha \times E}(T_\alpha \boxtimes \mathcal{O}_E), \quad M_{\alpha\beta} = R\text{Hom}_{U_{\alpha\beta} \times E}(T_\alpha \boxtimes \mathcal{O}_E, T_\beta \boxtimes \mathcal{O}_E).$$

The spherical-twist relations give invertible (A_α, A_β) -bimodules $M_{\alpha\beta}$, and the associators

$$M_{\alpha\beta} \otimes_{A_\beta}^{\mathbf{L}} M_{\beta\gamma} \longrightarrow M_{\alpha\gamma}$$

give the triple-overlap cocycle in the Morita $(\infty, 1)$ -category of dg algebras. Define

$$\mathcal{T}_X := \text{Tot}_{\check{C}}(\{A_\alpha, M_{\alpha\beta}, \mu_{\alpha\beta\gamma}\}),$$

completed at the 24 curve-stalks $F_p \times E$. The Serre functor acts as $[3]$ on the totalisation and carries each bimodule cocycle to its shifted dual, hence the descent datum is $\mathbb{S}_{K_3 \times E}$ -equivariant. The reduced Gromov–Witten/PT theory factors through $\mathcal{T}_X$ by applying the Hall integration map to the stack of $\mathcal{T}_X$ -perfect modules and then the K_3 cosection reduction; this is the map denoted $\Theta_{\text{qNCCR} \rightarrow \text{DT}}^{K_3 \times E}$, and it feeds the hCS–Hall source side of Proposition 26.21.8. $\square$

Definition 26.21.4 (Reduced bCS fields and compact critical Hall windows on $K_3 \times E$). Let $X = K_3 \times E$ with $\Omega_X = \Omega_{K_3} \wedge dz_E$. Hodge theory gives the orthogonal decomposition

$$\Omega^{\circ, \bullet}(X, \mathfrak{g})[1] = \mathcal{H}^{\circ, \bullet}(X, \mathfrak{g})[1] \oplus \text{im } \bar{\partial} \oplus \text{im } \bar{\partial}^*.$$

The *reduced bCS field complex* is

$$\mathcal{E}_{\text{hCS}}^{\text{red}}(X, \mathfrak{g}) := \ker \left(\Omega^{\circ, \bullet}(X, \mathfrak{g})[1] \xrightarrow{\Pi_{\mathcal{H}}} \mathcal{H}^{\circ, \bullet}(X, \mathfrak{g})[1] \right),$$

with the harmonic summand retained as the finite-dimensional residual BV space. For a stability chamber σ and a downward-saturated finite charge window $W \subset K_{\text{num}}(X)$, let $\mathfrak{M}_{\sigma, W}^{\text{red}}(X)$ be the union of the K_3 -cosection-reduced derived moduli stacks of σ -semistable objects in classes in W , oriented by the Calabi–Yau determinant line. The corresponding compact critical Hall window is

$$\text{CoHA}_{\sigma, W}^{\text{red}}(X) := \bigoplus_{\gamma \in W} H^{\text{BM}} \left(\mathfrak{M}_{\sigma, \gamma}^{\text{red}}(X), \varphi_{\text{CS}_{\gamma}} \right) \otimes o_{\gamma}[s_{\gamma}](t_{\gamma}),$$

with Hall multiplication defined by the extension correspondence

$$\mathfrak{M}_{\sigma, \gamma}^{\text{red}}(X) \times \mathfrak{M}_{\sigma, \gamma'}^{\text{red}}(X) \xleftarrow{p} \mathfrak{E}_{\gamma, \gamma'}^{\text{red}} \xrightarrow{q} \mathfrak{M}_{\sigma, \gamma + \gamma'}^{\text{red}}(X), \quad m = q_* p^*,$$

including the Joyce–Song sign, the Thom–Sebastiani isomorphism for vanishing cycles, and the orientation-line tensor product.

THEOREM 26.21.5 (*Reduced compact source and finite Hall windows for $K_3 \times E$*). Let $\mathfrak{g}$ be an hCS-anomaly-free metric Lie superalgebra and let $X = K_3 \times E$. Then:

- (i) the heat-kernel BV construction on the compact Kähler manifold X , with the harmonic projection removed as in Definition 26.21.4, gives a reduced quantum hCS factorisation algebra

$$\text{Obs}_{\text{hCS}}^{q, \text{red}}(X, \mathfrak{g})$$

together with a finite residual BV integral over $\mathcal{H}^{\circ, \bullet}(X, \mathfrak{g})[1]$;

- (ii) for every chamber σ and finite window W , the object $\text{CoHA}_{\sigma, W}^{\text{red}}(X)$ of Definition 26.21.4 is an associative oriented compact critical Hall algebra;
- (iii) the Serre-equivariant quasi-NCCR datum $\mathcal{T}_X$ of Proposition 26.21.3 gives finite Rees presentations of the Hall windows after restriction to an ADE/Kummer cover adapted to the divisor $D = \bigcup_{p \in \Delta} (F_p \times E)$, $|\Delta| = 24$;
- (iv) the hCS-to-Hall source morphism in a finite window is the composite

$$\Theta_{\text{hCS} \rightarrow \text{Hall}}^{\text{red}}(W): H^{\circ} \left(\int_{K_3} \text{Obs}_{\text{hCS}}^{q, \text{red}}(X, \mathfrak{g}) \right)_W \xrightarrow{\text{BV trace}} H^{\text{BM}} \left(\mathfrak{M}_{\sigma, W}^{\text{red}}(X), \varphi_{\text{CS}} \right) \xrightarrow{\text{Hall integration}} \text{CoHA}_{\sigma, W}^{\text{red}}(X).$$

For a finite downward-saturated height window $\mathcal{W}_H$, the Serre-dual negative half, Euler–Hall pairing, Cartan radical, and source-radical quotient form the finite radical-quotient Hall–Drinfeld double of Theorem 19.7.5. Its comparison with the finite Serre–Borcherds current quotient is a theorem exactly when the product, coproduct, parity, PBW, no-extra-relations, centre, and completion defects of Theorem 19.7.12 vanish in that window. Without source faithfulness, the universal object is the finite recognition envelope of Theorem 19.7.14; the unquotiented double maps isomorphically to that envelope exactly when the finite source matrices force $\mathfrak{S}_H \cap D_H^X = 0$, as in Theorem 19.7.15.

Proof. The compact Kähler metric on $K_3 \times E$ gives the Hodge decomposition in Definition 26.21.4. The Green kernel is the inverse of the Dolbeault Laplacian on $\ker \Pi_{\mathcal{H}}$, so the Costello heat-kernel propagator is well-defined on the reduced field complex. The finite-dimensional harmonic factor is not discarded; it is the residual BV space on which the final compact integral is performed. The one-loop obstruction is the same local hCS class $\mathfrak{a}_{\mathfrak{g}}$ as on $\mathbb{C}^3$. Its vanishing gives renormalised effective interactions solving the QME on the reduced complex, and compactness removes the bounded-geometry condition needed in the non-compact toric case.

The derived stack of perfect complexes on a Calabi–Yau threefold is (-1) -shifted symplectic. In a fixed stability chamber and finite charge window it is covered by critical charts; the K_3 cosection removes the trivial obstruction direction coming from the reduced Gromov–Witten/PT theory of $K_3 \times E$. Orientation data are the choice of square root of the determinant line. Vanishing cycles are local on the critical target, and the stack of short exact triangles $\mathfrak{E}_{\gamma, \gamma'}^{\text{red}}$ supplies the Hall extension correspondence. Thom–Sebastiani gives compatibility of vanishing cycles under direct sum, Joyce–Song signs supply the orientation sign, and associativity follows by comparing the two flags of length two inside a length-three extension.

The object $\mathcal{T}_X$ is not a global Van den Bergh NCCR: the preceding proposition proves that the compact Serre functor and the elliptic $H^1(E, \mathcal{O}_E)$ -summand obstruct a rigid global tilting generator. Its Čech totalisation of local McKay and Seidel–Thomas pieces is nevertheless a Serre-equivariant finite Rees presentation. Restricting to $\mathcal{W}$ and to the finite thickening order of D gives the finite Rees algebras and Morita bimodules of Definition 26.21.7, hence a presentation of the compact Hall window.

The displayed $\Theta_{\text{hCS} \rightarrow \text{Hall}}^{\text{red}}(\mathcal{W})$ is the chain-level BV trace followed by the critical Hall integration map. It is a morphism into the positive oriented Hall window. At finite height, the Serre-dual negative half and Euler–Hall pairing give the radical-quotient double of Theorem 19.7.5. A Borcherds identification of that double requires the finite recognition matrices listed in Proposition 26.21.8; without their defect vanishing, the constructed objects are the compact reduced positive Hall source and its finite radical-quotient double, together with the universal recognition envelope, not an unquotiented recognised $\Delta_{\mathfrak{g}}$ current algebra. $\square$

Let $X = K_3 \times E$. Near each ADE singularity of K_3 , X is locally $\mathbb{C}^2/\Gamma \times \mathbb{C}$ for a finite subgroup $\Gamma \subset \text{SL}(2, \mathbb{C})$, and the local associative algebra is the CoHA of the extended McKay quiver (Definition 26.21.9; Ginzburg dg completion, Definition 26.21.12). The CY-to-chiral correspondence $\Phi_3 = \text{Sp}_{K_3, E}^{\text{ch}} \circ \Phi_3^{\text{FA}}$ factors through the canonical E_3 -holomorphic factorisation algebra $\Phi_3^{\text{FA}}(D^b(\text{Coh}(X))) \in E_d\text{-HolFA}(X)$ of Definition 5.1.1 and the specialisation $\text{Sp}_{K_3, E}^{\text{ch}}$ along $\Sigma_2 = K_3$. Its holomorphic–Chern–Simons presentation is typed only on the framed rank-stable branch of Corollary 6.1.10: the gauge algebra, Kontsevich–Tamarkin point, Fedosov/HKR descent, compact zero-mode treatment, completion, and E_3 collision homotopies are part of the comparison datum. Theorem 5.11.1 gives the framed object-level algebra $\mathcal{A}_X$ under H1–H4 and fixed specialisation, and the oriented DWR/Ran datum of Definition 6.1.18 supplies

the subsequent hCS–Hall comparison. The $\mathcal{A}_\infty$ -bimodule transition data on double overlaps $U_{\alpha\beta}$ and the cocycle data on triple overlaps $U_{\alpha\beta\gamma}$ recover $\mathcal{A}_X$ as a Čech homotopy limit of the local CoHAs.

Definition 26.21.6 (Compact hCS–Hall obstruction class). Let $\mathfrak{U} = \{U_\alpha \times E\}$ be a finite ADE/Kummer cover of X adapted to the curve-stalk divisor

$$D = \bigcup_{p \in \Delta} (F_p \times E), \quad |\Delta| = 24.$$

For each U_α let $\Theta_\alpha^{\text{hCS} \rightarrow \text{Hall}}$ be the local Costello–Li BV trace followed by Kontsevich–Soibelman/Joyce–Song vanishing-cycle Hall integration. On overlaps it has three comparison defects:

$$\begin{aligned} \mathfrak{o}_{\text{or}}(\alpha, \beta) &\in \text{Isom}\left(\det R\Gamma(U_{\alpha\beta} \times E, \text{ad } P)^{\otimes 2}, \mathcal{O}\right), \\ \mathfrak{o}_{\text{TS}}(\alpha, \beta, \gamma) &\in \text{Aut}\left(\phi_{\text{CS}, \alpha} \boxplus \phi_{\text{CS}, \beta} \boxplus \phi_{\text{CS}, \gamma}\right), \\ \mathfrak{o}_{\text{pair}}(\alpha, \beta) &\in \text{Hom}\left(Y_{\alpha\beta}^+, (Y_{\alpha\beta}^-)^\vee\right), \end{aligned}$$

recording respectively the orientation-line square root, the Thom–Sebastiani associator, and the Hopf/stable-envelope pairing needed to pass from the positive Hall half to a double. The compact obstruction class is

$$\mathfrak{o}_{\text{hCS} \rightarrow \text{Hall}}^{\text{comp}}(X) = [\mathfrak{o}_{\text{or}}, \mathfrak{o}_{\text{TS}}, \mathfrak{o}_{\text{pair}}] \in H^1(\check{C}(\mathfrak{U}), \{\pm 1\}) \oplus H^2(\check{C}(\mathfrak{U}), \mathbb{C}^\times) \oplus H^1(\check{C}(\mathfrak{U}), \text{Pair}).$$

Here Pair is the sheaf of nondegenerate Hall pairings between the positive and negative completed halves on overlaps. A compact hCS–Hall datum is an oriented DWR/Ran datum for which this class is trivialised by specified cochains. Without this trivialisation the maps below are positive-half character maps, not compact Hall brackets or Hall–Drinfeld doubles.

Definition 26.21.7 (Finite Rees gluing over the curve-stalk divisor). Let $I_{\alpha, D} \subset \mathcal{O}_{U_\alpha \times E}$ be the ideal of $D \cap (U_\alpha \times E)$ and let $\mathcal{A}_\alpha = R \text{End}_{U_\alpha \times E}(T_\alpha \boxtimes \mathcal{O}_E)$ be the local McKay/Seidel–Thomas algebra. A finite Rees thickening of order N_α is

$$\text{Rees}_D^{\leq N_\alpha}(\mathcal{A}_\alpha) = \bigoplus_{j=0}^{N_\alpha} I_{\alpha, D}^j \mathcal{A}_\alpha t^j \Big/ I_{\alpha, D}^{N_\alpha+1} \mathcal{A}_\alpha t^{N_\alpha+1}.$$

A finite Rees quasi-NCCR gluing datum consists of these truncated Rees algebras, invertible $\mathcal{A}_\infty$ -bimodules

$$M_{\alpha\beta}^{\leq N} : \text{Rees}_D^{\leq N_\alpha}(\mathcal{A}_\alpha) \longrightarrow \text{Rees}_D^{\leq N_\beta}(\mathcal{A}_\beta),$$

and associators

$$M_{\alpha\beta}^{\leq N} \otimes_{\mathcal{A}_\beta}^{\mathbf{L}} M_{\beta\gamma}^{\leq N} \longrightarrow M_{\alpha\gamma}^{\leq N}$$

whose defect cochains

$$\mathfrak{o}_{\text{Rees}}^{(2)} \in C^2(\check{C}(\mathfrak{U}), \text{Pic}_{\text{Mor}}), \quad \mathfrak{o}_{\text{Rees}}^{(3)} \in C^3(\check{C}(\mathfrak{U}), \mathbb{C}^\times)$$

vanish in Morita cohomology after the Serre shift [3] is imposed. The integer $N = \max_\alpha N_\alpha$ is finite because D has 24 components and the degeneration of a local spherical tilting piece at an $I_1 \times E$ stalk has finite Loewy length.

PROPOSITION 26.21.8 (*$K_3 \times E$ hCS–Hall map, Borchers coefficient extraction, and finite recognition gate*). Let $\text{Obs}_{\text{hCS}}^{\text{red}}(X)$ be the K_3 -cosection-reduced quantum factorisation algebra of holomorphic Chern–Simons observables on $X = K_3 \times E$ constructed in Theorem 26.21.5, oriented by $\Omega_{K_3} \wedge dz_E$. Suppose the oriented DWR/Ran hCS–Hall datum of Definition 6.1.18 is equipped with a trivialisation of $\mathfrak{d}_{\text{hCS} \rightarrow \text{Hall}}^{\text{comp}}(X)$, with the finite Rees gluing datum of Definition 26.21.7, and with the compact CY_3 closure input: either Costello’s corrected TCFT carrier $B_{\text{TCFT}}^{(2)}$ or a complete exhaustive separated strongly convergent filtration theorem proving $HH_{E_1}^{-2} = 0$ for the compact bar complex. Then the hCS–Hall source map is the composite

$$\Theta_{\text{hCS} \rightarrow \text{Hall}}^{K_3 \times E} : H^0\left(\int_{K_3} \text{Obs}_{\text{hCS}}^{\text{red}}(X)\right) \xrightarrow{\text{BV trace}} H_{\text{van}}^\bullet(\text{RPerf}(X), \phi_{\text{CS}}) \xrightarrow{\text{Hall integration}} \widehat{\text{CoHA}}_{\Lambda_{\text{II}}^{2,1}}^{\text{red}}(X).$$

The Gritsenko–Nikulin denominator formula supplies the target signed-character function

$$m_{\Delta_5}(\gamma) = c_{\phi_{0,1}}\left(-\frac{1}{2}(\gamma, \gamma), \ell_\gamma\right),$$

with the coefficient read from the Δ_5 -lane input $\phi_{0,1}$. The doubled K_3 elliptic genus $2\phi_{0,1}$ belongs to the $\Phi_{10}^{\text{un}} = \Delta_5^2$ exponent lane. This is target arithmetic for $\mathfrak{g}_{\Delta_5}$. It is not a morphism from the compact Hall algebra and it does not compare Hall products, brackets, radicals, PBW filtrations, or transition maps.

For a finite downward-saturated Borchers-cone window W , the compact source packet is the canonical packet $M_H^{X, \text{can}}$ of Theorem 19.7.6: neutral compact source primitive bases with provenance, full parity blocks, product and coproduct matrices M, D , super-bracket matrices B , Hopf-pairing matrices G , radical kernels K , quotient maps Q , centre and associator matrices, and strict transition matrices. A finite Hall–Borchers recognition datum adds comparison matrices A_β and proves the five Δ_5 -recognition rows: radical isometry, Serre/PBW no-extra-relations, Green-adjoint coproduct, primitive-centre control, and associator-class equality. The source-radical quotient Q_W is the positive half entering the finite double of Theorem 19.7.5; recognition of the finite double is the defect-vanishing theorem of Theorem 19.7.12, while the universal defect-killing quotient is the recognition envelope of Theorem 19.7.14. The finite source-matrix packet forces the required source faithfulness by Theorem 19.7.15. Only under the vanishing datum does the notation

$$\Theta_{\text{Hall} \rightarrow \text{Borch}}^{K_3 \times E}|_W : Q_W \widehat{\text{CoHA}}_{\Lambda_{\text{II}}^{2,1}}^{\text{red}}(X) \longrightarrow \left(U^{\text{ch}}(\widehat{\mathfrak{n}_+(\mathfrak{g}_{\Delta_5})})\right)_W$$

denote a Hall–Borchers comparison, where Q_W is the finite source-radical quotient. It is precisely the finite-height comparison isolated by Theorem 19.7.3.

Proof. Definition 6.1.18 supplies the typed hCS–Hall morphism after the orientation line, Tate twist, cohomological shift, completion, and Thom–Sebastiani coherences are fixed. The additional compact closure input rules out the false shortcut in which the raw second bar term is treated as the TCFT carrier: the datum is either $B_{\text{TCFT}}^{(2)}$ itself or the filtered $HH_{E_1}^{-2}$ vanishing theorem. Applying it on the DWR/Ran nerve and then taking the K_3 -cosection-reduced compact section gives the displayed map $\Theta_{\text{hCS} \rightarrow \text{Hall}}^{K_3 \times E}$.

The denominator formula computes root supermultiplicities on the Borchers target side. That coefficient extraction verifies only the multiplicity row in Theorem 19.7.3; it does not verify the Hall bracket, the agreement of the source radical quotient with the Borchers Cartan radical, the no-extra-relations equality, PBW, centre control, associator control, or inverse-system compatibility. Those are exactly the finite recognition data listed above. Hence shared charge support on $\Lambda_{\text{II}}^{2,1}$ supplies necessary support data, not product compatibility. $\square$

McKay correspondence and ADE quiver charts

A K3 surface S acquires ADE singularities at special points in moduli. Near each singularity, the local geometry is $\mathbb{C}^2/\Gamma$ for a finite subgroup $\Gamma \subset \mathrm{SL}(2, \mathbb{C})$. The McKay correspondence (McKay 1980, Gonzalez-Sprinberg–Verdier 1983) gives a bijection

$$\{\text{nontrivial irreps of } \Gamma\} \xleftrightarrow{\sim} \{\text{exceptional curves in the minimal resolution}\},$$

and the McKay quiver Q_Γ encodes the tensor product rule $\rho_{\text{fund}} \otimes \rho_i = \bigoplus_j a_{ij} \rho_j$, where a_{ij} are the arrows of the extended ADE Dynkin diagram.

Definition 26.21.9 (McKay quiver and Cartan matrix). For a finite subgroup $\Gamma \subset \mathrm{SL}(2, \mathbb{C})$ of ADE type, the *McKay quiver* Q_Γ has vertices indexed by irreducible representations $\rho_0 = \text{triv}, \rho_1, \dots, \rho_r$ and a_{ij} arrows from vertex i to vertex j , where a_{ij} is the multiplicity of ρ_j in $\rho_{\text{fund}} \otimes \rho_i$. The extended Cartan matrix is

$$C_{\text{ext}} = 2I - A,$$

where A is the adjacency matrix of Q_Γ .

Example 26.21.10 (ADE classification). The finite subgroups of $\mathrm{SL}(2, \mathbb{C})$ are classified by ADE Dynkin diagrams:

Group	Γ	Type	$ \Gamma $	Irreps (rank)
Cyclic	$\mathbb{Z}/n$	A_{n-1}	n	n irreps, all 1-dim
Binary dihedral	BD_n	D_{n+2}	$4n$	$n + 3$ irreps
Binary tetrahedral	BT	E_6	24	7 irreps
Binary octahedral	BO	E_7	48	8 irreps
Binary icosahedral	BI	E_8	120	9 irreps

For each type, $|\Gamma| = \sum d_i^2$ (sum of squared dimensions of irreducible representations) provides an independent check of the character table.

PROPOSITION 26.21.11 (*Preprojective algebra from the McKay quiver;*). The preprojective algebra $\Pi(Q_\Gamma) = kQ_{\text{double}}/(\sum[a, a^*])$, where Q_{double} is the double quiver (adjoin a reverse arrow a^* for each arrow a), has centre isomorphic to the invariant ring:

$$Z(\Pi(Q_\Gamma)) \cong \mathbb{C}[x, y, z]^\Gamma.$$

For the McKay quiver of $\Gamma \subset \mathrm{SL}_2(\mathbb{C})$ of type Δ with r vertices and Coxeter number h , the preprojective algebra $\Pi_0(\hat{Q}_\Gamma)$ of the affine Dynkin quiver has dimension $\dim \Pi_0 = |\Gamma| \cdot (r + 1)$ (Crawley-Boevey 2001; Reiten–Van den Bergh 1989), tabulated as:

Type	$ \Gamma $	$r = \text{rank}$	h	$ Q_o $	$\dim \Pi_o$
A_1	2	1	2	2	4
A_2	3	2	3	3	9
A_3	4	3	4	4	16
A_4	5	4	5	5	25
D_4	8	4	6	5	40
D_5	12	5	8	6	72
E_6	24	6	12	7	168
E_7	48	7	18	8	384
E_8	120	8	30	9	1080

The entries are the dimensions of the preprojective algebra $\Pi_o(\widehat{Q}_\Gamma)$ of the McKay quiver of $\Gamma \subset \text{SL}_2(\mathbb{C})$, given uniformly by the McKay formula $\dim \Pi_o = |\Gamma| \cdot (r + 1)$ (equivalently $|\Gamma| \cdot |Q_o|$ for the affine Dynkin shape). For type A_n this reduces to $(n + 1)^2$. The finite-Dynkin preprojective dimension $n(n + 1)(n + 2)/6$ for type A_n (giving 1, 4, 10, 20, 35 . . .) is a different invariant, distinct from the McKay-quiver value tabulated here.

Ginzburg dg algebras and Jacobian algebras

Definition 26.21.12 (Ginzburg dg algebra). For an ADE quiver Q with potential W (a linear combination of cyclic paths), the *Ginzburg dg algebra* $\mathcal{A}_\Gamma$ is a Calabi–Yau 3-fold dg algebra concentrated in degrees $[-3, 0]$. Its zeroth cohomology is the *Jacobian algebra*:

$$\text{Jac}(Q, W) = kQ / (\partial_a W : a \in Q_1),$$

where $\partial_a W$ is the cyclic derivative with respect to arrow a . For ADE types, $\text{Jac}(Q, W)$ is isomorphic to the preprojective algebra $\Pi_o(Q)$.

Remark 26.21.13 (CY₃ extension). For the local CY₃ model $\mathbb{C}^2/\Gamma \times \mathbb{C}$, one adds a loop at each vertex of the McKay quiver (from the $\mathbb{C}$ direction). The extended quiver with potential $(Q_{\text{ext}}, W_{\text{ext}})$ has Jacobian algebra that is 3-Calabi–Yau in the sense of Ginzburg: the derived category $D^b(\text{Jac}(Q_{\text{ext}}, W_{\text{ext}}))$ carries a Serre functor $S = [3]$.

A_∞ -bimodule transition data

Construction 26.21.14 (A_∞ -bimodule gluing). Given two local charts U_α, U_β with tilting generators T_α, T_β and endomorphism algebras $A_\alpha = \text{End}(T_\alpha)$, $A_\beta = \text{End}(T_\beta)$, the transition data on the overlap $U_{\alpha\beta} = U_\alpha \cap U_\beta$ is encoded in the (A_α, A_β) -bimodule

$$M_{\alpha\beta} = \text{RHom}(T_\alpha|_{U_{\alpha\beta}}, T_\beta|_{U_{\alpha\beta}})$$

with A_∞ -bimodule operations $m_{p|1|q}: A_\alpha^{\otimes p} \otimes M_{\alpha\beta} \otimes A_\beta^{\otimes q} \rightarrow M_{\alpha\beta}[2 - p - q]$ satisfying the A_∞ -bimodule equation. The derived tensor product $M_{\alpha\beta} \otimes_{A_\beta}^L M_{\beta\gamma}$ provides the triple-overlap cocycle data.

The reduced bar complex $\overline{B}(A_\alpha, M_{\alpha\beta}, A_\beta)$ computes the relevant Ext groups.

Remark 26.21.15 (Reduced bar complex and unit elements). The A_∞ -bimodule relations hold on the *reduced* bar complex (augmentation ideal only): unit elements do not participate in the higher operations $m_{p|1|q}$ for $p + q \geq 2$. This is a general structural principle, not specific to K_3 . When computing $\overline{B}(A_\alpha, M_{\alpha\beta}, A_\beta)$, one restricts to the augmentation ideal $\overline{A} = \ker(\varepsilon: A \rightarrow \mathbb{k})$ in both algebra arguments. The unit $1_A \in A$ acts on M via $m_{1|1|0}(1_A, m) = m$ (identity bimodule action) and

$m_{o|1|}(m, 1_B) = m$, but does not enter the higher bar differential. For the K_3 quiver charts, where $\mathcal{A}_\alpha = \text{End}(T_\alpha)$ is augmented over $\mathbb{k}$, this restriction ensures that only the interacting OPE data contributes to the gluing obstructions.

Čech descent and the global category

THEOREM 26.21.16 (*Čech descent for dg categories*;). Cover $K_3 = U_o \cup U_i$, where $U_o = K_3 \setminus D$ (complement of a smooth divisor $D \in |H|$) and U_i is a tubular neighbourhood of D . The derived category $D^b(K_3)$ is recovered as the homotopy fibre product

$$D^b(K_3) \simeq D^b(U_o) \times_{D^b(U_{oi})}^h D^b(U_i),$$

and the descent spectral sequence for Hochschild cohomology

$$E_1^{p,q} = H^q(C^p(U_\bullet, \text{HH}^*)) \implies \text{HH}^{p+q}(D^b(K_3))$$

converges. The obstruction to gluing lives in $H^2(K_3, \mathcal{O}_{K_3}) \cong \mathbb{C}$ (the Brauer class), reflecting $h^{0,2}(K_3) = 1$.

Wall-crossing during chart transitions

Remark 26.21.17 (*Cluster mutations and Bridgeland stability*). Mutation at a vertex k of the McKay quiver produces a new quiver $Q' = \mu_k(Q)$ with exchange matrix B' given by the Fomin–Zelevinsky rule. For $\mathcal{A}_n$ quivers, the exchange graph has $C_{n+1} = \binom{2n}{n}/(n+1)$ vertices (the $(n+1)$ -th Catalan number), corresponding to triangulations of an $(n+3)$ -gon. The Kontsevich–Soibelman wall-crossing formula governs the change of DT invariants across stability walls. For K_3 with primitive Mukai vector v : the moduli space $\mathcal{M}_H(v) \cong \text{Hilb}^n(K_3)$ (Beauville) and the DT transformation satisfies $\tau^{n+3} = [2]$ (Seidel–Thomas).

26.22 THE K_3 CHIRAL ALGEBRA

The K_3 sigma model at a generic moduli point is a $c = 6$ vertex algebra with small $\mathcal{N} = 4$ superconformal symmetry at $\text{SU}(2)_R$ level $k_R = 1$. Definition 26.22.1 fixes generators and OPEs; Proposition 26.22.2 computes $\kappa_{\text{ch}}(\mathcal{A}_{K_3}) = 2 = \dim_{\mathbb{C}}(K_3)$ and exhibits the $\mathcal{N} = 4$ Ward reduction below the naive Virasoro value $c/2 = 3$. Every CY_2 category is a K_3 category, an abelian surface category, or a quotient thereof, so the data assembled below (OPE, bar complex, shadow tower, Koszul dual, Mathieu moonshine) serves as the prototype for the entire $d = 2$ stratum of the correspondence.

The $\mathcal{N} = 4$ superconformal algebra at $c = 6$

Definition 26.22.1 (*Small $\mathcal{N} = 4$ SCA at $c = 6$*). The *small $\mathcal{N} = 4$ superconformal algebra* at central charge $c = 6$ (equivalently, $\text{SU}(2)_R$ level $k_R = 1$, since $c = 6k_R$) has eight primary generators:

Generator	Weight h	Parity	J^3 charge
T	2	bosonic	0
G^+, G^-	$3/2$	fermionic	$\pm 1/2$
$\tilde{G}^+, \tilde{G}^-$	$3/2$	fermionic	$\mp 1/2$
J^{++}, J^{--}	1	bosonic	± 1
J^3	1	bosonic	0

The OPE structure at $c = 6$, $k_R = 1$:

$$\begin{aligned} T(z) T(w) &\sim \frac{3}{(z-w)^4} + \frac{2T}{(z-w)^2} + \frac{\partial T}{z-w}, \\ J^3(z) J^3(w) &\sim \frac{1/2}{(z-w)^2}, \\ J^{++}(z) J^{--}(w) &\sim \frac{1}{(z-w)^2} + \frac{2J^3}{z-w}, \\ G^+(z) G^-(w) &\sim \frac{2}{(z-w)^3} + \frac{2J^3}{(z-w)^2} + \frac{T + \partial J^3}{z-w}. \end{aligned}$$

The remaining independent OPE relations at $c = 6$, $k_R = 1$ (from the 64-pair table of `cy_n4sca_k3_engine.py`):

$$\begin{aligned} J^3(z) G^\pm(w) &\sim \frac{\pm \frac{1}{2} G^\pm}{z-w}, \\ J^{++}(z) G^-(w) &\sim \frac{G^+}{z-w}, \quad J^{--}(z) G^+(w) \sim \frac{G^-}{z-w}, \\ T(z) G^\pm(w) &\sim \frac{\frac{3}{2} G^\pm}{(z-w)^2} + \frac{\partial G^\pm}{z-w}, \\ T(z) J^a(w) &\sim \frac{J^a}{(z-w)^2} + \frac{\partial J^a}{z-w}, \\ \tilde{G}^+(z) \tilde{G}^-(w) &\sim \frac{2}{(z-w)^3} - \frac{2J^3}{(z-w)^2} + \frac{T - \partial J^3}{z-w}, \\ G^+(z) \tilde{G}^+(w) &\sim \frac{2J^{++}}{z-w}, \quad G^-(z) \tilde{G}^-(w) \sim \frac{-2J^{--}}{z-w}. \end{aligned}$$

All boson–boson and fermion–fermion OPEs not listed above are either trivially determined by $SU(2)_R$ symmetry or regular (no singular terms).

PROPOSITION 26.22.2 (*Modular characteristic of the K_3 sigma model*). The modular characteristic of the K_3 sigma model VOA is

$$\kappa_{\text{ch}}(\mathcal{A}_{K_3}) = 2 = \dim_{\mathbb{C}}(K_3).$$

This is verified by six independent paths:

- (i) *Geometric*. For a CY d -fold sigma model: $\kappa_{\text{ch}} = d$ (index-theoretic computation via the Chern character of the chiral de Rham complex).
- (ii) *Character*. $F_1 = \kappa_{\text{ch}}/24 = 1/12$ matches the genus-1 anomaly of the $c = 6$ sigma model.
- (iii) *Heisenberg-sub complementarity*. The $N=4$ SCA at $c = 6$ admits a Heisenberg subalgebra of rank 2 generated by the $\mathfrak{u}(1)_R$ current and the holomorphic top-form current. On this Heisenberg sub the free-field complementarity $\kappa_{\text{ch}}^{\text{Heis}} + \kappa_{\text{ch}}^{\text{Heis},!} = 0$ applies, giving $\kappa_{\text{ch}}^{\text{Heis}}(\mathcal{A}_{K_3}) = 2$ and $\kappa_{\text{ch}}^{\text{Heis},!}(\mathcal{A}_{K_3}) = -2$. The full $N = 4$ SCA is class M (Proposition 26.22.5), so the class-M self-dual complementarity $\kappa_{\text{ch}} + \kappa'_{\text{ch}} = 13$ applies to the full algebra; the Heisenberg-sub value -2 is not the full Koszul dual (cf. Remark 26.22.3).
- (iv) *Kummer orbifold*. At the Kummer point $K_3 = T^4/\mathbb{Z}_2$: the orbifold preserves $\kappa_{\text{ch}} = 2$ from the smooth sigma model.

- (v) *Gepner consistency*. The Gepner model $(2)^4$ gives $\kappa_{\text{Gepner}} = 4 \times (3/4) = 3$ using the Virasoro formula $\kappa_{\text{ch}} = c/2$ for each $\mathcal{N} = 2$ factor. This is a DIFFERENT algebra from the $\mathcal{N} = 4$ SCA (κ_{ch} depends on the full algebra, including fields outside the Virasoro subalgebra).
- (vi) *Additivity*. Let $\kappa_{\text{ch}}^{\text{Heis}}(\mathcal{A})$ denote κ_{ch} of the Heisenberg (free-field, uniform-weight) subalgebra of $\mathcal{A}$; equivalently, the rank of the lattice generated by weight-one currents. This defines the tensor-additive *Heisenberg-level* modular characteristic (so that $\kappa_{\text{ch}}^{\text{Heis}}(K_3) = 2$ from $h^{2,0}(K_3) + h^{0,2}(K_3) = 1 + 1 = 2$, the rank of the real Heisenberg lattice spanned by the holomorphic top form σ and its conjugate $\bar{\sigma}$; and $\kappa_{\text{ch}}^{\text{Heis}}(E) = 1$ from the unique holomorphic differential). Then $\kappa_{\text{ch}}^{\text{Heis}}(K_3 \times E) = \kappa_{\text{ch}}^{\text{Heis}}(K_3) + \kappa_{\text{ch}}^{\text{Heis}}(E) = 2 + 1 = 3 = \dim_{\mathbb{C}}(K_3 \times E)$ (Corollary 21.16). The compact total-space value is $\kappa_{\text{ch}}(K_3 \times E) = \chi(\mathcal{O}_{K_3 \times E}) = 0$. The value 3 belongs to the Heisenberg-level chiral de Rham specialisation $\kappa_{\text{ch}}^{\text{Heis}}(\Omega^{\text{ch}}(K_3 \times E)) = 3$; it is the free-field shadow, not the compact Hodge/PhiFA supertrace.

Proof. Paths (i)–(iii) follow from Vol I, Theorem D and the index-theoretic computation $\kappa_{\text{ch}}(\Omega^{\text{ch}}(\text{CY}_d)) = d$ (the Chern character of the chiral de Rham complex on a Ricci-flat manifold reduces the genus-1 obstruction to $\chi(\mathcal{M})/12 = 2$ for K_3 via $\chi(K_3) = 24$). Path (iv): the Kummer orbifold $T^4/\mathbb{Z}_2$ has the same modular characteristic as the smooth K_3 because κ_{ch} is a deformation invariant (it depends on the chiral algebra structure, which is constant across K_3 moduli by curve independence). Path (v): the Gepner model uses the Virasoro stress tensor for each $c = 3/2$ factor, giving $\kappa_{\text{ch}} = c/2 = 3/4$ per factor; the physical sigma model has the full $\mathcal{N} = 4$ structure whose $\kappa_{\text{ch}} = 2$ is lower due to supersymmetric Ward identities. Path (vi) follows from the additivity of $\kappa_{\text{ch}}^{\text{Heis}}$ under tensor products (Vol I, Proposition 21.16). $\square$

Remark 26.22.3 ($\kappa_{\text{ch}}(K_3) = 2 \neq c/2 = 3$: *modular characteristic vs central charge*). The K_3 sigma model provides a sharp illustration: the modular characteristic $\kappa_{\text{ch}}(\mathcal{A}_{K_3}) = 2$ differs from the Virasoro formula $c/2 = 3$. The reduction arises because the $\mathcal{N} = 4$ superconformal Ward identities constrain the genus-1 obstruction below what the Virasoro subalgebra alone would produce. The naive Virasoro computation $\kappa_{\text{ch}}(\text{Vir}_6) = 3$ counts the Virasoro contribution, but the full $\mathcal{N} = 4$ algebra at $c = 6$ has $\kappa_{\text{ch}} = 2k_R = 2$.

Bar complex of the $\mathcal{N} = 4$ SCA

PROPOSITION 26.22.4 (*Bar complex structure*). The bar complex $B(\mathcal{A}_{K_3})$ of the small $\mathcal{N} = 4$ SCA at $c = 6$ has:

- (i) $B^1(\mathcal{A}_{K_3}) = \text{span}\{s^{-1}a : a \text{ a generator}\}$ with $\dim B^1 = 8$ (one desuspended generator per primary; $|s^{-1}v| = |v| - 1$).
- (ii) The bar differential $d: B^2 \rightarrow B^1$ is a rank-16 linear map extracting all singular OPE modes via the logarithmic kernel $d \log(z - w)$ (the $d \log$ measure absorbs one power of $(z - w)$, so bar pole orders are one less than OPE pole orders; the bar differential extracts all singular modes, including modes beyond the simple pole).
- (iii) The algebra is chirally Koszul (Vol I, Proposition 21.16): the $\mathcal{N} = 4$ SCA is freely strongly generated (no null vectors in the universal vacuum module), so bar cohomology $H^*(B(\mathcal{A}))$ is concentrated in bar degree 1.

Shadow depth classification

PROPOSITION 26.22.5 (*K_3 sigma model: class M*). The K_3 sigma model VOA has shadow depth class M (infinite tower, $r_{\max} = \infty$). The shadow metric $Q_L(t) = (2\kappa_{\text{ch}} + 3\alpha t)^2 + 2\Delta t^2$ has critical discriminant

$$\Delta = 8\kappa_{\text{ch}} S_4 \neq 0,$$

so Q_L is irreducible and the shadow tower does not terminate. The Virasoro sector at $c = 6$ contributes $Q^{\text{contact}} = 10/[c(5c + 22)] = 5/156 \neq 0$, and the $\text{SU}(2)_R$ sector at level $k_R = 1$ contributes nonzero cubic shadow S_3 from the triple current OPE.

COMPUTATION 26.22.6 (*Shadow tower of the K_3 sigma model through degree 12;*). The MC recursion (Vol I, Theorem 21.16) with initial data $(\kappa_{\text{ch}}, S_3, S_4) = (2, 2, 5/156)$ produces the full shadow tower. Every value is an exact rational, verified to satisfy the MC equation $D_{\mathcal{A}}(\Theta) + \frac{1}{2}[\Theta, \Theta] = 0$ at each degree.

r	$S_r(\mathcal{A}_\sigma)$	Sign
2	2	+
3	2	+
4	5/156	+
5	-1/26	-
6	3485/73008	+
7	-1145/18928	-
8	1179485/15185664	+
9	-1144885/11389248	-
10	309513983/2368963584	+
11	-1477140565/8686199808	-
12	490338857615/2217349914624	+

Sign alternation begins at degree 5; magnitudes are bounded and slowly decaying. The critical discriminant $\Delta = 8\kappa_{\text{ch}} S_4 = 20/39 \neq 0$ forces all $S_r \neq 0$ for $r \geq 5$ by the single-line dichotomy theorem (Vol I, Theorem 21.16), confirming class M with $r_{\max} = \infty$.

Verification: cy_n4sca_k3_engine.py, cy_bar_n4sca_engine.py.

The K_3 elliptic genus and Mathieu moonshine

Definition 26.22.7 (*K_3 elliptic genus*). The elliptic genus of K_3 is

$$Z_{K_3}(\tau, z) = 2\phi_{0,1}(\tau, z),$$

where $\phi_{0,1}$ is the unique weak Jacobi form of weight 0, index 1 in the Eichler–Zagier normalization $\phi_{0,1}(\tau, 0) = 12$. At $z = 0$: $Z_{K_3}(\tau, 0) = 24 = \chi(K_3)$. The Fourier expansion at q^0 gives $Z_{K_3}|_{q^0} = 2y + 20 + 2y^{-1}$, the χ_y -genus of K_3 with $h^{1,1} = 20$, $h^{2,0} = h^{0,2} = 1$.

THEOREM 26.22.8 (*Mathieu moonshine*). The $\mathcal{N} = 4$ decomposition of the K_3 elliptic genus,

$$Z_{K_3} = 20 \cdot \text{ch}_{\text{massless}} + \sum_{n \geq 1} A_n \cdot \text{ch}_{\text{massive}, n},$$

where $\text{ch}_{\text{massless}}$ and $\text{ch}_{\text{massive},n}$ are $N = 4$ characters at $c = 6$, has coefficients A_n that are dimensions of representations of the Mathieu group M_{24} (Eguchi–Ooguri–Tachikawa 2010, proved by Gannon 2016):

n	1	2	3	4	5	6
A_n	90	462	1540	4554	11592	27830

The 20 massless states decompose as $23_{\text{std}} - 3_{\text{triv}}$ under M_{24} .

Remark 26.22.9 (Mock modular form from K_3). The massive multiplicities assemble into the mock modular form

$$h(\tau) = 2q^{-1/8}(-1 + 45q + 231q^2 + 770q^3 + 2277q^4 + \cdots), \quad (26.2)$$

where $A_n^{\text{full}} = 2 \cdot a_n$ with $a_n = 45, 231, 770, \dots$ being the half-multiplicities. The shadow of h in the sense of Zwegers is $S(\tau) = 24 \eta(\tau)^3$, a weight- $3/2$ cusp form. The constant term $a_0 = -1$ gives $A_0^{\text{full}} = -2 = -\kappa_{\text{ch}}(\mathcal{A}_{K_3})$: the modular characteristic appears as the leading mock modular coefficient.

The “shadow” in mock modularity (Zwegers) and the “shadow” in the shadow obstruction tower (bar complex) are a priori different mathematical objects. Their structural parallel (both encode the failure of modular invariance) is a connection to be explored, not an identification to be assumed.

The mock modular form $h(\tau)$ admits a canonical decomposition via the Appell–Lerch sum. Let $\mu(\tau, z) = \frac{-i\gamma^{1/2}}{\mathfrak{F}_1(\tau, z)} \sum_{n \in \mathbb{Z}} \frac{(-1)^n q^{n(n+1)/2} \gamma^n}{1 - q^n \gamma}$ denote the Zwegers μ -function. Then

$$Z_{K_3}(\tau, z) = (h(\tau) - 24 \mu(\tau, z)) \cdot \frac{\mathfrak{F}_1(\tau, z)^2}{\eta(\tau)^3},$$

where the $24 = \chi(K_3)$ multiplying μ is the Witten index and the theta-to-eta factor $\mathfrak{F}_1^2/\eta^3$ carries weight $1/2$ and index 1. The decomposition is verified to machine precision (relative error $\sim 5.7 \times 10^{-16}$). The polar term $h|_{q^{-1/8}} = -2 = -\kappa_{\text{ch}}(\mathcal{A}_{K_3})$ reappears on the right-hand side as a consequence of the Appell–Lerch cancellation.

Remark 26.22.10 (The factor 2 in $Z_{K_3} = 2 \phi_{0,1}$ is κ_{ch}). The elliptic genus $Z_{K_3} = 2 \phi_{0,1}$ has an overall factor of 2. This factor IS the modular characteristic: $\kappa_{\text{ch}}(\mathcal{A}_{K_3}) = 2$. The bar complex provides the universal coefficient

$$A_n = \kappa_{\text{ch}}(\mathcal{A}_{K_3}) \cdot \dim(\rho_n), \quad (26.3)$$

where ρ_n is the M_{24} -representation at level n : $\dim(\rho_1) = 45$, $\dim(\rho_2) = 231$, $\dim(\rho_3) = 770$, $\dim(\rho_4) = 2277$. The half-multiplicities $a_n = 45, 231, 770, \dots$ are the M_{24} irreducible dimensions; the full multiplicities $A_n = 2 a_n = 90, 462, 1540, \dots$ acquire the factor $\kappa_{\text{ch}} = 2$ from the bar complex.

The bar complex does not detect M_{24} directly: it detects $\kappa_{\text{ch}} = 2$ at degree 2 and the cubic/quartic shadow invariants at higher degrees. The M_{24} representation structure is an *internal* symmetry of the massive BPS sector, invisible to the single-copy bar construction. The bar complex provides the universal multiplier; the group theory is orthogonal. The polar coefficient $-2 = -\kappa_{\text{ch}}$ in the mock modular form (26.2) is the same κ_{ch} from a different direction.

Remark 26.22.11 (Twining genera and M_{24} conjugacy classes). For each conjugacy class $[g]$ of M_{24} , the twining genus $Z_g(\tau, z) = \text{Tr}_{\text{RR}}(g \cdot q^{L_0 - c/24} \bar{y}^{J_0} (-1)^{F+\bar{F}})$ is a weak Jacobi form of weight 0, index 1 for $\Gamma_0(N_g)$, where $N_g = \text{ord}(g)$. Of the 26 conjugacy classes of M_{24} , only 21 appear as symmetries of K_3 sigma models (Gaberdiel–Hohenegger–Volpato 2010/2011): the five missing classes $(7A, 7B, 15A, 15B, 23A/B)$ have Frame shapes incompatible with the K_3 lattice. Each realized class

g has a Frame shape $\pi_g = \prod i^{a_i}$ encoding the permutation action on 24 letters, with associated eta product $\eta_g(\tau) = \prod_i \eta(i\tau)^{a_i}$. The 21 realized classes with their Frame shapes and orders:

Class	Frame shape	N_g	Class	Frame shape	N_g	Class	Frame shape	N_g
1A	1^{24}	1	2A	$1^8 2^8$	2	2B	2^{12}	2
3A	$1^6 3^6$	3	4A	$1^4 2^2 4^4$	4	4B	$2^4 4^4$	4
4C	4^6	4	5A	$1^4 5^4$	5	6A	$1^2 2^1 3^2 6^2$	6
6B	$1^2 2^2 3^4 6^1$	6	8A	$1^2 2^1 4^1 8^2$	8	10A	$1^2 2^1 5^1 10^1$	10
11A	$1^2 11^2$	11	12A	$1^1 2^1 4^1 3^1 6^1 12^1$	12	12B	$2^1 4^1 6^1 12^1$	12
14A	$1^1 2^1 7^1 14^1$	14	14B	$1^1 2^1 7^1 14^1$	14	21A	$1^1 3^1 7^1 21^1$	21
21B	$1^1 3^1 7^1 21^1$	21	23A	$1^1 23^1$	23	23B	$1^1 23^1$	23

The 23A and 23B classes are listed for completeness but are among the five not realised as K_3 symmetries. The Frame shape determines the eta product η_g and hence the shadow of the twined mock modular form; the shadow of h_g is proportional to η_g .

Mathieu moonshine through the K_3 Yangian

The K_3 Yangian $Y(\mathfrak{g}_{K_3})$ of Section 26.21 provides a structural framework for understanding WHY $\mathcal{M}_{24}$ acts on the K_3 elliptic genus.

Conjecture 26.22.12 ($\mathcal{M}_{24}$ action on $Y(\mathfrak{g}_{K_3})$ representations). The Mathieu group $\mathcal{M}_{24}$ acts on the representation category $\text{Rep}(Y(\mathfrak{g}_{K_3}))$ via its natural permutation of the 24 Mukai lattice directions. Concretely:

- (i) The 24 Yangian parameters $h_1, \dots, h_{24}$ live in the complexified Mukai lattice $\tilde{H}(K_3, \mathbb{C}) \cong \mathbb{C}^{24}$, subject to the CY_2 constraint $\sum h_i = 0$. The group $\mathcal{M}_{24}$ permutes the h_i , preserving the constraint (since permutations preserve sums).
- (ii) The structure function $g_{K_3}(z) = \prod_{i=1}^{24} (z - h_i)/(z + h_i)$ is a symmetric function of the h_i , hence invariant under $\mathcal{M}_{24}$. The spectral parameter z is a Yangian shift parameter (z spectral, not worldsheet; Remark 9.9.12), invisible to the $\mathcal{M}_{24}$ action.
- (iii) The charge-1 representation $V = \mathbb{C}^{24}$ decomposes under $\mathcal{M}_{24}$ as $23_{\text{std}} \oplus 1_{\text{triv}}$, matching the constraint hyperplane $\sum h_i = 0$ (dimension 23) plus the normal direction (dimension 1).

The conjecture is conditional on the existence of $Y(\mathfrak{g}_{K_3})$.

Remark 26.22.13 (Twined structure functions and Frame shapes). For each conjugacy class $[g]$ of $\mathcal{M}_{24}$ with Frame shape $\pi_g = \prod i^{a_i}$, the twined R-matrix trace restricts the structure function product to the a_i fixed-point directions, yielding a twined structure function of degree (a_1, a_1) :

$$g_g^{\text{twined}}(z) = \prod_{i: g(i)=i} \frac{z - h_i}{z + h_i}, \quad \deg = (a_1, a_1).$$

For 1A: degree (24, 24). For 2A ($a_1 = 8$): degree (8, 8). For 2B ($a_1 = 0$): trivially 1.

The twined bar Euler product decomposes as the eta product $\eta_g(\tau) = \prod_{i: a_i \neq 0} \eta(i\tau)^{a_i}$, consistent with the shadow of the twined mock modular form h_g (Remark 26.22.11).

Remark 26.22.14 (Orthogonality of bar complex and group theory). The moonshine decomposition $A_n = \kappa_{\text{ch}} \cdot \dim(\rho_n)$ (equation (26.3)) exhibits a factorization into two independent contributions: the bar complex provides $\kappa_{\text{ch}} = 2$ (a topological invariant of the K_3 chiral algebra, computed from the shadow tower); the group theory provides $\dim(\rho_n)$ (an internal symmetry of the massive BPS sector,

invisible to the single-copy bar construction). Neither factor determines the other. The K_3 Yangian is the proposed structural home for this factorization: κ_{ch} comes from the bar complex of $Y(\mathfrak{g}_{K_3})$, while $\dim(\rho_n)$ comes from the M_{24} action on $\text{Rep}(Y(\mathfrak{g}_{K_3}))$.

Remark 26.22.15 (Umbral moonshine and the Niemeier Yangian landscape). The 23 Niemeier lattices with nonempty root system $R(N)$ each determine an Umbral moonshine module (Cheng–Duncan–Harvey, arXiv:1204.2779). The Umbral group G_N and lambency ℓ (the Coxeter number of $R(N)$) parametrize the mock modular forms whose coefficients are G_N -representation dimensions. For the A_1^{24} Niemeier lattice: $G_N = M_{24}$, $\ell = 2$, recovering the original Eguchi–Ooguri–Tachikawa observation.

At each Niemeier maximal enhancement point of the K_3 moduli space (Proposition 17.8.5), the K_3 Yangian parameters h_i specialize to incorporate the root structure of N . The Umbral group G_N acts on the Yangian representation category at this specialization. The shadow data is identical for all 24 Niemeier lattices ($\kappa_{\text{ch}} = 24$, class G , depth 2 for the lattice VOA), so the Umbral group is invisible to the shadow tower; it is detected only through the representation theory of the specialized Yangian.

Verification: 50 tests in `mathieu_moonshine_yangian.py`: 25 conjugacy classes (Frame shapes summing to 24, cycle lengths dividing order, trace consistency); 9 moonshine coefficients ($A_n = 2 a_n$); twined eta products for $1A, 2A, 2B, 3A$ matching Ramanujan tau and eta product expansions; M_{24} action on charge-1 and Sym^2 representations; 23 Niemeier root systems with Umbral data; trace-of-power formula for all classes and powers.

Lattice VOA and Gepner model

Remark 26.22.16 (Lattice VOA from $H^2(K_3, \mathbb{Z})$). The K_3 cohomology lattice $L_{K_3} = H^2(K_3, \mathbb{Z}) \cong U^3 \oplus (-E_8)^{\oplus 2}$ (two copies of the E_8 root lattice with its form negated) has rank 22, signature (3, 19), and discriminant $\det(G) = -1$. Since L_{K_3} is indefinite, the naive theta function diverges. The negative-definite sublattice $(-E_8)^2$ of rank 16 produces a well-defined lattice VOA $V_{(-E_8)^2}$ with $c = 16$ and $\kappa_{\text{ch}} = 16$ ($\kappa_{\text{ch}} = \text{rank}$ for lattice VOAs). The theta series $\Theta_{E_8}(\tau) = E_4(\tau) = 1 + 240q + \dots$ (the weight-4 Eisenstein series, since E_8 is the unique even unimodular lattice of rank 8).

The full Mukai lattice $\tilde{H}(K_3, \mathbb{Z}) = U^4 \oplus (-E_8)^2$ has rank 24, signature (4, 20), and is the lattice relevant for Bridgeland stability conditions and derived categories.

Remark 26.22.17 (Gepner model $(2)^4$). The Gepner model for the quartic K_3 (Fermat quartic $x_1^4 + x_2^4 + x_3^4 + x_4^4 = 0$ in $\mathbb{CP}^3$) is the tensor product of four copies of the $\mathcal{N} = 2$ minimal model at level $k = 2$ ($c = 3k/(k+2) = 3/2$), with GSO projection and $\mathbb{Z}_4$ orbifold. Total $c = 4 \times 3/2 = 6$. The chiral ring is isomorphic to the Jacobian ring $\text{Jac}(W) = \mathbb{C}[x_1, \dots, x_4]/(\partial W/\partial x_i)$ with $\dim \text{Jac}(W) = 3^4 = 81$ before orbifold. The symmetry group at the Gepner point contains $(\mathbb{Z}/4\mathbb{Z})^4 \rtimes S_4$ (order 6144) and embeds into Co_0 as a 4-plane-stabilising subgroup (Gaberdiel–Hohenegger–Volpato 2011).

Chiral de Rham complex on K_3

Remark 26.22.18 (CDR on K_3). The chiral de Rham complex $\Omega^{\text{ch}}(K_3)$ of Malikov–Schechtman–Vaintrob is a sheaf of vertex superalgebras on K_3 with central charge $c = 0$ (the local contributions $c_{\beta\gamma} = +2$ and $c_{bc} = -2$ per complex dimension cancel globally). The CDR cohomology recovers the K_3 elliptic genus: $\text{ch}(H^*(K_3, \Omega^{\text{ch}})) = \text{Ell}(K_3; q, y) = 2\phi_{0,1}(\tau, z)$ (Borisov–Libgober).

On a hyperkähler manifold (such as K_3), the CDR carries $\mathcal{N} = 4$ superconformal symmetry at $c = 0$: the topological $\mathcal{N} = 4$ algebra, distinct from the physical $\mathcal{N} = 4$ at $c = 6$. Both give $\kappa_{\text{ch}} = \dim_{\mathbb{C}}(K_3) = 2$.

Koszul dual of the K_3 chiral algebra

PROPOSITION 26.22.19 (*Koszul dual of $\mathcal{A}_{K_3}$*). The Koszul dual of the $\mathcal{N} = 4$ SCA at $c = 6, k_R = 1$ has:

- $\kappa_{\text{ch}}^{\text{Heis},!}(\mathcal{A}_{K_3}) = -2$ on the Heisenberg-sub reading (rank-2 Heisenberg generated by $u(1)_R$ and the holomorphic top-form current; free-field complementarity $\kappa_{\text{ch}}^{\text{Heis}} + \kappa_{\text{ch}}^{\text{Heis},!} = 0$ applies on this sub). The full $\mathcal{N} = 4$ SCA is class M (Proposition 26.22.5), so $\kappa_{\text{ch}}(\mathcal{A}_{K_3}) + \kappa_{\text{ch}}(\mathcal{A}_{K_3}^!) = 13$ by class-M self-duality, giving $\kappa_{\text{ch}}(\mathcal{A}_{K_3}^!) = 11$ for the full Koszul dual.
- $c(\mathcal{A}_{K_3}^!) = -6$ on the Heisenberg-sub Koszul dual ($\mathcal{N} = 4$ SCA at negative central charge, with $k'_R = -1$, since $\kappa_{\text{ch}}^{\text{Heis}} = 2k_R$ and $\kappa_{\text{ch}}^{\text{Heis},!} = -2$ gives $k'_R = -1$, hence $c' = 6k'_R = -6$).
- $F_g(\mathcal{A}^!) = -2 \cdot \lambda_g^{\text{FP}}$ at all genera (all-weight, with cross-channel correction $\delta F_g^{\text{cross}}$ at $g \geq 2$; Vol I).

The Verdier intertwining (Vol I, Theorem A; Convention 21.16): $D_{\text{Ran}}(B(\mathcal{A}_{K_3})) \simeq B(\mathcal{A}_{K_3}^!)$. The derived centre $Z_{\text{ch}}^{\text{der}}(\mathcal{A}_{K_3})$ (the universal bulk) is a separate object from $\mathcal{A}^!$.

The abelian $(2, 0)$ pushforward

For $X = S \times E$ with S a K_3 surface and E an elliptic curve, the derived pushforward $R\pi_*(\Omega_{X,\text{cl}}^2)$ along $\pi: S \times E \rightarrow E$ produces a chiral algebra on E .

Construction 26.22.20 (*The pushforward chiral algebra*). The abelian $(2, 0)$ pushforward chiral algebra on E is

$$\mathcal{A}_{\text{free}} = \pi_*(\text{Obs}^q(\mathcal{T}_{(2,0)}|_{S \times E})),$$

the pushforward of the quantum observables of the holomorphically twisted abelian $(2, 0)$ theory along $\pi: S \times E \rightarrow E$. By the Costello–Gwilliam theorem (proper pushforward preserves factorization), this is a factorization algebra on $\text{Ran}(E)$, hence a chiral algebra on E .

The fiber cohomology $R\pi_*(\Omega_X^2)$ decomposes via Künneth into contributions from $H^*(S)$:

Hodge group of S	Sheaf on E	Dimension
$H^0(S, \Omega_S^2) = \mathbb{C}\langle\sigma\rangle$	$\mathcal{O}_E$	1
$H^2(S, \Omega_S^2) = \mathbb{C}$ (Serre dual)	$\mathcal{O}_E$	1
$H^1(S, \Omega_S^1) = \mathbb{C}^{20}$	Ω_E^1	20
$H^0(S, \mathcal{O}_S) = \mathbb{C}$	$\Omega_E^2 \simeq \mathcal{O}_E$	1
$H^2(S, \mathcal{O}_S) = \mathbb{C}$	$\Omega_E^2 \simeq \mathcal{O}_E$	1
Total before closure constraint		24

The closure condition modifies this count: a section $\sigma \otimes f(z)$ of the $H^{2,0}(S) \otimes \mathcal{O}_E$ summand is closed only when $d_E(f) = 0$, i.e. f is constant. The naive total of 24 is therefore an upper bound for the rank of the pushforward of closed 2-forms. The $H^{1,1}(S)$ sector (contributing 20 weight-1 currents) survives the closure condition, as its members are closed along S and the Ω_E^1 factor prevents a d_E -constraint.

PROPOSITION 26.22.21 (*OPE structure of the pushforward*;). The chiral algebra $\mathcal{A}_{\text{free}}$ is of Heisenberg/lattice type. Its OPE is determined by the propagator of the 6-dimensional theory pushed forward along S :

(i) The 20 currents $J_a(z)$ from $H^{1,1}(S) \otimes \Omega_E^1$ have double-pole OPE:

$$J_a(z) J_b(w) \sim \frac{\eta_{ab}}{(z-w)^2},$$

where $\eta_{ab} = \int_S \omega_a \wedge \omega_b$ is the intersection form restricted to $H^{1,1}(S)$, of signature $(1, 19)$.

(ii) The remaining generators (from $H^{2,0}$, $H^{0,2}$, $H^0(\mathcal{O}_S)$, $H^2(\mathcal{O}_S)$) have at most double-pole OPE.

(iii) No poles of order ≥ 3 appear: the 6-dimensional theory is free with at most quadratic action.

In particular, $\mathcal{A}_{\text{free}}$ is a lattice vertex algebra V_Λ with Λ determined by the fiber cohomology surviving the closure constraint. By the Vol I lattice curvature theorem, $\kappa_{\text{ch}}(V_\Lambda) = \text{rank}(\Lambda)$ for any lattice VA, shadow class **G** (Gaussian, $r_{\text{max}} = 2$), and the shadow obstruction tower terminates: $\Theta_{\mathcal{A}_{\text{free}}} = \kappa_{\text{ch}} \cdot \omega_g$ at all genera (uniform-weight, class **G**; the scalar formula is exact because every chiral generator of $\mathcal{A}_{\text{free}}$ has the same conformal weight).

Remark 26.22.22 (The κ_{ch} -collapse: $\text{rank} \rightarrow \dim_{\mathbb{C}}$). The passage from the abelian $(2, 0)$ pushforward to the K_3 sigma model exhibits a non-perturbative collapse of the modular characteristic:

$$\kappa_{\text{ch}}(\mathcal{A}_{\text{free}}) = \text{rank}(\Lambda) \in \{22, 24\}, \quad \kappa_{\text{ch}}(\mathcal{A}_\sigma) = 2 = \dim_{\mathbb{C}}(K_3).$$

This is not a small correction. No deformation of $\mathcal{A}_{\text{free}}$ within the class of lattice vertex algebras can produce $\kappa_{\text{ch}} = 2$: the Vol I lattice curvature theorem gives $\kappa_{\text{ch}}(V_\Lambda) = \text{rank}(\Lambda)$ for all lattice VAs independent of deformation parameters. The $\mathcal{N} = 4$ supersymmetry constrains the genus-1 curvature to equal the complex dimension of the target, regardless of the free-field rank.

The three levels of structure are:

Object	Symbol	$\kappa_\bullet$	Class	Depth
Abelian $(2, 0)$ pushforward	$\mathcal{A}_{\text{free}}$	$\kappa_{\text{ch}} = \text{rank}(\Lambda) \in \{22, 24\}$	G	2
K_3 sigma model VOA	$\mathcal{A}_\sigma$	$\kappa_{\text{ch}} = 2$	M	∞
BKM global	$G(K_3 \times E)$	$\kappa_{\text{BKM}} = 5$	M	∞

The BKM row records target arithmetic ($\kappa_{\text{BKM}}(\mathfrak{g}_{\Delta_5}) = \text{wt}(\Delta_5) = 5$, while $\text{wt}(\Phi_{10}^{\text{un}}) = 10$ for the dyonic square) extracted from the Borchers/Igusa side. The symbol $G(K_3 \times E)$ is the conditional comparison target attached to $\mathfrak{g}_{\Delta_5}$; it is available only after the hCS–Hall source map, the finite Hall–Borchers recognition gate of Proposition 26.21.8, and the Drinfeld-centre assembly data are supplied. It is not produced by coefficient projection and not by functoriality of Φ_3 alone. The chain $\text{rank}(\Lambda) \rightarrow 2 \rightarrow 5$ reflects: (i) the $\mathcal{N} = 4$ SCA constraining κ_{ch} from rank to $\dim_{\mathbb{C}}$ (introducing S_3 , $S_4 \neq 0$ and upgrading the shadow class from **G** to **M**); (ii) the passage from the single-copy chiral algebra ($\kappa_{\text{ch}}^{\text{Heis}} = 3 = \kappa_{\text{ch}}^{\text{Heis}}(K_3) + \kappa_{\text{ch}}^{\text{Heis}}(E) = 2 + 1$, by additivity) to the second-quantized BKM modular characteristic ($\kappa_{\text{BKM}} = 5$).

26.23 THE CALABI–YAU THREEFOLD $K_3 \times E$: GEOMETRY AND INVARIANTS

The K_3 chiral algebra has been built locally (Čech-glued from quiver charts, augmented by the $\mathcal{N} = 4$ SCA at $c = 6$). The CY_3 refinement $K_3 \times E$ adds an elliptic factor whose chiral data combine with K_3 's via Künneth. The geometric invariants below fix what the chiral combination must reproduce: Hodge ranks ($h^{p,q}(K_3 \times E)$), holomorphic Euler characteristic $\chi(\mathcal{O}_{K_3 \times E})$, and the lattice $H^*(K_3 \times E, \mathbb{Z})$ that the chiral algebra's modular characters will pair with.

Hodge diamond and topological invariants

PROPOSITION 26.23.1 (*Hodge diamond of $K_3 \times E$; .*). The Künneth formula gives the Hodge diamond of $K_3 \times E$ ($\dim_{\mathbb{C}} = 3$):

$$\begin{array}{ccccccc}
 & & & & \mathbf{I} & & \\
 & & & & \mathbf{I} & & \mathbf{I} \\
 & & & \mathbf{I} & & \mathbf{2I} & & \mathbf{I} \\
 & & \mathbf{I} & & \mathbf{2I} & & \mathbf{2I} & & \mathbf{I} \\
 & & \mathbf{I} & & \mathbf{2I} & & \mathbf{I} & & \\
 & & & & \mathbf{I} & & \mathbf{I} & & \\
 & & & & & & \mathbf{I} & &
 \end{array}$$

Key invariants:

- $h^{1,1} = h^{2,1} = 2\mathbf{I}$, giving $\chi(K_3 \times E) = 2(h^{1,1} - h^{2,1}) = 0$.
- Betti numbers: $b_0 = b_6 = 1$, $b_1 = b_5 = 2$, $b_2 = b_4 = 23$, $b_3 = 44$. Total: $\sum b_k = 96$.
- $K_0(K_3 \times E) \cong \mathbb{Z}^{48} (K_0(K_3) \otimes K_0(E) = \mathbb{Z}^{24} \otimes \mathbb{Z}^2)$.

Proof. Apply Künneth: $h^{p,q}(K_3 \times E) = \sum_{a+c=p, b+d=q} h^{a,b}(K_3) \cdot h^{c,d}(E)$. For example: $h^{1,1} = h^{1,1}(K_3) \cdot h^{0,0}(E) + h^{0,0}(K_3) \cdot h^{1,1}(E) = 2\mathbf{0} + \mathbf{I} = 2\mathbf{I}$. The alternating sum $1 - 2 + 23 - 44 + 23 - 2 + 1 = 0$ verifies $\chi = 0$. $\square$

HKR decomposition and deformation space

PROPOSITION 26.23.2 (*Deformation space of $D^b(K_3 \times E)$; .*). By the HKR isomorphism for a smooth CY 3-fold: $\mathrm{HH}^n(X) = \bigoplus_{p+q=n} h^{3-p,q}(X)$. For $K_3 \times E$:

$\mathrm{HH}^0 = 1$	automorphisms	$h^{3,0}$
$\mathrm{HH}^1 = 2$	outer derivations	$h^{3,1} + h^{2,0}$
$\mathrm{HH}^2 = 23$	first-order deformations	$h^{3,2} + h^{2,1} + h^{1,0}$
$\mathrm{HH}^3 = 44$	obstructions	$h^{3,3} + h^{2,2} + h^{1,1} + h^{0,0}$

The 23-dimensional deformation space: 21 complex structure (from $h^{2,1}$), 1 B-field (from $h^{1,0}$), 1 volume (from $h^{3,2}$). Serre duality on a CY 3-fold gives $\mathrm{HH}^n \cong \mathrm{HH}^{6-n}$, so $\mathrm{HH}^4 = 23$, $\mathrm{HH}^5 = 2$, $\mathrm{HH}^6 = 1$, and the full range $0 \leq n \leq 6$ has total $\dim \mathrm{HH}^* = 1 + 2 + 23 + 44 + 23 + 2 + 1 = 96$.

Noncommutative deformations and Brauer group

Remark 26.23.3 (*Brauer group of $K_3 \times E$*). $\mathrm{Br}(K_3 \times E) = \mathrm{Br}(K_3) \oplus \mathrm{Br}(E)$ contains $(\mathbb{Q}/\mathbb{Z})^{21}$ (K_3 at Picard rank $\rho = 1$) plus $\mathbb{Q}/\mathbb{Z}$ from E . The K_3 symplectic form provides the unique Poisson structure $\pi = \omega^{-1}$ (since $\dim H^0(\wedge^2 T_{K_3}) = 1$), but the E -direction carries none ($\wedge^2 T_E = 0$).

Autoequivalences and semiorthogonal structure

PROPOSITION 26.23.4 (*Indecomposability of $D^b(K_3 \times E)$; .*). $D^b(K_3)$ admits no proper semiorthogonal decomposition (Bridgeland, Kawamata, Huybrechts: $\omega_{K_3} = \mathcal{O}$ forces Serre functor [2], and the only fractional CY category with Serre [2] is $D^b(K_3)$ itself). Hence $D^b(K_3 \times E) = D^b(K_3) \otimes D^b(E)$ is indecomposable.

Autoequivalences: $\mathrm{Aut}(D^b(K_3)) \rightarrow O^+(H(K_3, \mathbb{Z}))$ via oriented Hodge isometries (line bundle twists, shifts, spherical twists T_E with $T_E^2 = [-2]$). $\mathrm{Aut}(D^b(E)) = (E \times E^\vee) \rtimes (\mathrm{SL}(2, \mathbb{Z}) \rtimes \mathbb{Z})$. The virtual dimension of all moduli problems on $K_3 \times E$ vanishes: $\mathrm{vdim} = -\chi(\mathcal{E}, \mathcal{E}) = 0$.

Factorization homology

Remark 26.23.5 (Factorization homology on $K_3 \times E$). The factorization homology of the HT-twisted sigma model: $\int_{K_3 \times E} A^{\text{HT}} \simeq H^*(K_3 \times E, \Omega^{\text{ch}})$. The CDR character gives $\chi(\Omega^{\text{ch}}) = 0$, but the Hodge-graded character is nontrivial. $\dim \text{HH}^*(D^b(K_3 \times E)) = 96$.

Torelli–GK Hodge-supertrace target for the Borcherds weight $\kappa_{\text{BKM}}(\mathfrak{g}_{\Delta_5}) = 5$

The paramodular cusp form $\Delta_5 \in S_5(\Gamma_2^{\text{para}})$ has weight $5 = c_N(0)/2|_{N=1}$ with $c_1(0)$ the Fourier seed of the singular-theta input $2\phi_{0,1}$ (the K_3 elliptic genus; Gritsenko–Nikulin 1995 Pt II *Int. J. Math.* 9 Theorem 2.1; Borcherds 1998 *Invent. Math.* 132 Theorem 10.4). The proved source of $\kappa_{\text{BKM}}(\mathfrak{g}_{\Delta_5}) = 5$ is this Borcherds-lift construction. The chain-level Hodge-supertrace object below is a conditional Torelli–Getzler–Kapranov pullback target for the same weight: if the Stage-1 modular-operadic supertrace identifies with $\tilde{j}^* \Delta_5$, its weight coefficient is 5. It is not a fifth $\kappa_\bullet$ -invariant and not an independent derivation of κ_{BKM} from the compact Hodge supertrace.

THEOREM 26.23.6 (*Atiyah class on $K_3 \times E$ is block-diagonal and Kapranov minimal model truncates*). Let $X = K_3 \times E$ with projections $p_1: X \rightarrow K_3$, $p_2: X \rightarrow E$. The Atiyah class of the holomorphic tangent bundle decomposes block-diagonally,

$$\text{At}(T_X) = p_1^* \text{At}(T_{K_3}) \oplus p_2^* \text{At}(T_E) \in H^1(X, \Omega_X^1 \otimes \text{End} T_X),$$

and the elliptic summand vanishes on the nose, $\text{At}(T_E) = 0$, because $T_E \simeq \mathcal{O}_E$ admits a flat translation-invariant holomorphic connection (Atiyah 1957 *Trans. AMS* 85 Theorem 1). Hence $\text{At}(T_X) = p_1^* \text{At}(T_{K_3})$. The Kapranov L_∞ -structure on $T_X[-1]$ (Kapranov 1999 *Compositio Math.* 115 Theorem 4.1) is therefore pulled back from K_3 ; by Bogomolov–Tian–Todorov unobstructedness of K_3 (Bogomolov 1978; Tian 1987; Todorov 1989) every higher bracket $\ell_n^{\min}$ for $n \geq 3$ vanishes on the minimal model pulled back from the K_3 factor.

Proof. Naturality of the 1-jet exact sequence $0 \rightarrow \Omega_X^1 \otimes T_X \rightarrow J^1(T_X) \rightarrow T_X \rightarrow 0$ along the Cartesian projections p_1, p_2 places the Atiyah class in the diagonal summand of $H^1(X_1 \times X_2, (\Omega^1 \otimes \text{End} T)_{X_1 \times X_2})$ under Künneth. Triviality of T_E trivialises its Atiyah class via any translation-invariant connection. Bogomolov–Tian–Todorov unobstructedness of K_3 forces every higher L_∞ bracket $\ell_n^{\min}$ for $n \geq 3$ on the minimal model of $\Omega^{\circ,*}(K_3, T_{K_3})$ to vanish. $\square$

PROPOSITION 26.23.7 (*Three Atiyah cocycles on $K_3 \times E$ are Hodge-disjoint; BCOV one-loop cancels via $\chi = 0$*). On $X = K_3 \times E$ the Atiyah class of T_X sources three cohomologically distinct cocycles, each in its own Hodge slot of the Dolbeault-polyvector diamond:

- (i) **Kapranov generator** $\text{At}(T_X) \in H^1(X, \Omega_X^1 \otimes \text{End} T_X)$ the L_∞ -bracket ℓ_2 (Kapranov 1999).
- (ii) **Tree-level Yukawa** $Y_3 = \ell_3^{\min} \in H^{\circ,3}(X) = H^3(X, \mathcal{O}_X)$ paired with the holomorphic volume form Ω_X to give a symmetric cubic form on $H^1(X, T_X)$ (Kapranov 1999 §4).
- (iii) **One-loop BCOV curving** $\alpha_{\text{BCOV}} = (\chi_{\text{top}}(X)/24) [\Omega_X]^{\circ,1} \in H^{\circ,1}(X)$ the BV anomaly of the Costello–Li BCOV action (Costello–Li 2016 arXiv:1605.09930 Proposition 5.2).

The three live in pairwise distinct Hodge bidegrees, so conflation is a Hodge-degree distinction. On $K_3 \times E$ the topological Euler characteristic is Künneth-multiplicative, $\chi_{\text{top}}(K_3 \times E) = \chi_{\text{top}}(K_3) \cdot \chi_{\text{top}}(E) = 24 \cdot 0 = 0$, so

$$\alpha_{\text{BCOV}}(K_3 \times E) = \frac{\chi_{\text{top}}(K_3 \times E)}{24} [\Omega_X]^{\circ,1} = 0,$$

and the BV quantisation of the BCOV action admits no one-loop obstruction from the $(0, 1)$ -curving slot.

Proof. Hodge bidegree counting: $(0, 1)$ -with-End T -coefficients, $(0, 3)$, and $(0, 1)$ -without-End-coefficients are three distinct receptacles in the Dolbeault-polyvector diamond; Serre duality pairs $H^{0,3}(X) \cong H^0(X, \Omega_X^3)^\vee$ with the volume form Ω_X , and pairs $H^{0,1}(X) \cong H^1(X, \Omega_X^3)^\vee$ after tensoring by ω_X . All three are sourced by $\text{At}(T_X)$ via derived compositions but do not collapse to a single class. The BCOV cancellation follows from the Künneth computation $\chi_{\text{top}}(K_3 \times E) = 24 \cdot 0 = 0$ and the Costello–Li BCOV formula $\alpha_{\text{BCOV}} = (\chi/24)[\Omega]^{0,1}$. $\square$

Remark 26.23.8 (Hodge diamond pointwise data). The Hodge-supertrace column of $K_3 \times E$ reads $(h^{0,0}, h^{0,1}, h^{0,2}, h^{0,3}) = (1, 1, 1, 1)$ (Künneth of K_3 diamond $(1, 0, 1)$ with E diamond $(1, 1)$); its alternating sum is $\sum_q (-1)^q h^{0,q}(K_3 \times E) = 1 - 1 + 1 - 1 = 0 = \chi(O_{K_3 \times E}) = \kappa_{\text{ch}}(K_3 \times E) = \kappa_{\text{cat}}(K_3 \times E)$. This pointwise vanishing of the naive supertrace is *not* the Borchers weight of $\mathfrak{g}_{\Delta_5}$: $\kappa_{\text{BKM}}(\mathfrak{g}_{\Delta_5}) = 5$ is carried by the $\overline{\mathcal{M}}_{2,0}$ -fibration of the supertrace twisted by the Hodge line bundle $\mathcal{L}$, not by the pointwise scalar.

Definition 26.23.9 (Chain-level Hodge-supertrace integrand). Let $B^{E_3}(\Phi_3^{\text{FA}}(\text{Coh}(K_3 \times E)))$ be the bar complex of the canonical Stage-1 E_3 -holomorphic factorisation algebra on $X = K_3 \times E$. Its cyclic E_3 -structure (from the CY-3 Serre pairing) assembles into a Getzler–Kapranov modular envelope (Getzler–Kapranov 1998 *Compositio Math.* 110 §3, §6; Costello 2007 *Adv. Math.* 210 Theorem A), producing for each stable (g, n) a chain complex $\text{GK}_{g,n}(X)$ over $\overline{\mathcal{M}}_{g,n}$. The *chain-level Hodge-supertrace integrand* at genus two is

$$I_{\text{GK},2}^{\text{Hodge}}(K_3 \times E) := \text{str}(\text{GK}_{2,0}(X) \otimes_{\overline{\mathcal{M}}_{2,0}} \mathcal{L}^{\wedge 5}) \in H^\bullet(\overline{\mathcal{M}}_{2,0}, \mathcal{L}^{\wedge 5}),$$

with $\mathcal{L}$ the Hodge line bundle on $\overline{\mathcal{M}}_{2,0}$. The exponent 5 is the automorphic Borchers weight tested by the Torelli–GK comparison of Theorem 26.23.11.

Remark 26.23.10 (Why genus two, why weight five). Selection of $(g, n) = (2, 0)$ is forced by the Howe dual pair $(O(2, 2), \text{Sp}_4)$ of Howe 1979 *Proc. Sympos. Pure Math.* 33 §5: the Borchers lift of $\phi_{0,1}$ carries a Jacobi form of signature $(2, 2)$ through the dual pair onto Sp_4 -automorphic output, *not* onto Sp_6 or higher. Higher-genus $\overline{\mathcal{M}}_{g,0}$ fibres of the Getzler–Kapranov envelope encode different BKM algebras via different Howe-dual inputs; they are structurally decoupled from $\mathfrak{g}_{\Delta_5}$. The exponent 5 on the Hodge bundle is pinned by the automorphic Borchers weight and becomes a chain-level statement through the Torelli–GK comparison of Theorem 26.23.11.

THEOREM 26.23.11 (Conditional Torelli–GK pullback target for Δ_5). Let $X = K_3 \times E$, let $\bar{j}: \overline{\mathcal{M}}_{2,0} \dashrightarrow \overline{\mathcal{A}}_2$ denote the Torelli map from the Deligne–Mumford moduli of genus-two stable curves to the Satake compactification of the moduli of principally polarised abelian surfaces, let $\mathcal{L}$ be the Hodge line bundle, let Φ_3^{FA} be the Stage-1 canonical E_3 -holomorphic factorisation algebra functor of the two-stage factorisation $\Phi_3 = \text{Sp}_{\Sigma_2, C}^{\text{ch}} \circ \Phi_3^{\text{FA}}$, and let $I_{\text{GK},2}^{\text{Hodge}}(X)$ be the chain-level Hodge-supertrace integrand of Definition 26.23.9. Assume that the Stage-1 modular-operadic supertrace comparison from the GK integrand to the Borchers line on $\overline{\mathcal{A}}_2$ has been constructed on the fixed H1–H4 branch, with the compact CY₃ closure input of either $B_{\text{TCFT}}^{(2)}$ or the filtered $HH_{E_1}^{-2}$ theorem, and that this comparison matches the Gritsenko–Nikulin divisor and leading coefficient. Then

- (i) $I_{\text{GK},2}^{\text{Hodge}}(X) = \tilde{j}^* \Delta_5$ as a section of $\mathcal{L}^{\wedge 5}$ on $\overline{\mathcal{M}}_{2,0}$, where $\Delta_5 \in S_5(\Gamma_2^{\text{para}})$ is the Gritsenko–Nikulin paramodular cusp form of weight 5.
- (ii) The chain-level Hodge-supertrace coefficient

$$a_{\text{Hodge} \rightarrow \text{BKM}}(\mathfrak{g}_{\Delta_5}) := \text{wt}(I_{\text{GK},2}^{\text{Hodge}}(K_3 \times E)) = \text{wt}(\Delta_5) = 5,$$

coincides with the automorphic Borchers weight on this comparison locus.

- (iii) The equality $a_{\text{Hodge} \rightarrow \text{BKM}} = c_N(o)/2|_{N=1} = 10/2 = 5$ holds for the Fourier seed $c_1(o)$ of the singular-theta input $2\phi_{o,1}$ (the K_3 elliptic genus), matching the universal Borchers weight identity $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2$ at $N = 1$ (Theorem 32.8.1 of Chapter 32).

Proof. The automorphic part is unconditional. The Borchers singular-theta lift (Borchers 1998 Theorem 10.4) carries the Jacobi form $\phi_{o,1} \in J_{o,1}(\Gamma_o(1))$ under the $(O(2,2), \text{Sp}_4)$ Howe dual pair to a paramodular cusp form of weight $c(o)/2$ on $\text{Sp}_4(\mathbb{Z})$; Gritsenko–Nikulin 1995 Pt II Theorem 2.1 identifies the output with Δ_5 of weight 5. Bruinier 2002 *Lecture Notes Math.* 1780 Proposition 5.1 and Example 5.3 give the same Hodge-line exponent by Heegner Chern-class reciprocity, and the K_3 elliptic-genus seed has $c_1(o) = 10$.

The chain-level assertion is exactly the stated comparison hypothesis. Under that hypothesis the genus-two Getzler–Kapranov supertrace lands in $\tilde{j}^* H^o(\overline{\mathcal{A}}_2, \mathcal{L}^{\wedge 5})$ with the same divisor and leading coefficient as the Gritsenko–Nikulin section. The one-dimensionality of the normalised Borchers line on this locus then identifies the image with $\tilde{j}^* \Delta_5$. Thus the GK equality is a conditional bridge statement, while the numerical Borchers value $\kappa_{\text{BKM}}(\Delta_5) = c_1(o)/2 = 5$ is already proved by the automorphic denominator theorem. $\square$

PROPOSITION 26.23.12 (*Two automorphic proofs and one conditional bridge for $\kappa_{\text{BKM}}(\mathfrak{g}_{\Delta_5}) = 5$*). The equality $\kappa_{\text{BKM}}(\mathfrak{g}_{\Delta_5}) = 5$ has two independent primary-literature derivations and one conditional chain-level GK–Torelli consistency test converging on the same number:

Path 1 (conditional Hodge-supertrace comparison). Theorem 26.23.11: chain-level Getzler–Kapranov modular-operadic pairing on $\overline{\mathcal{M}}_{2,0}$, Torelli-pulled to $\overline{\mathcal{A}}_2$ and identified with Δ_5 after the modular-operadic comparison and compact CY_3 closure inputs are supplied. The Hodge line-bundle exponent is then 5.

Path 2 (Gritsenko additive lift). Gritsenko–Nikulin 1995 Pt I *Int. J. Math.* 9 Theorem 1.3 constructs Δ_5 as the Gritsenko additive theta lift of the K_3 elliptic genus $2\phi_{o,1}$, with weight $(c(o) + 2)/2$; at $c(o) = 8$ on the additive convention one reads weight 5 directly.

Path 3 (Bruinier Heegner Chern-class reciprocity). Bruinier 2002 *Lecture Notes Math.* 1780 Proposition 5.1, Example 5.3: the Borchers Chern-class reciprocity $c_1(\text{BL}_{\Theta}(\phi_{o,1})) = 5 \cdot c_1(\mathcal{L})$ reads the weight off the Heegner divisor sum on the orthogonal Shimura variety $\mathcal{A}_2^{\text{para}}$.

The two automorphic paths are independent of the chain-level GK–Torelli comparison; all three share the primary-literature input that Δ_5 is the Borchers lift of $\phi_{o,1}$ (Lorgat 2020 reproduces the explicit construction). The proved conclusion is the Borchers value $\kappa_{\text{BKM}}(\mathfrak{g}_{\Delta_5}) = 5$; the genus-two chain-level Hodge supertrace remains a conditional bridge witness until the comparison and compact closure inputs are constructed.

Proof. Path 1 is the conditional comparison theorem 26.23.11. Path 2 is Gritsenko–Nikulin 1995 Pt I Theorem 1.3 and Gritsenko 1999 *Abh. Math. Sem. Hamburg* 69 §3. Path 3 is Bruinier 2002 §5. The

independence claim applies to the two automorphic proofs and to the chain-level comparison machinery: the latter depends on E_3 -formality, the Getzler–Kapranov modular envelope, and the Torelli–Kuga–Satake descent; the automorphic paths depend respectively on additive theta-series and Heegner divisors. $\square$

Remark 26.23.13 (Object-level chain-level comparison). Theorem 26.23.11 is an object-level chain-level comparison target on the specific CY datum $K_3 \times E$: it requires the specific chain complex $B^{E_3}(\Phi_3^{\text{FA}}(\text{Coh}(K_3 \times E)))$, the specific Hodge decomposition of $K_3 \times E$, and the specific Borchers lift of $\phi_{0,1}$. No morphism-preservation of Φ_3^{FA} across CY-3 inputs is required, no $(\infty, 1)$ -categorical functoriality is invoked, and the enhancement to Φ_3^{FA} -as-functor on $(\infty, 1)$ -categories of CY data is orthogonal. The comparison target above is conditional on the Torelli–GK identification and does not define a new $\kappa_\bullet$ -invariant.

Twenty-four curve-stalks, not twenty-four $\mathbb{C}^3$ -points

The locality of the $K_3 \times E$ chiral datum refers to the *curve-stalks* of the elliptic Kodaira fibration on K_3 pulled back to $K_3 \times E$, not to 24 smooth $\mathbb{C}^3$ -points. Conflating the two produces a toric-quiver skeleton where a curve-fibration belongs; it undercounts the local dimension of the protected sector by one.

PROPOSITION 26.23.14 (*Kodaira I_1 curve-stalks on $K_3 \times E$*). Let $\pi : K_3 \rightarrow \mathbb{P}^1$ be a generic elliptic fibration (étale-generic K_3 lattice-polarised by U ; Huybrechts 2016, *Lectures on K_3* , Chapter 11). Kodaira’s canonical divisor formula gives $\chi_{\text{top}}(K_3) = \sum_p \chi_{\text{top}}(F_p) = 24$, with 24 singular fibres $F_p = I_1$ (each a nodal rational curve). On the CY₃ $Y = K_3 \times E$ with second projection $\text{pr}_E : Y \rightarrow E$ suppressed, the discriminant locus $\Delta \subset \mathbb{P}^1$ of $\pi \circ \text{pr}_1$ consists of 24 points and pulls back to 24 curve-stalks

$$F_p \times E \subset K_3 \times E, \quad p \in \Delta, \quad |\Delta| = 24,$$

each a nodal elliptic curve $I_1 \times E$ of complex dimension 2; the *union* is a divisor of class $\pi^*[\text{pt}] \cdot 24 + \text{pr}_E^*[\text{pt}] \cdot 0 = 24 \cdot [F] \times E$ with $[F]$ the class of a generic elliptic K_3 fibre.

Attribution. Kodaira 1963 (*Ann. Math.* 77:563); Miranda 1989 (*The basic theory of elliptic surfaces*, Dottorato di Ricerca, Pisa) classifies singular fibres; the sum $\sum \chi_{\text{top}}(F_p) = c_2(K_3) = 24$ is the topological Euler-characteristic relation for a smooth elliptic K_3 . Base-change via pr_E preserves fibre type; $F_p \times E$ is of complex dimension 2 since $\dim F_p = 1$ and $\dim E = 1$. $\square$

PROPOSITION 26.23.15 (*Curve-stalk positive-half firewall*). The 24 singular pieces of $K_3 \times E$ are $I_1 \times E$ curve-stalks, not toric $\mathbb{C}^3$ vertices. A toric $\mathbb{C}^3$ -point carries the critical CoHA

$$\text{CoHA}(\mathbb{C}^3) \cong Y^+(\widehat{\mathfrak{gl}}_1),$$

the positive half of the affine Yangian; the full affine Yangian, its centre, and the $\mathcal{W}_{1+\infty}$ vacuum module appear only after the Drinfeld double/centre/vacuum passage. An $I_1 \times E$ curve-stalk carries a 2-dimensional nodal model whose quiver is the A_1 Dynkin quiver with a loop at each node, and whose Yangian is $Y(\widehat{\mathfrak{sl}}_2)^E$ -coupled, not $Y(\widehat{\mathfrak{gl}}_1)$ on 24 copies. The local algebra at the Kodaira node $F_p \cap E_q$ of the $I_1 \times E$ stalk is

$$\mathcal{O}_{F_p \times E, (p,q)} \simeq \mathbb{C}[[x_1, x_2, z]]/(x_1 x_2), \quad z \in T_q E,$$

a two-sheet crossing times a smooth curve, *not* $\mathbb{C}^3$. The chiral-datum counts factorise as (K₃-fibre contribution) $\otimes_{\mathbb{C}}$ (E-contribution), not as 24 copies of a three-dimensional local model.

Proof. The completed local ring of a nodal Kodaira fibre is $\mathbb{C}[[x_1, x_2]]/(x_1x_2)$; base-change along the elliptic factor tensors this ring with $\mathbb{C}[[z]]$. Its singularity category is therefore the $\mathcal{A}_1$ surface node transported along a smooth curve. The Jordan-quiver cubic potential giving $\text{CoHA}(\mathbb{C}^3)$ is absent: there is no regular completed local ring $\mathbb{C}[[x, y, z]]$ and no isolated toric fixed point. Schiffmann–Vasserot identify the toric critical CoHA with $Y^+(\widehat{\mathfrak{gl}}_1)$; the vacuum $\mathcal{W}_{1+\infty}$ module is obtained only after adjoining the opposite half and evaluating the centre. Hence replacing the 24 curve-stalks by 24 copies of $\mathbb{C}^3$ changes both the singularity category and the algebra half. $\square$

PROPOSITION 26.23.16 (*Quasi-NCCR character under finite Rees and compact hCS–Hall hypotheses*). Let $X = K_3 \times E$. There is no global Van den Bergh NCCR on X . Assume instead the following data.

- (i) A Serre-equivariant finite Rees quasi-NCCR datum $\mathcal{A}_X^{\text{qNCCR}}$ in the sense of Definition 26.21.7.
- (ii) A compact hCS–Hall trivialisation $\mathfrak{o}_{\text{hCS} \rightarrow \text{Hall}}^{\text{comp}}(X) = \mathfrak{o}$ in the sense of Definition 26.21.6.
- (iii) The compact CY_3 closure input: either the corrected TCFT carrier $B_{\text{TCFT}}^{(2)}$ for the second-order bracket comparison, or a complete exhaustive separated strongly convergent filtration theorem proving $HH_{E_i}^{-2} = \mathfrak{o}$ for the compact bar complex.
- (iv) A reduced character map

$$\Theta_{\text{qNCCR} \rightarrow \text{DT}}^{K_3 \times E}: K_{\mathfrak{o}}\left(\text{Perf}\left(\mathcal{A}_X^{\text{qNCCR}}\right)\right)_{\Lambda_{\Pi}^{2,1}} \longrightarrow \mathbb{Z}[[q, \tilde{q}, y^{\pm 1}]]$$

compatible with K_3 -cosection reduction and Hall integration.

Write OP for the Oberdieck–Pandharipande/Oberdieck reduced PT/DT scalar normalisation and OPi for the Oberdieck–Pixton stability component. The theta-normalised primitive section and the OP monic square are

$$D_5 = 64^{-1} \Delta_5, \quad \Phi_{10}^{\text{OP}} = D_5^2 = 4096^{-1} \Delta_5^2.$$

Then the reduced character is the OP/DT scalar

$$\chi(\mathcal{A}_X^{\text{qNCCR}})(q, \tilde{q}, y) = -(\Phi_{10}^{\text{OP}}(\tau, z, \sigma))^{-1} = -D_5^{-2} = -4096 \Delta_5^{-2},$$

equal to the Behrend-weighted reduced Donaldson–Thomas scalar partition function in this normalisation. The primitive BKM denominator remains the Gritsenko–Nikulin Δ_5 datum, with monic denominator section $D_5(2Z) = 64^{-1} \Delta_5(2Z)$ for $\mathfrak{g}_{\Delta_5}$; the OP/DT square forgets the orientation character and does not by itself construct the compact critical CoHA or identify the finite radical-quotient Hall–Drinfeld double with the Borchers current quotient. The Fake-Monster form Φ_{12} belongs to the $d = 5$ Borchers lift on $\Pi_{25,1}$ and is not a normalisation of the $K_3 \times E$ scalar.

The obstruction to a global NCCR is the following five-term failure:

- (a) $\omega_{K_3 \times E} = \mathcal{O}$ (trivial dualising) but ω -structure fails reflexive-tilting: no global tilting bundle T on $K_3 \times E$ has $\text{End}(T)$ of finite global dimension covering all points (Van den Bergh 2004 obstruction for products with $\dim > 2$).
- (b) Derived McKay equivalence (Bridgeland–King–Reid 2001) requires a finite Aut-group fixing a point; the K_3 factor’s lattice $\Pi_{3,19}$ autoequivalences and the elliptic factor’s translation group combine into an infinite discrete-plus-translation group, obstructing the BKR hypothesis globally.
- (c) Homological projective duality (Kuznetsov 2007) self-dual on K_3 does not respect the product polarisation; the HPD base change along pr_E distinguishes polarisations on K_3 and $K_3 \times E$.

- (d) Mukai vanishing $\text{Ext}^i(\mathcal{F}, \mathcal{F}) = 0$ for $i = 1$ on rigid spherical objects of K_3 fails off the K_3 factor: $\text{Ext}_{K_3 \times E}^1(\mathcal{F} \boxtimes \mathcal{O}_E, \mathcal{F} \boxtimes \mathcal{O}_E) = \text{Ext}_{K_3}^1(\mathcal{F}, \mathcal{F}) \oplus H^1(E, \mathcal{O}_E) \neq 0$.
- (e) No global CY-3 symmetric obstruction theory exists: the Mukai obstruction theory on K_3 is 2-shifted symplectic (PTVV); the E -factor contributes degree 1; the total space is -1 -shifted symplectic on a stratified locus (the complement of the 24 curve-stalks), not globally.

Proof chain. *Step 1 (NCCR obstructions):* (a)–(e) are standard (Van den Bergh 2004, *Duke* 122, §3; Bridgeland–King–Reid 2001, *JAMS* 14; Kuznetsov 2007, *Adv. Math.* 210; Mukai 1987, *Nagoya Math. J.* 106; PTVV 2013, *Publ. IHÉS* 117).

Step 2 (finite Rees descent): Seidel–Thomas 2001 (*Duke* 108, §3) construct spherical twist autoequivalences T_E on $D^b(K_3)$; pulled back along $\text{pr}_1: K_3 \times E \rightarrow K_3$ they supply the local tilting pieces on the complement of the 24 curve-stalks. At each curve-stalk $F_p \times E$ the tilting piece degenerates by one step (Kuznetsov 2008 degeneration). The finite Rees datum records this degeneration by the truncated algebras $\text{Rees}_D^{\leq N}(A_\alpha)$ and asks for the Morita defects $\mathfrak{o}_{\text{Rees}}^{(2)}$ and $\mathfrak{o}_{\text{Rees}}^{(3)}$ to vanish. Thus the quasi-NCCR input is exactly the finite Rees descent datum, not a consequence of spherical twists alone.

Step 3 (compact hCS–Hall map): the trivialisation $\mathfrak{o}_{\text{hCS} \rightarrow \text{Hall}}^{\text{comp}}(X) = 0$ identifies the local BV traces and Hall integrations on the Čech nerve. The compact closure input supplies the missing second-order TCFT or filtered $HH_{E_1}^{-2}$ vanishing needed to promote those traces to compact Hall brackets. Without these data the construction stops at a local positive-half character and cannot be promoted to compact Hall brackets.

Step 4 (OP/DT scalar): after applying $\Theta_{\text{qNCCR} \rightarrow \text{DT}}^{K_3 \times E}$ the derived character on the BPS lattice $\Lambda_{\Pi}^{2,1}$ is the generating function of Ext^* -graded dimensions of the Rees-glued tilting object, evaluated against $(q, \tilde{q}, y)$. Oberdieck–Pandharipande 2016 (arXiv:1411.1514, Theorem 1) and Oberdieck’s reduced DT theorem identify this scalar with $-(\Phi_{10}^{\text{OP}})^{-1}$. With $D_5 = 64^{-1}\Delta_5$ and $\Phi_{10}^{\text{OP}} = D_5^2 = 4096^{-1}\Delta_5^2$, the scalar is $-4096\Delta_5^{-2}$.

Step 5 (primitive denominator): Gritsenko–Nikulin 1998 (arXiv:alg-geom/9611028; see also [108]) supply the primitive BKM denominator algebra $\mathfrak{g}_{\Delta_5}$ with denominator section $D_5(2Z) = 64^{-1}\Delta_5(2Z)$ and Borcherds weight $\kappa_{\text{BKM}}(\mathfrak{g}_{\Delta_5}) = 5$. Squaring to the OP/DT scalar changes the scalar partition function and the weight-10 Igusa square; it does not change the primitive BKM denominator and does not introduce Φ_{12} . $\square$

Remark 26.23.17 (Rank-23 Cartan via $\Pi_{4,20}/U = \Pi_{3,19}$ plus Leech addback). The Cartan subalgebra of the BKM superalgebra $\mathfrak{g}_{\Delta_5}$ has rank $23 = 22 + 1$, assembled as the Mukai quotient plus a Leech-lattice addback:

- *Mukai quotient seed of rank 22.* The Mukai lattice $\tilde{H}(K_3, \mathbb{Z}) \simeq \Pi_{4,20} = U^4 \oplus (-E_8)^2$ (Mukai 1987, §1) modulo a hyperbolic plane U (the $H^0 \oplus H^4$ summand aligned with the Mukai vector) yields $\Pi_{4,20}/U = U^3 \oplus (-E_8)^2 = \Pi_{3,19}$, rank 22, signature $(3, 19)$, stabiliser of the reduced K_3 transcendental lattice plus the Kähler-modulus direction.
- *Leech-shadow addback:* the Leech lattice Λ_{24} contributes a rank-one Niemeier shadow through the Conway–Norton orbifold correspondence at the $N \in \{1, 2, 3, 4, 6\}$ CHL slice (Carnahan 2010; Conway–Sloane 1988 §16). The addback adds rank 1 to the Cartan, yielding rank $22 + 1 = 23$.

The rank-23 Cartan is *not* the same as $\text{rk } \Pi_{3,19} = 22$; the Leech addback is forced by the $N = 4$ decomposition of the K_3 elliptic genus and the index-1 Jacobi form structure, and lives in an eigenspace of the Mukai Hodge involution orthogonal to the $\Pi_{3,19}$ seed.

Remark 26.23.18 (Humbert divisor H_1 monodromy order 8 = $2c_+ \nu(\mu_0)$ with $c_+ = 4$). The Humbert divisor $H_1 \subset \mathcal{A}_2$ of discriminant 1 parametrises principally polarised abelian surfaces that split as products $E_1 \times E_2$ of two elliptic curves (Gritsenko–Nikulin 1998, Int. J. Math. 9, §2); around this divisor the Δ_5 -automorphic $\mathcal{D}$ -module $\mathcal{L}^{\Delta_5}$ carries local monodromy of order 8. The order decomposes as

$$8 = 2 \cdot c_+ \cdot \nu(\mu_0), \quad c_+ = 4, \quad \nu(\mu_0) = 1,$$

with $c_+ = c_+(\tilde{H}(K_3, \mathbb{Z})) = 4$ the positive-signature rank of the Mukai lattice and $\nu(\mu_0) = 1$ the multiplicity of the fundamental Humbert eigenvalue. The signature $(4, 20)$ of $\tilde{H}(K_3, \mathbb{Z}) = H^0 \oplus H^2 \oplus H^4 \cong U^{\oplus 4} \oplus (-E_8)^{\oplus 2}$ decomposes additively through the Hodge structure as

$$(1, 1)_{H^0 \oplus H^4} \oplus (2, 0)_{(H^{2,0} \oplus H^{0,2})_{\mathbb{R}}} \oplus (1, 19)_{H_{\mathbb{R}}^{1,1}},$$

where: the hyperbolic plane $U \cong H^0 \oplus H^4$ under the off-diagonal Mukai pairing $\langle (r_1, s_1), (r_2, s_2) \rangle = -r_1 s_2 - r_2 s_1$ contributes $(1, 1)$; the real slice $(H^{2,0} \oplus H^{0,2})_{\mathbb{R}}$ spanned by $\text{Re}(\omega_{K_3})$ and $\text{Im}(\omega_{K_3})$ is positive-definite of dimension 2 via the Kähler identity $\int_{K_3} \omega \wedge \bar{\omega} > 0$; $H_{\mathbb{R}}^{1,1}$ under the cup product has signature $(1, 19)$ with the one positive direction being the Kähler class. Summing the positive contributions gives $c_+ = 1 + 2 + 1 = 4$. Under the Mukai Hodge involution ι_{Muk} (fixing $H^0 \oplus H^{1,1} \oplus H^4$, flipping $H^{2,0} \oplus H^{0,2}$) the $+1$ -eigenspace has signature $(2, 20)$ and the -1 -eigenspace has signature $(2, 0)$; the four positive Mukai directions thus split $2 + 2$ across the two ι_{Muk} -eigenspaces. The prefactor 2 is the Jacobi $\mathbb{Z}/2$ -cover from $\text{Sp}_4 \rightarrow \text{SO}_+(\Lambda^{3,2})$; the net order 8 matches Bruinier’s Heegner Chern-class reciprocity (Bruinier 2002, arXiv:math/0212081, Proposition 5.1) and the Lusztig $\ell = 8$ specialisation of the small quantum group at the eighth root of unity.

The same integer 8 is the Vol I Theorem-C complementarity value on the $\mathcal{B}$ -family:

$$K_{\mathcal{B}}^{\text{comp}} := 2c_+(\text{Mukai}(K_3)) = 8 \in \{0, 8, 13, 250/3, 98/3\},$$

where $K_{\mathcal{B}}^{\text{comp}}$ denotes the paired derived-centre complementarity conductor and the bucket $\{0, 8, 13, 250/3, 98/3\}$ is the canonical five-archetype G/L/C/M/B ceiling. The $\mathcal{B}$ -row witness is the Vol III Mukai-enhanced K_3 Heisenberg derived-centre complementarity; the Chern-class reciprocity route is recorded in Chapter 20, Theorem 20.14.4.

26.24 ENUMERATIVE GEOMETRY OF $K_3 \times E$

Gromov–Witten theory and BPS invariants

Remark 26.24.1 (Reduced GW theory on K_3). For K_3 , the standard virtual class vanishes for $\beta \neq 0$ (cosection from $H^{2,0}(K_3) = \mathbb{C}$). The reduced theory (Bryan–Leung, Maulik–Pandharipande–Thomas) removes this obstruction. The KKV formula (proved by Pandharipande–Thomas 2016) gives the BPS state counts. The genus-0 BPS invariants satisfy the Yau–Zaslow formula:

$$\sum_{h \geq 0} n_h^0 q^h = \prod_{n \geq 1} \frac{1}{(1 - q^n)^{24}}.$$

PROPOSITION 26.24.2 (BPS invariants of K_3). Selected BPS invariants (all integers, proved by Pandharipande–Thomas 2016):

h	0	1	2	3	4	5	6	7
n_h^0	1	24	324	3200	25650	176256	1073720	5930496
n_h^1	0	−2	−54	−800	−8550	−73440	−536860	−3464264
n_h^2	0	0	3	104	1701	19656	176358	1316808
n_h^3	0	0	0	−4	−155	−2832	−34470	−320320

Signed convention: $n_h^g = (-1)^g |n_h^g|$. The genus-0 values are the Yau–Zaslow numbers (OEIS A006922); $n_1^0 = 24 = \chi(K_3)$. The Hilbert scheme Euler characteristics $\chi(\text{Hilb}^n(K_3))$ provide the genus-0 column: $\chi(\text{Hilb}^n) = n_n^0$, with generating function $\sum_{n \geq 0} \chi(\text{Hilb}^n) q^n = \prod_{k \geq 1} (1 - q^k)^{-24}$ (Göttsche formula). The first eight values are 1, 24, 324, 3200, 25650, 176256, 1073720, 5930496.

Bridgeland stability on K_3

Remark 26.24.3 (Stability conditions). $\text{Stab}^\dagger(K_3) \rightarrow P^+(K_3)$ is a covering of the period domain (Bridgeland 2008). Walls of marginal stability for Mukai vectors $v = v_1 + v_2$ are semicircles in the (B, ω) -plane; crossing them applies the KS wall-crossing. For primitive v with $v^2 = 2n - 2$: $\Omega(v) = \chi(\text{Hilb}^n(K_3))$.

26.25 BPS SPECTRUM AND BLACK HOLE ENTROPY

The Hodge data and topological invariants of $K_3 \times E$ fix the geometric stage. The chiral algebra $\mathcal{A}_{K_3 \times E}$ must encode these invariants and the BPS spectrum of Type IIA compactified on $K_3 \times E$: $\frac{1}{4}$ -BPS dyons whose degeneracies are organised by the unnormalised Igusa square $\Phi_{10}^{\text{un}} = \Delta_5^2$ (DVV; (26.7) below). The arithmetic of the charge lattice $\Gamma = H^{\text{even}}(K_3 \times E, \mathbb{Z})$, the Cardy growth of black-hole entropy, and the Rademacher expansion of $1/\Phi_{10}^{\text{un}}$ together pin the modular content the chiral algebra must reproduce.

Charge lattice and BPS states

The lattice on which the Igusa form acts must be specified before the BPS spectrum can be tabulated. We record its generators and intersection form.

PROPOSITION 26.25.1 (Charge lattice). Type IIA on $K_3 \times E$ gives 4d $\mathcal{N} = 4$ supergravity with 22 vector multiplets. The D-brane charge lattice $\Gamma = H^{\text{even}}(K_3 \times E, \mathbb{Z})$:

Cohomology	Brane type	Rank
$H^0 = \mathbb{Z}$	D6-branes	1
$H^2 = \mathbb{Z}^{23}$	D4-branes	23
$H^4 = \mathbb{Z}^{23}$	D2-branes	23
$H^6 = \mathbb{Z}$	D0-branes	1

Total: rank $\Gamma = 48$.

Black hole entropy from $1/\Phi_{10}^{\text{un}}$

PROPOSITION 26.25.2 (BMPV and $\frac{1}{4}$ -BPS entropy;). In 5d (IIA on $K_3 \times S^1$): the BMPV black hole with charges (Q_1, Q_5, n) has $S_{\text{BH}} = 2\pi\sqrt{Q_1 Q_5 n}$ (Cardy with $c_L = 6 Q_1 Q_5$). In 4d (IIA on $K_3 \times T^2$): the $\frac{1}{4}$ -BPS dyon with discriminant Δ has

$$S_{\text{BH}} = 4\pi\sqrt{\Delta},$$

and the DVV formula $Z_{1/4\text{-BPS}} = 1/\Phi_{10}^{\text{un}}$ ((26.7)) gives the exact microscopic count. For large Δ : $\log d(\Delta) \sim 4\pi\sqrt{\Delta} - \frac{3}{2} \log \Delta + \dots$, where the subleading term is the universal one-loop correction (Sen 2005, 2012). The asymptotic expansion is the leading term of the Rademacher exact formula for the Fourier coefficients of $1/\Phi_{10}^{\text{un}}$:

$$d(\Delta) = \frac{2\pi}{\sqrt{\Delta}} \sum_{c=1}^{\infty} \frac{K(c, \Delta)}{c} I_{27/2}\left(\frac{4\pi\sqrt{\Delta}}{c}\right) + \text{polar contributions},$$

where $I_{27/2}$ is the modified Bessel function of the first kind of order $27/2$ and $K(c, \Delta)$ is a Kloosterman-type sum over $\mathrm{Sp}(4, \mathbb{Z})$. The $c = 1$ term dominates at large Δ . Combining the Bessel asymptotic $I_{27/2}(z) \sim e^z / \sqrt{2\pi z}$ at $z = 4\pi\sqrt{\Delta}$ with the $1/\sqrt{\Delta}$ Rademacher prefactor and the one-loop measure on the polar contour ($\mathrm{Sp}(4, \mathbb{Z})$ stationary-phase determinant) gives $d(\Delta) \sim e^{4\pi\sqrt{\Delta}} \cdot \Delta^{-3/2}$, matching $\log d(\Delta) \sim 4\pi\sqrt{\Delta} - \frac{3}{2} \log \Delta$. The convergence of the Rademacher series is exponentially fast: the $c = 2$ correction is suppressed by $e^{-2\pi\sqrt{\Delta}}$ relative to the leading term.

Remark 26.25.3 (OSV conjecture). The Ooguri–Strominger–Vafa relation $Z_{\mathrm{BH}} = |Z_{\mathrm{top}}|^2$ connects the black hole partition function to the topological string. For $K_3 \times E$, the topological string is exactly solvable at genus 0 and 1. The shadow tower gives $F_g = 3 \cdot \lambda_g^{\mathrm{FP}}$ at each genus, exact at $g = 1$ and with multi-weight cross-channel correction $\delta F_g^{\mathrm{cross}}$ at $g \geq 2$ (Vol I).

Fourier–Jacobi as genus escalation

PROPOSITION 26.25.4 (*Bridge: elliptic R -matrix data determines BKM root system*). The Fourier–Jacobi expansion of the unnormalised Igusa cusp form $\Phi_{10}^{\mathrm{un}}(\Omega) = \sum_{m \geq 1} \phi_m(\tau, z) p^m$ uses Jacobi forms $\phi_m(\tau, z)$ on E_τ . The leading coefficient

$$\phi_1(\tau, z) = \eta(\tau)^{18} \mathfrak{J}_1(\tau, z)^2$$

is built from the same theta function $\mathfrak{J}_1(\tau, z)$ that defines the elliptic propagator $d \log \mathfrak{J}_1(z|\tau)$ ((22.2)) and Felder’s elliptic R -matrix entries $a(u) = \theta(u+\eta)/\theta(\eta)$ (Definition 22.2.2).

The passage from genus-1 data (Jacobi forms on E_τ) to genus-2 data has two normalisations. The square-root BKM lane lifts the Eichler–Zagier form $\phi_{0,1}$ and gives $\mathrm{sdim} \mathfrak{g}_{\Delta, \alpha} = c_0(4nm - \ell^2)$. The full K_3 elliptic genus $Z_{K_3} = 2 \phi_{0,1}$ (Definition 26.22.7) gives the doubled product (26.6) for $\Phi_{10}^{\mathrm{un}} = \Delta_5^2$, whose exponents are $2c_0(4nm - \ell^2)$. Proposition 26.27.1 is the normalization map from the doubled product to the Δ_5 -root-character lane.

In the factorization $\eta^{18} = \eta^{24} \cdot \eta^{-6}$: $\eta^{24} = \Delta$ is the Ramanujan discriminant (the 24 free bosons of $\mathcal{A}_E$, with $\kappa_{\mathrm{ch}}(\mathcal{A}_E) = 24$), and $\eta^{-6} = \eta^{-2\kappa_{\mathrm{ch}}^{\mathrm{Heis}}}$ with $\kappa_{\mathrm{ch}}^{\mathrm{Heis}} = \kappa_{\mathrm{ch}}^{\mathrm{Heis}}(\Omega^{\mathrm{ch}}(K_3 \times E)) = 3$. The shadow obstruction tower detects $\kappa_{\mathrm{ch}}^{\mathrm{Heis}} = 3$ (Proposition 26.29.6); the Borchers lift escalates this genus-1 datum to the genus-2 Siegel modular form.

26.26 TWISTED HOLOGRAPHY ON $K_3 \times E$

The BPS arithmetic identifies the modular content $1/\Phi_{10}^{\mathrm{un}}$ that the chiral algebra must reproduce. A bulk-to-boundary construction is needed to derive the chiral algebra *from the geometry* rather than read it off the partition function. The Costello–Li twisted-holography programme (HT twist of IIB on $K_3 \times E$, Kodaira–Spencer reduction along the K_3 directions) provides the boundary chiral algebra $\mathcal{A}_E$ on the elliptic factor whose central charge $c(\mathcal{A}_E) = 24$ matches $\kappa_{\mathrm{fiber}}(K_3) = \mathrm{rk} \tilde{H}(K_3)$.

Construction 26.26.1 (Costello–Li KS boundary algebra). The Costello–Li programme extracts a boundary chiral algebra from the HT twist of Type IIB on $K_3 \times E$. Reduction of Kodaira–Spencer theory along the topological directions (K_3) produces a chiral algebra $\mathcal{A}_E$ on E with generators from harmonic forms on K_3 . The identification $c(\mathcal{A}_E) = \chi(K_3) = 24$ below is physical heuristic: the precise OPE level matrix is $J^a J^b \sim \delta^{ab}/(z-w)^2$ (Remark 26.26.2; the δ^{ab} records the Kaluza–Klein measure, not the Mukai form). The construction of $\mathcal{A}_E$ as a 2D VOA factorising from a 6D twisted-supergravity partition function is a separate OPE-level problem.

$h^{p,q}(K_3)$	Contribution	Generators
$h^{0,0} = 1$	Scalar boson	1
$h^{2,0} = 1$	Symplectic boson	1
$h^{1,1} = 20$	Weight-1 bosons	20
$h^{0,2} = 1$	Conjugate boson	1
$h^{2,2} = 1$	Volume boson	1

Total: $c(A_E) = \chi(K_3) = 24$. This is not the K_3 sigma model ($c = 6$) but 24 free bosons from the B-model reduction. $\kappa_{\text{ch}}(A_E) = 24$ (rank of the free-boson lattice), $\kappa_{\text{ch}}(A_E^\dagger) = -24$ (free-field scope, class G: A_E is 24 free bosons, for which the two chiral characteristics cancel on classes G and L where $\rho_K = 0$; this is distinct from the Virasoro class M conductor 13).

Remark 26.26.2 (OPE level matrix for KS boundary bosons). The 24 free bosons $J^a(z)$ ($a = 1, \dots, 24$) of the KS boundary algebra A_E have OPE $J^a(z) J^b(w) \sim \delta^{ab}/(z-w)^2$, so the OPE level matrix is δ^{ab} (the unit matrix), *not* the Mukai pairing G^{ab} of signature $(4, 20)$ on $H^*(K_3, \mathbb{Z})$. The Mukai pairing enters through the vertex operators $V_\gamma(z) = :\exp(i\gamma_a J^a(z)):$ for lattice vectors $\gamma \in \Gamma_{\text{Mukai}}$, whose correlation functions involve $\langle V_\gamma V_{\gamma'} \rangle \propto \exp(\gamma \cdot G \cdot \gamma')$. Confusing the OPE level δ^{ab} with the lattice pairing G^{ab} produces wrong κ_{ch} values: the OPE level gives $\kappa_{\text{ch}}(A_E) = 24$ (sum of diagonal entries), while the Mukai norm $\text{tr}(G) = 4 - 20 = -16$ would give a wrong and negative κ_{ch} .

Remark 26.26.3 (Holographic modular Koszul datum). $H(K_3 \times E) = (A, A^\dagger, C, r(z), \Theta_A, \nabla^{\text{hol}})$ with $A = A_E$ ($c = 24$, $\kappa_{\text{ch}} = 24$), $A^\dagger = A_E^\dagger$ ($\kappa_{\text{ch}} = -24$), $C = Z_{\text{ch}}^{\text{der}}(A)$ (universal bulk), $r(z) = \kappa_{\text{ch}} \Omega/z$ (Casimir, 24-dim: level prefix $\kappa_{\text{ch}} = 24$), Θ_A (bar-intrinsic MC element), ∇^{hol} (shadow connection, class G).

PROPOSITION 26.26.4 (Boundary-to-sigma ratio). The boundary algebra A_E and the sigma model VOA V_{K_3} have modular characteristics in ratio 12. At genus 1:

$$\frac{\kappa_{\text{ch}}(A_E)}{\kappa_{\text{ch}}(V_{K_3})} = \frac{24}{2} = 12, \quad \frac{F_1(A_E)}{F_1(V_{K_3})} = 12.$$

Here A_E has $c = 24$ from the 24 free bosons of the Kaluza–Klein reduction on K_3 (Construction 26.26.1) indexed by the Mukai lattice $H^*(K_3, \mathbb{Z})$, and V_{K_3} is the $\mathcal{N} = 4$ SCA at $c = 6$ with $\kappa_{\text{ch}}(V_{K_3}) = 2$ (Proposition 26.22.2). The SUSY Ward identities of the $\mathcal{N} = 4$ algebra reduce κ_{ch} by a factor of $2/3$ relative to the Virasoro formula $\kappa_{\text{ch}}(\text{Vir}_6) = 3$ (Remark 26.22.3).

For A_E (24 free bosons, class G, uniform weight), the scalar formula $F_g(A_E) = 24 \cdot \lambda_g^{\text{FP}}$ holds at all genera. For V_{K_3} (class M, generators at weights 1, $3/2$, 2), the scalar formula $F_g = \kappa_{\text{ch}} \cdot \lambda_g^{\text{FP}}$ is proved at genus 1; at $g \geq 2$ the multi-weight genus expansion receives cross-channel corrections $\delta F_g^{\text{cross}}$ (all-weight; Vol I). The ratio 12 is therefore proved at $g = 1$ and conditional at $g \geq 2$.

Proof. $\kappa_{\text{ch}}(A_E) = 24$ (rank of the free-boson lattice). $\kappa_{\text{ch}}(V_{K_3}) = 2$ (Proposition 26.22.2). Their ratio is $24/2 = 12$. At genus 1, $F_1(\mathcal{A}) = \kappa_{\text{ch}}(\mathcal{A})/24$ for both algebras, giving the ratio 12. At $g \geq 2$: A_E is uniform-weight (class G), so $F_g(A_E) = 24 \cdot \lambda_g^{\text{FP}}$ at all genera (uniform-weight; class G, scalar formula exact). V_{K_3} has generators at weights 1, $3/2$, 2; the scalar formula $F_g = 2 \cdot \lambda_g^{\text{FP}}$ is proved at $g = 1$ but receives multi-weight cross-channel corrections $\delta F_g^{\text{cross}}$ at $g \geq 2$ (all-weight; Vol I). $\square$

Remark 26.26.5 (Leech connection). The boundary partition function of the 24 chiral free bosons A_E at genus 1 is

$$Z_1(A_E; \tau) = 1/\eta(\tau)^{24} = q^{-1}(1 + 24q + 324q^2 + \dots).$$

The Leech lattice VOA V_Λ (holomorphic lattice VOA of central charge 24) has character

$$\Theta_\Lambda(\tau)/\eta(\tau)^{24} = q^{-1}(1 + 24q + 196884q^2 + \cdots),$$

where $\Theta_\Lambda = 1 + 196560q^2 + \cdots$ counts Leech-lattice vectors by norm. The two characters agree at weights 0 and 1 and diverge at weight 2: the 196560 minimal Leech vectors have no counterpart in the bare 24-boson Fock space (weight 2 dimension $324 = 24 + 300$: the 24 singly-excited states $\alpha_{-2}^\mu|0\rangle$, plus the $\binom{24+1}{2} = 300$ symmetric pairs $\alpha_{-1}^\mu\alpha_{-1}^\nu|0\rangle$). The Leech lattice has $\kappa_{\text{ch}}(V_\Lambda) = 24 = \kappa_{\text{ch}}(\mathcal{A}_E)$ (both are 24 free bosons at level 1), but their weight-2 spaces differ.

26.27 MOCK MODULAR FORMS AND THE BKM ROOT SYSTEM

The boundary-to-sigma ratio identifies the modular characteristics on the two sides of the $\text{AdS}_3/\text{CFT}_2$ correspondence; the underlying BPS counting function $1/\Phi_{10}^{\text{un}}$ now demands an algebraic interpretation. Borchers's denominator-formula construction has a square-root lane: Δ_5 is the Weyl–Kac–Borchers denominator of the target BKM superalgebra $\mathfrak{g}_{\Delta_5}$, with signed root character read from $\phi_{0,1}$. The K_3 elliptic genus $Z_{K_3} = 2\phi_{0,1}$ instead gives the doubled $\Phi_{10}^{\text{un}} = \Delta_5^2$ product. The first task is to extract the normalization map between these lanes; the second is to read off the mock-modular completion of the K_3 elliptic genus that controls the *wall-crossing* discontinuities of the dyon spectrum.

BKM signed root characters

PROPOSITION 26.27.1 (*Signed root-character coefficients*). The BKM superalgebra $\mathfrak{g}_{\Delta_5}$ uses the Eichler–Zagier normalisation: writing $c_o(D)$ for the discriminant coefficient of $\phi_{0,1}$, the target root superdimension is $\text{sdim } \mathfrak{g}_{\Delta_5, \alpha} = c_o(D_\alpha)$. Ordinary even/odd dimensions or generator counts require a parity fixture or finite Hall–Borchers recognition of the root space. The full K_3 elliptic genus $Z_{K_3} = 2\phi_{0,1}$ supplies the doubled exponents in the product formula for $\Phi_{10}^{\text{un}} = \Delta_5^2$, not the root character of $\mathfrak{g}_{\Delta_5}$ itself.

$$\text{Exp}_{\Delta_5}(D) = c_o(D), \quad \text{Exp}_{\Phi_{10}^{\text{un}}}(D) = 2c_o(D), \quad \Phi_{10}^{\text{un}} = \Delta_5^2.$$

- Real roots ($D = -1, \alpha^2 = 2$): $\text{sdim } \mathfrak{g}_\alpha = c_o(-1) = 1$.
- Lightlike roots ($D = 0, \alpha^2 = 0$): $\text{sdim } \mathfrak{g}_\alpha = c_o(0) = 10$.
- Imaginary roots ($D > 0$): $\text{sdim } \mathfrak{g}_\alpha = c_o(D)$, unbounded as a signed character. Leading: $c_o(3) = -64$, $c_o(4) = 108$, $c_o(7) = -513$, $c_o(8) = 808$.

Negative coefficients at odd D indicate a signed odd branch in the standard target parity convention; they are not negative dimensions. The discriminant coefficients $c_o(D)$ of $\phi_{0,1}$ through $D = 12$ are (Eichler–Zagier convention; the subscript 0 labels the weight-0 Jacobi form $\phi_{0,1}$, not the paramodular level N of Proposition 17.6.7, where $c_N(0)/2$ is the Borchers weight):

D	−1	0	3	4	7	8	11	12	15	16	19	20
$c_o(D)$	1	10	−64	108	−513	808	−2752	4016	−11775	16524	−43263	58956

The K_3 elliptic genus $Z_{K_3} = 2\phi_{0,1}$ has Fourier coefficients $2c_o(D)$; the BKM $\mathfrak{g}_{\Delta_5}$ is the Borchers lift of $\phi_{0,1}$ itself, so its target root supercharacters satisfy $\text{sdim } \mathfrak{g}_{\Delta_5, \alpha} = c_o(D)$ for discriminant $D = 4nm - \ell^2$. (The companion BKM $\mathfrak{g}_{\Phi_{10}^{\text{un}}}$ associated with $\Phi_{10}^{\text{un}} = \Delta_5^2$ has doubled signed root-character coefficients $2c_o(D)$.) The theta decomposition $\phi_{0,1} = h_o(\tau)\vartheta_{0,1}(\tau, z) + h_1(\tau)\vartheta_{1,1}(\tau, z)$ separates even (ℓ even, $D \equiv 0 \pmod{4}$) and odd (ℓ odd, $D \equiv 3 \pmod{4}$) sectors, with $h_o(\tau) = 10 + 108q + 808q^2 + \cdots$ and $h_1(\tau) = q^{-1/4}(1 - 64q + \cdots)$.

PROPOSITION 26.27.2 (*Signed root-character constancy*). Define the *level* of a positive root $\alpha = (n, l, m)$ as $\ell(\alpha) = n + m$. For all levels $\ell \geq 1$:

$$\sum_{\substack{\alpha \in \Delta_+ \\ \ell(\alpha) = \ell}} \text{sch}(\alpha) = 24 = \chi(K_3), \quad \text{sch}(\alpha) := \text{sdim } \mathfrak{g}_{\Delta, \alpha} = c_o(4nm - l^2).$$

Proof. At each level ℓ , the positive roots decompose into boundary roots (those with $n = 0$ or $m = 0$) and interior roots (those with $n, m \geq 1$).

Boundary contribution. Roots with $m = 0$: $(n, l, 0)$ for $n = \ell$, varying l . The signed root character is $c_o(-l^2)$, which is nonzero only for $l = 0$ (giving $c_o(0) = 10$) and $l = \pm 1$ (giving $c_o(-1) = 1$ each). Total: $10 + 1 + 1 = 12$. Similarly for $n = 0$: total 12. Boundary total: 24.

Interior cancellation. For each pair (n, m) with $n + m = \ell$ and $n, m \geq 1$:

$$\sum_{l \in \mathbb{Z}} c_o(4nm - l^2) = 0.$$

This is the modular constancy of $\phi_{o,1}$ at $z = 0$. The weak Jacobi form $\phi_{o,1}(\tau, z)$ has weight 0 and index 1; evaluating at $z = 0$ gives a modular form of weight 0 on $\text{SL}_2(\mathbb{Z})$, which is necessarily constant (the space $M_0(\text{SL}_2(\mathbb{Z}))$ is one-dimensional, spanned by 1). The value is $\phi_{o,1}(\tau, 0) = 12$ (Eichler–Zagier, *The Theory of Jacobi Forms*, 1985, p. 108). At the level of Fourier coefficients: $\sum_l c_o(4N - l^2) = 0$ for all $N \geq 1$, since the q^N coefficient of the constant function 12 vanishes for $N \geq 1$. The boundary gives 24, the interior gives 0, so the total at every level is 24. $\square$

Remark 26.27.3 (*The interior cancellation at level 2*). The interior at level 2 consists of roots $(1, l, 1)$ with $\text{sch} = c_o(4 - l^2)$. From the Eichler–Zagier table: $l = 0$: $D = 4, c_o(4) = 108$; $l = \pm 1$: $D = 3, c_o(3) = -64$ each; $l = \pm 2$: $D = 0, c_o(0) = 10$ each. Sum: $108 - 2 \cdot 64 + 2 \cdot 10 = 108 - 128 + 20 = 0$. The cancellation is a direct consequence of $\sum_l c_o(4 - l^2) = 0$ (the q^1 coefficient of $\phi_{o,1}(\tau, 0) = 12$).

Remark 26.27.4 (*Signed root-character constancy and the shadow tower*). The constancy $\sum_{\ell(\alpha)=\ell} \text{sch}(\alpha) = 24 = \chi(K_3)$ reflects the topological datum $\chi(K_3)$ persisting through the BKM construction. This is precisely the datum that the abelian $(2, 0)$ pushforward (Construction 26.22.20) captures: the Euler characteristic of the fiber enters through the lattice rank and the partition function of the free-field theory. The pushforward gives the correct topological backbone ($\chi = 24$) even though it gives the wrong shadow class (class **G** instead of class **M**) and the wrong κ_{ch} (rank(Λ) instead of $\dim_{\mathbb{C}}(K_3) = 2$).

The Hilbert scheme bridge

THEOREM 26.27.5 (*Toroidal action on K -theory of Hilbert schemes [92]*). Let S be a smooth projective surface. The toroidal algebra $U_{q,t}(\hat{\mathfrak{gl}}_1)$ acts on $\bigoplus_{n \geq 0} K(\text{Hilb}^n(S))$ by correspondences on the nested Hilbert scheme $\text{Hilb}^{n,n+1}(S)$ (Schiffmann–Vasserot). Specializations:

- (i) *Nakajima operators* ($q = 1$): the Heisenberg algebra $\bigoplus_{n \in \mathbb{Z}} \mathbb{Q} \mathbf{a}_n$ acts on $\bigoplus_n H^*(\text{Hilb}^n(S))$ via Nakajima correspondences, with $\mathbf{a}_{-n}|o\rangle$ the class of the punctual Hilbert scheme.
- (ii) *Haiman’s theorem* ($S = \mathbb{C}^2$): the DAHA $\check{H}_n(q, t)$, a quotient of $U_{q,t}(\hat{\mathfrak{gl}}_1)$, acts on $K(\text{Hilb}^n(\mathbb{C}^2))$ with fixed-point basis indexed by partitions $\lambda \vdash n$, and the character of the natural representation is the Macdonald polynomial $\check{H}_\lambda(x; q, t)$.

(iii) $S = K_3$: $\chi(\text{Hilb}^n(K_3)) = p_{24}(n)$ (24-coloured partitions), so $\sum_{n \geq 0} \chi(\text{Hilb}^n(K_3)) p^n = \prod_{m \geq 1} (1 - p^m)^{-24}$.

PROPOSITION 26.27.6 (*DMVV from Hilbert scheme characters;*). The DVV formula (26.7) $1/\Phi_{10}^{\text{un}} = \sum_N p^N \chi(\text{Sym}^N(K_3); \tau, z)$ is the generating function of equivariant Euler characteristics of $\text{Hilb}^N(K_3)$ refined by the $\text{SU}(2)_R$ fugacity z and the L_0 fugacity $q = e^{2\pi i \tau}$. The 24 coloured partitions arise from Nakajima's Heisenberg action ($24 = \chi(K_3) = b_0 + b_2 + b_4 = 1 + 22 + 1$): each colour corresponds to a cohomology class of K_3 , matching the 24 free bosons of the boundary algebra A_E (Construction 26.26.1).

Remark 26.27.7 (Synthesis: toroidal algebras meet BPS counting). The three strands of this chapter converge on the Hilbert scheme. The toroidal algebra $U_{q,t}(\hat{\mathfrak{g}})$ of §22.1 provides the symmetry algebra acting on $K(\text{Hilb}^n(S))$. The elliptic R -matrix of §22.2 appears as the transition matrix between stable-envelope bases of $K(\text{Hilb}^n(S))$ (Aganagic–Okounkov). The BKM signed root-character coefficients $c_0(D)$ of Proposition 26.27.1 are the Fourier coefficients of $\phi_{0,1}$. The K_3 elliptic genus $Z_{K_3} = 2\phi_{0,1}$ is the doubled Φ_{10} -lane and has coefficients $2c_0(D)$; it counts the protected symmetric-product index seen by $\bigoplus_n H^*(\text{Hilb}^n(K_3))$. The shadow invariant $\kappa_{\text{ch}}^{\text{Heis}} = 3$ measures the single-copy chiral algebra $\Omega^{\text{ch}}(K_3 \times E)$; the BKM algebra $\mathfrak{g}_{\Delta}$ encodes the second-quantized (symmetric-product) extension, and the gap between them is the content of the shadow–Siegel gap analysis (§26.29).

Fourier–Jacobi expansion

Remark 26.27.8 (Fourier–Jacobi structure). $\Phi_{10}^{\text{un}} = \sum_{m \geq 1} \phi_m(\tau, z) p^m$ with: $\phi_1 = \phi_{10,1} = \eta^{18} \mathfrak{J}_1^2 = -\Delta \cdot \phi_{-2,1}$ (unique Jacobi cusp form of weight 10, index 1); $\phi_2 = 2\Delta \phi_{-2,1} \phi_{0,1}$ ($\dim J_{10,2}^{\text{cusp}} = 1$). The factorization $\eta^{18} = \eta^{24} \cdot \eta^{-6}$ separates the Ramanujan discriminant from $\eta^{-2\kappa_{\text{ch}}}$ with $\kappa_{\text{ch}}^{\text{Heis}} = 3$. The Jacobi form ring $J_{*,*}^{\text{weak}} = \mathbb{C}[E_4, E_6, \phi_{-2,1}, \phi_{0,1}]$ (Eichler–Zagier).

26.28 GRAND SYNTHESIS AND OPEN PROBLEMS

Remark 26.28.1 (Master data table for $K_3 \times E$). The complete invariant data assembled from the CY compute layer:

Invariant	Value
$\dim_{\mathbb{C}}(K_3 \times E)$	3
$\chi(K_3 \times E)$	0
$h^{1,1} = h^{2,1}$	21
$\text{rank } K_0$	48
$\dim \text{HH}^*$	96
$\kappa_{\text{ch}}^{\text{Heis}} = \kappa_{\text{ch}}^{\text{Heis}}(\Omega^{\text{ch}})$	3
$\kappa_{\text{BKM}}(\mathfrak{g}_{\Delta_5}) = \text{wt}(\Delta_5)$	5
$\kappa_{\text{BCOV}} = \chi/24$	0
Shadow depth	class M ($r_{\max} = \infty$)
F_1	1/8
F_2	7/1920
F_3	31/322560
$Z_{\text{DT},0}$	1
n_1^0 (genus-0 BPS, $h = 1$)	24
$S_{\text{BH}}(\Delta)$	$4\pi\sqrt{\Delta}$
$c(A_E^{\text{KS}})$ (twisted holography)	24
$\kappa_{\text{ch}}(A_E^{\text{KS}})$	24
$\text{Br}(K_3 \times E)$	$\supset (\mathbb{Q}/\mathbb{Z})^{22}$

The preceding master-data table records several distinct numerical values attached to $K_3 \times E$ under the heading “ $\kappa_{\bullet}$ ”. These are *not* competing measurements of a single invariant: each belongs to a named construction. To make this precise we record, for a given X , the subscripted package of construction-dependent invariants rather than a pure chiral modular-characteristic spectrum.

Definition 26.28.2 ($\kappa_{\bullet}$ -construction spectrum). For a Calabi–Yau threefold X , the $\kappa_{\bullet}$ -construction spectrum is

$$\text{Spec}_{\kappa_{\bullet}}(X) := \{(\alpha, \kappa_{\alpha}^{\mathfrak{s}}(X)) : \alpha \in \{\text{ch, cat, BKM, fiber}\}, \mathfrak{s} \text{ a specified construction where } \kappa_{\alpha} \text{ is defined}\}.$$

Each element carries its subscript and its source construction. The definition is deliberately not a set of plain numbers: equality of numerical values does not identify constructions, and different subscripts cannot be collapsed into a single modular characteristic.

Example 26.28.3 ($K_3 \times E$: composite $\kappa_{\bullet}$ -spectrum). The geometry $K_3 \times E$ supplies four invariant slots. The $\kappa_{\bullet}$ -construction spectrum (Definition 26.28.2) records the slot and the construction simultaneously:

Construction	$\kappa_{\bullet}$	Value
Compact total-space Hodge branch	$\kappa_{\text{ch}}(K_3 \times E) = \kappa_{\text{cat}}(K_3 \times E)$	0
Heisenberg–Mukai Stage-2 specialisation	$\kappa_{\text{ch}}^{\text{Heis}}(K_3 \times E)$	3
BKM algebra $\mathfrak{g}_{\Delta_5}$ (Borcherds lift)	$\kappa_{\text{BKM}}(\Delta_5)$	5
Mukai lattice of the K_3 fibre	$\kappa_{\text{fiber}}(K_3 \times E)$	24

Thus the canonical numerical package is $\{0, 3, 5, 24\}$, but the numbers are meaningful only with their subscripts and constructions. The K_3 -fibre categorical value $\chi(\mathcal{O}_{K_3}) = 2$ is a K_3 -restricted check, not

a total-space value and not κ_{fiber} . The 24-free-boson boundary algebra realises the Mukai-rank slot; it is not the compact total-space Hodge supertrace. The Borchers value $\kappa_{\text{BKM}} = 5$ is the automorphic weight invariant of the Gritsenko lift, not the modular characteristic of the compact chiral output.

Remark 26.28.4 (The $\kappa_{\bullet}$ -construction spectrum as invariant). The $\kappa_{\bullet}$ -construction spectrum (Definition 26.28.2) is analogous to the multiple spectra of a Riemannian manifold (Laplacian, Dirac, length): different constructions applied to the same geometry probe different aspects of the modular structure. Whether $\text{Spec}_{\kappa_{\bullet}}(X)$ is a complete invariant (i.e., whether $\text{Spec}_{\kappa_{\bullet}}(X) = \text{Spec}_{\kappa_{\bullet}}(X')$ implies $X \simeq X'$) is open.

Remark 26.28.5 (The second-quantization gap). The shadow tower is first-quantized (single-copy). $1/\Phi_{10}^{\text{un}}$ is second-quantized (DMVV symmetric product). The ratio $\kappa_{\text{BKM}}/\kappa_{\text{ch}}^{\text{Heis}} = 5/3$ reflects the passage from single copy to Sym^N and is specific to $K_3 \times E$ (the quintic gives a different ratio). The Borchers lift converts additive genus-1 data into multiplicative genus-2 data: shadow genus escalation.

PROPOSITION 26.28.6 (The BPS modular characteristic). The BPS modular weight is

$$\kappa_{\text{BKM}}(\mathfrak{g}_{\Delta_5}) = \frac{1}{2} c_1(o) = \text{wt}(\Delta_5) = 5$$

(Borchers weight theorem; Proposition 17.6.7). The tempting additive rule asking whether the BKM weight is the sum of the compact chiral Hodge supertrace and the fibre Euler characteristic *fails at every* $N \in \{1, 2, 3, 4, 6\}$ (Remark 26.30.11): at $N = 1$ it predicts $5 = 0 + 0$, since the Hodge-supertrace is $\kappa_{\text{ch}}(K_3 \times E) = \sum q(-1)^q h^{0,q} = 0$, not 3, and $\chi(\mathcal{O}_E) = 0$. For $K_3 \times E$ specifically, the numerical coincidence

$$\kappa_{\text{BKM}} = \kappa_{\text{ch}}^{\text{Heis}}(K_3 \times E) + \chi(\mathcal{O}_{K_3}) = 3 + 2 = 5$$

holds under a *different* subscript, $\kappa_{\text{ch}}^{\text{Heis}}(K_3 \times E) = 3 = \dim_{\mathbb{C}}$ being the threefold Heisenberg-level modular characteristic (Proposition 26.29.6) and $\chi(\mathcal{O}_{K_3}) = 2$ the fibre categorical invariant (the Künneth-multiplicative fibre value, distinct from $\kappa_{\text{cat}}(K_3 \times E) = \chi(\mathcal{O}_{K_3 \times E}) = \chi(\mathcal{O}_{K_3}) \cdot \chi(\mathcal{O}_E) = 2 \cdot 0 = 0$). This $\kappa_{\text{ch}}^{\text{Heis}} + \chi(\mathcal{O}_{\text{fibre}})$ equality is not universal and not a substitute for the Borchers identity: it is a convention-mixing artefact of $K_3 \times E$ ($N = 1$) and fails for $\mathbb{Z}/N\mathbb{Z}$ -orbifolds with $N \geq 2$ (Remark 17.6.6). The ratio

$$\frac{\kappa_{\text{BKM}}}{\kappa_{\text{ch}}^{\text{Heis}}} = \frac{5}{3} = \frac{\text{wt}(\Delta_5)}{\dim_{\mathbb{C}}(K_3 \times E)}$$

is only a comparison of two independently computed invariants; it is not a correction term from the single-copy algebra to the symmetric-product denominator. The distinction between Hilb^N and Sym^N accounts for additional BPS states: $\chi(\text{Hilb}^2(K_3)) - \chi(\text{Sym}^2(K_3)) = 324 - 300 = 24 = \chi(K_3)$, arising from the exceptional divisor of the Hilbert–Chow morphism $\text{Hilb}^2(K_3) \rightarrow \text{Sym}^2(K_3)$. The DMVV formula (26.7) uses the orbifold Sym^N formula; the Göttsche formula gives $\sum_N q^N \chi(\text{Hilb}^N(K_3)) = \prod_{k \geq 1} (1 - q^k)^{-24}$.

Proof. The Borchers weight theorem gives $\kappa_{\text{BKM}} = c_N(o)/2|_{N=1} = 10/2 = 5$ unconditionally. The numerical coincidence $\kappa_{\text{ch}}^{\text{Heis}}(K_3 \times E) + \chi(\mathcal{O}_{K_3}) = 3 + 2 = 5$ is verified by independent computation of each summand: the threefold Heisenberg reading $\kappa_{\text{ch}}^{\text{Heis}}(K_3 \times E) = 3$ (Proposition 26.29.6) and the fiber categorical invariant $\chi(\mathcal{O}_{K_3}) = 2$ (K_3 Hodge diamond). That the sum agrees with $c_N(o)/2|_{N=1}$ is a convention-mixing accident specific to $K_3 \times E$ ($N = 1$ orbifold): for $(\mathbb{Z}/N\mathbb{Z})$ -orbifolds with $N \geq 2$, independent computation confirms that $\kappa_{\text{ch}}^{\text{Heis}}(\text{total}) + \chi(\mathcal{O}_{\text{fiber}}) \neq c_N(o)/2$ while the Borchers weight identity $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2$ continues to hold. The Hilbert–Chow difference: $\text{Hilb}^2(S)$ for

a K_3 surface S is the blowup of $\text{Sym}^2(S)$ along the diagonal, with exceptional divisor $\mathbb{P}(T_S) \cong \mathbb{P}^1$ -bundle. By the blowup formula, $\chi(\text{Hilb}^2) = \chi(\text{Sym}^2) + \chi(S) = \binom{25}{2} + 24 = 300 + 24 = 324$. $\square$

Remark 26.28.7 (Hilbert–Chow difference at higher N). The identity $\chi(\text{Hilb}^2(S)) - \chi(\text{Sym}^2(S)) = \chi(S)$ generalizes: for all $N \geq 1$, $\chi(\text{Hilb}^N(S))$ is the coefficient of q^N in $\prod_{k \geq 1} (1 - q^k)^{-\chi(S)}$ (Göttsche’s formula), while $\chi(\text{Sym}^N(S)) = \binom{\chi(S) + N - 1}{N}$ (the combinatorial formula for orbifold Euler characteristics). The difference $\delta_N = \chi(\text{Hilb}^N) - \chi(\text{Sym}^N)$ grows with N ; the leading corrections come from the exceptional loci of the Hilbert–Chow resolution $\text{Hilb}^N(S) \rightarrow \text{Sym}^N(S)$, which become increasingly complicated as partitions of N acquire more parts. For K_3 : $\delta_1 = 0$, $\delta_2 = 24 = \chi(K_3)$, $\delta_3 = 600$, $\delta_4 = 8100$, matching the Göttsche coefficients 1, 24, 324, 3200, 25650, . . . minus the symmetric product coefficients 1, 24, 300, 2600, 17550, . . .

Open Problem 26.28.8 (Does the bar complex of $\mathcal{A}_{K_3}$ detect $\mathcal{M}_{24}$?). The mock modular half-multiplicities $a_n = 45, 231, 770, \dots$ are dimensions of $\mathcal{M}_{24}$ representations. The bar complex $B(\mathcal{A}_{K_3})$ detects $\kappa_{\text{ch}} = 2$ at degree 2 and the cubic shadow at degree 3. Does the full shadow obstruction tower $\Theta_{\mathcal{A}_{K_3}}$ encode the $\mathcal{M}_{24}$ action? The mock modular shadow $24\eta^3$ and the bar-complex shadow connection ∇^{sh} share the structural feature of encoding modular non-invariance. Whether they are related by a precise functor remains open.

Open Problem 26.28.9 (Factorization envelope of the K_3 chiral algebra). The factorization envelope $U_X^{\text{mod}}(\mathcal{A}_{K_3})$ in the sense of Nishinaka (2025/26) and Vicedo (2025) is not yet constructed. At the genus-0 level, the K_3 sigma model provides a factorization algebra on $\text{Ran}(X)$ for any algebraic curve X ; the modular completion (incorporating all genera) is open. The six-fold package $\Pi_X(\mathcal{A}_{K_3})$ is well-defined (Construction 21.16); what remains is the modular factorization envelope as the left adjoint of Prim^{mod} .

Remark 26.28.10 (Constructive reconstruction of $D^b(K_3 \times E)$). The derived category $D^b(K_3 \times E) \simeq D^b(K_3) \otimes D^b(E)$ is constructively reconstructible by three independent methods:

- (i) *Čech descent.* Two affine charts suffice for a smooth K_3 surface (any smooth projective surface over an algebraically closed field is covered by at most two affines). The Čech descent spectral sequence (Theorem 26.21.16)

$$E_1^{p,q} = \bigoplus_{|I|=p+1} \text{HH}^q(D^b(U_I)) \implies \text{HH}^{p+q}(D^b(K_3))$$

recovers $D^b(K_3)$ from local data on U_0, U_1 with transition data on U_{01} .

- (ii) *BKR equivalence.* At the Kummer point $K_3 = T^4/\mathbb{Z}_2$, the Bridgeland–King–Reid theorem gives $D^b(\text{Hilb}^2(T^4/\mathbb{Z}_2)) \simeq D_{\mathbb{Z}_2}^b(T^4)$, providing an explicit equivariant description. The equivariant category $D_{\mathbb{Z}_2}^b(T^4)$ is generated by equivariant line bundles and is computationally accessible.
- (iii) *Brauer obstruction.* $\text{Br}(K_3) \supset (\mathbb{Q}/\mathbb{Z})^{21}$ (Remark 26.23.3) obstructs only *twisted* derived categories. The untwisted category $D^b(K_3)$ is unobstructed.

A structural constraint: CY threefolds carry no exceptional objects ($\chi(\mathcal{O}_X, \mathcal{O}_X) = 0$ by the antisymmetry of Serre duality on a CY₃), so $D^b(K_3 \times E)$ admits no semiorthogonal decomposition and must be treated as an indecomposable block (Proposition 26.23.4).

Open Problem 26.28.11 (Global CY category from finitely many quiver charts). Given the constructive methods of Remark 26.28.10, can $D^b(K_3 \times E)$ be assembled from finitely many quiver charts with

explicit A_∞ -bimodule transition data? The McKay correspondence provides the local charts at orbifold points; the cluster mutation structure controls transitions; the KS wall-crossing governs the DT invariant transformations. A constructive algorithm would connect the local-to-global CY gluing of §26.21 to the global enumerative data of §26.24.

Research programmes

Ten open problems record what the $K_3 \times E$ shadow tower leaves undetermined; each is falsifiable against the CY compute layer at a concrete parameter point.

Open Problem 26.28.12 (Programme A: constructive Calabi–Yau gluing). The Čech descent of §26.21 reconstructs $D^b(K_3 \times E)$ from local quiver charts in principle. Three questions sharpen the programme.

- (A1) *Minimum chart number.* For a K_3 surface S of Picard rank ρ , what is the minimum number of ADE-type quiver charts whose A_∞ -bimodule transition data recovers $D^b(S)$? The Mukai lattice $\tilde{H}(S, \mathbb{Z}) \cong U^4 \oplus E_8(-1)^2$ has rank 24; categorical generation requires a spanning class for thick subcategory generation, not merely K -theory spanning. For orbifold K_3 (Kummer $T^4/\mathbb{Z}_2$), the BKR equivalence $D^b(\text{Kum}(A)) \simeq D^b_{\mathbb{Z}/2}(A)$ provides a single global chart; for smooth K_3 without ADE singularities, no full exceptional collection exists (Bridgeland 1999), and one must generate via spherical objects and their twist functors.
- (A2) *Brauer obstruction.* The gluing obstruction lives in $H^2(S, \mathcal{O}_S) \cong \mathbb{C}$ (the Brauer class). When does a nontrivial Brauer class kill the descent? For generic K_3 with $\rho = 0$, $\text{Br}(S)$ contains $(\mathbb{Q}/\mathbb{Z})^{22}$; for $K_3 \times E$, $\text{Br}(K_3 \times E) \supset (\mathbb{Q}/\mathbb{Z})^{22+1}$.
- (A3) *Beyond ADE.* The McKay correspondence handles orbifold singularities. For smooth K_3 at a generic moduli point (no singularities), the relevant local charts are formal neighborhoods of subvarieties, not ADE resolution charts. Does the spherical twist functor orbit of $\mathcal{O}_S$ generate $D^b(S)$ with finitely many transitions?

Conjecture 26.28.13 (ADE chart decomposition of K_3). Every algebraic K_3 surface admits a finite ADE-chart decomposition of its derived category: there exist finitely many open sets $\{U_\alpha\}$ with tilting generators T_α on each U_α , and A_∞ -bimodule transition data on overlaps, such that $D^b(S) \simeq \text{holim}_{\check{C}} D^b(U_\alpha)$. The minimum number of charts is bounded below by $\lceil \text{rank } K_0(S) / \max_\alpha \text{rank } K_0(\text{End}(T_\alpha)) \rceil$.

Open Problem 26.28.14 (Programme B: κ_{ch} as universal moonshine multiplier). The Mathieu moonshine decomposition gives $A_n = 2 \cdot \dim(\rho_n)$ with $\rho_n \in \text{Irr}(\mathcal{M}_{24})$, where the factor $2 = \kappa_{\text{ch}}(\mathcal{A}_{K_3})$ is the modular characteristic of the K_3 sigma model (Remark 26.22.10). This suggests a universal principle.

- (B1) *Monster moonshine.* For the Monster module $V^{\natural}$ ($c = 24$, $\kappa_{\text{ch}}(V^{\natural}) = 12$ by Remark 26.22.16 and Vol I, Theorem 21.16, applied to the Leech lattice construction): does $A_n^{\text{Monster}} = \kappa_{\text{ch}}(V^{\natural}) \cdot \dim(\rho_n^{\mathbb{M}})$ for the Monster group $\mathbb{M}$? The McKay–Thompson series $T_g(\tau) = \sum_n \text{tr}(\rho_n(g)) q^{n-1}$ is a genus-zero Hauptmodul; the question is whether the *dimensions* (not characters) factor through κ_{ch} .
- (B2) *Conway moonshine.* For $V^{\sharp}$ ($c = 12$, the shorter moonshine module): $\kappa_{\text{ch}}(V^{\sharp}) = ?$ and does $A_n = \kappa_{\text{ch}} \cdot \dim(\rho_n^{Co_0})$? The Conway group Co_0 acts on the Leech lattice; $V^{\sharp}$ is the $\mathbb{Z}/2$ -orbifold of the rank-12 lattice VOA.
- (B3) *General principle.* For a holomorphic VOA V of central charge c with finite automorphism group G , does the elliptic genus decompose as $Z_g(\tau, z) = \kappa_{\text{ch}}(V) \cdot \sum_n \dim(\rho_n) \text{ch}_n(g)$ for $g \in G$?

Conjecture 26.28.15 (Universal moonshine multiplier). For a holomorphic VOA V with finite automorphism group G , the twined partition function decomposes as

$$Z_g(\tau, z) = \kappa_{\text{ch}}(V) \cdot \sum_{n \geq 0} \dim(\rho_n) \text{ch}_n(g), \quad g \in G,$$

where $\kappa_{\text{ch}}(V)$ is the bar-complex modular characteristic, $\{\rho_n\}$ are virtual G -representations, and ch_n are character functions determined by the elliptic genus of V . For $V = \mathcal{A}_{K_3}$ ($c = 6$) with $G = M_{24}$: $\kappa_{\text{ch}} = 2$ and $A_n = 2 \cdot \dim(\rho_n)$ as established by Gannon [47].

Open Problem 26.28.16 (Programme C: second-quantization bridge). The ratio $\kappa_{\text{BKM}}/\kappa_{\text{ch}}^{\text{Heis}} = 5/3$ (Proposition 26.28.6) encodes the passage from first to second quantization for $K_3 \times E$.

- (C1) *Universality.* The additive decomposition $\kappa_{\text{BKM}} = \kappa_{\text{ch}}(\text{surface}) + \kappa_{\text{ch}}(\text{CY}_3)$ is a numerical coincidence for $K_3 \times E$ ($N = 1$) and fails for $\mathbb{Z}/N\mathbb{Z}$ -orbifolds with $N \geq 2$ (Remark 17.6.6). The correct universal formula is $\kappa_{\text{BKM}} = c_N(\mathfrak{o})/2$ (Borcherds weight theorem). For the quintic: κ_{BKM} is undefined (no K_3 fibration); the replacement invariant $\kappa_{\text{BCOV}} = \chi/24 = -200/24$ must be extracted from the genus-2 topological string amplitude.
- (C2) *Plethystic shadow.* The DMVV formula $1/\Phi_{10}^{\text{un}} = \text{PE}[2\phi_{0,1}]$ expresses the second-quantized partition function as the plethystic exponential of the single-copy elliptic genus. What is the shadow tower of $\text{PE}[\mathcal{A}]$ in terms of the shadow tower of $\mathcal{A}$? The tensor product gives $\kappa_{\text{ch}}(\mathcal{A}^{\otimes N}) = N \kappa_{\text{ch}}(\mathcal{A})$ by additivity, but the $\mathbb{Z}_N$ -orbifold projection to Sym^N modifies the tower through twisted sectors.
- (C3) *Adams operations.* The Adams operations ψ^k act on the shadow partition function by rescaling:

$$\psi^k(Z^{\text{sh}})(\hbar) = Z^{\text{sh}}(k\hbar) = \exp\left(\sum_{g \geq 1} k^{2g} F_g \hbar^{2g}\right).$$

This is the λ -ring structure on the shadow partition function: ψ^k multiplies the genus- g amplitude by k^{2g} , consistent with the interpretation of $\hbar^{2g}$ as a genus-counting weight. The Adams operations are ring homomorphisms ($\psi^k \circ \psi^l = \psi^{kl}$) and commute with the $\hat{A}$ -genus generating function (Vol I, Theorem 21.16). Does this intertwine with the Hecke operators V_k on the Jacobi form $\phi_{0,1}$ via the DMVV formula (26.7)? The Hecke transform $V_k(\phi_{0,1})$ and the Adams-rescaled shadow $\psi^k(Z^{\text{sh}})$ would need to be related through the Borcherds product for the intertwining to be exact.

Remark 26.28.17 (BPS modular characteristic: universal formula vs. coincidence). The correct universal formula for K_3 -fibered CY_3 s is

$$\kappa_{\text{BKM}} = \frac{1}{2} c_N(\mathfrak{o})$$

(Borcherds weight theorem; Proposition 17.6.7), where $c_N(\mathfrak{o})$ is the constant term of the $\mathbb{Z}/N\mathbb{Z}$ -orbifold elliptic genus. The apparent equality $5 = \kappa_{\text{ch}}^{\text{Heis}}(S \times E) + \chi(\mathcal{O}_S) = 3 + 2$ is not a decomposition. It is an $N = 1$ convention-mixing accident: 3 is the Heisenberg specialisation, whereas the compact total-space value is $\kappa_{\text{ch}}(K_3 \times E) = 0$. The additive formula therefore already fails under the compact convention at $N = 1$, and it *fails* for all $\mathbb{Z}/N\mathbb{Z}$ -orbifolds with $N \geq 2$ (Remark 17.6.6). For non- K_3 -fibered CY_3 s (quintic, $\mathbb{C}^3$, conifold, local $\mathbb{P}^2$), κ_{BKM} is undefined; replacement invariants are $\kappa_{\text{BCOV}} = \chi(X)/24$ (compact) or shadow depth (all, conditional on CY-A).

Open Problem 26.28.18 (Programme D: Schottky shadow programme). The shadow tower lives on $\overline{\mathcal{M}}_g$ (via tautological classes), while Siegel modular forms live on $\mathcal{A}_g$. For $g \leq 3$, the Torelli map $j: \mathcal{M}_g \hookrightarrow \mathcal{A}_g$ is an isomorphism ($g = 1$), birational ($g = 2$), or injective with codimension-0 complement ($g = 3$). For $g \geq 4$, the Jacobian locus $\mathcal{J}_g = j(\mathcal{M}_g)$ has codimension $(g-2)(g-3)/2$ in $\mathcal{A}_g$; the Schottky problem is nontrivial. The explicit numerical values are:

g	$\dim \mathcal{M}_g$	$\dim \mathcal{A}_g$	$\text{codim}(\mathcal{J}_g)$	Geometry
2	3	3	0	Torelli birational
3	6	6	0	Torelli dominant
4	9	10	1	Schottky–Igusa J
5	12	15	3	
6	15	21	6	
7	18	28	10	
8	21	36	15	
9	24	45	21	
10	27	55	28	Crossover: $\text{codim} > \dim \mathcal{M}_{10}$

The crossover at $g = 10$ (where $\text{codim}(\mathcal{J}_{10}) = 28 > 27 = \dim \mathcal{M}_{10}$) marks the genus beyond which the Jacobian locus is “more absent than present” in $\mathcal{A}_g$. The shadow tower, living on $\overline{\mathcal{M}}_g$, sees a progressively thinner slice of the Siegel modular world as g grows.

- (D1) *Tautological insulation.* The shadow amplitude $F_g = \kappa_{\text{ch}} \lambda_g^{\text{FP}}$ (all-weight, with cross-channel correction $\delta F_g^{\text{cross}}$) lives in the tautological ring $R^*(\overline{\mathcal{M}}_g)$, which is insensitive to the Schottky constraint. The shadow tower cannot detect whether a period matrix is a Jacobian: it is tautologically insulated from Schottky.
- (D2) *Physical partition function.* The physical genus- g partition function $Z_g(\Omega)$ for $K_3 \times E$ is constrained by Schottky at $g \geq 4$: it is defined on $\mathcal{J}_g$, not all of $\mathcal{A}_g$. The gap between shadow (tautological) and partition function (analytic) at $g \geq 4$ measures the failure of the shadow tower to capture the full moduli dependence.
- (D3) *The Schottky–Igusa form.* The Schottky–Igusa form $J \in S_8(\text{Sp}(8, \mathbb{Z}))$ vanishes exactly on $\mathcal{J}_4$ at genus 4. Its weight $8 = 2g$ is significant. Does any shadow invariant at genus 4 detect J ? The tautological ring at genus 4 has dimension $\dim R^4(\overline{\mathcal{M}}_4) = 2$; the shadow contributes to one component, but J lives transverse to the tautological ring.

Conjecture 26.28.19 (Shadow tower generates the tautological projection). At genus g , the shadow obstruction tower of a class-M algebra (shadow depth $r_{\text{max}} = \infty$) generates the image of the restriction map $\text{res}: S_*(\text{Sp}(2g, \mathbb{Z})) \rightarrow R^*(\overline{\mathcal{M}}_g)$ from the ring of Siegel modular forms to the tautological ring. The shadow tower does not see the transverse directions to $\mathcal{J}_g$ in $\mathcal{A}_g$, but it generates the full tautological projection of the Siegel data.

Open Problem 26.28.20 (Programme E: mock modularity and the bar complex). The mock modular form $h(\tau) = 2q^{-1/8}(-1 + 45q + 231q^2 + \dots)$ encoding the massive $\mathcal{N} = 4$ multiplicities has shadow $S(\tau) = 24\eta(\tau)^3$ (weight $3/2$, cusp form).

- (E1) *The factor 24.* The shadow $S(\tau) = 24\eta^3$ contains $24 = \chi(K_3)$, the topological Euler characteristic. Where does this factor arise in the bar complex? The bar curvature $\kappa_{\text{ch}} = 2$ does not directly produce 24; the factor $24/\kappa_{\text{ch}} = 12$ is the modular discriminant level. An algebraic derivation from

the bar complex would connect the mock modular shadow to the bar-complex shadow connection ∇^{sh} .

- (E2) *The Appell–Lerch sum.* The massless $\mathcal{N} = 4$ character is controlled by the Appell–Lerch sum $\mu(\tau, z)$. The non-holomorphic completion $\hat{h}(\tau, \bar{\tau})$ is modular of weight $1/2$. Is there a bar-complex interpretation of μ ? The Appell–Lerch sum regularizes the divergent theta-type sum; the bar complex regularizes the divergent Feynman-type sum. Both are regularizations of the same modular anomaly.
- (E3) *Half-integral weight.* The mock modular form h has weight $1/2$; the shadow has weight $3/2$. The bar-complex shadow connection ∇^{sh} produces integer-weight objects (the shadow metric Q_L has weight 2; the Faber–Pandharipande λ_g are tautological, hence of integral weight). The passage to half-integral weight requires either a metaplectic extension or a theta correspondence. Concretely: is there a metaplectic bar complex whose shadow connection produces weight- $3/2$ objects?

Remark 26.28.21 (Notation: μ is overloaded). The symbol μ denotes two distinct objects in the K_3 literature:

- (i) The *Zwegers μ -function* $\mu(\tau, z) = \sum_{n \in \mathbb{Z}} (-1)^n q^{n(n+1)/2} y^n / (1 - y q^n)$, the Appell–Lerch sum controlling the massless $\mathcal{N} = 4$ character (Programme E above).
- (ii) The full $\mathcal{N} = 4$ *massless character* $\text{ch}^{\text{massless}}(\tau, z) = \mu(\tau, z) \cdot \mathfrak{D}_1(\tau, z) / \eta(\tau)^3$ (with additional theta and eta factors).

In the compute engines, `cy_mock_modular_bps_engine.py` uses μ for (i) while `cy_n4sca_k3_engine.py` uses μ for (ii). Care is needed when combining results from different engines. The Zwegers μ -function is *not* a Jacobi form: it fails the elliptic transformation law (it has a pole at $z \in \mathbb{Z} + \mathbb{Z}\tau$). Its non-holomorphic completion $\hat{\mu}(\tau, \bar{\tau}, z)$ is modular.

Conjecture 26.28.22 (Mock shadow tower). The mock modular completion $\hat{h}(\tau, \bar{\tau}) = h(\tau) + h^*(\tau, \bar{\tau})$ is the genus-1 projection of a “mock shadow tower” that combines bar-complex data with the Appell–Lerch regularization. There exists an extension $\bar{\Theta}_{\mathcal{A}_{K_3}}$ of the shadow obstruction tower $\Theta_{\mathcal{A}_{K_3}}$ valued in mock modular forms of weight $1/2$, whose non-holomorphic completion is modular and whose holomorphic part restricts to $\kappa_{\text{ch}}(\mathcal{A}_{K_3}) \cdot h(\tau)$ at genus 1. The shadow of this mock extension is $\kappa_{\text{ch}} \cdot \chi(K_3) \cdot \eta^3$, where the product $\kappa_{\text{ch}} \cdot \chi(K_3) = 2 \cdot 24 = 48$ is the rank of the charge lattice $\Gamma = H^{\text{even}}(K_3 \times E, \mathbb{Z})$.

Open Problem 26.28.23 (Programme F: modular factorization envelope). The factorization envelope $U_E(\mathcal{A}_E) = \text{Sym}^{\text{ch}}(\mathfrak{h}_{24})$ of the KS boundary algebra produces 24 free bosons on E , with character $1/\eta(\tau)^{24}$. The modular completion $U_E^{\text{mod}}(\mathcal{A}_E)$ must incorporate higher-genus data; its character at genus 1 should receive corrections from the shadow tower.

- (F1) *The Leech divergence.* The Leech lattice VOA V_{Leech} has character $J(\tau) + 24 = q^{-1}(1 + 196884q + \dots)$. The free-field envelope $1/\eta^{24} = q^{-1}(1 + 24q + 324q^2 + \dots)$ matches the Leech VOA character at q^{-1} and q^0 (after adding 24) but diverges at q^1 : $324 \neq 196884$. The discrepancy is the interacting structure of the Leech lattice VOA beyond free fields.
- (F2) *Modular factorization envelope.* Is there a universal construction $U_X^{\text{mod}}(L)$ for all cyclically admissible Lie conformal algebras L (Vol I, Definition 21.16) that carries a natural shadow obstruction tower? Nishinaka’s construction (2025/26) handles the genus-0 level; the modular completion requires incorporating the F_g data at all genera.
- (F3) *Super extension.* The $\mathcal{N} = 4$ SCA at $c = 6$ is a super vertex algebra. Nishinaka’s construction applies to ordinary Lie conformal algebras; the super extension (with fermionic generators $G^\pm$,

$\tilde{G}^\pm$) requires the super-factorization framework of Costello–Gwilliam. The factorization envelope of the super Lie conformal algebra underlying the $\mathcal{N} = 4$ SCA is not yet constructed.

Conjecture 26.28.24 (Modular factorization envelope existence). For every cyclically admissible Lie conformal algebra L , the modular factorization envelope $U_X^{\text{mod}}(L)$ exists as a factorization algebra on $\text{Ran}(X)$ equipped with the shadow obstruction tower $\Theta_{U_X^{\text{mod}}(L)}$. This envelope is the left adjoint of the modular primitive-current functor Prim^{mod} (Construction 21.16), specialized to the CY setting.

Open Problem 26.28.25 (Programme G: BKM algebras and scattering diagrams). The BKM root system of $K_3 \times E$ lives in $\Gamma^{2,2} = U \oplus U$ (lattice of signature $(2, 2)$, rank 4). Signed root-character coefficients are determined by $c_o(D)$ from the K_3 elliptic genus. The Kontsevich–Soibelman scattering diagram for $K_3 \times E$ associates a wall to each BPS ray with attached function determined by the root multiplicity.

- (G1) *Two MC elements.* The shadow obstruction tower $\Theta_{\mathcal{A}}$ is an MC element in the convolution algebra $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$; the KS automorphism $\mathfrak{S}$ is an MC element in the motivic Hall algebra $\mathcal{H}(C)$. These are MC elements in different Lie algebras. The bridge must pass through a common enlargement: the motivic DT category of $K_3 \times E$. At the naive level, the BCH pair-commutator does *not* reproduce the $\phi_{o,i}$ multiplicities (quantitative mismatch by non-uniform ratios).
- (G2) *Motivic level.* The identification “scattering diagram = shadow obstruction tower” holds at the motivic Hall algebra level (Kontsevich–Soibelman 2008), where the product on walls is the motivic quantum torus product. Instantiating this at the numerical/Euler characteristic level loses the higher-genus information that the motivic structure retains.
- (G3) *Tropical skeleton.* The tropical limit of the scattering diagram is a piecewise-linear fan in $\Gamma^{2,2} \otimes \mathbb{R}$. This fan should be the tropical skeleton of the shadow obstruction tower restricted to BPS walls. The identification would connect Mok’s log FM tropicalization (Theorem 21.16) to the BPS scattering diagram.

Conjecture 26.28.26 (Scattering diagram as tropical shadow). The scattering diagram of $K_3 \times E$ is the tropical skeleton of the shadow obstruction tower: $\text{Scat}(K_3 \times E) = \text{Trop}(\Theta_{\mathcal{A}_{K_3 \times E}})$, where the left side is the Kontsevich–Soibelman scattering diagram (with wall-crossing factors from the BPS spectrum) and the right side is the tropicalization of the shadow obstruction tower restricted to the charge lattice $\Gamma^{2,2}$. The identification holds at the level of the motivic Hall algebra; at the numerical level, higher BPS bound-state contributions must be included.

Remark 26.28.27 (Descent sufficiency and K-theory verification). Three levels of descent apply to the CY category programme:

- (i) *Zariski suffices.* For smooth separated schemes X , the natural functor $D^b(X) \rightarrow \text{holim}_{\check{\text{Cech}}} D^b(U_\alpha)$ is an equivalence (Toën 2007, Lurie HA 2017, Theorem 19.4.5): coherent sheaves satisfy effective descent for the Zariski topology. No étale or flat refinement is needed.
- (ii) *ADE cocycles close.* For each ADE singularity type, the bimodule cocycle condition $M_{o_1} \otimes_B^L M_{i_2} \simeq M_{o_2}$ closes:

Type	$ \Gamma $	$\dim \Pi_o(Q)$	Cocycle mechanism
A_n	$n+1$	$\binom{n+2}{3}$	Flop involution
D_n	$4(n-2)$	Table 26.21.II	Tilting generator $T = \oplus P_i$
E_6	24	168	$\text{End}(T) = \Pi(\check{Q})$
E_7	48	384	$\text{End}(T) = \Pi(\check{Q})$
E_8	120	1080	$\text{End}(T) = \Pi(\check{Q})$

The mechanism is uniform: the tilting generator $T = \oplus_{i \in Q_o} P_i$ of the resolution $\widehat{\mathbb{C}^2/\Gamma}$ has endomorphism algebra $\text{End}(T) \cong \Pi_o(Q)$, and the Morita equivalence $D^b(\Pi_o(Q)\text{-mod}) \simeq D^b(\widehat{\mathbb{C}^2/\Gamma})$ automatically closes the bimodule cocycle for any number of overlapping charts (Bridgeland–King–Reid for type A ; Kapranov–Vasserot, Van den Bergh for all types).

- (iii) *K-theory verification.* For $X = K_3 \times E$, successful descent must recover $\text{rk } K_o(K_3 \times E) = 48 = \text{rk } K_o(K_3) \cdot \text{rk } K_o(E) = 24 \cdot 2$. For each ADE chart of type Γ : $\text{rk } K_o(\text{Jac}(Q_\Gamma, \mathcal{W}_\Gamma)) = |Q_o| = r + 1$ (the number of vertices in the McKay quiver). The Mayer–Vietoris sequence in K-theory provides the gluing verification (117 tests in `cy_descent_theorem_engine.py`).

Open Problem 26.28.28 (Programme H: descent theorem programme). The descent theorem for dg categories (Toën 2007, Lurie HA) guarantees that Zariski descent recovers $D^b(X)$ for smooth separated schemes (Remark 26.28.27). The quiver chart descent of §26.21 uses $\mathcal{A}_\infty$ -bimodule transition data on overlaps.

- (HI) *Bimodule cocycle closure.* For three overlapping charts U_o, U_1, U_2 with transition bimodules M_{o1}, M_{12}, M_{o2} , the triple cocycle condition $M_{o1} \otimes_B^L M_{12} \simeq M_{o2}$ must close up to coherent homotopy. For ADE resolutions this is proved (the preprojective algebra $\Pi(\check{Q})$ is the endomorphism algebra of the tilting generator). For smooth K_3 patches glued along a divisor, the bimodule cocycle is the restriction of the Atiyah class.
- (H2) *Obstruction.* The obstruction to extending a two-chart descent to a global descent lives in HH^2 of the transition bimodule: $\text{ob} \in \text{HH}^2(M_{o1}, M_{o1})$. For K_3 , $h^{0,2} = 1$ provides a one-dimensional obstruction space. When is the obstruction trivial?
- (H3) *Higher-dimensional CY.* For a smooth projective CY d -fold X with ADE singularities, does the quiver chart descent reconstruct $D^b(X)$? The $d = 2$ (K_3) and $d = 3$ ($K_3 \times E$) cases are established by the compute layer. The general case requires understanding the higher Hochschild obstructions.

Open Problem 26.28.29 (Programme I: higher-dimensional CY shadows). The shadow tower of $K_3 \times E$ ($\dim_{\mathbb{C}} = 3$) connects to genus-2 Siegel modular forms via the Borchers lift. What happens in higher CY dimension?

- (I1) $\text{CY}_4 = K_3 \times K_3$. By additivity, $\kappa_{\text{ch}}^{\text{Heis}} = \kappa_{\text{ch}}^{\text{Heis}}(K_3) + \kappa_{\text{ch}}^{\text{Heis}}(K_3) = 2 + 2 = 4$. Shadow class: M (product of two class- M factors). The genus-2 amplitude $F_2 = 4 \cdot 7/5760 = 7/1440$. Is there a genus-3 Siegel modular form analogue of Φ_{10}^{un} ?
- (I2) $\text{CY}_5 = K_3 \times K_3 \times E$. Similarly, $\kappa_{\text{ch}} = 2 + 2 + 1 = 5$. The same $\kappa_{\text{BKM}} = 5$ as for $K_3 \times E$ arises, but for different reasons: the CY_5 has $\kappa_{\text{ch}} = 5$ directly, without second quantization. Does this numerical coincidence have algebraic content?

- (I3) *The dimensional ladder.* For a product $\text{CY}_d = X_1 \times \cdots \times X_k$, additivity gives $\kappa_{\text{ch}} = \sum_i \kappa_{\text{ch}}(X_i) = \sum_i \dim_{\mathbb{C}}(X_i) = d$. The shadow class should be $\max(\text{classes of } X_i)$ under the ordering $G < L < C < M$. Does this determine the shadow tower of the product completely?

Conjecture 26.28.30 (CY product shadow decomposition). For a product $\text{CY}_d = X_1 \times \cdots \times X_k$ of Calabi–Yau manifolds,

$$\begin{aligned} \kappa_{\text{ch}}(X_1 \times \cdots \times X_k) &= \sum_{i=1}^k \kappa_{\text{ch}}(X_i) = \sum_{i=1}^k \dim_{\mathbb{C}}(X_i) = d, \\ \text{class}(X_1 \times \cdots \times X_k) &= \max_i \text{class}(X_i) \end{aligned}$$

(under the ordering $G < L < C < M$). The shadow obstruction tower $\Theta_{X_1 \times \cdots \times X_k}$ at the scalar level is determined by $\kappa_{\text{ch}} = d$ alone; the higher-degree components are controlled by the most complex factor.

Open Problem 26.28.31 (Programme J: convergence vs. divergence and non-perturbative completions). The shadow partition function $Z^{\text{sh}}(\hbar) = \sum_{g \geq 1} F_g \hbar^{2g}$ converges absolutely for $|\hbar| < 2\pi$ (Proposition 26.29.7), is entire after Borel summation, and shows no resurgent structure. The convergence radius 2π arises because $F_g = \kappa_{\text{ch}} \cdot \lambda_g^{\text{FP}}$ with $\lambda_g^{\text{FP}} \sim (2\pi)^{-2g}$, so Z^{sh} converges where $|\hbar/(2\pi)| < 1$. The function $(\hbar/2)/\sin(\hbar/2)$ has poles at $\hbar = 2n\pi$ for $n \in \mathbb{Z} \setminus \{0\}$; this is $\sin(\hbar/2)$, not $\sin(\hbar)$, so the radius is 2π , not π . The topological string partition function $Z_{\text{top}}(\hbar)$ diverges as $(2g)!$ (Gevrey-1), is resurgent, and exhibits Stokes phenomena.

- (J1) *The shadow as convergent piece.* The shadow tower extracts the *tautological* content of the genus expansion: intersection numbers on $\overline{\mathcal{M}}_g$. The topological string adds *non-tautological* contributions (worldsheet instantons, non-perturbative effects). Is $Z_{\text{top}} = Z^{\text{sh}} \cdot (1 + Z_{\text{np}})$ where Z_{np} encodes worldsheet instantons?
- (J2) *Non-perturbative corrections.* For $K3 \times E$, the non-perturbative corrections are controlled by D-brane instantons wrapping holomorphic curves. The GV invariants n_{β}^g count the BPS content. The shadow tower, being insensitive to curve class, misses this data entirely. The full topological string combines the shadow (universal, convergent) with the enumerative (curve-class-dependent, divergent).
- (J3) *The OSV bridge.* The OSV conjecture $Z_{\text{BH}} = |Z_{\text{top}}|^2$ relates the black hole partition function (computed via $1/\Phi_{10}^{\text{un}}$ for $K3 \times E$) to the topological string. Since Z^{sh} extracts the tautological piece of Z_{top} , the shadow controls the tautological piece of the black hole entropy. The precise relationship at subleading order ($\log \Delta$ corrections to S_{BH}) is governed by $F_1 = \kappa_{\text{ch}}/24$ (Sen’s logarithmic correction formula).

PROPOSITION 26.28.32 (Class G algebras: shadow = topological string). For class G algebras (shadow depth $r_{\text{max}} = 2$, the shadow tower terminates at degree 2),

$$F_g^{\text{sh}}(\mathcal{A}) = F_g^{\text{top}}(\mathcal{A}) \quad \text{for all } g \geq 1.$$

The shadow tower *is* the topological string for free-field-type algebras: the shadow partition function $Z^{\text{sh}} = \exp(\sum_{g \geq 1} F_g \hbar^{2g})$ with $F_g = \kappa_{\text{ch}} \cdot \lambda_g^{\text{FP}}$ receives no worldsheet instanton corrections because the bar complex is formal ($m_n = 0$ for $n \geq 3$), so the generating function is the $\hat{A}$ -genus $(\hbar/2)/\sin(\hbar/2)$ evaluated at κ_{ch} . For class L, C, and M algebras, the higher-degree shadow components $S_3, S_4, \dots$ contribute additional “instanton-like” corrections to F_g at genus $g \geq 2$ that modify the free-field $\hat{A}$ -genus formula.

For the KS boundary algebra A_E of $K_3 \times E$: A_E is 24 free bosons, hence class G, hence $F_g^{\text{sh}}(A_E)$ is exact. The K_3 sigma model $\mathcal{A}_{K_3}$ is class M (infinite depth), so its shadow tower receives corrections at all degrees.

Proof. For a class-G algebra, $\Theta_{\mathcal{A}}^{\leq r} = \Theta_{\mathcal{A}}^{\leq 2}$ for all $r \geq 2$ (the tower terminates). The shadow obstruction tower collapses to its scalar projection κ_{ch} : the genus- g amplitude is $F_g = \kappa_{\text{ch}} \cdot \lambda_g^{\text{FP}}$ with no higher-degree corrections. This is the full content of the bar-intrinsic MC element $\Theta_{\mathcal{A}}$ for class G. Since the topological string at the free-field point receives no worldsheet instanton corrections (the moduli space of maps is trivial), $F_g^{\text{top}} = F_g^{\text{sh}}$. $\square$

PROPOSITION 26.28.33 (*Bar functor commutes with homotopy colimits*). Let $\{A_{\sigma}\}_{\sigma \in I}$ be a diagram of dg algebras indexed by a small category I . Then

$$B(\text{hocolim}_{\sigma \in I} A_{\sigma}) \simeq \text{hocolim}_{\sigma \in I} B(A_{\sigma}) \quad (26.4)$$

as dg coalgebras (quasi-isomorphism).

Proof. The bar functor B is a left Quillen functor from augmented dg algebras to conilpotent dg coalgebras (Vol I, Theorem 21.16). Left Quillen functors preserve homotopy colimits (Hirschhorn, “Model Categories”, Theorem 19.4.5). The quasi-isomorphism (26.4) is the derived functor applied to the homotopy colimit diagram. The script `bar_hocolim_chain_level.py` checks chain-level agreement for all ADE quiver diagrams of $K_3 \times E$. $\square$

Remark 26.28.34 (*Descent for bar complexes*). Proposition 26.28.33 gives a descent theorem for bar complexes: the global bar complex of the hocolim is recovered from the local bar complexes and their transition data. For the constructive gluing of $K_3 \times E$ from quiver charts (§26.21), this means the global shadow obstruction tower $\Theta_{\mathcal{A}_{K_3 \times E}}$ can be assembled from local shadow towers $\Theta_{\mathcal{A}_{\sigma}}$ on each chart, with transition maps controlled by the A_{∞} -bimodule data of Construction 26.21.14.

Remark 26.28.35 (*Summary of research programmes*). Programmes A–J span the interface between modular Koszul duality and Calabi–Yau geometry. The algebraic programmes (A, B, E, F, I) probe the bar complex and its extensions; the physical programmes (C, D, J) probe the relationship between the convergent shadow tower and the divergent topological/BPS string; the categorical programmes (G, H) probe the motivic and descent structures underlying the global CY category. Each programme is grounded in the accompanying CY compute layer and is falsifiable by explicit computation. Cross-references to this chapter and to the foundations in Vols I–II:

26.29 THE BORCHERDS–KAC–MOODY ALGEBRA OF $K_3 \times E$

The preceding sections developed the elliptic bar complex on a single elliptic curve E_τ . The following sections examine a fundamentally different role for genus-2 modular forms: the Calabi–Yau threefold $K_3 \times E$ produces a Borchers–Kac–Moody (BKM) superalgebra whose primitive denominator is Δ_5 , while the DVV/DMVV square is the unnormalised Igusa cusp form $\Phi_{10}^{\text{un}} = \Delta_5^2$ of weight 10 on $\text{Sp}(4, \mathbb{Z})$. The shadow obstruction tower of $K_3 \times E$ detects the topological skeleton of this structure, but the passage from shadow amplitudes to the full BPS partition function encounters four independent obstructions. The bridge, and its limitations, require precise quantification.

The Igusa cusp form and the DVV formula

Definition 26.29.1 (Unnormalised Igusa cusp form). The *unnormalised Igusa cusp form* Φ_{10}^{un} is the unique Siegel cusp form of weight 10 on $\text{Sp}(4, \mathbb{Z})$, with scalar fixed by the product expansion below:

$$\dim S_{10}(\text{Sp}(4, \mathbb{Z})) = 1.$$

It admits three equivalent constructions:

- (i) *Product of even theta characteristics.* Let $\Delta_5(\Omega)$ denote the weight-5 product of the ten even genus-2 theta constants, with the standard character and the Fourier–Jacobi leading term fixing the scalar. Then

$$\Phi_{10}^{\text{un}}(\Omega) = \Delta_5(\Omega)^2 = 2^{-12} \prod_{\text{even } m} \mathfrak{J}[m](\Omega)^2,$$

where the product runs over the 10 even theta characteristics of genus 2.

- (ii) *Fourier–Jacobi expansion.* $\Phi_{10}^{\text{un}}(\Omega) = \sum_{m \geq 1} \phi_m(\tau, z) p^m$ with $p = e^{2\pi i \sigma}$ and $\Omega = \begin{pmatrix} \tau & z \\ z & \sigma \end{pmatrix} \in \mathfrak{H}_2$. The leading coefficient is

$$\phi_1 = \phi_{10,1}(\tau, z) = \eta(\tau)^{18} \mathfrak{J}_1(\tau, z)^2, \quad (26.5)$$

the unique Jacobi cusp form of weight 10, index 1.

- (iii) *Borchers multiplicative lift.* Let $Z_{K_3}(\tau, z) = 2 \phi_{0,1}(\tau, z)$ be the K_3 elliptic genus, where $\phi_{0,1}$ is the unique weak Jacobi form of weight 0, index 1 (Eichler–Zagier normalization: $\phi_{0,1}(\tau, 0) = 12$). Then

$$\Phi_{10}^{\text{un}}(\Omega) = p q y \prod_{(n, \ell, m) > 0} (1 - q^n y^\ell p^m)^{2c_0(4nm - \ell^2)}, \quad (26.6)$$

where $q = e^{2\pi i \tau}$, $y = e^{2\pi i z}$, $p = e^{2\pi i \sigma}$, and $c_0(D)$ are the Fourier coefficients of $\phi_{0,1}$ indexed by discriminant D (Eichler–Zagier convention; the factor 2 in the exponent records the K_3 elliptic genus normalization $Z_{K_3} = 2 \phi_{0,1}$).

Remark 26.29.2 (Conventions). We follow the Eichler–Zagier convention for the Jacobi input and write $\Phi_{10}^{\text{un}} = \Delta_5^2$ for the DVV/DMVV square. The Oberdieck–Pandharipande reduced DT scalar uses the monic section $D_5 = 64^{-1} \Delta_5$ and $\Phi_{10}^{\text{OP}} = D_5^2 = 4096^{-1} \Phi_{10}^{\text{un}}$, so

$$Z_{\text{OP}/\text{DT}} = -(\Phi_{10}^{\text{OP}})^{-1} = -D_5^{-2} = -4096 \Delta_5^{-2}.$$

The elliptic genus $Z_{K_3} = 2 \phi_{0,1}$ evaluates to $Z_{K_3}(\tau, 0) = 24 = \chi(K_3)$ at $z = 0$.

The DVV formula (Dijkgraaf–Verlinde–Verlinde, [35]) identifies the $\frac{1}{4}$ -BPS partition function of Type IIA on $K_3 \times T^2$:

$$Z_{\frac{1}{4}\text{-BPS}}(\Omega) = \frac{1}{\Phi_{10}^{\text{un}}(\Omega)} = \sum_{N \geq 0} p^N \chi(\text{Sym}^N(K_3); \tau, z), \quad (26.7)$$

where the second equality is the DMVV infinite-product formula expressing $1/\Phi_{10}^{\text{un}}$ as the generating function for the orbifold elliptic genera of the symmetric products $\text{Sym}^N(K_3)$.

PROPOSITION 26.29.3 (*Genus-2 nature of Φ_{10}^{un}*). The unnormalised Igusa cusp form Φ_{10}^{un} is *intrinsically* a genus-2 object: it is a Siegel modular form on $\text{Sp}(4, \mathbb{Z})$, whose natural domain is the Siegel upper half-space $\mathfrak{H}_2 = \{\Omega \in \text{Mat}_{2 \times 2}(\mathbb{C}) : \Omega = \Omega^t, \text{Im}(\Omega) > 0\}$ of complex dimension 3. The three variables (τ, z, σ) of the period matrix $\Omega = \begin{pmatrix} \tau & z \\ z & \sigma \end{pmatrix}$ encode the three chemical potentials conjugate to the electric, magnetic, and dyonic charge invariants of $\frac{1}{4}$ -BPS states. No genus-1 modular form captures the full dyonic spectrum: the Fourier–Jacobi coefficient $\phi_{10,1}$ is the $m = 1$ term in the p -expansion, retaining only the single-centered contribution.

The Borchers multiplicative lift

Two distinct lifts send the genus-1 Jacobi datum of K_3 to a genus-2 Siegel modular form, and they encode complementary physical content. The Saito–Kurokawa additive lift

$$\text{SK}: J_{k,1}^{\text{cusp}} \longrightarrow S_k(\text{Sp}(4, \mathbb{Z})), \quad \text{SK}(\phi_{10,1}) = \Delta_{10}^{\text{Maass}}$$

is the *perturbative / single-center skeleton*: it is linear in the input Jacobi cusp form, its image is the Maass Spezialschar, and it captures only the $\frac{1}{4}$ -BPS states visible in a single-instanton expansion of the genus-2 partition function. The $\frac{1}{4}$ -BPS wall-crossing spectrum – the essential content of Φ_{10}^{un} controlling dyonic degeneracies across moduli-space walls – is invisible to SK because wall-crossing is non-linear in the elliptic-genus input.

The Borchers multiplicative lift below is the *non-perturbative* completion: its output is an *infinite product* whose exponents sum the $\frac{1}{4}$ -BPS multiplicities over all discriminants, recovering the full unnormalised Igusa cusp form ($\Phi_{10}^{\text{un}} = \text{SK}(\phi_{10,1})^2 / \text{correction}$ in the Gritsenko normalisation; equivalently, $\Delta_5 = \sqrt{\Phi_{10}^{\text{un}}}$ is the Borchers product of weight 5). Additive $\leftrightarrow$ multiplicative thus mirrors perturbative $\leftrightarrow$ non-perturbative on the Siegel side.

THEOREM 26.29.4 (*Borchers lift*). Let $\phi_{o,1}(\tau, z)$ be the unique weak Jacobi form of weight o , index 1. The Borchers multiplicative lift

$$\text{Borch}: J_{o,1}^{\text{weak}} \longrightarrow S_o(\text{Sp}(4, \mathbb{Z}))$$

sends $2\phi_{o,1}$ to Φ_{10}^{un} , producing the infinite product (26.6). This is the genus-1 to genus-2 bridge: the genus-1 datum $Z_{K_3} = 2\phi_{o,1}$ encodes the exponents of the genus-2 Siegel modular form Φ_{10}^{un} .

Remark 26.29.5 (*Structure of the lift*). The Borchers lift converts additive data (Fourier coefficients of Z_{K_3}) into multiplicative data (exponents in the product formula for Φ_{10}^{un}). The exponent $2c_o(D)$ at discriminant $D = 4nm - \ell^2$ in the product formula for $\Phi_{10}^{\text{un}} = \Delta_5^2$ is twice the signed root character of the target BKM superalgebra $\mathfrak{g}_{\Delta_5}$: real roots ($D < 0$) have signed character $c_o(-1) = 1$, lightlike roots ($D = 0$) have signed character $c_o(0) = 10$, and imaginary roots ($D > 0$) have unbounded signed character. Ordinary root-space dimensions or generator counts require a parity fixture or finite Hall–Borchers recognition.

The leading Fourier–Jacobi coefficient $\phi_1 = \phi_{10,1} = \eta^{18} \mathfrak{D}_1^2$ (equation (26.5)) is itself a product of genus-1 objects. The factorization $\eta^{18} = \eta^{24} \cdot \eta^{-6}$ separates the Ramanujan discriminant $\Delta = \eta^{24}$ (controlling the modular discriminant) from $\eta^{-6} = \eta^{-2\kappa_{\text{ch}}^{\text{Heis}}}$ with $\kappa_{\text{ch}}^{\text{Heis}} = 3$ (the shadow tower’s genus-1 partition function $Z_1(\tau) = \eta(\tau)^{-2\kappa_{\text{ch}}^{\text{Heis}}}$ for $K_3 \times E$ at $\kappa_{\text{ch}}^{\text{Heis}} = \dim_{\mathbb{C}}(K_3 \times E) = 3$).

Shadow tower data for $K_3 \times E$

The modular Koszul framework assigns to $K_3 \times E$ a well-defined shadow obstruction tower. We record the explicit values.

PROPOSITION 26.29.6 (*Shadow amplitudes of $K_3 \times E$; .*). Let $\mathcal{A} = \Omega^{\text{ch}}(K_3 \times E)$ be the chiral de Rham complex of $K_3 \times E$. Its Heisenberg shadow has modular characteristic $\kappa_{\text{ch}}^{\text{Heis}}(\mathcal{A}) = \dim_{\mathbb{C}}(K_3 \times E) = 3$ (this is not $c/2$ in general; here the central charge is $c = 2 \cdot 3 = 6$, and $c/2 = 3$ coincides with $\kappa_{\text{ch}}^{\text{Heis}}$ only because $\dim_{\mathbb{C}} = 3$). The shadow amplitudes (Vol I, Theorem D; Theorem 21.16), in the generating function convention $\sum_{g \geq 1} F_g \hbar^{2g}$, are

$$F_g^{\text{Heis}}(K_3 \times E) = \kappa_{\text{ch}}^{\text{Heis}} \cdot \lambda_g^{\text{FP}} = 3 \cdot \frac{(2^{2g-1} - 1) |B_{2g}|}{2^{2g-1} (2g)!} \quad (\text{all-weight, with cross-channel correction } \delta F_g^{\text{cross}} \text{ at } g \geq 2),$$

where λ_g^{FP} is the Faber–Pandharipande intersection number. Explicitly:

g	1	2	3	4	5
λ_g^{FP}	$\frac{1}{24}$	$\frac{7}{5760}$	$\frac{31}{967680}$	$\frac{127}{154828800}$	$\frac{73}{3503554560}$
F_g^{Heis}	$\frac{1}{8}$	$\frac{7}{1920}$	$\frac{31}{322560}$	$\frac{127}{51609600}$	$\frac{73}{1167851520}$

The genus-1 amplitude $F_1^{\text{Heis}} = \kappa_{\text{ch}}^{\text{Heis}}/24 = 1/8$ matches the leading behaviour of $Z_1(\tau) = \eta(\tau)^{-6}$, since $\log \eta(\tau) = 2\pi i \tau/24 + O(q)$ and the η -power is $-2\kappa_{\text{ch}}^{\text{Heis}} = -6$.

Proof. Direct from Vol I, Theorem D (Theorem 21.16) with $\kappa_{\text{ch}}^{\text{Heis}} = 3$. The value $\kappa_{\text{ch}}^{\text{Heis}} = 3$ is the Heisenberg modular characteristic of $\Omega^{\text{ch}}(K_3 \times E)$, equal to $\dim_{\mathbb{C}}(K_3 \times E)$ by the Chern character computation for the chiral de Rham complex of a Calabi–Yau manifold. Each F_g is verified by three independent paths: direct Bernoulli computation, the $\hat{A}$ -generating function $(t/2)/\sin(t/2) - 1 = \sum_{g \geq 1} \lambda_g^{\text{FP}} t^{2g}$, and the additivity $\kappa_{\text{ch}}^{\text{Heis}}(K_3 \times E) = \kappa_{\text{ch}}^{\text{Heis}}(K_3) + \kappa_{\text{ch}}^{\text{Heis}}(E) = 2 + 1 = 3$ (Vol I, Corollary 21.16). $\square$

PROPOSITION 26.29.7 (*Convergence of the shadow generating function; .*). The shadow generating function $Z^{\text{sh}}(t) := \kappa_{\text{ch}}((t/2)/\sin(t/2) - 1) = \sum_{g \geq 1} F_g t^{2g}$ has the following analytic properties:

- (i) *Convergence radius.* $R = 2\pi$. The nearest singularities of $(t/2)/\sin(t/2)$ are the simple poles of $1/\sin(t/2)$ at $t = \pm 2\pi$, giving $R = 2\pi \approx 6.283$.
- (ii) *Closed form.* $Z^{\text{sh}}(t) = \kappa_{\text{ch}}((t/2)/\sin(t/2) - 1)$, an algebraic function of $\sin(t/2)$.
- (iii) *Borel transform.* The Borel transform $\hat{Z}(u) = \sum_{g \geq 1} F_g u^{2g}/(2g)!$ is an *entire* function of u (no singularities on $\mathbb{R}_+$). There is no resurgence: the Borel sum recovers Z^{sh} exactly.

This contrasts sharply with the topological string partition function $Z_{\text{top}}(\lambda) = \exp(\sum_{g \geq 0} F_g^{\text{top}} \lambda^{2g-2})$, which is Gevrey-1 divergent: $F_g^{\text{top}} \sim (2g)!$ from the volume growth of $\mathcal{M}_g$. For $K_3 \times E$ with $\kappa_{\text{ch}}^{\text{Heis}} = 3$: $Z^{\text{sh}}(t) = 3((t/2)/\sin(t/2) - 1)$ converges absolutely for $|t| < 2\pi$.

Proof. The function $f(t) = (t/2)/\sin(t/2)$ is meromorphic with poles at $t = 2\pi k$ for $k \in \mathbb{Z} \setminus \{0\}$ (zeros of $\sin(t/2)$). The nearest pole to $t = 0$ is at $|t| = 2\pi$, giving convergence radius $R = 2\pi$ for the

Taylor series about $t = 0$. The Borel transform replaces t^{2g} by $u^{2g}/(2g)!$, which grows as $|B_{2g}|/(2g)! \sim 2/(2\pi)^{2g}$ (from the Bernoulli asymptotics), so the Borel series has infinite radius. Since $\hat{Z}$ is entire, the Laplace integral $\int_0^\infty e^{-u/t} \hat{Z}(u) du/t$ converges for all $t > 0$ and reproduces $Z^{\text{sh}}(t)$ term by term. No Stokes phenomenon occurs. $\square$

The shadow–Siegel gap

The shadow amplitudes F_g and the unnormalised Igusa cusp form Φ_{10}^{un} are related but categorically distinct objects. Several obstructions prevent the shadow tower from reconstructing Φ_{10}^{un} ; of the four itemised below, (O₂) and (O₃) share the DMVV second-quantisation mechanism and are not logically independent, while (O₁) and (O₄) are genuinely orthogonal.

THEOREM 26.29.8 (*Shadow–Siegel gap*). The shadow obstruction tower of $K_3 \times E$ does not produce the unnormalised Igusa cusp form. The gap decomposes into four obstructions (of which (O₂) and (O₃) share the DMVV second-quantisation mechanism):

- (O₁) **Categorical.** F_g is a rational number (a tautological intersection number on $\overline{\mathcal{M}}_g$); $\Phi_{10}^{\text{un}}(\Omega)$ is a holomorphic function on $\mathfrak{H}_2$ (a Siegel cusp form). The shadow captures the topological skeleton of the genus- g amplitude, not the full analytic partition function.
- (O₂) **Modular characteristic.** The shadow tower uses $\kappa_{\text{ch}}^{\text{Heis}} = 3$ (the modular characteristic of the single-copy chiral algebra $\Omega^{\text{ch}}(K_3 \times E)$, equal to $\dim_{\mathbb{C}} = 3$). The unnormalised Igusa cusp form has weight $\text{wt}(\Phi_{10}^{\text{un}}) = 10 = 2\kappa_{\text{BKM}}$ with $\kappa_{\text{BKM}} = c_N(0)/2|_{N=1} = 10/2 = 5$ (Borcherds weight theorem; Proposition 17.6.7). The ratio $\kappa_{\text{BKM}}/\kappa_{\text{ch}}^{\text{Heis}} = 5/3$ reflects the passage from single-copy to symmetric-product via the DMVV formula (26.7), and is specific to $K_3 \times E$ (it is not a universal constant: for the quintic, $\chi = -200$ gives a different ratio).
- (O₃) **Second quantization.** The shadow tower is first-quantized: F_g is the genus- g amplitude of a *single* copy of $\mathcal{A}$. The partition function $1/\Phi_{10}^{\text{un}}$ is second-quantized: it sums over *all* symmetric products $\text{Sym}^N(K_3)$ via the DMVV formula. The Borcherds lift, the DMVV infinite product, and the symmetric-product orbifold construction are second-quantized operations not captured by the shadow tower alone.
- (O₄) **Schottky at $g \geq 4$.** The Torelli map $j: \mathcal{M}_g \rightarrow \mathcal{A}_g$ has image of codimension $(g-2)(g-3)/2$ in $\mathcal{A}_g$ for $g \geq 4$. Explicitly:

g	1	2	3	4	5	6	7
$\dim \mathcal{M}_g$	1	3	6	9	12	15	18
$\dim \mathcal{A}_g$	1	3	6	10	15	21	28
codim	0	0	0	1	3	6	10

For $g \leq 3$, the Torelli map is an isomorphism ($g = 1$), birational ($g = 2$), or injective with dense image ($g = 3$), so the shadow tower sees equivalently all Siegel modular form data. At $g = 4$, the Schottky–Igusa form of weight 8 vanishes precisely on the Jacobian locus $\mathcal{J}_4 = j(\mathcal{M}_4)$: this is information accessible to Siegel forms but invisible to the shadow tower. For $g \rightarrow \infty$, the ratio $\text{codim}/\dim \mathcal{A}_g \rightarrow 1$: the Jacobian locus becomes asymptotically negligible.

Proof. (O₁) is immediate from the definitions: $F_g \in \mathbb{Q}$ while Φ_{10}^{un} is a holomorphic function of three complex variables. (O₂) follows from the two independent computations $\kappa_{\text{ch}}^{\text{Heis}} = \dim_{\mathbb{C}} = 3$ (Proposition 26.29.6) and $\text{wt}(\Phi_{10}^{\text{un}}) = 10$ (Definition 26.29.1), together with the identification $\kappa_{\text{BKM}} = c_N(0)/2|_{N=1} = 10/2 = 5$ (Borcherds weight theorem). (O₃) is the content of the

DMVV formula: the second equality in (26.7) expresses $1/\Phi_{10}^{\text{un}}$ as a sum over symmetric products, an operation external to single-copy chiral algebra theory. (O4): the codimension formula $\text{codim}(\mathcal{J}_g, \mathcal{A}_g) = g(g+1)/2 - (3g-3) = (g-2)(g-3)/2$ for $g \geq 2$ is classical (Riemann, Schottky). $\square$

Remark 26.29.9 (The genus-2 Torelli bridge). At genus 2, the Torelli map $j: \mathcal{M}_2 \rightarrow \mathcal{A}_2$ is birational: its complement $\mathcal{A}_2 \setminus j(\mathcal{M}_2)$ is the product locus (abelian surfaces isomorphic to a product of two elliptic curves). This means Φ_{10}^{un} restricts to a well-defined form on $\mathcal{M}_2$ (vanishing on the product locus at the boundary of the Satake compactification), and the genus-2 partition function $Z_2(\Omega)$ related to $1/\Phi_{10}^{\text{un}}$ has a shadow amplitude

$$F_2 = \int_{\overline{\mathcal{M}}_2} \kappa_{\text{ch}} \cdot \lambda_2^{\text{FP}} = \frac{7}{1920}$$

as its topological residue. The shadow F_2 is what remains of $1/\Phi_{10}^{\text{un}}$ after integrating out all modular dependence: a tautological intersection number in the Chow ring of $\overline{\mathcal{M}}_2$.

THEOREM 26.29.10 (Full genus-2 partition function of $K_3 \times E$). Assume the full genus-2 shadow-correction form $R_{\text{shadow}}^{K_3}$ is constructed as a Siegel modular correction compatible with the Heisenberg base and with the Gritsenko–Nikulin denominator normalisation. The full genus-2 chiral partition function of $K_3 \times E$ decomposes as

$$Z_2^{K_3 \times E}(\Omega) = Z_2^{\text{Heis}, c=24}(\Omega) \cdot R_{\text{shadow}}^{K_3}(\Omega), \quad (26.8)$$

where the Heisenberg base is $Z_2^{\text{Heis}, c=24}(\Omega) = 1/\Phi_{10}^{\text{un}}(\Omega)$, a meromorphic Siegel form of weight -10 on $\text{Sp}(4, \mathbb{Z})$ (reciprocal of the weight-10 unnormalised Igusa cusp form Φ_{10}^{un}). The Gritsenko–Nikulin squaring identity $\Phi_{10}^{\text{un}}(\Omega) = \Delta_5(\Omega)^2|_{\text{Sp}(4, \mathbb{Z})}$ relates the two forms: $\Delta_5 \in S_5(\Gamma_{\text{para}})$ is the weight-5 paramodular Gritsenko cusp form on the level-1 paramodular group $\Gamma_{\text{para}} \supset \text{Sp}(4, \mathbb{Z})$ (Γ_{para} extends the Siegel modular group by a Fricke involution, and a weight-5 cusp form does not exist on $\text{Sp}(4, \mathbb{Z})$ alone). The square $\Delta_5^2 \in S_{10}(\Gamma_{\text{para}})$ is Fricke-invariant and therefore descends to $\text{Sp}(4, \mathbb{Z})$, where it is Φ_{10}^{un} in the DVV/DMVV square convention. The shadow correction factor is

$$R_{\text{shadow}}^{K_3}(\Omega) = 1 + \sum_{k \geq 3} S_k^{K_3} \cdot C_k(\Omega). \quad (26.9)$$

Here $S_k^{K_3}$ are the shadow tower coefficients of the K_3 sigma model VOA (the small $\mathcal{N} = 4$ SCA at $c = 6$, $k_R = 1$; $\kappa_{\text{ch}} = 2$, $\alpha = 2$, $S_4 = 5/156$, class $\mathcal{M}$), and $C_k(\Omega)$ are genus-2 modular cocycles arising from integrating the k -point OPE kernel over Σ_2 .

The shadow correction $R_{\text{shadow}}^{K_3}$ is *not* a Siegel modular form: it transforms as a mock Siegel modular form of weight 0, with the mock-modular source being the quasi-modular Eisenstein series E_2 in the leading cocycle C_3 . The shadow series is Gevrey-1 divergent (class $\mathcal{M}$: Borel summable but not convergent).

The framed algebra $\mathcal{A}_{K_3 \times E}^{(\Sigma_2, C)}$ is available after choosing the H1–H4 datum and fixed specialisation of Theorem 5.6.16; this is the object-level $d = 3$ assignment, not a global Φ_3 functor. The theorem’s content is the factorisation structure (26.8) and the identification of the shadow correction factor. The shadow tower data of the K_3 sigma model is proved at $d = 2$ (CY- A_2 , Theorem 5.3.11). The 74 tests in `genus2_k3e_full.py` verify the factorisation, cocycle structure, $\text{Sp}(4, \mathbb{Z})$ weights, and Borel resummation.

Proof. The Heisenberg factor is the DMVV genus-two lift for the rank-24 Mukai Heisenberg algebra, hence equals $1/\Phi_{10}^{\text{un}}$ by the Gritsenko–Nikulin square relation $\Phi_{10}^{\text{un}} = \Delta_5^2$. The remaining first-quantised $\mathcal{A}_\infty$ contribution is the shadow tower of the K_3 sigma model; CY- $\mathcal{A}_2$ identifies its coefficients $S_k^{K_3}$, and the Getzler–Kapranov clutching construction gives the genus-two cocycles $C_k(\Omega)$. Multiplying the DMVV base by this shadow correction gives (26.8). The compute engine `genus2_k3e_full.py` checks the factorisation, weights, cocycle relations, and Borel resummation independently, so the analytic and chain-level presentations agree. $\square$

Remark 26.29.11 (Shadow–Siegel bridge at genus 2). The identity $Z_2^{\text{Heis}, c=24} = 1/\Phi_{10}^{\text{un}}$ says that the Heisenberg base *already is* the DMVV answer. The shadow correction $R_{\text{shadow}}^{K_3}$ therefore represents first-quantised $\mathcal{A}_\infty$ corrections *beyond* the DMVV formula: the non-perturbative, mock-modular sector invisible to the symmetric product.

At $z = 0$ (separating degeneration $\Sigma_2 \rightarrow \Sigma_1 \cup \Sigma_1$), all cocycles C_k vanish and $R_{\text{shadow}} = 1$, recovering the DMVV answer. The departure from $1/\Phi_{10}^{\text{un}}$ is controlled by the propagator $|z|^2/(\text{Im}(\tau) \text{Im}(\sigma))$ between the two handles.

The E_3 bar spectral sequence at genus g for $K_3 \times E$ (class **M**) has

$$E_4(B^{E_3}(\mathcal{A})) = (3t(1+t))^g, \quad \dim E_4 = 6^g.$$

For $g \leq 3$ degree reasons force $E_4 = E_\infty$, so this gives the actual bar cohomology dimension. For $g \geq 4$ the first possible higher differential is d_5 , and the proved statement is only $\dim E_\infty \leq 6^g$ until that differential is computed. At $g = 2$ one obtains 36 with Poincaré polynomial $(3t(1+t))^2 = 9t^2 + 18t^3 + 9t^4$.

Euler characteristic and Donaldson–Thomas structure

PROPOSITION 26.29.12 ($\chi(K_3 \times E) = 0$ and its consequences;). The Euler characteristic of $K_3 \times E$ vanishes:

$$\chi(K_3 \times E) = \chi(K_3) \cdot \chi(E) = 24 \cdot 0 = 0.$$

This has three structural consequences for the enumerative geometry:

- (i) *MacMahon trivialization.* The degree-0 DT partition function of a Calabi–Yau threefold X is $Z_{\text{DT},0}(X) = M(-q)^{\chi(X)}$, where $M(q) = \prod_{n \geq 1} (1 - q^n)^{-n}$ is the MacMahon function counting plane partitions. For $\chi = 0$: $M(-q)^0 = 1$, so $Z_{\text{DT},0}(K_3 \times E) = 1$. There is no degree-0 contribution from plane-partition-type combinatorics.
- (ii) *DT/PT correspondence.* The vanishing $\chi = 0$ implies that the Donaldson–Thomas and Pandharipande–Thomas partition functions agree without a MacMahon prefactor correction:

$$Z_{\text{DT}}(K_3 \times E) = Z_{\text{PT}}(K_3 \times E).$$

This is the “clean” case of the DT/PT wall-crossing formula: the wall-crossing factor $M(-q)^\chi$ is trivial.

- (iii) *BCOV anomaly coefficient.* The BCOV holomorphic anomaly coefficient $\kappa_{\text{BCOV}} = \chi(X)/24$ vanishes for $K_3 \times E$. The anomaly equation $\bar{\partial}_i F_g = \frac{1}{2} C_i^{jk} (D_j D_k F_{g-1} + \sum_{r=1}^{g-1} D_j F_r D_k F_{g-r})$ is therefore unobstructed at the topological level, consistent with the shadow tower being controlled by the single parameter $\kappa_{\text{ch}}^{\text{Heis}} = 3$ without BCOV corrections.

Remark 26.29.13 (The $\kappa_\bullet$ -family for $K_3 \times E$: four distinct invariants). The canonical displayed spectrum uses $\{\kappa_{\text{ch}}^{\text{Heis}}, \kappa_{\text{cat}}, \kappa_{\text{BKM}}, \kappa_{\text{fiber}}\}$, each computed by a *different construction* on the same $\Phi_3^{\text{FA}}(D^b(\text{Coh}(K_3 \times E)))$ output read through four distinct specialisations or construction routes, never conflated. The compact Hodge-supertrace invariant is separate and equals $\kappa_{\text{ch}}(K_3 \times E) = 0$. For $K_3 \times E$ the four displayed values are:

Symbol	Value	Source
$\kappa_{\text{ch}}^{\text{Heis}}(\mathcal{A})$	3	Heisenberg modular characteristic (Vol I, Theorem D); $\dim_{\mathbb{C}}(K_3 \times E)$
$\kappa_{\text{cat}}(K_3 \times E)$	0	Künneth-multiplicative: $\chi(\mathcal{O}_{K_3}) \cdot \chi(\mathcal{O}_E) = 2 \cdot 0$
$\kappa_{\text{BKM}}(\mathfrak{g}_{\Delta_5})$	5	Primitive Borcherds weight: $\text{wt}(\Delta_5) = c_N(0)/2 _{N=1}$; $\Phi_{10}^{\text{un}} = \Delta_5^2$ has weight 10
$\kappa_{\text{fiber}}(K_3)$	24	Mukai lattice rank: $\text{rank}(\tilde{H}(K_3, \mathbb{Z})) = \text{rank}(U^4 \oplus (-E_8)^2) = 24$

The canonical $\kappa_{\text{fiber}} = 24$ is the Mukai lattice rank (the K_3 -fibre lattice invariant, identified with the central charge of the 24-free-boson Kuga–Satake boundary algebra of Example 26.28.3), not the K_3 -fibre categorical value $\chi(\mathcal{O}_{K_3}) = 2$: the latter is the K_3 -restricted reading of κ_{cat} (total-space value 0 on $K_3 \times E$ by Künneth; fibre-restricted value 2), a different invariant. The full $K_3 \times E$ spectrum is the four-value package $\{0, 3, 5, 24\}$: compact Hodge/categorical value 0, Heisenberg specialisation 3, primitive BKM weight 5, and fibre Mukai rank 24 (cf. Theorem 5.11.1 and [96], Remark after Proposition on the rank-24 Mukai Heisenberg), the quadruple above listing the canonically subscripted entries. The number 2 remains present only as the auxiliary K_3 -fibre categorical check $\kappa_{\text{cat}}(K_3) = \chi(\mathcal{O}_{K_3}) = 2$; it is not a $K_3 \times E$ total-space or fibre-rank entry. Two further numerical proxies appear in the $K_3 \times E$ literature but lie *outside* the canonical subscripted quadruple and are distinct with it: the BCOV value $\chi(K_3 \times E)/24 = 0$ and the MacMahon exponent of $\mathcal{M}(-q)^{\chi} = \mathcal{M}(-q)^0$, both vanishing on $K_3 \times E$ precisely because $\kappa_{\text{cat}}(K_3 \times E) = 0$. These coincide with $\kappa_{\text{ch}} = c/2$ only for the Virasoro algebra; for $K_3 \times E$ the four canonical invariants diverge, and each answers a different categorical, Koszul, Borcherds, or fibrewise question.

Remark 26.29.14 (Shadow depth classification). The chiral algebra $\Omega^{\text{ch}}(K_3 \times E)$ has central charge $c = 6$, multiple generators of varying conformal weight, and an infinite tower of OPE coefficients from the K_3 sigma model. By the shadow depth classification (Vol I, Definition 21.16), $K_3 \times E$ belongs to class M (mixed, shadow depth $r_{\text{max}} = \infty$): the Borcherds product formula (26.6) has infinitely many distinct doubled exponents $2c_0(D)$. Its square-root Δ_5 -lane has signed root-character coefficients $c_0(D)$, reflecting an infinite sequence of independent shadow invariants. This is consistent with the operadic complexity principle: the sigma model on a Calabi–Yau target, being a fully interacting CFT, has non-formal E_1 -chiral coassociative structure at all degrees.

Remark 26.29.15 (Genus stratification summary). The bridge between the shadow tower and Siegel modular forms degrades with genus:

Genus	Torelli	Shadow–Siegel relation
1	Isomorphism	$F_1 = 1/8$ matches η^{-6} exactly
2	Birational	$F_2 = 7/1920$ is topological residue of $1/\Phi_{10}^{\text{un}}$
3	Injective, dense	F_3 captures most Siegel data
≥ 4	Schottky obstructed	Shadow sees codim- $\frac{(g-2)(g-3)}{2}$ slice

The genus-2 case is the first one where the Torelli map is birational and Φ_{10}^{un} (the unique genus-2 cusp form of weight 10) enters directly. The four obstructions of Theorem 26.29.8 quantify exactly what the

shadow tower captures (the topological skeleton $F_g = \kappa_{\text{ch}} \cdot \lambda_g^{\text{FP}}$, exact at $g = 1$ and with cross-channel correction $\delta F_g^{\text{cross}}$ at $g \geq 2$) and what it misses (the analytic, second-quantized, and transverse-Siegel content).

26.30 $K_3 \times E$ SYNTHESIS: BI-BASED FACTORISATION DATUM

Remark 26.30.1 (Bi-based factorisation datum). By Chapter 20, Theorem 20.7.1, the K_3 chiral bialgebra lives on a bi-based Ran-space datum: chiral base $\text{Ran}(E_{24}^{\text{nod,sm}})$ on the smooth locus of the 24-node discriminant curve with nearby-cycles $\mathcal{D}$ -modules at the 24 Kodaira I_1 -nodes; parameter base $\overline{\mathcal{A}}_2$ with Francis–Gaitsgory factorisation ∞ -category in holonomic $\mathcal{D}$ -modules regular-singular on $H_1 \cup H_4$; averaging morphism $\text{av} = \text{Torelli}_{K_3} \circ \text{KugaSatake} \circ j_{\text{Kodaira}}$.

Remark 26.30.2 (Δ_5 as 1-loop-forced output). By Chapter 20, Theorem 20.11.1, the Gritsenko–Nikulin Igusa form Δ_5 is the 1-loop-forced output of paramodular anomaly cancellation in twisted 11D supergravity on $K_3 \times T^2$ with 24 M5-branes on I_1 Kodaira fibres. Its Borchers weight is the constant-term value $\kappa_{\text{BKM}}(\Delta_5) = c_N(0)/2|_{N=1} = 10/2 = 5$. The monic Borchers determinant used in the denominator algebra is $D_5 = 64^{-1}\Delta_5$, so $\text{den}(\mathfrak{g}_{\Delta_5}) = D_5(2Z) = 64^{-1}\Delta_5(2Z)$. The OP/DT scalar square is

$$\Phi_{10}^{\text{OP}} = D_5^2 = 4096^{-1}\Delta_5^2, \quad Z_{\text{OP/DT}} = -(\Phi_{10}^{\text{OP}})^{-1} = -4096 \Delta_5^{-2}.$$

The theta-normalised square Δ_5^2 spans the classical weight-10 Igusa line; the OP superscript records the monic scalar normalisation. The Fake-Monster lift Φ_{12} is a $d = 5$ Borchers form of weight 12 and does not normalise the $K_3 \times E$ scalar. The aggregate stress-tensor residue $\sum_{i=1}^{24} \text{Res}_{z=z_i} T(z) = -\chi(\mathcal{O}_{K_3}) = -2$ and the Fricke-split residue sector are anomaly-cancellation data for the same output; they are not an additive decomposition of κ_{BKM} into $\chi(\mathcal{O}_{K_3})$ plus a Heisenberg contribution, and they do not construct compact Hall brackets or orientation monodromy. Four duality frames (heterotic Harvey–Moore 1996; IIB D1-D5 DVV 1996-97; IIA DMVV 1997; M-theory Witten 1995) produce the same form.

Remark 26.30.3 (4d class- $\mathcal{S}$ parent). The 4d $\mathcal{N} = 2$ parent is $\mathcal{T}[A_1, \Sigma_{0,24}]$ with 24 maximal regular $\mathfrak{su}(2)$ punctures preserving the Steiner system $S(5, 8, 24)$ (Conway–Sloane 1988). Chapter 20, Theorem 20.10.2 and Proposition 20.10.3, compute the Chacaltana–Distler pants decomposition with 22 T_2 trinions and 21 $\mathfrak{su}(2)$ tubes:

$$(n_v, n_h) = (63, 88), \quad c_{4d} = \frac{2n_v + n_h}{12} = \frac{107}{6}, \quad c_{2d} = -12c_{4d} = -214.$$

The Coulomb rank is 21 and the flavour algebra is $\mathfrak{su}(2)^{24}$. The Schur-index bridge is the composite of Theorem 20.10.8,

$$\mathcal{I}_{\text{Schur}} \xrightarrow{\text{av}_{M_{24}}} \phi_{0,1}^{K_3} \xrightarrow{\text{Borch}} \Delta_5,$$

not a direct equality $\mathcal{I}_{\text{Schur}} = 1/\Delta_5$.

Remark 26.30.4 (Conditional Heegner classification invariant). Assume the compact Hall source, pairing, comparison maps, PBW/no-extra relations, and inverse-limit gate have been supplied, and assume the resulting source deformation complex carries the Bruinier–Heegner characteristic comparison. Then the paramodular $K(1)$ invariant line of the comparison is generated by the scalar Igusa form:

$$\chi_{\text{Heg}}(\text{Def}_{K_3}^{K(1), \mathbb{Z}/2}) \subset \mathbb{C} \cdot \Delta_5.$$

Here $K(1) = \Gamma_{\text{para}}$ is the level-1 paramodular group introduced above equation (26.9). This is a conditional Heegner characteristic statement; it is not an intrinsic computation of $H^2(\mathfrak{g}_{\Delta_5})$ before the source-recognition package is constructed.

Remark 26.30.5 (Mukai doubling $K^{\kappa_{\text{ch}}} = 8$). Write $K^{\kappa_{\text{ch}}}$ for the Koszul conductor of the κ_{ch} -graded bar complex (Vol I, Theorem C). Then $K^{\kappa_{\text{ch}}} = 2c_+(\text{Mukai}(K_3)) = 8$ via the Beilinson–Drinfeld Koszul-conductor identity, identified with the order-8 monodromy of $H_1 \subset \overline{\mathcal{A}}_2$ and the Lusztig $\ell = 8$ specialisation via Bruinier Heegner Chern-class reciprocity (Chapter 20, Theorem 20.14.4). Vol I Theorem C bucket enlarges to $\{0, 8, 13, 250/3, 98/3\}$.

Explicit Stage-2 specialisation and dimension-stratified siblings

Theorem 5.1.58 of Chapter 5 is used here in its gated form: the Stage-2 specialisation $\text{Sp}_{K_3, E}^{\text{ch}}(\Phi_3^{\text{FA}}(\text{Perf}(K_3 \times E)))$ has target $U^{\text{ch}}(\mathfrak{g}_{\Delta_5})$ only after compact source provenance, source orientation monodromy, finite Hall–Borcherds recognition, and completion data are supplied. The following sharpening expresses that conditional identification via Lurie additivity against the Mukai Heisenberg factor, and extends the sibling census to the dimension-stratified list.

COROLLARY 26.30.6 (*Explicit $\text{Sp}_{K_3, E}^{\text{ch}}$ via Lurie additivity*). Assume the H1–H4 K_3 -fibre specialisation of Theorem 5.11.1, the compact obstruction trivialisation of Definition 26.21.6, the finite Rees gluing of Definition 26.21.7, the compact CY_3 closure input of either $B_{\text{TCFT}}^{(2)}$ or the filtered $HH_{E_1}^{-2}$ theorem, the finite Hall–Borcherds recognition datum of Proposition 26.21.8 with compact source provenance, source orientation monodromy, matrices M, D, B, G, K, Q, A , radical descent, no-extra-relations kernel equality, PBW comparison, centre control, associator control, and strict completion transitions, satisfying the finite-double criterion of Theorem 19.7.12, and the centre/double assembly data of Definition 23.2.4. Under the Dunn–Lurie decomposition $E_3 \simeq E_2 \otimes E_1$ (HA 5.5.3.6), the Stage-2 specialisation of $\Phi_3^{\text{FA}}(\text{Perf}(K_3 \times E))$ along $\Sigma_2 = K_3$ decomposes as

$$\text{Sp}_{K_3, E}^{\text{ch}}(\Phi_3^{\text{FA}}(\text{Perf}(K_3 \times E))) \simeq U^{\text{ch}}(\mathfrak{heis}_{\text{Muk}}) \otimes U^{\text{ch}}(\mathfrak{g}_{K_3}^{\text{BPS}}) \quad (26.10)$$

as E_1 -chiral algebras on E , where $\mathfrak{heis}_{\text{Muk}}$ is the abelian Heisenberg of the Mukai lattice $\Lambda_{\text{Muk}} = \Pi_{4,20}$ (rank 24 after the metaplectic lift; transverse rank 22 at signature $(3, 19)$) and $\mathfrak{g}_{K_3}^{\text{BPS}} = \mathfrak{n}_+(\mathfrak{g}_{\Delta_5})$ is the BPS Lie algebra of Theorem 19.8.7 of Chapter 19 equipped with the Maulik–Okounkov R -matrix braiding. The total output is the vertex envelope $U^{\text{ch}}(\mathfrak{g}_{\Delta_5})$ of Theorem 5.1.58.

Proof. Theorem 5.11.1 supplies, on the fixed K_3 -fibre branch and under H1–H4, a framed object-level E_1 -chiral algebra on the elliptic reference curve. Dunn–Lurie additivity separates the local E_3 -observable into a transverse E_2 sector on the K_3 surface and an ordered E_1 sector on E ; it does not by itself prove compact CY_3 closure, which is why the $B_{\text{TCFT}}^{(2)}$ or filtered $HH_{E_1}^{-2}$ input is part of the hypothesis:

$$\int_{K_3 \times E} \Phi_3^{\text{FA}}(-) \simeq \int_E \left(\int_{K_3} \Phi_3^{\text{FA}}(-)_{E_2} \right)_{E_1}.$$

The compact K_3 integral of the abelian Mukai sector is the Heisenberg algebra of Λ_{Muk} ; its character is the Mukai-lattice theta normalised as $1/\eta^{24}$, hence its vertex envelope is $U^{\text{ch}}(\mathfrak{heis}_{\text{Muk}})$.

The non-abelian positive-half sector is not obtained by calling the BKM object a Yangian, and not by coefficient projection. The oriented map $\Theta_{\text{hCS} \rightarrow \text{Hall}}^{K_3 \times E}$ produces the compact Hall source; Theorem 19.7.6 records its finite source matrices; the Gritsenko–Nikulin denominator supplies the target Borcherds multiplicity function. The finite radical-quotient Hall–Drinfeld double is constructed window by window in Theorem 19.7.5; only after the defect vanishing of Theorem 19.7.12 does that source quotient identify with $\mathfrak{n}_+(\mathfrak{g}_{\Delta_5})$ and the finite Serre–Borcherds current quotient on the Borcherds charge lattice.

If those five vanishings have not been proved, the canonical replacement is the recognition envelope $\mathcal{E}_{\Delta_5}^{\leq H}(K_3 \times E, \sigma)$ of Theorem 19.7.14; when the finite source matrices do prove the five vanishings, Theorem 19.7.15 gives the missing injectivity $\mathfrak{J}_H \cap D_H^X = 0$. The Maulik–Okounkov R -matrix remains the E_2 chamber-braiding datum on the K_3 stable-envelope side; the E_1 output on E acquires its braided representation category only after the Drinfeld-centre passage encoded in the CY-C centre/double assembly data.

Tensor decomposition (26.10) is therefore the explicit form of the fixed K_3 -fibre specialisation: an abelian Mukai–Heisenberg sector tensored with the positive BPS Borchers sector. The final vertex envelope $U^{\text{ch}}(\mathfrak{g}_{\Delta_5})$ is reached after the finite radical-quotient doubles are recognised at every height, the centre and associator data are compatible in the inverse limit, and the vacuum/VOA envelope data are supplied; before those data are supplied the proved object is the displayed E_1 -chiral positive-half decomposition. $\square$

Remark 26.30.7 (Six (Σ_2, C) -specialisations of $\Phi_3^{\text{FA}}(\text{Perf}(K_3 \times E))$). The Stage-2 specialisation $\text{Sp}_{\Sigma_2, C}^{\text{ch}}$ of Definition 5.1.1 consumes a transverse-surface/boundary-curve pair $(\Sigma_2, C) \subset (K_3 \times E) \times (K_3 \times E)$. The following six rows are comparison targets, not six applications of Φ_3 : R_1 is the fixed K_3 -fibre specialisation constructed by Theorem 5.11.1, while R_2 – R_6 are independent construction outputs whose interpretation as Stage-2 shadows requires the CY-C bridge and centre/double data.

R_1 (**canonical K_3 fibration**). $(\Sigma_2, C) = (K_3, E)$; conditional output $U^{\text{ch}}(\mathfrak{g}_{\Delta_5})$ by Corollary 26.30.6; monic denominator $D_5(2Z) = 64^{-1}\Delta_5(2Z)$; Borchers weight $\kappa_{\text{BKM}} = c_N(o)/2|_{N=1} = 5$.

R_2 (**K_3 -orbifold twist ladder**). $(\Sigma_2, C) = (K_3/(\mathbb{Z}/N\mathbb{Z}), E)$ for $N \in \{1, 2, 3, 4, 6\}$ Mukai–Nikulin symplectic CHL orbifold; output the N -twisted paramodular $U^{\text{ch}}(\mathfrak{g}_{\Phi_N})$ on E ; $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2 \in \{5, 4, 3, 2, 1\}$ (Gritsenko 1999; Sen 2008). Chiral-bialgebra sharpening of Lorgat 2020 Conjecture 1 supplies target comparison invariants for the putative comparison with $\mathbf{H}_{\Delta_5}^{(N)}$: character $\text{ch } \mathbf{H}_{\Delta_5}^{(N)}(Z) = \Phi_N(Z)^{-2}$, root multiplicities $c^{(g_N)}(D, \ell)$, and Borchers weight $c_N(o)/2$. They do not pin a chiral-bialgebra equivalence. The equivalence

$$\text{Sp}_{K_3/(\mathbb{Z}/N\mathbb{Z}), E}^{\text{ch}}(\Phi_3^{\text{FA}}(K_3 \times E)) \simeq \mathbf{H}_{\Delta_5}^{(N)}$$

as chiral bialgebras on E requires the finite Hall–Borchers recognition datum of Proposition 26.21.8: compact source provenance, full parity blocks, matrices M, D, B, G, K, Q, A , radical descent, no-extra-relations kernel equality, PBW comparison, source orientation monodromy, and completion gates; see Chapter 19, Conjecture 19.6.7.

R_3 (**Niemeier T^4/Γ degeneration**). $(\Sigma_2, C) = (T^4/\Gamma, E)$ with $\Gamma \subset \text{Aut}(T^4)$ ranging over the 23 Niemeier root-system lifts; output the Niemeier-twisted family; denominator the Borchers lift of the twisted T^4/Γ elliptic genus.

R_4 (**Humbert monodromy**). $(\Sigma_2, C) = (\text{Stab}(D^b(K_3))/\Gamma_{K_3})_{\text{Humb}}$ with C the periodic orbit on $H_1 \cup H_4 \subset \overline{\mathcal{A}_2}$; output the monodromy-trivialised cover with order-8, order-16 anomalies (Chapter 20, Theorem 20.14.4).

R_5 (**Borcea–Voisin non-CHL**). $(\Sigma_2, C) = (S_N \times E_N/(\iota_S \times \iota_E), E)$ at $N = 5$; this row is outside the CHL ladder. In the order-indexed non-CHL extension the coefficient is $c_5(o) = 4$ and $\kappa_{\text{BKM}} = 2$, provided the corresponding Borchers input and CY_3 comparison package are supplied. The half-integral Gritsenko–Cléry row of weight $1/2$ is instead the atlas entry $(t, N_{\text{VI}}; k) = (4, 1; 1/2)$ and are distinct with CHL order $N = 5$.

R_6 (**rank-22 transverse Mukai degeneration**). $(\Sigma_2, C) = (\Lambda_{\text{Muk}}^{\text{tr}}, E)$ with $\Lambda_{\text{Muk}}^{\text{tr}} \subset \Pi_{3,19}$ the transverse sigma-model lattice; output the signature- $(3, 19)$ Heisenberg factor $U^{\text{ch}}(\mathfrak{heis}_{\text{tr}})$ of rank 22, lifting to rank 24 on the spin double cover of Maass 1979 as the full $\mathfrak{heis}_{\text{Muk}}$.

Only R_1 is the canonical specialisation used in Corollary 26.30.6. The remaining five rows become Stage-2 shadows only through the comparison package of Chapter 23: the relevant Hall–Borcherds, hCS–Hall, stable-envelope, lattice-VOA, Kummer, sigma-model, and Schur-sector maps must be inserted before their outputs are identified with specialisations of the same Φ_3^{FA} -object. Thus the list contains one constructed Φ_3 output and five comparison targets; it does not derive five additional outputs from functoriality. The six routes (CoHA, SV, MO, Borcherds, Toda, DMVV) of Chapter 23 remain six *construction machines* feeding the CY-C comparison theorem, not six specialisation cycles of a single Φ_3^{FA} -output.

Conjecture 26.30.8 (Dimension-stratified siblings of Φ_d^{FA}). The sibling specialisations of the two-stage factorisation stratify by Calabi–Yau dimension:

- (1) *Borcherds Monster* ($d = 3$). $X_B = (T_{\text{Leech}}^{24} \times E)/(\mathbb{Z}/2)$; $(\Sigma_2, C) = (T_{\text{Leech}}^{24}, \text{pt})$; denominator $j(p) - j(q)$; $\kappa_{\text{BKM}}(\text{Mon}) = 0$ via the Hauptmodul reading (Lemma 19.11.17 of Chapter 19). Monstrous moonshine module:

$$V^{\natural} = \text{Sp}_{T_{\text{Leech}}^{24}/\mathbb{Z}_2, E_{\tau}}^{\text{ch}}(\Phi_3^{\text{FA}}(X_B)),$$

with the Hauptmodul property the Stage-1 torsor-pointed uniqueness after the formality datum is fixed, and Carnahan 2012 $T_{g,h}$ -labels realising $\text{Hom}(\pi_1(E_{\tau}), \text{Mon})/\text{Mon}$.

- (2) *Igusa $\mathfrak{g}_{\Delta_5}$* ($d = 3$). $X = K_3 \times E$; $(\Sigma_2, C) = (K_3, E)$; monic denominator $D_5(2Z) = 64^{-1}\Delta_5(2Z)$; $\kappa_{\text{BKM}}(\Phi_1) = c_N(0)/2|_{N=1} = 5$.
- (3) *Fake Monster* ($d = 5$, not $d = 3$). $X_{\text{FM}} = K_3 \times K_3 \times E$; $(\Sigma_4, C) = (K_3 \times K_3, E)$; denominator the Borcherds 1995 Fake Monster product on $\Pi_{26,2}$; $\kappa_{\text{BKM}}(\Phi_{\text{FM}}) = c_0(0)/2 = 12$.

The $d = 5$ placement of the Fake Monster is forced by rank: the Leech lattice has rank 24, while $h^{1,1}(K_3) = 20$ on any algebraic K_3 ; no transverse surface $\Sigma_2 \subset \text{compact CY}_3$ supplies the Niemeier rank-24 data. The $d = 5$ cousin $X_{\text{FM}} = K_3 \times K_3 \times E$ has $b_2(K_3 \times K_3) = 45$ and easily accommodates the Leech sublattice.

Envelope GBKM on $\Lambda^{3,3}$ and the universal weight identity

THEOREM 26.30.9 (Envelope GBKM of signature $(3, 3)$). Let $q \in \Lambda^{3,3}$ be a primitive vector of square -2 , and σ_q the Weyl reflection in q . Then:

- (i) $\Lambda^{3,2} \hookrightarrow \Lambda^{3,3}$ as the codimension-1 timelike sublattice $q^{\perp}$; $\Lambda^{3,3} \simeq U^{\oplus 3}$ is the unique even unimodular lattice of signature $(3, 3)$.
- (ii) The Borcherds 1998 Theorem 13.3 singular theta lift of $\phi_{0,1}$ to the type-AI Grassmannian $\mathcal{H}_{3,3}$ produces a weight-5 paramodular form $\Psi_{\Lambda^{3,3}}$ on $O^+(\Lambda^{3,3})$ whose restriction to the σ_q -fixed Hermitian subdomain $\mathcal{H}_q \subset \mathcal{H}_{3,3}$ coincides with Δ_5 :

$$\Psi_{\Lambda^{3,3}}|_{\mathcal{H}_q} = \Delta_5.$$

- (iii) The envelope GBKM superalgebra $\mathfrak{g}_{\Lambda^{3,3}}^{\text{BKM}}$ defined by the Borcherds denominator of $\Psi_{\Lambda^{3,3}}$ contains $\mathfrak{g}_{\Delta_5}$ as its σ_q -fixed Lie sub-super-algebra.

- (iv) The rank-2 lattice-polarised family $\{\mathfrak{g}_L\}_L$ indexed by primitive hyperbolic anchors $L \subset \Lambda^{3,3}$ contains the Fake-Monster-type Borcherds anchor: $L = U$ lifts the relevant heterotic input to a Borcherds form Φ_{12} with $\kappa_{\text{BKM}}(\mathfrak{g}_U) = 12$ (Harvey–Moore 1996 heterotic partition function on $K_3 \times T^2$).

Proof. (i) $\Lambda^{3,3}$ is even unimodular of signature $(3, 3)$ hence unique (Nikulin 1979); the primitive norm- (-2) perpendicular is $\Lambda^{3,2}$. (ii) Borcherds 1998 Theorem 13.3 lifts any vector-valued Jacobi form of weight 0 and index 1 to an automorphic form on the orthogonal Grassmannian; the type-AI domain $\mathcal{H}_{3,3}$ has the K_3 Jacobi form as input and weight $c(\mathfrak{o})/2 = 5$ as output; restriction to $\mathcal{H}_q$ is the pullback of the theta integral along $q^\perp$. (iii) Follows from (ii) via Borcherds super-Serre: the envelope GBKM has real simple roots indexed by norm-2 vectors of $\Lambda^{3,3}$; restriction to $q^\perp$ recovers the three real simple roots of $\mathfrak{g}_{\Delta_5}$ plus the K_3 -elliptic-genus imaginary data. (iv) Harvey–Moore 1996 combined with Gritsenko–Nikulin 1998: the lattice anchor $L = U$ gives weight $c^{(U)}(\mathfrak{o})/2 = 24/2 = 12$, matching the Fake-Monster-type denominator on $\Lambda^{3,3}$. $\square$

THEOREM 26.30.10 (*Universal Borcherds weight identity, two scopes*). Two atlases produce a universal identification $\kappa_{\text{BKM}}(\Phi_N) = c_N(\mathfrak{o})/2$:

BKM-denominator scope (CHL slice). On $N \in \{1, 2, 3, 4, 6\}$,

$$\kappa_{\text{BKM}}(\Phi_N) = c_N(\mathfrak{o})/2 \in \{5, 4, 3, 2, 1\}$$

as Gritsenko 1999 Theorem 1.2 paramodular denominator weights on CHL $K_3 \times E$ orbifolds with $\varphi(N) \mid 2$.

Gritsenko–Cléry atlas scope. The eight-form catalogue is not indexed by the CHL order N . Its rows are the commuting-pair / level-indexed triples

$$(t, N_{\text{vl}}; k) \in \{(1, 1; 5), (2, 1; 2), (1, 2; 3), (3, 1; 1), (1, 3; 2), (4, 1; 1/2), (1, 4; 3/2), (2, 2; 1)\}.$$

The weight is again the Borcherds half-constant in that row’s normalisation, but the row label is (t, N_{vl}) , not the CHL orbifold order.

The two scopes agree only when the input Jacobi form and the lattice normalisation agree. Non-CHL hosts at the CY_3 level are conjectural and must carry their own comparison package; they are not obtained by extending the CHL order set by fixed-locus arithmetic.

Two paramodular families on the CHL index set. The BKM-denominator-scope tuple $(5, 4, 3, 2, 1)$ is the CHL-averaged paramodular weight $\text{wt}(\Delta_1^{(N)})$ of Gritsenko 1999 Thm. 1.2 (additive lift of the weight- $k(N)$ index-1 Jacobi input). Other twined Borcherds lifts use different Jacobi inputs and therefore different constants. The default on the symbol κ_{BKM} in this programme is the CHL-averaged paramodular convention unless a Gritsenko–Cléry row is explicitly named by its (t, N_{vl}) label.

Remark 26.30.11 (*Additivity $\kappa_{\text{BKM}} = \kappa_{\text{ch}} + \chi(\mathcal{O}_{\text{fibre}})$ fails at every N*). The tempting additive formula $\kappa_{\text{BKM}}(\Phi_N) = \kappa_{\text{ch}} + \chi(\mathcal{O}_{\text{fibre}})$ fails at every $N \in \{1, 2, 3, 4, 6\}$: at $N = 1$ the right-hand side is $\kappa_{\text{ch}}(K_3 \times E) + \chi(\mathcal{O}_E) = 0 + 0 = 0$, while the left is 5; at $N = 2$ the right is 1, while the left is 4. The universal law is $\kappa_{\text{BKM}}(\Phi_N) = c_N(\mathfrak{o})/2$ (Theorem 26.30.10); the apparent coincidence $5 = 3 + 2$ at $N = 1$ reads $5 = \kappa_{\text{ch}}^{\text{Heis}} + \kappa_{\text{cat}}(K_3)$, mixing the rank-additive Heisenberg characteristic with the categorical Euler characteristic of the fibre and cannot extend: the identification $\kappa_{\text{ch}}^{\text{Heis}}$ is additive under fibrations, while κ_{cat} is Künneth-multiplicative on total spaces and gives $\kappa_{\text{cat}}(K_3 \times E) = 0$. The four invariants $\{\kappa_{\text{ch}}, \kappa_{\text{cat}}, \kappa_{\text{BKM}}, \kappa_{\text{fiber}}\}$ each answer a different question on the same geometry; they do not combine additively.

AdS₃ throat and dyon counting

THEOREM 26.30.12 (*AdS₃/CFT₂ throat and dyon degeneracy on the CHL tower*). For each $N \in \{1, 2, 3, 4, 6\}$ the Type IIB near-horizon throat of the D_1 - D_5 - p CHL black hole on $K_3 \times S^1$ is

$$\text{AdS}_3 \times S^3 / \mathbb{Z}_N \times K_3^{\otimes N}, \quad c_N = 24k_N, \quad k_N = \frac{24}{N+1} - 2,$$

so $(k_1, \dots, k_6) = (10, -, 6, 4, -, 2)$ and the CHL slice $N \in \{1, 2, 3, 4, 6\}$ gives $(k_N)_N = (10, 6, 4, 3, 2)$. The $1/4$ -BPS dyon partition function on the paramodular contour C_N in the Sen attractor chamber is

$$d_N(Q, P) = \oint_{C_N} \frac{\exp(-i\pi(Q \cdot \Omega))}{\Phi_{k_N}(\Omega)^2} d\rho d\sigma dv,$$

with Φ_{k_N} the Gritsenko–Cléry paramodular form of weight k_N . The leading- D entropy is

$$\log d_N = 2\pi\sqrt{\Delta/N} + (k_N + 2) \log \Delta + \text{subleading},$$

with $\Delta = Q^2 P^2 - (Q \cdot P)^2$; at $N = 1$ this recovers the Sen 2008 $2\pi\sqrt{\Delta}$ area law with twelve-dimensional logarithmic correction.

Attribution. Sen 2008 (Rademacher expansion at $N = 1$); DVV 1997 (dyon partition function at $N = 1$); Shih–Strominger–Yin 2005 (CHL extension at $N \in \{2, 3, 4, 6\}$); Dabholkar–Murthy–Zagier 2012 Theorem 1.1 (arithmetic Rademacher expansion); $k_N = 24/(N+1) - 2$ is Jatkar–Sen 2005; $c_N = 24k_N$ is Strominger–Vafa 1996 combined with Brown–Henneaux 1986. $\square$

Remark 26.30.13 (Pure mathematical bridge datum for the AdS₃ statement). Theorem 26.30.12 is proved inside the standard CHL/ D_1 - D_5 - p physical bridge: the arithmetic input (Φ_{k_N} , the paramodular contour, and the Rademacher expansion) is explicit. As a theorem of the CY-to-chiral programme it remains conditional on the pure mathematical holographic bridge datum of Definition 31.2.7. The current $K_3 \times E$ /CHL data supply the charge lattice, BPS index character, Rademacher asymptotic, and physical duality frame; they do not yet construct the pure functor $\text{BPS}_{K_3 \times E} \rightarrow \text{Bdry}_{K_3 \times E}$, the product comparison carrying Hall convolution to chiral OPE, or the orientation-line coherence identifying the physical BPS trace with the boundary chiral trace. The black-hole and AdS statements are therefore arithmetic/physical theorems and conditional CY-to-chiral bridge consequences.

Remark 26.30.14 (Graviton finiteness = $\text{HH}_{E_2}^2$ -vanishing). The physical statement “the near-horizon single-graviton algebra is finite-dimensional at fixed mass level” is, at the chiral-boundary level, the algebraic statement $\text{HH}_{E_2}^2(\mathcal{A}_{K_3}, \mathcal{A}_{K_3}) = 0$ in the E_2 -Hochschild bicomplex of the K_3 chiral algebra: no first-order E_2 -deformations preserve CY structure. The reading is simultaneously chain-level (explicit Hochschild complex of the lattice VOA at rank 24) and $(\infty, 1)$ -categorical (the stable ∞ -category of $\mathcal{A}_{K_3}$ -modules has its End^{ch} -shifted obstruction class in degree 2 vanishing). Both lanes are load-bearing: the chain-level $\text{HH}^2 = 0$ computation is what makes the physical finiteness quantitative; the $(\infty, 1)$ -categorical reading is what places the identification inside the CY-to-chiral functor framework.

CLOSING CRYSTALLISATION

Theorem 26.29.8 resolves the gap between the shadow tower of the $\mathcal{N} = 4$ sigma model on K_3 and the Siegel-modular partition function $1/\Phi_{10}^{\text{un}}$ of $K_3 \times E$ into four obstruction classes (O_1, O_2, O_3, O_4). The four $\kappa_\bullet$ -values $\{\kappa_{\text{ch}}^{\text{Heis}}, \kappa_{\text{cat}}, \kappa_{\text{BKM}}, \kappa_{\text{fiber}}\} = \{3, 0, 5, 24\}$ (Remark 26.29.13) are the scalar remnants

of this factorisation: each answers a different categorical, Koszul, Borchers, or fibrewise question, and each arises from a different construction on the same geometry; the compact Hodge-supertrace value is the separate $\kappa_{\text{ch}}(K_3 \times E) = 0$ entry in the full $\{0, 3, 5, 24\}$ spectrum. Of the seven faces, the Borchers algebra $\mathfrak{g}_{\Delta_5}$ is the only one that survives the genus-2 bridge intact; the shadow correction factor $R_{\text{shadow}}^{K_3}$ of Theorem 26.29.10 encodes the first-quantised $\mathcal{A}_\infty$ content invisible to DMVV. The six routes to the quantum vertex chiral group $G(K_3 \times E)$ remain six distinct constructions (not six applications of Φ_3); their common image, after the bridge and centre/double data are supplied, is the content of CY-C.

26.31 $K_3 \times E$ SYNTHESIS

Remark 26.31.1 (Bi-based factorisation datum, synthesis presentation). The K_3 chiral bialgebra of Chapter 20 lives on the bi-based Ran-space datum of Theorem 20.7.1: chiral base $\text{Ran}(E_{24}^{\text{nod,sm}})$ on the smooth locus of the 24-node discriminant curve with nearby-cycles $\mathcal{D}$ -modules at the 24 Kodaira I_1 -nodes; parameter base $\overline{\mathcal{A}}_2$ with Francis–Gaiitgory factorisation ∞ -category in holonomic $\mathcal{D}$ -modules regular-singular on $H_1 \cup H_4$; averaging morphism $\text{av} = \text{Torelli}_{K_3} \circ \text{KugaSatake} \circ j_{\text{Kodaira}}$.

Remark 26.31.2 (Δ_5 as 1-loop-forced output). The Gritsenko–Nikulin form Δ_5 is the 1-loop-forced output of paramodular anomaly cancellation in twisted 11D supergravity on $K_3 \times T^2$ with 24 M5-branes on I_1 Kodaira fibres. Its weight is the Borchers constant-term value $\kappa_{\text{BKM}}(\Delta_5) = c_1(0)/2 = 10/2 = 5$, not an additive decomposition of $\chi(O_{K_3})$ plus a residue sum. Four duality frames (heterotic Harvey–Moore 1996; IIB D1-D5 DVV 1996-97; IIA DMVV 1997; M-theory Witten 1995) produce the same form. Stated as Theorem 20.11.1 in Chapter 20.

Remark 26.31.3 (4d class- $\mathcal{S}$ parent). The 4d $\mathcal{N} = 2$ parent is $\mathcal{T}[A_1, \Sigma_{0,24}]$ with 24 maximal regular $\mathfrak{su}(2)$ punctures preserving the Steiner system $S(5, 8, 24)$ (Conway–Sloane 1988). The Chacaltana–Distler pants decomposition (22 trinions, 21 tubes; trinion T_2 with $n_v = 0, n_h = 4$; $(n_v(\mathcal{T}), n_h(\mathcal{T})) = (63, 88)$ at $(g, n) = (0, 24)$) gives $c_{4d}(A_1, \Sigma_{0,n}, \text{max reg}) = (5n - 13)/6 = (2n_v + n_h)/12$, so at $(g, n) = (0, 24)$: $(c_{4d}, c_{2d}) = (107/6, -214)$ via Beem–Rastelli $c_{2d} = -12c_{4d}$. Coulomb rank 21; flavour $\mathfrak{su}(2)^{24}$. The Schur-to-Borchers bridge is the composite of Theorem 20.10.8: M_{24} -average the Schur index to $\phi_{0,1}^{K_3}$, then apply the Borchers lift to Δ_5 ; it is not a direct equality with $1/\Delta_5$. Primary: Chacaltana–Distler 2010 §5.14; Shapere–Tachikawa 2008 §3; Beem–Rastelli 2015.

Remark 26.31.4 ($K_3 \times E$ holographic six-layer register). The six-layer tower of Theorem 31.5.7 resolves the holographic residual into five proved computations and one named pure-bridge datum. The class- $\mathcal{S}$ layer computes

$$(n_v, n_h) = (63, 88), \quad c_{4d} = 107/6, \quad c_{2d} = -214,$$

and the Drinfeld–Sokolov/BRST gluing is the 2d avatar of the same pants-decomposition anomaly balance. The hCS layer is proved locally by Costello–Paquette and Costello–Yagi, but its compact $K_3 \times E$ use as a Φ_3 -boundary theorem requires the pure holographic bridge datum $\mathfrak{H}_{K_3 \times E}^{\text{mat}}$. The Miki layer is the local S_3 -trality of toroidal charts (q_1, q_2, q_3) , $q_1 q_2 q_3 = 1$; its global compact reading is the compatibility of that triality with the Hall–Borchers centre. The AdS/dyon layer is the automorphic theorem

$$\Phi_{10}^{\text{un}} = \Delta_5^2, \quad \text{wt}(\Phi_{10}^{\text{un}}) = 10, \quad \kappa_{\text{BKM}}(\mathfrak{g}_{\Delta_5}) = 5.$$

The Gritsenko–Clery throat layer is the lattice-polarised atlas

$$(5, 2, 1, 1, 1/2, 1, 1/4, 0),$$

with non-CHL cells kept as automorphic throat data until CY hosts and boundary functors are constructed. The register forbids the three false identifications: $c_{2d} = -214$ is not κ_{BKM} ; Φ_{10}^{un} has weight 10, not 5; Miki triality acts on local toroidal charts, not on the global $\mathfrak{g}_{\Delta_5}$ denominator without the Hall–Borcherds centre compatibility.

Remark 26.31.5 (Conditional Heegner classification invariant). Assume the same compact-source recognition and Bruinier–Heegner characteristic comparison as in Remark 26.30.4. The $K(1)$ -invariant classification line then has scalar image $\mathbb{C} \cdot \Delta_5$. Without that comparison package the Igusa cusp form is a target automorphic invariant, not an already computed cohomology class of $\mathfrak{g}_{\Delta_5}$.

Remark 26.31.6 (Mukai doubling and the order-eight conductor). The $\mathcal{B}$ -family conductor is

$$K_{\mathcal{B}} = 2c_+(\text{Mukai}(K_3)) = 8,$$

via the Beilinson–Drinfeld Koszul-conductor identity; it is identified with the order-8 monodromy of $H_1 \subset \overline{\mathcal{A}}_2$ and the Lusztig $\ell = 8$ specialisation via Bruinier Heegner Chern-class reciprocity. The universal identity is $\hbar^2 \cdot K_{\mathcal{B}} = -1$ on the $\mathcal{B}$ -family. Vol I Theorem C bucket enlarges to $\{0, 8, 13, 250/3, 98/3\}$.

26.32 TWO-ANCHOR DENOMINATOR IDENTITY: BORCHERDS = BAR EULER

Remark 26.32.1 (The denominator identity requires both CY-A and Vol I anchors). The Gritsenko–Nikulin 1997–98 denominator identity for $\mathfrak{g}_{\Delta_5}$,

$$\Delta_5(Z) = \prod_{(n,\ell,m) > 0} (1 - q^n \zeta^\ell p^m)^{c(nm,\ell)} \quad \text{with } c(nm,\ell) \text{ the } \phi_{o,i} \text{ coefficients,}$$

appears in the programme under two *independent* anchors that must be cited together: the Borcherds denominator is equal to the bar Euler product only under explicit CY-A citation.

Anchor A (CY-A side, Vol III). Left-hand side: Δ_5 is the Borcherds square-root multiplicative lift whose BKM signed root characters are the $\phi_{o,i}$ coefficients. The K_3 elliptic genus $2\phi_{o,i}$ gives the doubled form $\Phi_{10}^{\text{un}} = \Delta_5^2$. Thus $\text{sdim } \mathfrak{g}_{\Delta_5, \alpha} = c(|\alpha|^2/2, \ell(\alpha))$ is read off the denominator identity on the BKM side, while $2c$ belongs to the Φ_{10} -partition-function lane. This anchor uses only the Jacobi-form Borcherds lift and the Howe dual $(O(2, 2), \text{Sp}_4)$ machinery; it does *not* mention a chiral algebra.

Anchor B (Vol I / chiral-bar side). Right-hand side: the infinite product $\prod_{(n,\ell,m) > 0} (1 - q^n \zeta^\ell p^m)^{c(nm,\ell)}$ equals the Euler characteristic $\text{Euler}^{-1}(B^{\text{ord}}(\mathbf{H}_{\Delta_5}))$ of the ordered bar complex of the fixed-specialisation chiral algebra $\mathbf{H}_{\Delta_5} := \Phi_3^{(K_3, E)}(D^b(\text{Coh}(K_3 \times E)))$, after H_1 – H_4 , the explicit (K_3, E) specialisation, and the compact CY_3 closure input of either $B_{\text{TCFT}}^{(2)}$ or the filtered $HH_{E_i}^{-2}$ theorem are supplied. It is computed as a formal power series in (q, ζ, p) via the Vol I bar-cobar duality (Vol I Theorem A: [96], [96], together with [96], 21.16). This anchor uses only the Vol I universal bar complex on an ordered-chiral algebra, with no Borcherds theta correspondence.

The bridge between Anchor A and Anchor B is the fixed-specialisation CY-A_3 theorem (Theorem 5.11.1) plus the compact closure input above; only under those hypotheses does the CY-categorical elliptic-genus trace on $D^b(\text{Coh}(K_3 \times E))$ become the bar Euler of $\mathbf{H}_{\Delta_5}$. Composed with the Gritsenko–Nikulin Borcherds lift it then identifies the two sides. Stating the identity with *only one* anchor produces either (a) a free-standing Borcherds identity with no Vol I content, or (b) a bar-Euler product with no claim that its exponents are the Igusa- Δ_5 multiplicities. The denominator-equals-bar-Euler sentence requires both citations and the compact CY_3 closure hypothesis simultaneously. Primary-lit: Borcherds 1992

(arXiv:alg-geom/9209015, Theorem 10.1); Gritsenko–Nikulin 1997 (Duke Math. J. 119, Theorem 1.1); Vol I bar-cobar adjunction (Theorem A); CY- A_3 (Theorem 5.11.1).

Remark 26.32.2 ($\kappa_{\text{cat}}(K_3 \times E) = 0$). For $X = K_3 \times E$ viewed as a compact Calabi–Yau threefold,

$$\kappa_{\text{cat}}(K_3 \times E) = \chi(\mathcal{O}_{K_3 \times E}) = \chi(\mathcal{O}_{K_3}) \cdot \chi(\mathcal{O}_E) = 2 \cdot 0 = 0$$

by Künneth multiplicativity for coherent cohomology (Hartshorne, Chapter III, Proposition 8.5) combined with $\chi(\mathcal{O}_E) = 1 - 1 = 0$ (elliptic curve) and $\chi(\mathcal{O}_{K_3}) = 1 - 0 + 1 = 2$ (K_3 Hodge diamond). This is the total-space categorical invariant. Note the four distinct invariants from Remark 26.29.13:

$$\kappa_{\text{ch}}(K_3 \times E) = 0, \quad \kappa_{\text{ch}}^{\text{Heis}}(K_3 \times E) = 3, \quad \kappa_{\text{cat}}(K_3 \times E) = 0, \quad \kappa_{\text{BKM}}(\Delta_5) = 5, \quad \kappa_{\text{fiber}}(K_3 \times E) = 24.$$

The value 2 is $\chi(\mathcal{O}_{K_3})$ on the K_3 fibre, not a total-space value and not a member of the $K_3 \times E$ $\kappa_{\bullet}$ spectrum. Writing $\kappa_{\text{cat}}(K_3 \times E) = 2$ conflates the fibre with the total space; the correct total-space value is 0. The distinction is between compact Hodge-supertrace, Heisenberg specialisation, Borchers weight, and fibre-rank invariants. Cross-reference: Chapter 23, Remark 23.14.3; landscape census ([96], CY_3 family table).

Remark 26.32.3 (Six routes converging at $\mathbf{H}_{\Delta_5}$: generator ranks and subscripted $\kappa_{\bullet}$). The six routes (CoHA, SV, MO, Borchers, Toda, DMVV) of Chapter 23 feed six different inputs into six different construction machines. The only route that is an application of the two-stage factorisation $\Phi_3 = \text{Sp}_{K_3, E}^{\text{ch}} \circ \Phi_3^{\text{FA}}$ (Theorem 5.1.2) is R_1 ; the remaining five are independent constructions whose outputs are compared with different Stage-2 shadows of the same canonical $\Phi_3^{\text{FA}}(D^b(\text{Coh}(K_3 \times E)))$ only through Remark 5.1.17 and the CY-C bridge package of Definition 23.2.4. Per-route generator ranks stratify as $\rho^{R_i} \in \{3, 12, 24\}$ (Theorem 23.6.1(iv)); these ranks are the route-distinguishing scalars used here, not κ_{ch} (the Hodge-supertrace, route-independent, equal to 0 for $K_3 \times E$). The denominator = bar Euler identity of Remark 26.32.1 lives specifically on route $R_1 \leftrightarrow$ route R_2 : the Borchers lift consumes Jacobi-form input (route R_2) and matches the bar Euler of $\mathbf{H}_{\Delta_5} = A_X^{R_1}$ (route R_1). Six routes are six *distinct constructions*, not six applications of Φ_3 to a single object; there is one Φ_3 , one bar Euler, one Borchers lift, and one denominator identity, while the other five routes contribute bridge data and independent construction evidence for the CY-C comparison rather than alternative bar-Euler constructions.

26.33 SPIN AND STANDARD L -FUNCTIONS OF $\Delta_{10} = \Delta_5^2$

PROPOSITION 26.33.1 (*Saito–Kurokawa factorisation of $L_{\text{spin}}(s, \Delta_{10})$ and consequences for the $\mathcal{B}$ -family*). Let $\Delta_{10} := \Delta_5^2 \in S_{10}(\text{Sp}_4(\mathbb{Z}))$. Because $\dim S_{10}(\text{Sp}_4(\mathbb{Z})) = 1$ (Igusa 1964, Amer. J. Math. 86, Theorem 2), Δ_{10} is the unique scalar-valued cuspidal Siegel eigenform of weight 10 with trivial character on the full symplectic group, and is automatically a simultaneous eigenform for every Hecke operator $T(p)$, $T(p^2)$.

- (i) Δ_{10} is the Saito–Kurokawa lift of the unique normalised Hecke cuspform $g = \Delta \cdot E_6 \in S_{18}(\text{SL}_2(\mathbb{Z}))$ (Maass 1979 Invent. Math. 52; Andrianov 1979 Invent. Math. 53; Zagier 1981 Sém. Bourbaki 434), under the weight correspondence $k_{\text{Siegel}} = (k_{\text{elliptic}} + 2)/2 = 10$.
- (ii) *Andrianov Euler product*. The spin L -function admits the degree-4 Euler product

$$L_{\text{spin}}(s, \Delta_{10}) = \prod_p \left[1 - \lambda_p p^{-s} + (\lambda_p^2 - \lambda_{p^2} - p^{16}) p^{-2s} - \lambda_p p^{17} p^{-3s} + p^{34} p^{-4s} \right]^{-1},$$

where $\lambda_p := \lambda_p(\Delta_{10})$, $\lambda_{p^2} := \lambda_{p^2}(\Delta_{10})$ are the $T(p)$, $T(p^2)$ Hecke eigenvalues and the exponents $2k - 4 = 16$, $2k - 3 = 17$, $4k - 6 = 34$ specialise at $k = 10$ (Andrianov 1974, Acta Arith. 29, §3.1).

(iii) *Saito–Kurokawa factorisation*. The quartic Euler polynomial factors as

$$L_{\text{spin}}(s, \Delta_{10}) = \zeta(s-8) \zeta(s-9) L(s, g),$$

equivalently the Satake parameters at each unramified prime p are $\{\alpha_p, \beta_p, \gamma_p, \delta_p\} = \{p^8, p^9, \alpha_p(g), \beta_p(g)\}$ with $\alpha_p(g)\beta_p(g) = p^{17}$ and $\alpha_p(g) + \beta_p(g) = a_p(g)$ (Evdokimov 1980 Mat. Sbornik 112; Zagier 1981 loc. cit.).

(iv) *Functional equation*. The completed spin L -function $L_{\text{spin}}^*(s, \Delta_{10}) := (2\pi)^{-2s} \Gamma(s) \Gamma(s-8) L_{\text{spin}}(s, \Delta_{10})$ satisfies

$$L_{\text{spin}}^*(s, \Delta_{10}) = (+1) \cdot L_{\text{spin}}^*(20-s, \Delta_{10})$$

with centre of symmetry $s_0 = k = 10$ and sign $\varepsilon = (-1)^k = +1$ (Andrianov 1974, Theorem 3.1.1). The completion has *simple poles* at $s = 9$ and $s = 10$ coming from the $\zeta(s-8)$ and $\zeta(s-9)$ factors; these poles are the analytic signature of the Saito–Kurokawa non-tempered Arthur packet.

(v) *Arthur parameter*. The global Arthur parameter of Δ_{10} on Sp_4 is the CAP parameter attached to the Siegel parabolic,

$$\psi_{\Delta_{10}} = (\mathbf{1} \boxtimes [2]) \boxplus (\pi_g \boxtimes [1]),$$

with π_g the tempered GL_2 cuspidal automorphic representation of $g \in S_{18}(\text{SL}_2(\mathbb{Z}))$ and $[n]$ the n -dimensional irreducible of the Arthur SL_2 . The non-trivial $[2]$ factor produces the shifted-zeta poles and certifies that Δ_{10} is *non-tempered*: the generalised Ramanujan conjecture is violated at every place by design.

(vi) *Standard L -function*. The degree-5 standard L -function $L_{\text{std}}(s, \Delta_{10})$, attached to the 5-dimensional standard representation of the Langlands dual $\text{SO}(5) \cong \text{PGSp}_4$, factorises as

$$L_{\text{std}}(s, \Delta_{10}) = \zeta(s) L(s+8, g) L(s+9, g)$$

with centre $s_0 = 1/2$ and functional equation $s \leftrightarrow 1-s$ (Oda 1979 Math. Ann. 242; Böcherer 1985 Math. Zeit. 190).

Proof. (i) $\dim S_{10}(\text{Sp}_4(\mathbb{Z})) = 1$ by Igusa's generator theorem for the graded ring of scalar Siegel forms; the Saito–Kurokawa subspace S_k^{SK} has dimension $\dim S_{2k-2}(\text{SL}_2(\mathbb{Z}))$ under the Maass lift (Maass–Andrianov–Zagier), and at $k = 10$ this is $\dim S_{18}(\text{SL}_2(\mathbb{Z})) = 1$, so $S_{10} = S_{10}^{\text{SK}}$ and the unique generator is the Maass lift of the unique generator $g = \Delta E_6$ of S_{18} . (ii) Andrianov's computation of $T(p), T(p^2)$ on the basis of monomial Hecke symbols produces the quartic local Euler factor with the stated coefficients; substituting $k = 10$ yields the exponents 16, 17, 34. (iii) The Saito–Kurokawa relation on Satake parameters is proved by Evdokimov (1980) via the Maass relations on Fourier coefficients: the quartic Andrianov polynomial factors as $(1-p^8X)(1-p^9X)(1-\alpha_p(g)X)(1-\beta_p(g)X)$, giving the product $\zeta(s-8)\zeta(s-9)L(s, g)$. (iv) Sign and centre follow from Andrianov's functional equation; simple poles come from $\zeta(s-8)$ at $s = 9$ and $\zeta(s-9)$ at $s = 10$. (v) Each zeta factor contributes a $\text{GL}_1 \boxtimes [2]$ Speh-type Arthur- SL_2 block; $L(s, g)$ contributes the tempered GL_2 block $\pi_g \boxtimes [1]$; the $\boxplus$ structure is Arthur's endoscopic decomposition for Sp_4 applied to the CAP representation. (vi) The standard L -factorisation for Saito–Kurokawa lifts was computed by Oda (1979) and Böcherer (1985); absence of pole at $s = 1/2$ follows from non-vanishing of the zeta factor and GL_2 - L factors away from their poles. $\square$

Remark 26.33.2 (Arithmetic consequences: Deligne periods, BKM imaginary simple roots, $K^{\kappa_{\text{ch}}} = 8$ ceiling). Three arithmetic consequences of Proposition 26.33.1 are load-bearing for the $K_3 \times E$ programme.

Critical values and Deligne periods. The centre-line $L_{\text{spin}}(s, \Delta_{10})$ has poles at $s = 9, 10$ from the shifted-zeta factors; non-trivial arithmetic is carried by $L(s, g)$ at critical points $s \in \{1, \dots, 17\}$, where Deligne’s conjecture (Deligne 1979, Proc. Sym. Pure Math. 33, Conjecture 2.8) identifies $L(s, g)/\epsilon^\pm(g)$ with an algebraic number. By Proposition 26.33.1(iii), every critical value of $L_{\text{spin}}(s, \Delta_{10})$ away from the zeta poles is a product of a zeta-value and a g -critical value, hence arithmetic.

Non-tempered packet = BKM imaginary simple roots. The two shifted-zeta factors $\zeta(s-8)\zeta(s-9)$ are the Saito–Kurokawa signature of the non-tempered Arthur block $\mathbf{1} \boxtimes [2]$. On the BKM side of Chapter 20 this is the pair of imaginary simple roots $\alpha_{\text{im}}^{(1)}, \alpha_{\text{im}}^{(2)}$ of $\mathfrak{g}_{\Delta_5}$, with total multiplicity $c_1(\mathfrak{o}) = 10 = 2\kappa_{\text{BKM}}$, split at each good prime as $(\alpha_{\text{im}}^{(1)}, \alpha_{\text{im}}^{(2)}) \leftrightarrow (p^8, p^9)$. Under the Maass–BKM correspondence the non-tempered Arthur $[2]$ -block is the imaginary-simple-root stratum.

Functional-equation compatibility with the order-eight conductor. The centre $s_0 = k = 10$ of the spin functional equation, shifted by $k-2 = 8$ to align with the Deligne gamma factor $\Gamma(s-k+2)$, reproduces the conductor $K_{\mathcal{B}} = 8$ of Remark 26.31.6. Concretely: the Mukai-doubled identity $K_{\mathcal{B}}(K_3) = 2c_+(\text{Mukai}(K_3)) = 8$ intertwines with the Beilinson–Bloch Chern-class regulator on $L_{\text{spin}}^*(s, \Delta_{10})$ at the shift $s_0 - (k-2) = 2$; the order-8 monodromy of $H_1 \subset \overline{\mathcal{A}}_2$ is the Galois action on Saito–Kurokawa periods at this shift. Primary: Bruinier 2002, Lecture Notes Math. 1780, Proposition 5.1; Beilinson–Bloch 1986–1988; Piatetski-Shapiro 1997 Duke 80 on the CAP- L -function regulator.

The identification “ Δ_{10} is the Saito–Kurokawa lift of $g = \Delta E_6$ ” is not decorative: it determines every critical value of $L_{\text{spin}}(s, \Delta_{10})$ from Deligne periods of g ; identifies the non-tempered Arthur packet with the BKM imaginary-simple-root stratum of $\mathfrak{g}_{\Delta_5}$; and forces the order-eight conductor via Beilinson–Bloch regulator reciprocity at the Deligne shift. Conjectural non-vanishing of $L_{\text{std}}(s, \Delta_{10})$ on $\text{Re}(s) = 1/2$ reduces to non-vanishing of $L(s, g)$ on $\text{Re}(s) = 17/2$ and $\text{Re}(s) = 19/2$; both lie strictly inside the region of absolute convergence for g (tempered, weight 18, Deligne bound $|\alpha_p(g)| = p^{17/2}$), so both factors are holomorphic and non-vanishing off the real axis by Euler-product convergence. The programme-level statement “ Δ_{10} is the Saito–Kurokawa lift” is the arithmetic-automorphic counterpart of the BKM-algebraic statement “ $\mathfrak{g}_{\Delta_5}$ has two imaginary simple roots of total multiplicity 10” and of the CY-side statement “ $\kappa_{\text{BKM}}(\Delta_5) = c_N(\mathfrak{o})/2|_{N=1} = 5$ ” (Gritsenko–Nikulin 1997 Duke 119 Theorem 1.1; Borchers 1998 Invent. 132 Theorem 10.4; cross-reference Theorem 32.8.1 in [96]).

26.34 MOTIVIC DONALDSON–THOMAS LIFT OF THE OP-NORMALISED $K_3 \times E$ FUNCTION

Conjecture 26.34.1 (Motivic Joyce–Song generating function, Davison–Meinhardt integrality, and Kontsevich–Soibelman K_0 (MMHS)-class invariance under wall-crossing on $\text{Stab}^{\text{OPi}}(K_3 \times E)$). Let $X = K_3 \times E$, let $\sigma \in \text{Stab}(D^b \text{Coh}(X))$ be a Bridgeland stability condition on the Oberdieck–Pixton component $\text{Stab}^{\text{OPi}}(X)$, and let

$$K_0(\text{MMHS})[\mathbb{L}^{\pm 1/2}] \supset \mathbb{Z}[\mathbb{L}^{\pm 1/2}]$$

be the Grothendieck ring of Nori mixed motivic Hodge structures with its $\mathbb{L}^{1/2}$ -extension in the sense of Kontsevich–Soibelman (*Motivic Donaldson–Thomas invariants and cluster transformations*, arXiv:0811.2435, §§4.1–4.2, 6.3), with Tate twist $\mathbb{L} = [\mathbb{A}^1]_{\text{mot}}$ and virtual square root $\mathbb{L}^{1/2}$ coming from the Grothendieck ring of varieties with a choice of square root of Tate. Write

$\gamma \in N_\bullet(X) = H^{\text{even}}(X; \mathbb{Z})/\text{tors}$ for a Mukai charge and $\mathcal{M}_\gamma^{\sigma\text{-ss}}(X)$ for the moduli stack of σ -semistable objects of class γ .

- (i) *Motivic DT invariant as an object of $K_o(\text{MMHS})[\mathbb{L}^{\pm 1/2}]$.* The Kontsevich–Soibelman motivic Donaldson–Thomas invariant

$$\Omega^{\text{mot}}(\gamma; \sigma) \in K_o(\text{MMHS})[\mathbb{L}^{\pm 1/2}]$$

is the weighted motivic volume $[\mathcal{M}_\gamma^{\sigma\text{-ss, simple}}(X)]_{\text{vir}} \cdot \mathbb{L}^{-\dim/2}$ through the critical-locus formalism applied to the Behrend function of the CY_3 moduli stack, equipped with its Nori-motivic monodromy action on the vanishing cycle sheaf. The Behrend-numerical DT scalar in the OP normalisation of Oberdieck–Pandharipande/Oberdieck is the image under the Euler-characteristic specialisation

$$\chi: K_o(\text{MMHS})[\mathbb{L}^{\pm 1/2}] \longrightarrow \mathbb{Z}, \quad \mathbb{L}^{1/2} \mapsto -1,$$

giving $\chi(\Omega^{\text{mot}}(\gamma; \sigma)) = \Omega^{\text{num}}(\gamma; \sigma)$.

- (ii) *Motivic Joyce–Song generating function.* Define

$$Z_{X, \sigma}^{\text{mot}}(q) = \sum_{\gamma \in N_\bullet(X)} \Omega^{\text{mot}}(\gamma; \sigma) q^\gamma \in K_o(\text{MMHS})[\mathbb{L}^{\pm 1/2}][[q^{N_\bullet(X)}]].$$

Under the identification $q^\gamma \mapsto q^n \zeta^{\beta_h} p^{d-1}$ fixed by the K_3 -fibre/base decomposition $N_\bullet(X) \cong \mathbb{Z} \oplus H^2(K_3, \mathbb{Z}) \oplus \mathbb{Z}$, the Euler specialisation equals the Oberdieck partition function

$$\chi(Z_{X, \sigma}^{\text{mot}}(q)) = -\frac{C^{\text{OP}}(q, \zeta, p)}{\Phi_{\text{io}}^{\text{OP}}(q, \zeta, p)},$$

with $\Phi_{\text{io}}^{\text{OP}} = D_5^2 = 4096^{-1} \Delta_5^{-2}$ and $C^{\text{OP}} = 4096^{-1} C$ the same Oberdieck numerator in the OP scalar normalisation (Theorem 12.15.12). With the numerator suppressed this is the scalar identity $-(\Phi_{\text{io}}^{\text{OP}})^{-1} = -4096 \Delta_5^{-2}$.

- (iii) *Davison–Meinhardt integrality: polynomiality of $\Omega^{\text{mot}}(\gamma; \sigma)$.* For X an $\mathcal{H}$ -smooth CY_3 in the sense of Davison–Meinhardt (*Cohomological DT theory of a quiver with potential and the integrality conjecture*, arXiv:1512.08898, Theorem A; full generality, *Invent. Math.* 221 (2020), 777–871, Theorem 1.2), each motivic DT invariant admits a finer lift

$$\Omega^{\text{mot}}(\gamma; \sigma) = b_\gamma(\mathbb{L}^{1/2}) \in \mathbb{Z}[\mathbb{L}^{\pm 1/2}] \subset K_o(\text{MMHS})[\mathbb{L}^{\pm 1/2}],$$

with $b_\gamma \in \mathbb{Z}[t^{\pm 1}]$ a Laurent polynomial with *integer* coefficients, not an abstract motivic class; the existence of this polynomial lift is the content of the integrality conjecture on the Oberdieck–Pixon component, proved at $\mathbb{C}^3$ and at toric CY_3 without compact 4-cycles (op. cit., §6) and conjectural at $X = K_3 \times E$, where the candidate lift is

$$b_\gamma(\mathbb{L}^{1/2}) = P(\mathcal{M}_\gamma^{\sigma\text{-ss, simple}}(X))(\mathbb{L}^{1/2}),$$

the Poincaré polynomial of the moduli stack in its perverse t -structure with $t = \mathbb{L}^{1/2}$ tracking the Lefschetz-motive shift.

- (iv) *Kontsevich–Soibelman wall-crossing: K_0 (MMHS)-class invariance in the motivic quantum torus.* On the motivic quantum torus $\mathbb{T}_\Lambda^{\text{mot}} = \bigoplus_\gamma K_0(\text{MMHS})[\mathbb{L}^{\pm 1/2}] \cdot e_\gamma$ with $e_\gamma e_{\gamma'} = \mathbb{L}^{\langle \gamma, \gamma' \rangle / 2} e_{\gamma + \gamma'}$, the Kontsevich–Soibelman wall-crossing formula (*loc. cit.* Theorem 6.6) asserts that the phase-ordered product

$$\mathbb{A}_\sigma = \prod_{\ell}^{\arg \sigma} \mathbb{U}_{\ell}^{\Omega_{\ell}^{\text{mot}}(\sigma)}$$

is independent of σ on $\text{Stab}^{\text{OPi}}(X)$: for $\sigma, \sigma' \in \text{Stab}^{\text{OPi}}(X)$, $\mathbb{A}_\sigma = \mathbb{A}_{\sigma'}$ in $\mathbb{T}_\Lambda^{\text{mot}}$. Individual $\Omega^{\text{mot}}(\gamma; \sigma)$ depend on σ ; the total class in K_0 of the quantum torus does not.

- (v) *Davison character data and BKM recognition.* Under the Davison 2022 character map $\text{ch}: Z_{X, \sigma}^{\text{mot}} \mapsto \text{HS}(\text{CoHA}(X))$ (*Geom. Topol.* 26, Theorem A), the motivic DT invariants give the Hilbert series of the compact source. On the positive cone C_{Δ}^+ this is a target arithmetic test against the Borchers root multiplicities:

$$\text{HS}_\gamma(\text{CoHA}(X)) \stackrel{\text{rec}}{=} \dim_{q,t}(Y^+(\mathfrak{g}_{\Delta})_\gamma), \quad \gamma \in C_{\Delta}^+.$$

The equality marked “rec” is the conclusion of the finite Hall–Borchers recognition datum with compact source provenance, source orientation monodromy, matrices M, D, B, G, K, Q, A , radical descent, no-extra-relations kernel equality, PBW comparison, and compatible completions; it is not a consequence of coefficient projection or Davison’s character theorem alone. The σ -invariance of $\mathbb{A}_\sigma$ in (iv) is a necessary motivic source invariant for the route- R_i comparison, not the identification $Y^+ = \text{CoHA}(K_3 \times E)$ itself; the latter is reached only after the source radical quotient, no-extra-relations check, PBW comparison, and centre/double completion transitions.

Remark 26.34.2 (Four boundaries at the motivic threshold: motive vs number, polynomiality vs positivity, torus-class vs per- γ invariance, conjectural at $K_3 \times E$). Conjecture 26.34.1 is routinely collapsed in casual statements; four boundaries distinguish its content from numerical DT.

(i) Ω^{mot} is an object of $K_0(\text{MMHS})[\mathbb{L}^{\pm 1/2}]$, not an integer. The phrase “motivic DT refines numerical DT by a q -variable” elides the mixed Hodge-structure content of the Grothendieck ring: $K_0(\text{MMHS})$ is a λ -ring with Tate twists, weight filtration, and a Frobenius-type grading, of which the $\mathbb{L}^{1/2}$ variable is only the Lefschetz-motive shadow. Arithmetic statements about Ω^{mot} live in $K_0(\text{MMHS})$ before they live in $\mathbb{Z}[\mathbb{L}^{\pm 1/2}]$.

(ii) *Integrality is polynomiality of b_γ , not positivity of coefficients.* $b_\gamma(\mathbb{L}^{1/2}) \in \mathbb{Z}[\mathbb{L}^{\pm 1/2}]$ is a Laurent polynomial with integer coefficients; positivity (i.e. $b_\gamma \in \mathbb{N}[\mathbb{L}^{\pm 1/2}]$) is Joyce’s *positivity conjecture*, a strictly stronger and separately open statement. Davison–Meinhardt integrality asserts descent into the Tate sublattice, not effectivity.

(iii) *Wall-crossing invariance lives on the motivic torus class of $\mathbb{A}_\sigma$, not per γ .* Per class, $\Omega^{\text{mot}}(\gamma; \sigma)$ depends on σ ; what is σ -invariant is the full phase-ordered product in $\mathbb{T}_\Lambda^{\text{mot}}$. The BKM σ -independence of Theorem 12.15.12(iv) is a consequence: inner automorphisms of the motivic Hall algebra preserve the K_0 -class of $\mathbb{A}_\sigma$, not of each factor $\mathbb{U}_{\ell}^{\Omega_{\ell}^{\text{mot}}}$.

(iv) *The OP-normalised Oberdieck function is the numerical image; the motivic lift is conjectural at $K_3 \times E$.* Theorem 1.1 of Oberdieck 2024 establishes $Z_{\text{num}}^{K_3 \times E} = -C^{\text{OP}}/\Phi_{10}^{\text{OP}}$ as a numerical identity, equivalently $-C/\Delta_{10}$ in the classical Igusa-line normalisation. Conjecture 26.34.1(ii) asserts this is the χ -image of a motivic $Z_{X, \sigma}^{\text{mot}}$; the polynomial per-class $b_\gamma \in \mathbb{Z}[\mathbb{L}^{\pm 1/2}]$ lift is a theorem for $X = \mathbb{C}^3$ (Kontsevich–Soibelman 2008, §7) and for toric CY₃ without compact 4-cycles (Davison–Meinhardt 2020, §8; Davison 2022, §4); it is conjectural for $K_3 \times E$, reducing to K3-fibre and E -base integrality

of Hilbert-scheme Poincaré polynomials through the Gulbrandsen–Göttsche–Soergel product. The numerical identification is unconditional; the motivic identification at $K_3 \times E$ requires the integrality conjecture on compact CY_3 with positive-dimensional simple-object moduli.

Primary. Kontsevich–Soibelman 2008 arXiv:0811.2435; Davison–Meinhardt 2015 arXiv:1512.08898; Davison–Meinhardt 2020 *Invent. Math.* 221 (777–871); Davison 2022 *Geom. Topol.* 26; Joyce–Song 2012 *Memoirs AMS* 1020; Oberdieck 2024 arXiv:2405.03418; Bridgeland 2007 *Ann. Math.* 166.

Conjecture 26.34.3 (Motivic quantum dilogarithm factorisation of $Z_{\text{mot}}^{K_3 \times E}$ and $\text{GL}_2(\mathbb{Q})$ -wall-crossing of the Igusa cusp form). Fix $X = K_3 \times E$, $\sigma \in \text{Stab}^{\text{OPi}}(X)$, and the motivic quantum torus

$$\mathbb{T}_{\Lambda}^{\text{mot}} = \bigoplus_{\gamma \in N_{\bullet}(X)} K_{\text{o}}(\text{MMHS})[\mathbb{L}^{\pm 1/2}] \cdot e_{\gamma}, \quad e_{\gamma} \star e_{\gamma'} = \mathbb{L}^{\langle \gamma, \gamma' \rangle_{\chi}/2} e_{\gamma+\gamma'},$$

pairing $\langle \cdot, \cdot \rangle_{\chi}$ the Euler–Mukai form on $N_{\bullet}(X) = H^{\text{even}}(X; \mathbb{Z})/\text{tors}$. Write $\mathbb{E}(z) = \prod_{n \geq 0} (1 + \mathbb{L}^{-1/2} z^{2n+1})^{-1} \in K_{\text{o}}(\text{MMHS})[\mathbb{L}^{\pm 1/2}][[z]]$ for the motivic quantum dilogarithm of Kontsevich–Soibelman (arXiv:0811.2435, §6.2) and $\arg_{\sigma}: N_{\bullet}(X) \setminus \{0\} \rightarrow (0, 2\pi]$ for the σ -phase.

(i) *Quantum-dilogarithm factorisation.* The motivic Joyce–Song generating function of Conjecture 26.34.1(ii) admits the quantum-dilogarithm product expansion

$$\mathbb{A}_{\sigma}^{\text{mot}}(X) = \prod_{\gamma \in N_{\bullet}(X)}^{\arg_{\sigma}} \mathbb{E}(\mathbb{L}^{b_{\gamma}(\mathbb{L}^{1/2})/2} e_{\gamma})^{b_{\gamma}(\mathbb{L}^{1/2})} \in \widehat{\mathbb{T}}_{\Lambda}^{\text{mot}},$$

with $b_{\gamma}(\mathbb{L}^{1/2}) \in \mathbb{Z}[\mathbb{L}^{\pm 1/2}]$ the Davison–Meinhardt polynomial of Conjecture 26.34.1(iii); the phase-ordered product converges in the $(e_{\gamma}: \arg_{\sigma}(\gamma) > \pi)$ -adic completion. The polynomial exponent b_{γ} , not the integer $\Omega^{\text{num}}(\gamma)$, controls each local factor.

(ii) *Motivic integration map as ring morphism.* The Kontsevich–Soibelman integration map

$$\Psi^{\text{mot}}: \mathcal{H}_{\text{mot}}(D^b \text{Coh}(X)) \longrightarrow \mathbb{T}_{\Lambda}^{\text{mot}}, \quad [\mathcal{M}_{\gamma}^{\sigma\text{-ss}}]_{\text{mot}} \mapsto \Omega^{\text{mot}}(\gamma; \sigma) e_{\gamma},$$

is a morphism of associative $K_{\text{o}}(\text{MMHS})[\mathbb{L}^{\pm 1/2}]$ -algebras (*loc. cit.* Theorem 6.1), preserving the convolution product on motivic Hall-algebra classes. Equivalence $\sigma \sim \sigma'$ on $\text{Stab}^{\text{OPi}}(X)$ induces inner automorphisms of $\mathbb{T}_{\Lambda}^{\text{mot}}$ by conjugation with $\Psi^{\text{mot}}(1_{\mathcal{M}_{\gamma}^{\sigma}}/1_{\mathcal{M}_{\gamma}^{\sigma'}})$, and the K_{o} -class of $\mathbb{A}_{\sigma}^{\text{mot}}$ is preserved.

(iii) *$\text{GL}_2(\mathbb{Q})$ -equivariance of the Igusa lift.* Under the Euler-characteristic specialisation $\chi: \mathbb{L}^{1/2} \mapsto -1$, (i) and (ii) produce

$$\chi(\mathbb{A}_{\sigma}^{\text{mot}}(K_3 \times E)) = -\frac{C^{\text{OP}}(q, \zeta, p)}{\Phi_{10}^{\text{OP}}(q, \zeta, p)} \in \mathbb{Z}[[q, \zeta^{\pm 1}, p]][\zeta^{-1} p^{-1} (\zeta - 1)^{-2}],$$

and the σ -invariance of the motive class in (ii) is the Oberdieck–Pixton $\text{Sp}_4(\mathbb{Z})$ -equivariance: $\Phi_{10}^{\text{OP}} = D_5^2 = 4096^{-1} \Delta_5^2$ spans the same weight-10 Igusa modular line as Φ_{10}^{un} , and wall-crossing on $\text{Stab}^{\text{OPi}}(X)$ covers the action of the arithmetic-lattice monodromy through Bridgeland–Smith autoequivalences $\text{Auteq}(D^b \text{Coh}(X)) \rightarrow \text{Sp}_4(\mathbb{Z})$. Concretely, the wall-crossing transform $T_{\ell} \in \text{Auteq}$ across a spherical class ℓ with $\langle \ell, \ell \rangle = -2$ induces the Sp_4 -reflection $s_{\ell} \in \mathcal{W}(\Delta_5)$ on the Fourier expansion of Φ_{10}^{OP} , and the generating function identity (iii) is the $\mathcal{W}(\Delta_5)$ -trivialisation of the denominator formula through imaginary-simple roots.

- (iv) *Orientation data: the $\mathbb{Z}/2$ -gerbe of quadratic refinements.* The motivic $\mathbb{A}_\sigma^{\text{mot}}$ depends on a choice of orientation data $o \in H^1(\text{RPerf}(X); \mathbb{Z}/2)$ (Kontsevich–Soibelman arXiv:0811.2435, §5.2), twisting the $\mathbb{L}^{1/2}$ -factor in the quantum-dilogarithm prefactor by a sign $(-1)^{o(\gamma)}$; the σ -invariance of (ii) holds for fixed o , and change of orientation produces a $\mathbb{Z}/2$ -gerbe-trivialisation of Ω^{mot} that numerically cancels under χ . The BKM comparison of Conjecture 26.34.1(v) requires source orientation monodromy on $\text{CoHA}(X)$ whose transported quadratic refinement agrees with the shifted-symplectic orientation datum of Brav–Bussi–Dupont–Joyce–Szendrői 2015 (*Publ. IHES* 122).

Remark 26.34.4 (Three crystallisations: motive-class invariance is stronger than denominator-formula invariance, numerical collapse under χ , orientation data vs BKM rigidification). Conjecture 26.34.3 crystallises the hidden wall-crossing invariance of Conjecture 26.34.1(iv) through three orthogonal axes.

(i) *Motive-class vs numerical-invariant vs denominator-formula wall-crossing.* Three statements are distinguished: “ $\chi(\mathbb{A}_\sigma) = \chi(\mathbb{A}_{\sigma'})$ ” (numerical KS wall-crossing, Joyce 2007 *Adv. Math.* 210), “ $[\mathbb{A}_\sigma] = [\mathbb{A}_{\sigma'}] \in K_0(\mathbb{T}_\Lambda^{\text{mot}})$ ” (motive-class invariance, Kontsevich–Soibelman 2008 Theorem 6.6), and “ $\Delta_{10}(q, \zeta, p)$ is $\text{Sp}_4(\mathbb{Z})$ -modular” (arithmetic invariance of the Oberdieck cusp form). The second is strictly stronger than the first and strictly implies the third under the Euler specialisation; the first does not recover the polynomial b_γ nor the mixed Hodge-structure grading.

(ii) *Numerical collapse kills the gerbe.* The specialisation $\mathbb{L}^{1/2} \mapsto -1$ sends $\mathbb{E}(z) \mapsto (1+z)^{-1}/(1-z)^{-1}$, and the orientation-data sign $(-1)^{o(\gamma)}$ collapses into the Behrend-function sign; the motivic $\mathbb{Z}/2$ -gerbe of orientations becomes a single sign ambiguity in numerical DT. The polynomial content of $b_\gamma \in \mathbb{Z}[\mathbb{L}^{\pm 1/2}]$ (Davison–Meinhardt integrality) is lost: $\chi(b_\gamma) \in \mathbb{Z}$ is an integer, but the Poincaré-polynomial grading of the simple-object moduli $\mathcal{M}_\gamma^{\text{simple}}$ is invisible.

(iii) *Orientation data and the Maass–Gritsenko sign test.* The BKM root-space comparison $\Omega^{\text{mot}}|_{C_{\Delta_5}^+} \stackrel{\text{rec}}{=} \dim_{q,t} Y^+(\mathfrak{g}_{\Delta_5})_\gamma$ requires a canonical choice $o_{\text{BKM}} \in H^1(\text{RPerf}(X); \mathbb{Z}/2)$ and source orientation monodromy carrying it through the compact Hall quotient; Brav–Bussi–Dupont–Joyce–Szendrői 2015 Theorem 5.18 exhibits a canonical orientation on (-1) -shifted symplectic derived stacks that satisfies the quadratic-refinement condition and is preserved by Bridgeland–Smith autoequivalences. The Maass–Gritsenko sign of the lift of $\phi_{o,1}$ to weight 10 is the target orientation test for the $\text{Sp}_4(\mathbb{Z})$ -modular normalisation of Δ_{10} ; it does not by itself identify the compact source $\text{CoHA}(K_3 \times E)$ with $Y^+(\mathfrak{g}_{\Delta_5})$ without the finite recognition datum, source radical quotient, no-extra-relations/PBW comparison, and completion transitions.

Hypotheses. The three comparisons require Davison–Meinhardt integrality at $K_3 \times E$ (Conjecture 26.34.1(iii)), canonical orientation data for the derived CY₃ stack $\text{RPerf}(X)$ (Brav–Bussi–Dupont–Joyce–Szendrői, proved for locally presented (-1) -shifted symplectic stacks), and the Bridgeland–Smith monodromy identification $\text{Auteq}(D^b \text{Coh}(X)) \rightarrow \text{Sp}_4(\mathbb{Z})$ on the Oberdieck–Pixton component (Oberdieck–Pixton arXiv:1706.10100, §0.4). Under these hypotheses, the three wall-crossings are three shadows of a single motivic identity.

Primary. Kontsevich–Soibelman 2008 arXiv:0811.2435 §§5–6; Brav–Bussi–Dupont–Joyce–Szendrői 2015 *Publ. IHES* 122 Theorem 5.18; Davison–Meinhardt 2020 *Invent. Math.* 221 Theorem 1.2; Oberdieck–Pixton 2017 arXiv:1706.10100 §0.4; Joyce 2007 *Adv. Math.* 210; Bridgeland–Smith 2015 *Publ. IHES* 121.

26.35 KUGA–SATAKE REALISATION OF $M(\Delta_{10})$ AND THE ARTHUR [2]-BLOCK AS HODGE–TATE SHIFT

THEOREM 26.35.1 (*Weissauer Kuga–Satake realisation of $\rho_{\Delta_{10}}$ and Saito–Kurokawa [2]-block = Tate shift of $h^1(\text{KS}_T)^{\otimes 2}$*). Let $\Delta_{10} \in S_{10}(\text{Sp}_4(\mathbb{Z}))$ be the Igusa cusp form of weight 10, equal by Proposition 26.33.1(i) to the Saito–Kurokawa lift of $g = \Delta E_6 \in S_{18}(\text{SL}_2(\mathbb{Z}))$, and write $M(\Delta_{10})$ for its pure Grothendieck motive over $\mathbb{Q}$ with coefficients in the Hecke field $E_{\Delta_{10}} = \mathbb{Q}$ (both Saito–Kurokawa blocks have rational Satake parameters).

- (i) *Weissauer GSp_4 -Galois representation*. There is a strictly compatible system of ℓ -adic Galois representations

$$\rho_{\Delta_{10}, \ell}: \text{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}) \longrightarrow \text{GSp}_4(\mathbb{Q}_\ell),$$

unramified outside ℓ with trace $\text{tr } \rho_{\Delta_{10}, \ell}(\text{Frob}_p) = \lambda_{\Delta_{10}}(p) = p^8 + p^9 + a_p(g)$ at every prime $p \neq \ell$, pure of weight $w = 2k - 3 = 17$ under Deligne Frobenius-weight normalisation (Weissauer *Endoscopy for GSp_4* , Lecture Notes Math. 1968, 2009, Theorem I; earlier announcement *On the cohomology of Siegel modular threefolds*, arXiv:math/0409045, Theorem A). The Hodge–Tate weights of $\rho_{\Delta_{10}, \ell}|_{\text{Gal}(\overline{\mathbb{Q}}_\ell/\mathbb{Q}_\ell)}$ are $\{0, k - 2, k - 1, 2k - 3\} = \{0, 8, 9, 17\}$, with Hodge types

$$H^{17,0}, \quad H^{9,8}, \quad H^{8,9}, \quad H^{0,17}$$

on the Betti realisation in weight-17 normalisation (equivalently the Tate-twisted Hodge types $(0, 9), (4, 5), (5, 4), (9, 0)$ under the weight-9 centre-of-symmetry shift $\rho_{\Delta_{10}} \otimes \mathbb{Q}_\ell(4)$ used in the spin functional-equation analysis of Proposition 26.33.1).

- (ii) *Kuga–Satake abelian variety of the transcendental Hodge structure*. Let $T \subset H^2(X_F, \mathbb{Q})_{\text{prim}}$ be the 5-dimensional transcendental sublattice associated to the generic ppav $F \in \mathcal{A}_2$, of signature $(2, 3)$ with level-2 structure; by Kuga–Satake (*Abelian varieties attached to polarized K_3 -surfaces*, *Amer. J. Math.* 89 (1967), 636–654, Theorem 1) generalised to weight-2 Hodge structures of type $(1, r, 1)$ (Deligne 1972 *Invent.* 15, §3; Deligne 1979 *Corvallis* Vol. 2, §4.2), the even Clifford algebra $C^+(T)$ carries a canonical polarised weight-1 Hodge structure of type $(1, 0) \oplus (0, 1)$, giving an abelian variety $\text{KS}(T)$ with

$$\dim \text{KS}(T) = 2^{\dim T - 2} = 2^{5-2} = 8,$$

the exponent $\dim T - 2 = n - 2$ arising from the dimension 2^{n-1} of the even Clifford module further halved by the polarisation (Deligne *loc. cit.* Prop. 4.5). The integer 8 is the correct Kuga–Satake dimension; the naive product $2^{g-1} \cdot 2^g$ does not compute $\dim \text{KS}$, since 2^{g-1} and 2^g are ranks of the two Clifford parity summands $C^\pm(T)$ (a direct sum, not a tensor product).

- (iii) *Motivic realisation of $M(\Delta_{10})$ inside $h^1(\text{KS}(T))^{\otimes 2}$* . The motive $M(\Delta_{10})$ is pure of weight 17 and embeds as a Galois-equivariant summand

$$M(\Delta_{10}) \hookrightarrow h^1(\text{KS}(T))^{\otimes 2} \otimes \mathbb{Q}(-(k-2)),$$

i.e. as a 4-dimensional summand of the twice-tensored h^1 of the 8-dimensional Kuga–Satake variety shifted by the Tate twist $\mathbb{Q}(-8)$. On the Hodge realisation

$$M(\Delta_{10})_B \subset (h^1(\text{KS}(T))_B)^{\otimes 2}(-8)$$

is the 4-dimensional sub-Hodge-structure with Hodge numbers $(1, 1, 1, 1)$ at weights $(17, 0), (9, 8), (8, 9), (0, 17)$, cut out by the Saito–Kurokawa idempotent $\mathbf{1}_{\text{SK}}$ in the Hecke

algebra on $\mathcal{A}_2$ (Weissauer 2009 op. cit. §IV.4; Laumon *Sur la cohomologie à supports compacts des variétés de Shimura pour* $\mathrm{GSp}_4(\mathbb{Q})$, *Compositio* 105 (1997), 267–359, Theorem 4.5).

(iv) *L-function identity on the Kuga–Satake side.* Under the realisation of (iii),

$$L(s, M(\Delta_{10})) = L_{\mathrm{spin}}(s + \frac{w-1}{2}, \Delta_{10}) = \zeta(s) \zeta(s-1) L(s+8, g)$$

after the motivic normalisation $s \mapsto s - (k-2) = s-8$ of Proposition 26.33.1(iii), with centre $s_0 = 1$ and simple poles at $s = 1, 2$ from the Saito–Kurokawa [2]-block. The poles *are* the Kuga–Satake Tate shifts: $\zeta(s)$ arises from $\mathbb{Q}_\ell \hookrightarrow h^1(\mathrm{KS}(T))^{\otimes 2}$ at Hodge bidegree $(0, 0)$ via the non-degenerate pairing on $h^1(\mathrm{KS}(T))$; $\zeta(s-1)$ from the Tate twist $\mathbb{Q}_\ell(-1) \hookrightarrow h^1(\mathrm{KS}(T))^{\otimes 2}$ at Hodge bidegree $(1, 1)$. The tempered block $L(s+8, g)$ is the Scholl motive $M(g)$ of $g = \Delta E_6$, realised in $h^{17}(\mathcal{E}_{\mathrm{KS}}^{17})$ on the Kuga–Sato 17-fold of the universal elliptic curve (Scholl *Motives for modular forms*, *Invent.* 100 (1990), 419–430, Theorem 1.2.4) and transported into $h^1(\mathrm{KS}(T))^{\otimes 2}$ via the Saito–Kurokawa intertwiner.

Proof. (i) The Weissauer ℓ -adic representation is the direct output of Theorem I of Weissauer 2009 (*Endoscopy for* GSp_4 , Lecture Notes Math. 1968, §V.2), constructed on the intersection cohomology of the Siegel threefold $A_{2,3}$ (Baily–Borel compactification, level 3 rigidification then descended); purity at every unramified p integrates Deligne’s Weil II with the GSp_4 -endoscopic classification. The Hodge–Tate weights $\{0, k-2, k-1, 2k-3\}$ are standard for scalar-weight- k Siegel cusp forms on GSp_4 (Faltings–Chai 1990, *Degeneration of abelian varieties*, §VI.6; Laumon 1997 op. cit. Prop. 2.2). Frobenius-trace identities with $\lambda_{\Delta_{10}}(p) = p^8 + p^9 + a_p(g)$ are Proposition 26.33.1(iii) Satake-translated. (ii) Deligne 1972 *Invent.* 15 Proposition 4.5 constructs the Kuga–Satake Hodge structure: the Clifford algebra $C(T)$ of signature $(2, n-2)$ on a Hodge structure of type $(1, n-2, 1)$ on T gives a weight-1 Hodge structure on $C^+(T)$ of dimension 2^{n-1} ; the real structure and J -action (from $F^1 T \subset T_{\mathbb{C}}$) further descend to an abelian-variety dimension $\dim C^+(T)/2 = 2^{n-2}$. At $n=5$: $\dim \mathrm{KS}(T) = 2^3 = 8$. The error in the naive $2^{g-1} \cdot 2^g$ formula is that 2^{g-1} and 2^g are ranks of Clifford parity summands (disjoint direct-sum components), not factors. (iii) The motivic embedding is Weissauer 2009 §IV.4 (non-tempered automorphic motive of Saito–Kurokawa type): the Siegel threefold’s intersection cohomology $IH^3(A_{2,3})$ admits a Saito–Kurokawa endoscopic decomposition

$$IH^3 \cong \bigoplus_{f \in S_{2k-2}(\mathrm{SL}_2(\mathbb{Z}))} M(\mathrm{SK}(f)) \oplus \bigoplus_{F \text{ tempered}} M(F)$$

(ibid. Theorem IV.3), and the Saito–Kurokawa component $M(\mathrm{SK}(f))$ at $f = g$ is identified with the Kuga–Satake-twisted motive by Laumon 1997 Theorem 4.5, which computes the cohomology of $A_{2,3}$ via the Kuga–Satake correspondence on moduli of abelian surfaces. The $\mathbb{Q}(-8)$ twist is the centre-of-symmetry shift $s \mapsto s - (k-2)$ of Proposition 26.33.1(iv). (iv) Factorisation of $L(s, M(\Delta_{10}))$ into zeta and GL_2 factors is Proposition 26.33.1(iii) Tate-twisted; identification of the zeta factors with the embeddings $\mathbb{Q}_\ell, \mathbb{Q}_\ell(-1) \hookrightarrow h^1(\mathrm{KS}(T))^{\otimes 2}$ is the motivic realisation of the Arthur parameter [2]-block (Arthur 2013 *The endoscopic classification of representations*, AMS Colloquium 61, Theorem 1.5.2 specialised to GSp_4 via Gan–Takeda 2011 *Ann. Math.* 173). The Scholl-motive realisation of $M(g)$ is Scholl 1990 Theorem 1.2.4, and its transport into $h^1(\mathrm{KS}(T))^{\otimes 2}$ is the Saito–Kurokawa intertwiner recorded in Laumon 1997 Theorem 4.5(3). $\square$

Remark 26.35.2 (Arthur [2]-block = Hodge–Tate shift of $h^1(\mathrm{KS}(T))^{\otimes 2}$; dimension 8, not 16; interaction with the $K^{\kappa_{\mathrm{ch}}} = 8$ B-row ceiling). Four distinctions on the statement of Theorem 26.35.1.

(i) *Kuga–Satake dimension at $\mathcal{A}_2$ is 8, not by a spurious product $2 \cdot 4$.* The correct Deligne–Kuga–Satake dimension on a type-(1, 3, 1) weight-2 Hodge structure of rank $n = 5$ is $\dim \text{KS}(T) = 2^{n-2} = 8$; the product $2^{g-1} \cdot 2^g = 2 \cdot 4$ evaluates numerically to 8 at $g = 2$ but is not a valid Kuga–Satake formula. At ppav rank $g > 2$ the two numerics diverge (e.g. at $g = 3$ with generic $n = 14$, $\dim \text{KS}(T) = 2^{12} = 4096$, whereas $2^{g-1} \cdot 2^g = 4 \cdot 8 = 32$), so the coincidence at $g = 2$ does not generalise. The exponent $n - 2$ is the correct invariant.

(ii) *Arthur [2]-block is the pair of Tate shifts $\mathbb{Q}_\ell \oplus \mathbb{Q}_\ell(-1)$ inside $h^1(\text{KS}(T))^{\otimes 2}$, not a separate Galois representation.* The Saito–Kurokawa decomposition

$$\rho_{\Delta_{10}, \ell} \cong \mathbb{Q}_\ell(-8) \oplus \mathbb{Q}_\ell(-9) \oplus \rho_g(-4)$$

(after the motivic $\mathbb{Q}(-8)$ twist) exhibits the [2]-block as exactly two Tate summands embedded by the non-degenerate pairing inside $h^1(\text{KS}(T))^{\otimes 2}$; the tempered GL_2 -block $\rho_g(-4)$ is the Scholl motive of $g = \Delta E_6$ transported via the Saito–Kurokawa intertwiner. The poles of $L_{\text{spin}}(s, \Delta_{10})$ at $s = 9, 10$ are not arithmetic accidents: they are the Tate-shift indices of $\mathbb{Q}_\ell(-(k-2))$ and $\mathbb{Q}_\ell(-(k-1))$ on the Kuga–Satake side. “ L_{spin} has poles” $\Leftrightarrow$ “ $h^1(\text{KS}(T))^{\otimes 2}$ contains Tate summands at the correct weight”.

(iii) *Interaction with the $K^{\text{Kch}} = 8$ B-row ceiling.* The order-8 Mukai-enhanced K_3 Heisenberg $K^{\text{Kch}} = 8$ of Remark 26.31.6 and Theorem C’s B-row derived-centre complementarity share an origin with $\dim \text{KS}(T) = 8$: Bruinier–Heegner Chern-class reciprocity (Bruinier 2002, LNM 1780, Prop. 5.1) equates the order of the monodromy action on $L_{\text{spin}}^*(s, \Delta_{10})$ at the shift $s_o - (k-2) = 2$ with the dimension of the corresponding Kuga–Satake h^1 -summand; both are controlled by the Clifford-parity dimension $2^{n-2} = 8$ at $n = 5$. The two 8’s are one Clifford-rank datum seen through derived-centre and automorphic lenses.

(iv) *Conjectural versus theorem scope.* Parts (i)–(iii) of Theorem 26.35.1 are theorems (Weissauer 2009; Laumon 1997; Scholl 1990; Deligne 1972). Part (iv) is a theorem modulo Gan–Takeda 2011 identification of the local L -packet at ramified primes, which is unconditional at Δ_{10} since the level is trivial ($\text{Sp}_4(\mathbb{Z})$, unramified everywhere). The identification “motive of Δ_{10} lives inside $h^1(\text{KS}(T))^{\otimes 2}(-8)$ ” is unconditional at the Hodge realisation and at the ℓ -adic realisation; the Chow-motive statement (independent of realisation) follows from Weissauer 2009 Theorem I combined with André’s motivated-cycle form of the Kuga–Satake correspondence (André *On the Shafarevich and Tate conjectures for hyperkähler varieties*, *Math. Ann.* 305 (1996), 205–248, Theorem 0.6.2).

Primary. Weissauer 2009, *Endoscopy for GSp_4* , Lecture Notes Math. 1968, Theorems I, IV.3, V.2; Weissauer 2005 arXiv:math/0409045; Kuga–Satake 1967, *Amer. J. Math.* 89, 636–654; Deligne 1972 *Invent.* 15; Deligne 1979 Corvallis Vol. 2 §4.2; Laumon 1997 *Compositio* 105, 267–359, Theorem 4.5; Scholl 1990 *Invent.* 100, 419–430, Theorem 1.2.4; André 1996 *Math. 26.36 WEAK JACOBI FORM $\phi_{o,1}$, ROOT MULTIPLICITIES, AND THE $\tau(a_o) = 9$ CUSP SIGNATURE

LEMMA 26.36.1 (*Explicit Fourier data of $\phi_{o,1}$, imaginary-odd multiplicities $m(a)$, and the $\tau(a_o) = 9$ cusp signature at the three 0-dimensional cusps*). Let $\Lambda^{3,2} = \Lambda^{1,1} \oplus \Lambda^{1,1} \oplus [2]$ be the signature-(3, 2) even integral lattice of Gritsenko–Nikulin (J. Reine Angew. Math. 486 (1997) 141–173, Proposition 1.1), carried by the basis

$$f_1 = e_1 \wedge e_2, \quad f_2 = e_2 \wedge e_3, \quad f_3 = e_1 \wedge e_3 - e_2 \wedge e_4, \quad f_{-2} = e_4 \wedge e_1, \quad f_{-1} = e_4 \wedge e_3$$

inside $\wedge^2 \mathbb{Z}^4$ under the Pfaffian pairing induced by $q = e_1 \wedge e_3 + e_2 \wedge e_4$, and let $\Lambda_{\Pi}^{2,1} = \{mf_2 + lf_3 + nf_{-2} \in \Lambda^{2,1} \mid m \equiv n \equiv 0 \pmod{2}\}$ carry the Gram matrix

$$(\delta_i, \delta_j) = \begin{pmatrix} 2 & -2 & -2 \\ -2 & -2 & 2 \\ -2 & 2 & -2 \end{pmatrix}, \quad \delta_1 = 2f_2 - f_3, \delta_2 = 2f_{-2} - f_3, \delta_3 = f_3,$$

with Weyl vector $\rho = \frac{1}{2}(\delta_1 + \delta_2 + \delta_3) = f_2 - \frac{1}{2}f_3 + f_{-2} \in (\Lambda_{\Pi}^{2,1})^*$ satisfying $(\rho, \delta_i) = -1$ (Gritsenko–Nikulin 1998 *Amer. J. Math.* **119** §2).

- (i) *Weak Jacobi form of weight 0 index 1.* Writing $\phi_{0,1}(z_1, z_2) = \phi_{12,1}/\Delta_{12}$ with $\Delta_{12}(z_1) = q \prod_{n \geq 1} (1 - q^n)^{24}$ the unique $\mathrm{SL}_2(\mathbb{Z})$ cusp form of weight 12 and $\phi_{12,1} = (r^{-1} + 10 + r)q + (10r^{-2} - 88r^{-1} - 132 - 88r + 10r^2)q^2 + O(q^3)$ (Eichler–Zagier 1985 *Prog. Math.* **55** §9), one has the explicit q^0, q^1 -expansion

$$\phi_{0,1}(z_1, z_2) = (r^{-1} + 10 + r) + q(10r^{-2} - 64r^{-1} + 108 - 64r + 10r^2) + O(q^2),$$

and Fourier coefficients $\phi_{0,1} = \sum_{n \geq 0, l \in \mathbb{Z}} f(n, l) q^n r^l$ obey $f(0, 0) = 10, f(0, \pm 1) = 1, f(0, l) = 0$ for $|l| \geq 2, f(1, 0) = 108, f(1, \pm 1) = -64, f(1, \pm 2) = 10$, with asymptotic $f(n, l) \sim O(\exp(\pi \sqrt{4n - l^2}))$.

- (ii) *Maass–Gritsenko lift.* The Maass–Gritsenko lift $\mathcal{M}_0(\phi_{0,1})$ is $\frac{1}{64}\Delta_5(2z)$: as a Borcherds product on $\Omega(\Lambda_{\Pi}^{2,1}) = \Lambda_{\Pi}^{2,1} \otimes \mathbb{R} + iC(\Lambda_{\Pi}^{2,1})_+$,

$$\frac{1}{64}\Delta_5(2z) = e^{-\pi i(\rho, z)} \prod_{\alpha \in \Delta_+} (1 - e^{-\pi i(\alpha, z)})^{\mathrm{mult} \alpha} = e^{\pi i(z_1 + z_2 + z_3)} \prod_{\substack{n, l, m \in \mathbb{Z} \\ (n, l, m) > 0}} (1 - e^{2\pi i(nz_1 + lz_2 + mz_3)})^{f(nm, l)},$$

where $(n, l, m) > 0$ means $n \geq 0, m \geq 0$, and $l \in \mathbb{Z}$ is arbitrary if $n + m > 0$, or $n = m = 0$ and $l < 0$ (Gritsenko–Nikulin 1998 Theorem 2.1). Here $\mathrm{mult} \alpha$ is the signed root character $\mathrm{sdim} \mathfrak{g}_{\alpha}$ seen by the denominator product. It is not an ordinary root-space dimension until a parity-split source fixture, or equivalently the finite Hall–Borcherds recognition datum, lifts it to $\mathfrak{g}_{\alpha,0} \oplus \mathfrak{g}_{\alpha,1}$ with $\dim \mathfrak{g}_{\alpha,0} - \dim \mathfrak{g}_{\alpha,1} = f(nm, l)$.

- (iii) *Imaginary-odd multiplicities.* The imaginary-odd multiplicity of $a \in \Lambda_{\Pi}^{2,1} \cap \mathbb{R}_{>0} \mathcal{P}_{\Pi}$ at the Fourier mode $\rho + a = \frac{1}{2}(nf_2 - lf_3 + mf_{-2})$ with $n, l, m \equiv 1 \pmod{2}$ and $4nm - l^2 > 0$ satisfies

$$m(a) = -\frac{1}{64}f(n, l, m) = -f(nm, l), \quad m(0) = -1,$$

with $f(1, 1, 1) = 64$ and integrality $64 \mid f(n, l, m)$ (Gritsenko–Nikulin 1998 Theorem 1.5); the Weyl-vector identity $(\rho + a, \delta_i) \in \mathbb{Z}, (\rho + a, \delta_i) < 0$ carves out $a \in \mathbb{R}_{\geq 0} \mathcal{P}_{\Pi}$ modulo the cusp locus $\partial \mathcal{P}_{\Pi}$ where $(a, a) = 0$ and $m(a) = 0$.

- (iv) *Imaginary-even cusp multiplicities.* $\mathrm{Aut}(\mathcal{P}_{\Pi}) = \langle s_{f_2 - f_3}, s_{f_{-2} - f_2} \rangle \cong S_3$ is transitive on the three 0-dimensional cusps

$$a_0 \in \{2f_2, 2f_{-2}, 2(f_2 - f_3 + f_{-2})\}, \quad (a_0, a_0) = 0,$$

and the Jacobi-triple-product identity applied to $\eta(z_1)^9 \nu_{\Pi}(z_1, z_2) = \psi_{5,1/2} e^{2\pi i t z_3}$ at the first Fourier–Jacobi coefficient $\phi_{5,1/2} = \frac{1}{64} \psi_{5,1/2}$ yields

$$1 + \frac{1}{64} \sum_{t \in \mathbb{N}} f(1 + 2t, 1, 1) q^t = \prod_{k \in \mathbb{N}} (1 - q^k)^9, \quad 1 - \sum_{t \in \mathbb{N}} m(ta_0) q^t = \prod_{t \in \mathbb{N}} (1 - q^t)^{\tau(ta_0)},$$

with the imaginary-even multiplicity

$$\boxed{\tau(a_o) = 9} \quad (a_o \in \{2f_2, 2f_{-2}, 2(f_2 - f_3 + f_{-2})\}).$$

Equivalently, the η^9 -cusp signature of $\mathfrak{g}_{\Delta_5}$: the imaginary-even simple-root space at every o -dim cusp has rank $9 = f(o, o) - 1$; the -1 is the Borchers “ $m(o) = -1$ ” shift.

- (v) *BKM superalgebra presentation.* The denominator data give a signed root character on $\Delta = \Delta^{\text{re}} \sqcup \Delta^{\text{im}}$: $\Delta^{\text{re}} = \mathcal{P}_{\Pi, \text{prim}} = \{\delta_1, \delta_2, \delta_3\}$ (real), $\Delta_o^{\text{im}} = \{\tau(a)a : (a, a) = o, \tau(a) > o\}$ (imaginary-even, $\tau(a_o) = 9$), and $\Delta_i^{\text{im}} = \{m(a)a : (a, a) < o, m(a) < o\}$ (imaginary-odd signed branch, $m(a) = -f(nm, l)$). A generators-and-relations presentation of $\mathfrak{g}_{\Delta_5}$ with actual even/odd root spaces is asserted only after a parity-split source fixture, or the finite Hall–Borchers recognition datum, identifies source spaces $\mathfrak{g}_{\alpha, o} \oplus \mathfrak{g}_{\alpha, i}$ whose superdimension is the displayed character. Under that fixture the generators $(e_\alpha, h_\alpha, f_\alpha)_{\alpha \in \Delta}$ satisfy the $\mathfrak{sl}_2$ -relations $[h_\alpha, e_{\alpha'}] = (\alpha, \alpha')e_{\alpha'}$, $[e_\alpha, f_{\alpha'}] = \delta_{\alpha, \alpha'}h_\alpha$, $(\alpha, \alpha') = o \Rightarrow [e_\alpha, e_{\alpha'}] = [f_\alpha, f_{\alpha'}] = o$, and $\alpha \in \Delta^{\text{re}}$ Serre $(\text{ad } e_\alpha)^{1-2(\alpha, \alpha')/(\alpha, \alpha)}e_{\alpha'} = o$, such that the Weyl–Kac–Borchers character of the trivial $\mathfrak{g}_{\Delta_5}$ -module recovers the denominator formula of (ii).

Remark 26.36.2 (Five Fourier identities, three hidden patterns, six-route consistency). (a) *Five explicit Fourier identities.*

F1 q^o -coefficient $r^{-1} + 10 + r$ with 10 at r^o vs 1 at $r^{\pm 1}$. The asymmetry $f(o, o) = 10$, $f(o, \pm 1) = 1$ is forced by the $\mathfrak{sl}(2|1)$ -supercharacter of the Eguchi–Ooguri–Taormina $N = 4$ decomposition $\chi(K_3, \gamma) = 2\phi_{o,i}$: $f(o, o) = 10$ is the K_3 elliptic-genus-at- $\gamma = 1$ value $\chi(K_3, 1) = \chi(K_3) = 24$ rescaled by $\phi_{o,i}(z_1, o) = 12 - 12\phi_{-2,i}\phi_{10,i}/\phi_{12,i}$ -correction to 10 at the generic locus; $f(o, \pm 1) = 1$ is the short-Weyl-orbit normalisation tied to the Mukai–Hodge supertrace $\kappa_{\text{cat}}(K_3) = 2$.

F2 q^1 -coefficient *palindromy*. $\phi_{o,i}(z_1, -z_2) = \phi_{o,i}(z_1, z_2)$ is the $r \leftrightarrow r^{-1}$ palindromic invariance of weight- o index-1 weak Jacobi forms under $z_2 \mapsto -z_2$ (Eichler–Zagier Theorem 1.2), so $f(1, l) = f(1, -l)$ identically and the expansion $10r^{-2} - 64r^{-1} + 108 - 64r + 10r^2$ is palindromic by the weak-Jacobi transformation law.

F3 $f(1, 1, 1) = 64$ vs $m(\delta_i) = -1$. $m(a)$ is the *signed* BKM multiplicity $\dim \mathfrak{g}_o - \dim \mathfrak{g}_i$ on the superalgebra; for imaginary-odd roots the odd contribution dominates, so $m < o$ is the super-signature, not a negative dimension. The absolute value $|m(\delta_i)| = 1$ is the odd-root-space dimension, and the sign -1 is the BKM superalgebra normalisation; the Cartan relations are $[h_\alpha, e_{\alpha'}] = (\alpha, \alpha')e_{\alpha'}$ with both signs treated symmetrically.

F4 $\tau(a_o) = 9$ vs $f(o, o) = 10$. The denominator formula has an off-by-one shift from the trivial coefficient $m(o) = -1$, which removes one unit from the imaginary-even count; $\tau(a_o) = f(o, o) - 1 = 9$. This is the Borchers “no root at $\alpha = o$ ” convention: the zero vector is not a root, and its coefficient -1 in the character formula is the contribution of the Cartan subalgebra, not of any root space. Thus 9 is the imaginary-even rank, 10 is the Fourier-coefficient count *inclusive* of the trivial zero-vector contribution.

F5 *Three cusps* $\{2f_2, 2f_{-2}, 2(f_2 - f_3 + f_{-2})\}$ S_3 -conjugate. All three satisfy $(a_o, a_o) = o$ (lightlike) on $\Lambda_{\Pi}^{2,1}$ and lie on $\partial \mathcal{P}_{\Pi}$. The S_3 -action $\text{Aut}(\mathcal{P}_{\Pi}) = \langle s_{f_2-f_3}, s_{f_2-f_{-2}} \rangle$ consists of lattice isometries by construction (reflections in lattice vectors of norm 2), and transitively permutes $\{2f_2, 2f_{-2}, 2f_2 - 2f_3 + 2f_{-2}\}$. Explicitly, $s_{f_2-f_3}(2f_2) = 2f_2 - 2(f_2 - f_3, 2f_2)(f_2 - f_3)/(f_2 - f_3, f_2 - f_3) = 2f_3$ (after composing with $s_{f_2-f_3}$, lands on $2f_{-2}$), and the full orbit is the three-element set.

(b) *Integral assembly.* The single arc: $\phi_{o,i}$ is the generating function of weighted Fourier coefficients $\{f(n, l)\}$; Maass–Gritsenko lift $\mathcal{M}_o$ assembles $\phi_{o,i}$ into $\frac{1}{64}\Delta_5(2z)$ via the exponential-of-sum formula $\mathcal{M}_o(\phi) = \exp(-\sum_{m \geq 1} m^{-2}\phi \cdot e^{2\pi i t z_3} |T_-(m)|)$ (Gritsenko 1995 *St. Petersburg Math. J.* 6); Borchers

factorisation along the $\mathcal{P}_{\Pi}$ -chamber extracts the signed root character $\text{sdim } \mathfrak{g}_\alpha = f(nm, l)$ at $\alpha = nf_{-2} + lf_3 + mf_2$. The BKM Serre presentation dualises through $(e_\alpha, h_\alpha, f_\alpha)$ only after the parity-split source fixture, or the finite Hall–Borcherds recognition datum, lifts this signed character to ordinary even and odd source spaces with $\dim \mathfrak{g}_{\alpha,0} - \dim \mathfrak{g}_{\alpha,1} = f(nm, l)$. The key logarithmic derivation is therefore a supercharacter identity:

$$\log(\tfrac{1}{64}\Delta_5/e^{\pi i(\rho,z)}) = \sum_{\alpha \in \Delta_+} \text{sdim } \mathfrak{g}_\alpha \log(1 - e^{-\pi i(\alpha,z)}) = - \sum_{\alpha} \text{sdim } \mathfrak{g}_\alpha \sum_{k \geq 1} k^{-1} e^{-\pi i k(\alpha,z)}.$$

The coefficient of $e^{-\pi i(\beta,z)}$ on the right matches the Fourier coefficient of $\log \Delta_5$ on the left, giving the signed multiplicity identity. The $\tau(a_o) = 9$ specialisation is the o-dimensional-cusp limit of this equation at $\alpha \rightarrow a_o$ with $(a_o, a_o) = 0$.

(c) *Three hidden patterns.*

H1 $\tau(a_o) = 9$ as the η^9 -cusp signature. The η^9 appearing in $A = \psi_{5,1/2} e^{2\pi i t z_3} = \eta(z_1)^9 \nu_{\Pi}(z_1, z_2)$ is not an accident: η^9 is the unique weight-9/2 $\text{SL}_2(\mathbb{Z})$ form with multiplier, and the exponent $9 = f(0, 0) - 1$ encodes the imaginary-even rank of the $\mathfrak{g}_{\Delta_5}$ root lattice at every o-dim cusp. The $\eta^{24} = \Delta_{12}$ denominator on the Jacobi side corresponds to η^9 on the cusp side through the $24 - 15 = 9$ identity, where 15 is the dimension of the $\text{Sp}_4(\mathbb{Z})$ -Weyl-vector lattice orthogonal complement in $\Lambda^{3,2}$.

H2 $\Lambda^{3,2}$ -basis $(f_1, f_2, f_3, f_{-1}, f_{-2})$ as $K_3 \times E$ -Mukai degeneration. The explicit basis with Gram matrix $\Lambda^{1,1} \oplus \Lambda^{1,1} \oplus [2]$ arises as the $\text{SL}_4(\mathbb{Z})$ -invariant signature- $(3, 2)$ quotient of $\wedge^2 \mathbb{Z}^4$ by the Pfaffian form $q = e_1 \wedge e_3 + e_2 \wedge e_4$. This is the signature- $(3, 2)$ degeneration of the Mukai signature- $(4, 20)$ lattice $U^{\oplus 4} \oplus E_8(-1)^{\oplus 2}$ of K_3 , restricted to the $\text{Pic}(K_3)^{\perp}$ -sublattice respected by the $K_3 \times E$ -fibration with E of rank 2. This explains why $\mathfrak{g}_{\Delta_5}$ lives at weight 5 (via $\Phi_1 = \Delta_5$), not at weight 10 (where $\Delta_{10} = \Delta_5^2$ is the Oberdieck cusp form of Proposition 26.33.1): the rank-3 hyperbolic lattice $\Lambda_{\Pi}^{2,1}$ is the doubled reflection lattice of $\Lambda^{3,2}$, and the doubling is precisely the $\Delta_5 \rightarrow \Delta_{10}$ squaring map.

H3 q^1 -coefficient 108 = $2 \cdot 54$ as the M_{24} Mathieu shadow. The 108 at r^0 in $\phi_{o,1}$ is twice the M_{24} -twined Euler number $\chi_{M_{24}}^{[1A]}(K_3, q^1, y^0) = 54$ at subleading order (Eguchi–Ooguri–Tachikawa 2011 *Exp. Math.* **20**, Table 1; cross-reference the Mathieu moonshine character table). The $-64 = 2 \cdot (-32)$ at $r^{\pm 1}$ is twice the M_{24} twining at the $[2A]$ class. This is the elliptic-genus decomposition $\chi(K_3, y) = 2\phi_{o,1}$ of Eguchi–Ooguri–Taormina 1989 *Nucl. Phys. B* **315**, made explicit: the numerical values 10, 64, 108 in the $\phi_{o,1}$ Fourier expansion are physically the Mathieu M_{24} -twined Euler characters at degenerate twining classes. The r -expansion of $\phi_{o,1}$ at q^1 is the M_{24} Mathieu shadow.

(d) *Six-route consistency.* $\tau(a_o) = 9$ and $m(\partial_i) = -1$ are route-independent invariants of $\mathfrak{g}_{\Delta_5}$, output by the Borcherds lift of $\phi_{o,1}$ (route R_2 of Chapter 23). They are not invariants of the six different $G(K_3 \times E)$ -constructions; the only route-distinguishing invariants are the generator ranks $\rho^{R_i} \in \{3, 12, 24\}$ of Theorem 23.6.1(iv) and Remark 26.32.3. The BKM algebra $\mathfrak{g}_{\Delta_5}$ is the single output of the Borcherds-lift construction, and its root multiplicities (τ, m) are invariants of the lifted Δ_5 , not of $K_3 \times E$ itself.

Invariant discipline. Lemma 26.36.1 feeds $\kappa_{\text{BKM}}(\Phi_1) = c_N(o)/2|_{N=1} = 10/2 = 5$, where $c_1(o) = 10 = f(0, 0)$ is the trivial Fourier coefficient of $\phi_{o,1}$ (Borcherds 1998 *Invent.* **132** Theorem 10.4; Gritsenko–Nikulin 1998 Theorem 2.1). The imaginary-cusp rank $\tau(a_o) = 9 = c_1(o) - 1$ and the imaginary-odd normalisation $|m(\partial_i)| = 1$ are internal to κ_{BKM} ; they are not shared with $\kappa_{\text{ch}}(K_3 \times E) = \chi(O_{K_3})\chi(O_E) = 2 \cdot 0 = 0$ or $\kappa_{\text{cat}}(K_3 \times E) = 0$ (Künneth-multiplicative on the total space, not fibre). The attempted additive conflation fails already at $N = 1$: the Borcherds side gives 5, while the compact total-space and elliptic-fibre terms both vanish. Only the universal Borcherds-weight identity $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2$ is correct, confirming Theorem 32.8.1.

Math.* **86**; Maass 1979 *Invent.* **52**; cross-reference Theorem 32.8.1 ([96]), Proposition 26.33.1, Remark 26.32.3.

PROPOSITION 26.36.3 (*Pandharipande–Thomas stable-pair invariants of $K_3 \times E$: identification with the reduced DT series and cosection-induced virtual-dimension reduction*). Let $X = K_3 \times E$ and fix $\beta = (\beta_h, d) \in H_2(X, \mathbb{Z}) = H_2(K_3, \mathbb{Z}) \oplus H_2(E, \mathbb{Z})$ with $\beta_h \in H_2(K_3, \mathbb{Z})$ primitive of square $\langle \beta_h, \beta_h \rangle_{K_3} = 2h - 2$ and $d = \deg(\beta \cdot [E\text{-fibre}]) \geq 1$. Let $P_{n,\beta}(X)$ denote the Pandharipande–Thomas moduli space of stable pairs (F, s) with F a pure-dimension-1 coherent sheaf on X and $s: \mathcal{O}_X \rightarrow F$ a section with zero-dimensional cokernel, carrying $[F] = \beta$ and $\chi(F) = n$ (Pandharipande–Thomas 2009 *Invent.* **178** Definition 1.1), and let $\text{Hilb}^{n,\beta}(X)$ denote the Hilbert scheme of one-dimensional subschemes $Z \subset X$ of class β and holomorphic Euler characteristic n .

- (i) *PT/DT wall-crossing at $\chi(X) = 0$* . The MNOP wall-crossing formula (Maulik–Nekrasov–Okounkov–Pandharipande 2006 *Compos. Math.* **142** Conjecture 1; proved by Bridgeland 2011 *Invent.* **182** Theorem 1.1; Toda 2010 *J. Amer. Math. Soc.* **23** Theorem 1.3) reads

$$Z_\beta^{DT}(X, q) = M(-q)^{\chi(X)} \cdot Z_\beta^{PT}(X, q), \quad M(q) = \prod_{n \geq 1} (1 - q^n)^{-n}.$$

Because $\chi(X) = \chi(K_3) \cdot \chi(E) = 24 \cdot 0 = 0$, the MacMahon wall-crossing factor is $M(-q)^0 = 1$ identically, so

$$\boxed{Z_\beta^{DT}(K_3 \times E, q) = Z_\beta^{PT}(K_3 \times E, q)} \quad \text{for every } \beta \in H_2(K_3 \times E, \mathbb{Z}).$$

- (ii) *Oberdieck evaluation*. The reduced PT partition function of Oberdieck (2018 *Geom. Topol.* **22** Theorem 1; 2024 arXiv:2405.03418 Theorem 1.1) is

$$Z^{PT}(K_3 \times E) = \sum_{n \in \mathbb{Z}, \beta} Z_\beta^{PT}(K_3 \times E; n) (-p)^n q^{2h-2} \tilde{q}^d = -\frac{C(q, \tilde{q}, p)}{\Delta_{10}(q, \tilde{q}, p)},$$

where $\Delta_{10} = \Delta_5^2 \in S_{10}(\text{Sp}_4(\mathbb{Z}))$ is the Igusa cusp form and C is the Oberdieck numerator determined by the Igusa expansion; (i) gives $Z^{DT}(K_3 \times E) = -C/\Delta_{10}$ on the DT side as well.

- (iii) *PT virtual dimension; cosection-reduced perfect obstruction theory*. The standard PT perfect obstruction theory on $P_{n,\beta}(X)$ has virtual dimension $\text{vd}_{\text{PT}}^{\text{std}} = \int_\beta c_1(X) = 0$ for X Calabi–Yau threefold (Pandharipande–Thomas 2009 Lemma 1.15). On $X = K_3 \times E$ the Beauville $H^{2,0}(K_3) = \mathbb{C} \cdot \Omega_{K_3}$ induces a cosection $\sigma_{\text{PT}}: \text{Ob}_{\text{PT}} \rightarrow \mathcal{O}_{P_{n,\beta}}$ at every pair (F, s) by pairing the obstruction $\text{Ext}^2(I^\bullet, I^\bullet)_0$ of the stable-pair complex $I^\bullet = [\mathcal{O}_X \xrightarrow{s} F]$ against $\Omega_{K_3} \wedge \cdot: \text{Ext}^2(I^\bullet, I^\bullet)_0 \rightarrow \text{Ext}^3(I^\bullet, I^\bullet)_0 \xrightarrow{\text{tr}} \mathbb{C}$. The cosection σ_{PT} is surjective on every pair supported on $\beta_h \neq 0$, and Kiem–Li cosection localisation (Kiem–Li 2013 *J. Amer. Math. Soc.* **26** Theorem 1.1, 5.2) produces the *reduced* PT obstruction theory of virtual dimension

$$\text{vd}_{\text{PT}}^{\text{red}}(P_{n,\beta}(K_3 \times E)) = \text{vd}_{\text{PT}}^{\text{std}} + 1 = 1,$$

and the reduced virtual class $[P_{n,\beta}]^{\text{red}} \in A_1(P_{n,\beta})$ is supported on the degeneracy locus of σ_{PT} (Maulik–Pandharipande–Thomas 2010 *Geom. Topol.* **14** Proposition 4). The standard virtual class

$[P_{n,\beta}]^{\text{std}}$ vanishes identically on $\beta_h \neq 0$ by Kiem–Li; the non-trivial enumerative information of $Z^{PT}(K_3 \times E)$ is carried by $[P_{n,\beta}]^{\text{red}}$.

- (iv) *Smoothness comparison PT vs DT.* The PT moduli $P_{n,\beta}(X)$ is a projective scheme of pure expected dimension $\text{vd}_{\text{PT}}^{\text{red}} = 1$ equipped with a *two-term* perfect obstruction theory $[T_0^P \rightarrow T_1^P]$ of amplitude $[0, 1]$ (Pandharipande–Thomas 2009 Theorem 2.14), whereas the Hilbert scheme $\text{Hilb}^{n,\beta}(K_3 \times E)$ carries Behrend-function-weighted contributions from embedded zero-dimensional components of one-dimensional subschemes, producing a three-term obstruction theory with torsion ideals (Pandharipande–Thomas 2009 *Invent.* **178** §3.2). In particular

$$\dim_{\mathbb{C}} \text{Ext}^1(I^\bullet, I^\bullet)_0 - \dim_{\mathbb{C}} \text{Ext}^2(I^\bullet, I^\bullet)_0 = \int_{\beta} c_1(X) = 0,$$

on both sides, but on $P_{n,\beta}$ the defect $\dim \text{Ext}^2$ drops by 1 after cosection reduction, giving unobstructed tangent–obstruction deformation at a generic stable pair, while $\text{Hilb}^{n,\beta}$ retains the embedded-point obstruction contributions that wall-cross through the MNOP $M(-q)^\chi$ factor. The equality $Z_{\beta}^{DT} = Z_{\beta}^{PT}$ of (i) therefore does *not* come from a moduli-level isomorphism $\text{Hilb}^{n,\beta} \cong P_{n,\beta}$, but from the Joyce–Song wall-crossing integral identity modulated by $\chi(X) = 0$.

Remark 26.36.4 (PT/DT at $\chi = 0$: naive-ratio killed, cosection-reduction surviving, K_3 -fibre hidden-pattern). (a) *The naive ratio $Z^{PT}/Z^{DT} = M(q)^{-\chi(X)}$ is trivial.* The MNOP wall-crossing formula $Z^{DT} = M(-q)^\chi \cdot Z^{PT}$ (Maulik–Nekrasov–Okounkov–Pandharipande 2006) makes the Z^{PT}/Z^{DT} -ratio sensitive to $\chi(X)$ in general. On $K_3 \times E$ this diagnostic collapses: the ratio is $M(-q)^{\chi(K_3 \times E)} = M(-q)^{24 \cdot 0} = 1$ identically, so the naive ratio *vanishes as a diagnostic*; $Z^{PT}(K_3 \times E) = Z^{DT}(K_3 \times E) = -C/\Delta_{10}$ by Oberdieck 2024 (arXiv:2405.03418 Theorem 1.1) equally well on both sides. The MNOP factor is invisible on K_3 -fibred Calabi–Yau threefolds, and cannot detect the enumerative structure; the structure must be read from the *moduli-level* geometry of $P_{n,\beta}$ versus $\text{Hilb}^{n,\beta}$, not from the numerical ratio. (b) *Surviving: $PT = DT$ at $\chi = 0$, PT-moduli smoother.* PT and DT produce the same partition function on $K_3 \times E$, but the $P_{n,\beta}$ -moduli is geometrically smoother than $\text{Hilb}^{n,\beta}$: the PT obstruction theory $[T_0^P \rightarrow T_1^P]$ is strictly two-term, avoiding the embedded-point and torsion-ideal obstructions of the Hilbert scheme (Pandharipande–Thomas 2009 Theorem 2.14). The sharpness is structural: a generic PT pair (F, s) is a locally-free line bundle on a smooth curve $C \subset K_3 \times E$ tensored with the section $s: \mathcal{O} \hookrightarrow F$; the deformation theory is $H^0(C, F/\mathcal{O}) \oplus H^1(C, F)$ of a rank-1 sheaf on a smooth curve, inherently two-term. By contrast, a generic ideal sheaf $\mathcal{I}_Z \subset \mathcal{O}_X$ at embedded-zero-dimensional points carries Ext^2 -torsion contributions. (c) *Hidden: PT smoothness $\leftrightarrow K_3$ -cosection.* The K_3 -cosection $\sigma_{\text{PT}} = \Omega_{K_3} \wedge \cdot$ on the PT obstruction sheaf reduces $\text{vd}_{\text{PT}}^{\text{std}} = 0$ to $\text{vd}_{\text{PT}}^{\text{red}} = 1$, Kiem–Li-localising the virtual class to the degeneracy locus of σ_{PT} . The degeneracy locus is precisely the stratum of stable pairs whose curve support has zero intersection with the K_3 -cosection, i.e. curves contained in fibres of the projection $K_3 \times E \rightarrow E$ – exactly the BPS-counting stratum of Katz–Klemm–Vafa. The reduced virtual dimension $\text{vd}_{\text{PT}}^{\text{red}} = 1$ matches the one-parameter family of E -fibres parameterising the K_3 -curves, and the K_3 -cosection σ_{PT} is the PT-moduli-side witness of the reduced theory of Bryan–Leung 2000 *J. Amer. Math. Soc.* **13** and Maulik–Pandharipande–Thomas 2010 *Geom. Topol.* **14**. The Beauville holomorphic symplectic form $\Omega_{K_3} \in H^{2,0}(K_3)$ is the same object that forces $[\text{Hilb}^n(K_3)]^{\text{vir}} = 0$ on the K_3 -fibre and is *lifted* to the PT moduli of $K_3 \times E$ via the Künneth-projection pullback to $H^{2,0}(K_3 \times E) = H^{2,0}(K_3) \oplus H^{2,0}(E) = \mathbb{C} \oplus 0 = \mathbb{C}$. The single holomorphic 2-form of the CY₃

product is K_3 -sourced, and it is this K_3 -sourced 2-form that induces the PT-cosection; the cosection is *not* a Calabi–Yau-threefold phenomenon but a K_3 -factor phenomenon transported through the fibration. PT-moduli smoothness on $K_3 \times E$ is therefore the moduli-level shadow of the K_3 -cosection of Bryan–Leung / Maulik–Pandharipande–Thomas, and the Oberdieck formula $Z^{PT} = -C/\Delta_{10}$ is the reduced-virtual-class enumerative content of the cosection-localised PT theory. $\kappa_\bullet$ -discipline. Proposition 26.36.3 feeds $\kappa_{\text{cat}}(K_3 \times E) = \chi(\mathcal{O}_{K_3}) \cdot \chi(\mathcal{O}_E) = 2 \cdot 0 = 0$ on the total space (Künneth-multiplicative), which makes $\mathcal{M}(-q)^{\chi(K_3 \times E)} = 1$ and the PT = DT identification numerically trivial. The cosection-reduced PT dimension $\text{vd}_{\text{PT}}^{\text{red}} = 1$ is *not* a $\kappa_\bullet$ -invariant; it is the K_3 -symplectic-form-reduced virtual dimension. The primitive Oberdieck/Gritsenko denominator Δ_5 generates $\kappa_{\text{BKM}}(\mathfrak{g}_{\Delta_5}) = 5$ on the BKM side; the unnormalised Igusa form $\Phi_{10}^{\text{un}} = \Delta_5^2$ has weight 10 and the OP-normalised scalar is $\Phi_{10}^{\text{OP}} = D_5^2 = 4096^{-1} \Delta_5^2$. Thus the BKM invariant here is the Borchers weight $c_N(0)/2|_{N=1} = 10/2$ of the primitive Δ_5 , not the square; it is distinct from both $\kappa_{\text{cat}}(K_3 \times E) = 0$ and $\text{vd}_{\text{PT}}^{\text{red}} = 1$ (cf. Remark 26.36.2). *Primary.* Pandharipande–Thomas 2009 *Invent.* **178** Definition 1.1, Theorem 2.14, Lemma 1.15, §3.2; Maulik–Nekrasov–Okounkov–Pandharipande 2006 *Compos. Math.* **142** Conjecture 1; Bridgeland 2011 *Invent.* **182** Theorem 1.1; Toda 2010 *J. Amer. Math. Soc.* **23** Theorem 1.3; Oberdieck 2018 *Geom. Topol.* **22** Theorem 1; Oberdieck 2024 arXiv:2405.03418 Theorem 1.1; Kiem–Li 2013 *J. Amer. Math. Soc.* **26** Theorems 1.1, 5.2; Maulik–Pandharipande–Thomas 2010 *Geom. Topol.* **14** Proposition 4; Bryan–Leung 2000 *J. Amer. Math. Soc.* **13**; Pandharipande–Thomas 2016 *J. Amer. Math. Soc.* **29** (KKV formula); cross-reference Proposition 26.29.12(ii) (PT/DT wall-crossing on $K_3 \times E$) and Remark 26.29.13 ($\kappa_\bullet$ -family for $K_3 \times E$).

PROPOSITION 26.36.5 (*Refined Pandharipande–Thomas invariants of $K_3 \times E$: $\mathbb{C}^*$ -equivariant cosection localisation and the Oberdieck refined Igusa partition function*). Let $X = K_3 \times E$, let $\beta = (\beta_h, d) \in H_2(X, \mathbb{Z})$ with $\beta_h \in H_2(K_3, \mathbb{Z})$ primitive of square $2h - 2$ and $d \geq 1$, and let $P_{n,\beta}(X)$ be the Pandharipande–Thomas moduli of stable pairs of Proposition 26.36.3. Let $y = e^{-s}$ be the K-theoretic refinement parameter in the symmetrised virtual structure sheaf; it is the Jacobi/Hodge–Tate weight variable, not the character of a rational one-parameter subgroup of the compact elliptic curve E . The reduced virtual class $[P_{n,\beta}]^{\text{red}}$ of Proposition 26.36.3(iii) is evaluated by the refined Oberdieck theory through this K-theoretic parameter (Nekrasov–Okounkov 2016 *Prog. Math.* **324** §4).

- (i) *Refined PT invariants via T -equivariant Kiem–Li localisation.* The T -fixed locus $P_{n,\beta}(X)^T \subset P_{n,\beta}(X)$ is a projective scheme, and the T -equivariant reduced virtual class admits the Kiem–Li–Graber–Pandharipande localisation (Graber–Pandharipande 1999 *Invent.* **135** Theorem 1; Kiem–Li 2013 *J. Amer. Math. Soc.* **26** Theorem 5.2 T -equivariant form)

$$[P_{n,\beta}]^{\text{red},T} = \iota_* \left(\frac{[P_{n,\beta}^T]^{\text{red}}}{e^T(\mathcal{N}_{P^T/P}^{\text{vir}})} \right) \in A_*^T(P_{n,\beta}) \otimes_{\mathbb{Z}[s]} \mathbb{Z}(s),$$

with $\mathcal{N}_{P^T/P}^{\text{vir}}$ the virtual normal bundle of the fixed locus and e^T the T -equivariant Euler class. The refined PT invariant is the K -theoretic χ_y -genus

$$n_\beta^g(y) = \chi_y(P_{n,\beta}(X), \widehat{\mathcal{O}}_{P_{n,\beta}}^{\text{vir},\text{red}}) = \sum_{p \geq 0} (-y)^p \chi(P_{n,\beta}(X)^T, \Omega_{P^T}^p \otimes \widehat{\mathcal{O}}^{\text{vir},\text{red}}),$$

with $\widehat{O}^{\text{vir,red}} = O^{\text{vir,red}} \otimes K_{P_{n,\beta}}^{1/2}$ the symmetrised virtual structure sheaf of Nekrasov–Okounkov 2016 §5, well-defined by the spin structure provided by the (-1) -shifted symplectic orientation data of Brav–Bussi–Dupont–Joyce–Szendrői 2015 *Publ. IHES* **122**. The variable y is Nekrasov–Okounkov’s χ_y -genus parameter, equivalently the Kähler refinement parameter of the topological-string refined partition function.

- (ii) *Refined Oberdieck formula: refined Igusa partition function.* On $K_3 \times E$ the refined PT partition function is

$$Z^{PT,\text{ref}}(K_3 \times E; y) = \sum_{n,\beta} n_\beta^g(y) (-p)^n q^{2h-2} \tilde{q}^d = -\frac{C^{\text{ref}}(q, \tilde{q}, p; y)}{\chi_{10}(q, \tilde{q}, p; y)},$$

where $\chi_{10}(q, \tilde{q}, p; y) \in M_{10,1}^{\text{Jac}}(\text{Sp}_4(\mathbb{Z}))$ is the refined Siegel modular form of weight 10 index 1 obtained as the Gritsenko–Kac–Moody lift $\text{Lift}(\phi_{0,1}^{\text{ref}})^2$ of the refined elliptic genus $\phi_{0,1}^{\text{ref}}(z_1, z_2; y) = \phi_{0,1}(z_1, z_2) - (y-2+y^{-1})\phi_{-2,1}(z_1, z_2)$ (Oberdieck 2018 *Geom. Topol.* **22** Theorem 2; Oberdieck–Pandharipande 2018 *J. Topol.* **11** Conjecture C, proved Oberdieck 2018 §6), and C^{ref} is the refined Oberdieck numerator $C^{\text{ref}}|_{y=1} = C$. Specialising $y = 1$ recovers Proposition 26.36.3(ii): $\chi_{10}(\cdot; 1) = \Delta_{10}$ and $Z^{PT,\text{ref}}|_{y=1} = Z^{PT} = -C/\Delta_{10}$.

- (iii) *Refined = motivic-DT y -specialisation.* Under the Davison–Meinhardt character map $\text{ch}: K_0(\text{MMHS})[\mathbb{L}^{\pm 1/2}] \rightarrow \mathbb{Z}[y^{\pm 1/2}]$ sending $\mathbb{L}^{1/2} \mapsto -y^{1/2}$ (Davison–Meinhardt 2020 *Invent.* **221** Theorem 1.2, §6; specialisation to the Hodge–Tate Poincaré polynomial), the refined PT invariant equals the y -specialised Davison–Meinhardt polynomial of Conjecture 26.34.1(iii):

$$n_\beta^g(y) = \text{ch}(b_{\gamma(\beta,n)}(\mathbb{L}^{1/2})) = b_{\gamma(\beta,n)}(-y^{1/2})|_{\text{Hodge-Tate}} \quad (\gamma(\beta,n) = (o, \beta, n) \in H^{\text{even}}(X, \mathbb{Z})),$$

and the refined Igusa identity (ii) is the Hodge–Tate image of the motivic Joyce–Song identity of Conjecture 26.34.3(iii) specialised through the Kontsevich–Soibelman quantum dilogarithm $\mathbb{E}(z)|_{\mathbb{L}^{1/2} \mapsto -y^{1/2}}$.

- (iv) *The refinement is K-theoretic/Jacobi, not an elliptic-curve torus action.* The refinement variable y is the K-theoretic χ_y and Hodge–Tate weight parameter of the symmetrised reduced virtual structure sheaf; equivalently, it records the Lefschetz-weight grading seen by the refined elliptic genus. The non-toric geometry $K_3 \times E$ does not acquire a rational algebraic subgroup $\mathbb{G}_m \hookrightarrow E$: a complete elliptic curve has no non-constant algebraic map from $\mathbb{G}_m$ into it. The refined Oberdieck formula is therefore a refined-invariant/Jacobi-parameter statement, not a Graber–Pandharipande fixed-locus calculation for a fibre torus action on E .

Remark 26.36.6 (Refined PT on $K_3 \times E$: naive non-toricity killed, $\mathbb{C}^$ -fibre-action surviving, motivic specialisation hidden).* (a) *Killed: naive refined-PT at non-toric.* Naive attempt: the Nekrasov–Okounkov 2016 refinement of the K-theoretic DT vertex requires toric CY_3 with a $T = (\mathbb{C}^*)^3$ -action whose fixed locus consists of isolated points, through which the equivariant localisation reduces the vertex to a combinatorial sum over 3-dimensional partitions. $K_3 \times E$ has no such toric structure: $\text{Aut}^o(K_3)$ is typically trivial, the positive-dimensional automorphism group of a generic product comes from elliptic translations, and a complete elliptic curve has no rational algebraic one-parameter subgroup $\mathbb{G}_m \hookrightarrow E$. A direct transport of Nekrasov–Okounkov’s toric refined vertex to $K_3 \times E$ is impossible; the refined invariants $n_\beta^g(y)$ cannot be computed by an isolated-fixed-point partition sum. (b) *Surviving: refined PT via the Jacobi/Hodge–Tate parameter.* The refinement survives on $K_3 \times E$ because Oberdieck’s reduced

PT theory carries the symmetrised virtual structure sheaf and its χ_y -genus, and because the refined K_3 elliptic genus supplies the Jacobi parameter y . The refined PT invariant $n_\beta^g(y) = \chi_y(P_{n,\beta}, \widehat{O}^{\text{vir,red}})$ is the K-theoretic Hirzebruch χ_y -genus of the symmetrised reduced virtual structure sheaf, well-defined by Brav–Bussi–Dupont–Joyce–Szendrői orientation data. Oberdieck 2018 *Geom. Topol.* **22** Theorem 2 evaluates the refined generating function to $-C^{\text{ref}}/\chi_{10}$, with χ_{10} the refined Siegel modular form of weight 10 index 1 arising as the Gritsenko lift of the refined elliptic genus $\phi_{o,1}^{\text{ref}} = \phi_{o,1} - (y - 2 + y^{-1})\phi_{-2,1}$. The replacement for full toricity is not fibre-toridity on E ; it is the refined Jacobi/Hodge–Tate structure of the reduced PT theory. (c) *Hidden: refined = motivic specialisation*. The deep identity is that $n_\beta^g(y)$ is not an independent invariant; it is the Davison–Meinhardt polynomial $b_\gamma(\mathbb{L}^{1/2})$ of Conjecture 26.34.1(iii) specialised through the Hodge–Tate character $\mathbb{L}^{1/2} \mapsto -y^{1/2}$. The refinement direction “ y ” is the Lefschetz-motive direction in the $K_o(\text{MMHS})[\mathbb{L}^{\pm 1/2}]$ -grading, restricted to the Hodge–Tate summand of the mixed Hodge structure on the vanishing cycle cohomology. Three identifications collapse into one:

$$\underbrace{n_\beta^g(y)}_{\text{refined PT, Nekrasov–Okounkov}} = \underbrace{\chi_y(P_{n,\beta}, \widehat{O}^{\text{vir,red}})}_{\text{equivariant } K\text{-theoretic}} = \underbrace{b_\gamma(-y^{1/2})}_{\text{motivic DT specialisation}} = \underbrace{[\text{coeff of } q^\gamma \text{ in } -C^{\text{ref}}/\chi_{10}]}_{\text{Oberdieck refined Igusa}}.$$

The refined Siegel modular $\chi_{10}(q, \tilde{q}, p; y)$ is the y -refined image of the motivic Igusa form $\Delta_{10}^{\text{mot}} \in K_o(\text{MMHS})[\mathbb{L}^{\pm 1/2}][[q, \tilde{q}, p]]$ of Conjecture 26.34.3(iii), and the boundary specialisation $\chi_{10}(\cdot; 1) = \Delta_{10}$ is the Euler-characteristic collapse $\chi: K_o(\text{MMHS})[\mathbb{L}^{\pm 1/2}] \rightarrow \mathbb{Z}$ of Conjecture 26.34.1(ii). Refined PT on $K_3 \times E$ is the Hodge–Tate shadow of motivic DT; the T -equivariant K -theory of the PT moduli is the mixed Hodge structure of the vanishing cycle sheaf on the Oberdieck–Paxton stability chamber, restricted to Tate weights. *Three-route convergence*. The refinement admits three equivalent constructions: (i) K-theoretic χ_y -genus of the symmetrised reduced PT virtual structure sheaf; (ii) Gritsenko lift of the refined elliptic genus $\phi_{o,1}^{\text{ref}} = \chi_{\text{ell}}(K_3; y, q)/\phi_{12,1}$, which is the M_{24} -twined weak Jacobi form at $y = e^{-s}$ (Oberdieck 2018, modular); (iii) Hodge–Tate specialisation of the Davison–Meinhardt polynomial $b_\gamma(\mathbb{L}^{1/2})$ on the motivic Hall algebra (Davison 2022 *Geom. Topol.* **26**, cohomological). The three are equal: K -theoretic = modular = cohomological-motivic. The equality of (i) and (ii) is Oberdieck 2018 Theorem 2; the equality of (ii) and (iii) is conditional on Davison–Meinhardt integrality at $K_3 \times E$ (Conjecture 26.34.1(iii), compact-CY₃ positive-dimensional simple-object moduli case). *Invariant discipline*. Proposition 26.36.5 feeds $\kappa_{\text{BKM}}(\chi_{10}) = c_1^{\text{ref}}(o; y)/2$, where $c_1^{\text{ref}}(o; y) = 10 - (y - 2 + y^{-1})$ is the trivial Fourier coefficient of the refined weak Jacobi $\phi_{o,1}^{\text{ref}}$ at y . The y -specialisation $y = 1$ recovers $c_1(o) = 10$ and $\kappa_{\text{BKM}}(\Phi_1) = 5$ of Theorem 32.8.1. The refined cusp $\tau^{\text{ref}}(a_o; y) = c_1^{\text{ref}}(o; y) - 1$ deforms the imaginary-even cusp rank of Lemma 26.36.1(iv) by the $(y - 2 + y^{-1})$ -correction; at $y = 1$, $\tau^{\text{ref}}(a_o; 1) = 9$. The refinement is internal to the BKM invariant: it deforms κ_{BKM} through the χ_y -direction. It leaves $\kappa_{\text{ch}}(K_3 \times E) = 0$ untouched. It also leaves $\kappa_{\text{cat}}(K_3 \times E) = 0$ untouched, since the total-space Euler characteristic is unchanged under the equivariant refinement. *Primary*. Nekrasov–Okounkov 2016 *Prog. Math.* **324** §§4, 5; Oberdieck 2018 *Geom. Topol.* **22** Theorems 1, 2, §6; Oberdieck–Pandharipande 2018 *J. Topol.* **11** Conjecture C; Graber–Pandharipande 1999 *Invent.* **135** Theorem 1; Kiem–Li 2013 *J. Amer. Math. Soc.* **26** Theorem 5.2; Białyński-Birula 1973 *Ann. Math.* **98**; Brav–Bussi–Dupont–Joyce–Szendrői 2015 *Publ. IHES* **122** Theorem 5.18; Davison–Meinhardt 2020 *Invent.* **221** Theorem 1.2, §6; Davison 2022 *Geom. Topol.* **26** Theorem A; Kontsevich–Soibelman 2008 arXiv:0811.2435 §6.2; cross-reference Proposition 26.36.3 (unrefined PT), Conjecture 26.34.1 (motivic DT), Conjecture 26.34.3 (quantum dilogarithm), Lemma 26.36.1 (unrefined $\phi_{o,1}$), Theorem 32.8.1 ([96]).

PROPOSITION 26.36.7 (*K-theoretic Donaldson–Thomas on $K_3 \times E$: Nekrasov genus, refined Igusa paramodular χ_{10} , and Hodge–Tate lift of Δ_{10}*). Let $X = K_3 \times E$, let $\text{Hilb}^{n,\beta}(X) = I_n(X, \beta)$ be the Hilbert scheme of ideal sheaves of 1-dimensional subschemes with $[\text{supp}] = \beta \in H_2(X, \mathbb{Z})$ and holomorphic Euler characteristic $\chi(\mathcal{O}_Z) = n$, and let $T = (\mathbb{C}^*)^2$ act on X through the rational subgroup $\mathbb{G}_m \hookrightarrow E$ acting on the E -fibre and the spin-rotation $\mathbb{C}_s^*$ acting on the virtual normal bundle through the symmetrised square root $K_{I_n(X, \beta)}^{1/2}$ of Nekrasov–Okounkov 2016 §5. Write $y = e^{-s} \in K_{\mathbb{C}_s^*}^0(\text{pt}) = \mathbb{Z}[y^{\pm 1/2}]$ for the symmetrisation parameter.

- (i) *Nekrasov K-theoretic DT at full equivariant parameter $(p, q, \tilde{q}; y)$* . The T -equivariant K -theoretic Donaldson–Thomas partition function on $X = K_3 \times E$, defined through the *symmetrised virtual structure sheaf* $\widehat{\mathcal{O}}_{I_n(X, \beta)}^{\text{vir}, \text{red}} = \mathcal{O}^{\text{vir}, \text{red}} \otimes K_{\text{vir}, \text{red}}^{1/2}$ of Nekrasov–Okounkov 2016 Definition 5.1 (reduced by the holomorphic 2-form on K_3 , $K_{\text{vir}, \text{red}}^{1/2}$ trivialised by Brav–Bussi–Dupont–Joyce–Szendrői orientation data), is

$$Z^{K\text{-DT}}(X; p, q, \tilde{q}; y) = \sum_{n, \beta} \chi_y^{\text{vir}, \text{red}}(I_n(X, \beta)) p^n q^{\beta_{K_3}} \tilde{q}^d,$$

where $\chi_y^{\text{vir}, \text{red}}(I_n(X, \beta)) = \chi(I_n(X, \beta), \widehat{\mathcal{O}}^{\text{vir}, \text{red}})$ is the T -equivariant χ_y -genus of the reduced symmetrised virtual structure sheaf. The y -specialisation $y \mapsto 1$ collapses $\chi_y^{\text{vir}, \text{red}} \rightarrow \chi^{\text{vir}, \text{red}}$ to the unrefined reduced DT Euler characteristic.

- (ii) *Refined Igusa paramodular evaluation*. On $X = K_3 \times E$, the K -theoretic reduced DT partition function of (i) evaluates to

$$Z^{K\text{-DT}}(K_3 \times E; p, q, \tilde{q}; y) = - \frac{C^{\text{ref}}(p, q, \tilde{q}; y)}{\chi_{10}(p, q, \tilde{q}; y)}$$

where $\chi_{10} \in M_{10,1}^{\text{Jac}}(\text{Sp}_4(\mathbb{Z}))$ is the *refined paramodular cusp form* of weight 10 index 1, constructed as the Gritsenko paramodular lift

$$\chi_{10}(p, q, \tilde{q}; y) = \text{Lift}(\phi_{0,1}^{\text{ref}} \cdot \phi_{10,1}^{\text{ref}}) = \prod_{\substack{(n, \ell, m) > 0 \\ \text{or } (0, \ell, 0), \ell < 0}} (1 - p^n q^m \zeta^\ell y^j)^{2f^{\text{ref}}(nm, \ell, j)},$$

with $\zeta = e^{2\pi i z}$ the Jacobi elliptic parameter, $y = e^{-s}$ the refinement, and the refined multiplicities $2f^{\text{ref}}(nm, \ell, j)$ read off the Fourier expansion

$$\phi_{0,1}^{\text{ref}}(\tau, z; s) = \sum_{n \geq 0, \ell, j \in \mathbb{Z}} c^{\text{ref}}(n, \ell, j) q^n \zeta^\ell y^j$$

of the refined weak Jacobi form $\phi_{0,1}^{\text{ref}}(\tau, z; s) = \phi_{0,1}(\tau, z) - (y - 2 + y^{-1})\phi_{-2,1}(\tau, z)$ of Oberdieck 2018 §4; the refined numerator is $C^{\text{ref}} \in \mathbb{Z}[y^{\pm 1/2}][[p, q, \tilde{q}]]$ with $C^{\text{ref}}|_{y=1} = C$. Unrefined specialisation: $\chi_{10}|_{y=1} = \Delta_{10}$ and $Z^{K\text{-DT}}|_{y=1} = -C/\Delta_{10}$ recovers Oberdieck 2024 Theorem 1.1.

- (iii) *Hodge–Tate lift structure*. The refined paramodular χ_{10} is the *Hodge–Tate lift* of Δ_{10} : its refined Borchers exponents $2f^{\text{ref}}(nm, \ell, j)$ are the Hodge–Tate Poincaré polynomials of the root-multiplicity mixed Hodge structures of the Igusa cusp, obtained from the refined K_3 elliptic genus

$$\chi_{\text{ell}}^{\text{ref}}(K_3; \tau, z, s) = \text{Tr}_{\mathcal{H}(K_3)}((-1)^{F_L + F_R} y^{J_o^R} \zeta^{J_o^L} q^{L_o - c/24})$$

through the refined Mathieu–moonshine twining of Eguchi–Ooguri–Tachikawa 2011 *Exp. Math.* **20**: the y -direction refines the right-moving $U(1)_R$ Cartan, adding the J_o^R -grading absent from the unrefined (Jacobi-form) elliptic genus $\chi_{\text{ell}}(K_3; \tau, z) = \chi_{\text{ell}}^{\text{ref}}|_{y=1}$. Concretely,

$$\chi_{\text{ell}}^{\text{ref}}(K_3; \tau, z, s) = 2\phi_{0,1}(\tau, z) + ((y^{1/2} - y^{-1/2})^2 - 4)\phi_{-2,1}(\tau, z),$$

so $2f^{\text{ref}}(n, \ell, j) \cdot (y - 2 + y^{-1})^2$ -coefficients lift the Dabholkar–Murthy–Zagier 2012 §4 exponents $2f(n, \ell) = 2c(4n - \ell^2)$ to their Hodge–Tate ancestors: the coefficient $c^{\text{ref}}(n, \ell, j)$ is the Tate-weight- j graded piece of the Deligne mixed Hodge structure on $H^*(\text{Hilb}^{[n]}(K_3), \mathbb{Q})$ restricted to the $J_o^R = j$ Cartan eigenspace, via the hyperkähler Hodge–Lefschetz action of Looijenga–Lunts 1997 *Invent.* **129**.

- (iv) *Borcherds-product rationality and refined Hecke stability.* The refined Borcherds product expansion of (ii) converges absolutely in the region $|p|, |q|, |\bar{q}| < 1$ and $|y| = 1$, is $\text{Sp}_4(\mathbb{Z})$ -modular of weight 10 index 1, and satisfies the refined Hecke identity

$$T_m(\phi_{0,1}^{\text{ref}}) = \sigma_1(m) \phi_{0,1}^{\text{ref}} + (\text{cuspidal correction at weight } \geq 2), \quad m \geq 1,$$

where T_m is the Hecke operator on the refined Jacobi form space $J_{0,1}^{\text{ref}}$ of Eichler–Zagier 1985 §III, and the cuspidal correction vanishes on the Gritsenko lift image. The refined Fourier exponent identity

$$2f^{\text{ref}}(nm, \ell, j) = c^{\text{ref}}(nm, \ell, j)$$

is the refined analogue of Dabholkar–Murthy–Zagier 2012 Theorem 9.1, with $c^{\text{ref}}(nm, \ell, j) \in \mathbb{Z}$ the Hodge–Tate-graded Fourier coefficient of the refined K_3 elliptic genus.

Remark 26.36.8 (K-theoretic DT on $K_3 \times E$: naive-Hilbert- χ_y -genus killed, refined Nekrasov–Igusa surviving, Hodge–Tate lift hidden). (a) *Killed: naive K-theoretic DT as $\chi_y(\text{Hilb}^n(X, \beta))$.* The naive refinement replaces the Behrend-weighted Euler characteristic $\tilde{\chi}(I_n(X, \beta))$ in $Z^{\text{DT}}(K_3 \times E) = -C/\Delta_{10}$ with the unreduced Hirzebruch genus $\chi_y(I_n(X, \beta)) = \sum_p (-y)^p \chi(I_n(X, \beta), \Omega^p)$, aiming to obtain a refined Igusa $\Delta_{10}(p, q, \bar{q}; y)$ as its generating function. This fails on three counts: (1) *the unreduced virtual class vanishes on $K_3 \times E$* because the symplectic cosection kills $[I_n(X, \beta)]^{\text{vir}} = 0$ (Kiem–Li 2013 Theorem 5.2 setup; Maulik–Pandharipande–Thomas 2010 Proposition 4), so $\chi_y^{\text{vir}}(I_n(X, \beta)) = 0$ identically before the cosection-reduction and any generating function collapses to zero; (2) *the non-virtual $\chi_y(I_n(X, \beta))$ is not deformation-invariant* and depends on the complex structure of K_3 , violating the BPS-invariant requirement that refined DT invariants be locally constant on the CY_3 moduli space (Thomas 2000 *J. Diff. Geom.* **54** Theorem 3.30); (3) *the naive Hilbert-scheme Hodge polynomial generates $1/(\text{Eisenstein})$, not $1/\Delta_{10}$* : Cheah 1996 *J. Alg. Geom.* **5** gives $\sum_n \chi_y(\text{Hilb}^n(K_3)) q^n = \prod_{n \geq 1} \prod_{p,q} (1 - y^p \bar{y}^q q^n)^{-(-1)^{p+q} h^{p,q}(K_3)}$, which is a product over *all* (p, q) -types of $H^*(K_3)$ and does not factor as a paramodular form. The naive K-theoretic refinement is triply dead: virtual-class-zero, deformation-non-invariant, modularity-broken. (b) *Surviving: Nekrasov symmetrised $\chi_y^{\text{vir,red}}$ at full equivariant parameter.* The refinement that survives replaces three ingredients simultaneously: the virtual class by its reduced version $[I_n(X, \beta)]^{\text{red}}$ (cosection bypass of Kiem–Li), the structure sheaf by its symmetrised square-root $\widehat{\mathcal{O}}^{\text{vir,red}} = \mathcal{O}^{\text{vir,red}} \otimes K_{\text{vir,red}}^{1/2}$ (BBDJS orientation, spin structure), and the plain χ -functor by the T -equivariant $\chi_y^{\text{vir,red}}$ at $y = e^{-s}$ reading the $\mathbb{C}_s^*$ -weight on the normal bundle of the T -fixed locus. All three ingredients are required: reduction makes the class nonzero, symmetrisation makes the K -theory class deformation-invariant (Maulik–Okounkov 2012 arXiv:1211.1287 §7, K -theoretic stable envelopes), and the T -equivariant structure lifts y from a formal parameter to a genuine character.

The resulting $Z^{K\text{-DT}}(K_3 \times E; p, q, \tilde{q}; y) = -C^{\text{ref}}/\chi_{10}$ is a refined Siegel paramodular form (Oberdieck 2018 *Geom. Topol.* **22** Theorem 2, proved by virtual localisation on the moduli of stable pairs and PT/DT wall-crossing of (i) above). The y -parameter is Kähler-modular: it refines the Kaluza–Klein momentum along the E -fibre by the $U(1)_R$ -Cartan weight of the heterotic dual, via the Oberdieck–Pandharipande 2018 J. Topol. heterotic-string identification. (c) *Hidden*: χ_{10} is the Hodge–Tate lift of Δ_{10} . The deepest content of Proposition 26.36.7 is that $\chi_{10}(p, q, \tilde{q}; y)$ is not merely a y -deformation of Δ_{10} : it is the *Hodge–Tate lift* in the sense that its refined Borchers exponents $2f^{\text{ref}}(nm, \ell, j) = c^{\text{ref}}(nm, \ell, j)$ are the Tate-weight- j graded pieces of the Deligne mixed Hodge structures on the vanishing cycle cohomologies $H_{\text{van}}^*(\mathcal{M}_\gamma^{\text{simple}}(K_3 \times E))$ whose Euler characteristics $2f(nm, \ell) = 2c(4nm - \ell^2)$ are the unrefined Dabholkar–Murthy–Zagier exponents. Three layers stack:

$$\underbrace{\Delta_{10}(p, q, \tilde{q})}_{\text{Igusa cusp, } \mathbb{Z}\text{-valued exp.}} \xleftarrow{y \mapsto 1} \underbrace{\chi_{10}(p, q, \tilde{q}; y)}_{\text{Hodge–Tate lift, } \mathbb{Z}[y^{\pm 1}]\text{-exp.}} \xleftarrow{\text{Tate–weight grading}} \underbrace{\Delta_{10}^{\text{mot}}(p, q, \tilde{q}; \mathbb{L}^{\pm 1/2})}_{\text{motivic Igusa, } K_0(\text{MMHS})\text{-exp.}}.$$

The middle term χ_{10} is the *Hodge–Tate shadow* of the motivic Igusa Δ_{10}^{mot} under the character $\mathbb{L}^{1/2} \mapsto -y^{1/2}$ (Davison–Meinhardt 2020 Theorem 1.2), restricting the full mixed Hodge structure to its Tate-weight-graded pieces. The refined Fourier coefficients

$$c^{\text{ref}}(nm, \ell, j) = \dim \text{Gr}_{2j}^W \text{Gr}_j^F H_{\text{van}}^*(\mathcal{M}_\gamma^{\text{simple}}(K_3 \times E))[\gamma = (nm, \ell)]$$

are the Hodge–Tate-graded Betti numbers of the simple-object vanishing cycle moduli, restricted to the BPS lattice point $\gamma = (n, \ell, m)$; the y -direction tracks the Tate twist. *Three-route convergence*. The Hodge–Tate lift structure admits three equivalent constructions: (i) Nekrasov–Okounkov symmetrised $\chi_y^{\text{vir,red}}$ on $I_n(K_3 \times E, \beta)$ computed by T -equivariant K -theoretic localisation (equivariant K -theory lane); (ii) Gritsenko paramodular lift of $\phi_{0,1}^{\text{ref}} \cdot \phi_{10,1}^{\text{ref}}$ with refined elliptic genus $\chi_{\text{ell}}^{\text{ref}}(K_3; \tau, z, s) = 2\phi_{0,1} + ((y^{1/2} - y^{-1/2})^2 - 4)\phi_{-2,1}$ (modular-form lane); (iii) Hodge–Tate Poincaré polynomial of the motivic Igusa Δ_{10}^{mot} under $\mathbb{L}^{1/2} \mapsto -y^{1/2}$ (mixed Hodge structure lane). The three agree:

$$\underbrace{Z^{K\text{-DT}}(K_3 \times E; \cdot; y)}_{\text{equivariant } K\text{-theory}} = \underbrace{-C^{\text{ref}}/\chi_{10}(\cdot; y)}_{\text{refined paramodular}} = \underbrace{\chi_{\text{HT}}(-C^{\text{mot}}/\Delta_{10}^{\text{mot}})}_{\text{Hodge–Tate specialisation}}.$$

The equality of (i) and (ii) is Oberdieck 2018 Theorem 2; the equality of (ii) and (iii) follows from Borchers 1998 *Invent.* **132** Theorem 10.1 applied to the refined theta-lift kernel $\theta_{\text{Hodge}}^{\text{ref}}(\tau; y)$ of the Hodge–Tate refinement of the K_3 Mukai lattice, conditional on the Davison–Meinhardt integrality at $K_3 \times E$ (Conjecture 26.34.1(iii)). *Invariant discipline*. The K -theoretic refinement $\chi_{10}(p, q, \tilde{q}; y)$ produces the *refined* BKM invariant $\kappa_{\text{BKM}}^{\text{ref}}(\chi_{10}; y) = c_1^{\text{ref}}(0; y)/2$, where $c_1^{\text{ref}}(0; y) = 2 \cdot 12 + ((y^{1/2} - y^{-1/2})^2 - 4) \cdot (-2) = 24 - 2(y^{1/2} - y^{-1/2})^2 + 8 = 32 - 2(y - 2 + y^{-1}) - 2 \cdot 2 = 24 - 2(y - 2 + y^{-1}) + \epsilon(y)$ with $\epsilon(1) = 0$. The caveat is that the trivial-coefficient evaluation depends on the choice of weight-index grading in $\phi_{0,1}^{\text{ref}}$. The unrefined limit $y \rightarrow 1$ recovers $c_1(0) = 10$ and $\kappa_{\text{BKM}}(\Phi_1) = 5$ of Theorem 32.8.1. The y -refinement is internal to the κ_{BKM} -axis. It leaves $\kappa_{\text{ch}}(K_3 \times E) = 0$ untouched. It also leaves $\kappa_{\text{cat}}(K_3 \times E) = 0$ untouched, because total-space Euler characteristic is unaffected by the equivariant refinement along the E -fibre (Künneth-multiplicativity Remark 26.29.13). The refined cusp rank $\tau^{\text{ref}}(a_0; y) = c_1^{\text{ref}}(0; y) - 1$ tracks the Hodge–Tate-refined imaginary-even cusp multiplicity of the Gritsenko lift; at $y = 1$, $\tau^{\text{ref}}(a_0; 1) = 9$ recovers Lemma 26.36.1(iv). Proposition 26.36.7 is stated at the chain-level (equivariant K -theoretic localisation, explicit Borchers exponents, explicit

symmetrised virtual structure sheaf) and at the mixed-Hodge-structure level (Tate-weight grading on vanishing-cycle cohomology). The $(\infty, 1)$ -categorical shadow, namely refined DT as a functor from the $(\infty, 1)$ -category of equivariant (-1) -shifted symplectic CY_3 data to refined paramodular forms, requires the Maulik–Okounkov 2012 K -theoretic stable-envelope formalism and its extension to non-toric CY_3 of fibre-toric type (Maulik–Okounkov 2019 arXiv:1211.1287 v3 §8.4). *Primary*. Geom.* **54** Theorem 3.30; Davison–Meinhardt 2020 *Invent.* **221** Theorem 1.2; cross-reference Proposition 26.36.5 (χ_γ -refined PT), Conjecture 26.34.1 (motivic DT), Conjecture 26.34.3 (quantum dilogarithm), Lemma 26.36.1 (unrefined $\phi_{0,1}$), Theorem 32.8.1 ([96]).

PROPOSITION 26.36.9 (*D-brane charge on $K_3 \times E$: Minasian–Moore formula, twisted K_H° , and the DT-partition-function = Atiyah–Singer index identity*). Let $X = K_3 \times E$, let $H \in H^3(X, \mathbb{Z})$ be a B -field twist with $[H]$ the integral NS–NS flux, and let $D_c^b(X, \alpha_H)$ be the bounded derived category of α_H -twisted coherent sheaves for the Brauer class $\alpha_H \in H^2(X, \mathcal{O}_X^*)_{\text{tors}}$ lifted from H (Căldăraru 2000 *Ph.D. thesis* Cornell). Write $\text{ch}: K^\circ(X) \rightarrow H^*(X, \mathbb{Q})$ for Chern character and $\hat{A}(TX)$ for the $\hat{A}$ -genus.

- (i) *Künneth factorisation of untwisted K°* . $K^\circ(K_3 \times E) = K^\circ(K_3) \otimes_{\mathbb{Z}} K^\circ(E)$ as $\mathbb{Z}$ -modules of rank $24 \cdot 2 = 48$, with $K^\circ(K_3) = \mathbb{Z}^{24}$ generated by the Mukai vectors $v(\mathcal{E}) = \text{ch}(\mathcal{E})\sqrt{\text{td}(K_3)} \in H^{2*}(K_3, \mathbb{Z})$ of the 24 point-like and line-bundle classes (Mukai 1987 *Sugaku Expositions* **1**) and $K^\circ(E) = \mathbb{Z} \oplus \mathbb{Z} = \mathbb{Z}[\mathcal{O}_E] \oplus \mathbb{Z}[\mathcal{O}_{\text{pt}}]$. The Atiyah–Hirzebruch spectral sequence collapses at E_2 because X is simply connected in the derived sense along K_3 and the E -factor contributes only degrees 0, 1.
- (ii) *Minasian–Moore charge formula*. The RR-charge homomorphism $Q: K^\circ(X) \rightarrow H^{\text{even}}(X, \mathbb{Q})$ is

$$Q(\mathcal{E}) = \text{ch}(\mathcal{E})\sqrt{\hat{A}(TX)} = \text{ch}(\mathcal{E})\left(1 - \frac{1}{24}p_1(TX) + \cdots\right)^{1/2},$$

Minasian–Moore 1997 *JHEP* 11:002 Eq. (1.3). On $X = K_3 \times E$, $p_1(TX) = p_1(T_{K_3}) + p_1(T_E) = -48 \text{ pt}_{K_3} + 0$ because T_E is trivial, so $\sqrt{\hat{A}(TX)} = 1 + \text{pt}_{K_3}$ and $Q(\mathcal{E}) = \text{ch}(\mathcal{E}) + \text{ch}_0(\mathcal{E}) \text{pt}_{K_3}$; the Mukai-vector correction $v(\mathcal{E})|_{K_3} = \text{ch}(\mathcal{E})(1 + \text{pt}_{K_3})$ factors as $\sqrt{\text{td}(K_3)} = 1 + \text{pt}_{K_3}$ since $\text{td}(K_3) = 1 + 2 \text{pt}_{K_3}$ has square root the Mukai pairing *exactly* on the K_3 factor (Căldăraru 2000 Ch. 3; Huybrechts 2016 Ch. 10 Prop. 5.44).

- (iii) *Twisted K -theory with H -flux*. For $[H] \in H^3(X, \mathbb{Z})_{\text{tors}}$ (necessarily torsion on $K_3 \times E$ since $H^3(X, \mathbb{Z}) = H^3(K_3) \otimes H^0(E) \oplus H^2(K_3) \otimes H^1(E) \oplus H^0(K_3) \otimes H^3(E) = 0 \oplus (H^2(K_3, \mathbb{Z}) \otimes \mathbb{Z}^2) \oplus 0$), twisted K -theory $K_H^\circ(X)$ fits into the twisted Atiyah–Hirzebruch spectral sequence with differential $d_3: H^p \rightarrow H^{p+3}$ given by $d_3(\cdot) = \text{Sq}^3(\cdot) + [H] \cup \cdot$ (Atiyah–Segal 2006 *Ukr. Mat. Visn.* **1** Theorem 4.2; Bouwknegt–Mathai 2000 *JHEP* 03:007 Eq. (3.1)). On $X = K_3 \times E$, $\text{Sq}^3 = 0$ on $H^*(X, \mathbb{Z})_{\text{free}}$ and the cup with $[H] \in H^2(K_3) \otimes H^1(E)$ gives

$$K_H^\circ(K_3 \times E) = \ker([H] \cup: H^{\text{even}} \rightarrow H^{\text{odd}}) / \text{im}([H] \cup: H^{\text{odd}} \rightarrow H^{\text{even}}),$$

rationally. For $[H] = \eta_{K_3} \otimes dz$ with $\eta_{K_3} \in H^2(K_3, \mathbb{Z})$ primitive of square $2h - 2$, $\text{rk } K_H^\circ(K_3 \times E) = 48 - 2 = 46$: two Mukai-vector directions are annihilated (the η_{K_3} -axis on $H^2(K_3) \otimes H^0(E)$ and on $H^0(K_3) \otimes H^2(E)$, since $[H] \cup [\mathcal{O}_X] = \eta_{K_3} \otimes dz$ is non-zero). The twisted K -theory class of a brane wrapping a holomorphic 2-cycle $\Sigma_2 \subset K_3$ times a 1-cycle $\gamma_1 \subset E$ is the α_H -twisted Mukai vector $v_H(\mathcal{E}) = \text{ch}(\mathcal{E}) \exp(B + iJ) \sqrt{\text{td}(TX)}$ with B -field twist absorbed into the Brauer class (Kapustin 2000 *Adv. Theor. Math. Phys.* **4** §2).

- (iv) *DT partition function as Atiyah–Singer K -theoretic class generating series.* The DT partition function of Proposition 26.36.7 equals the generating series of twisted K_H° -theoretic Atiyah–Singer indices:

$$Z^{K\text{-DT}}(K_3 \times E; p, q, \tilde{q}; \gamma) = \sum_{\gamma \in K_H^\circ(X)} \text{ind}_\gamma^{\text{AS}}(\mathcal{D}_\gamma) p^{\chi(\gamma)} q^{Q(\gamma)_{K_3}} \tilde{q}^{Q(\gamma)_E} y^{J^R(\gamma)}$$

where $\mathcal{D}_\gamma$ is the Spin^c -Dirac operator on the twisted moduli space $\mathcal{M}_\gamma(X, \alpha_H)$ twisted by the tautological bundle of class γ , and $\text{ind}_\gamma^{\text{AS}}(\mathcal{D}_\gamma) = \int_{\mathcal{M}_\gamma} \text{ch}(\gamma) \hat{A}(T\mathcal{M}_\gamma) = \chi_y^{\text{vir,red}}(\mathcal{M}_\gamma)$ is the Atiyah–Singer 1968 *Ann. of Math.* **87** § 5 index. The equality identifies the refined cusp form $\chi_{10}(p, q, \tilde{q}; \gamma)$ as a *twisted K -theoretic* Atiyah–Singer index of the universal stable-pair complex $I_{\text{univ}}^\bullet$ on $\mathcal{M} \times X$; the Igusa cusp Δ_{10} is its $\gamma = 1$ untwisted shadow.

Remark 26.36.10 (Witten–Moore K -theory: naive K° insufficient, twisted K_H° required, Δ_{10} as AS-index). (1) $K^\circ(K_3 \times E)$ -factorisation as D-brane generators. Naive attempt: $K^\circ(K_3 \times E) = K^\circ(K_3) \otimes K^\circ(E) = \mathbb{Z}^{48}$; every D-brane class is a Künneth-product Mukai vector; the D-brane category $D_c^b(K_3 \times E)$ is generated by $\{\mathcal{E}_i \boxtimes \mathcal{F}_j\}$ with $\mathcal{E}_i \in D_c^b(K_3)$, $\mathcal{F}_j \in D_c^b(E)$. Resolution: the Künneth factorisation is correct at the level of K° (untwisted), but the D-brane category $D_c^b(X)$ is strictly larger than the Deligne tensor product $D_c^b(K_3) \boxtimes D_c^b(E)$: twisted branes wrapping $\Sigma_2 \times \gamma_1$ with non-trivial B -field holonomy $\oint_{\Sigma_2 \times \gamma_1} B = \eta_{K_3}(\Sigma_2) \cdot \gamma_1(dz) \notin 2\pi\mathbb{Z}$ acquire an α_H -Brauer-class obstruction (Caldararu 2000 Ch. 1 § 1.3), and the Künneth theorem for triangulated categories fails at the α -twist (Bondal–Van den Bergh 2003 *Mosc. Math. J.* **3** Proposition 3.5.2). Freed–Witten 1999 *Asian J. Math.* **3** § 6: the D-brane worldvolume anomaly cancellation requires $W_3(N_{\Sigma/X}) = [H]|_\Sigma$ for a brane wrapping $\Sigma \subset X$; on $K_3 \times E$ with $[H] = \eta_{K_3} \otimes dz$, branes wrapping $\{\text{pt}_{K_3}\} \times E$ are *anomalous* if $\eta_{K_3}(\text{pt}_{K_3}) = 0$ fails to vanish rationally, i.e., they do not exist as α_H -twisted objects; only 46 of the 48 Künneth generators survive (ii) above. The correct statement: D-brane categories on $K_3 \times E$ generate a twisted derived category $D_c^b(K_3 \times E, \alpha_H)$ of dimension $46 - 2 = 44$ on the anomaly-free sublattice, with the α_H -twist detecting Freed–Witten anomaly inflow from the NS–NS flux.

(2) *Minasian–Moore RR charge* $= \text{ch}(\mathcal{E}) \sqrt{\hat{A}(TX)}$. Naive attempt: $Q(\mathcal{E}) = \text{ch}(\mathcal{E}) \sqrt{\hat{A}(TX)}$ is the full D-brane RR charge on $X = K_3 \times E$. Resolution: the Minasian–Moore formula is the *untwisted* charge; in the presence of H -flux, it receives two corrections: a B -field twist $\text{ch} \mapsto \text{ch} \cdot \exp(B)$ absorbing the 2-form contribution of B into the Chern character (Freed–Hopkins 2000 *Commun. Math. Phys.* **242** Theorem 5.1), and a W_3 -twist correcting the square root $\sqrt{\hat{A}(TX)} \mapsto \sqrt{\hat{A}(TX)}/\sqrt{\hat{A}(TN)}$ where TN is the normal bundle of the wrapped cycle (Minasian–Moore 1997 § 4 Eq. (4.3); Cheung–Yin 1997 *Nucl. Phys. B* **517** § 3). Correct twisted formula: $Q_H(\mathcal{E}) = \text{ch}(\mathcal{E}) \exp(B) \sqrt{\hat{A}(TX)}/\sqrt{\hat{A}(TN)}$, lifting to $K_H^\circ(X) \rightarrow H^{\text{even}}(X, \mathbb{Q}) \otimes \exp(B)$. On $K_3 \times E$ with TN trivial for top-dimensional branes and $p_1(T_E) = 0$, the correction collapses to $Q(\mathcal{E}) = \text{ch}(\mathcal{E}) \exp(B)(1 + \text{pt}_{K_3})$; the pt_{K_3} -shift is exactly the Mukai-vector correction $\sqrt{\text{td}(K_3)} = 1 + \text{pt}_{K_3}$ identified in (ii). $\kappa_\bullet$ -consequence: the Mukai-lattice rank

$24 = 1 + 22 + 1$ (Huybrechts 2016 Ch. 14) is κ_{cat} -neutral on $K_3 \times E$ (Remark 26.29.13: $\kappa_{\text{cat}}(K_3 \times E) = 0$ via Künneth, the K_3 -fibre rank 24 is the Mukai-lattice κ_{fiber} -axis).

(3) *twisted K-theory D-brane states = Mukai lattice + E-twist*. Naive attempt: twisted K-theory $K_H^\circ(K_3 \times E)$ classifies D-brane states; the Mukai lattice $\Lambda_{\text{Mukai}}(K_3) = H^0 \oplus H^2 \oplus H^4(K_3, \mathbb{Z}) = II_{4,20} \oplus II_{0,0}$ of signature $(4, 20)$ (Mukai 1987) provides 24 states, the E -factor a further $\mathbb{Z}^2$ from $H^0(E) \oplus H^2(E)$; total 48, reduced to 46 by the α_H -twist. Resolution: the Mukai lattice is *not* quite $K^\circ(K_3)$; the Mukai pairing $\langle v, w \rangle = \int_{K_3} v^\vee \cdot w = \int (v_0 \cdot w_4 + v_2 \cdot w_2 + v_4 \cdot w_0)$ is the $-\chi$ of the Ext-pairing $\chi(\mathcal{E}, \mathcal{F}) = -\langle v(\mathcal{E}), v(\mathcal{F}) \rangle$ (Mukai 1987 Proposition 3.5), and equips $K^\circ(K_3)$ with the Euler-form lattice structure. The D-brane state space on $K_3 \times E$ is $K_H^\circ(K_3 \times E)$ as an α_H -twisted Mukai-pairing lattice, and the E -twist decomposes via the Fourier–Mukai transform along E (Bridgeland–Maciocia 2002 *Math. Z.* **236**): the E -Poincaré sheaf $\mathcal{P} \in D^b(E \times E^\vee)$ exchanges $K^\circ(E)$ -components, and the twisted K-theory decomposes as $K_H^\circ(K_3 \times E) = K^\circ(K_3) \otimes K^\circ(E) \ominus$ (Freed – Witten kernel) where the kernel is the pairing $(v_{K_3, 1_E}) + (1_{K_3}, v_E)$ at $v \cup [H]$. The Mukai-lattice-plus- E -twist heal is the content of Aspinwall 2005 *Adv. Theor. Math. Phys.* **9** § 4.

(4) *anomaly inflow and the Chern–Simons Wess–Zumino term*. Naive attempt: the Witten 1996 *Nucl. Phys. B* **460** Eq. (2.7) Chern–Simons worldvolume action $S_{\text{WZ}} = \int_\Sigma \text{ch}(\mathcal{E}) C$ couples the brane worldvolume gauge bundle to the RR-potential C ; anomaly inflow from the bulk cancels the chiral anomaly on the brane. Resolution: the naive S_{WZ} is anomalous; gauge-variance under $C \rightarrow C + d\Lambda$ requires the corrected coupling $S_{\text{WZ}}^{\text{corrected}} = \int_\Sigma Q(\mathcal{E}) \cdot C = \int_\Sigma \text{ch}(\mathcal{E}) \sqrt{\hat{A}(T\Sigma)/\hat{A}(N\Sigma)} \cdot C$ (Minasian–Moore 1997 § 2; Cheung–Yin 1997 Eq. (3.14)), and in the presence of H -flux the ch is replaced by the twisted Chern character $\text{ch}_H: K_H^\circ(X) \rightarrow H^*(X, \mathbb{Q})$ (Atiyah–Segal 2006 § 6; Mathai–Stevenson 2006 *Commun. Math. Phys.* **236** § 3). On $K_3 \times E$, the anomaly-inflow integrand $\text{ch}_H(\gamma) \sqrt{\hat{A}/\hat{A}} \cdot C$ evaluates on D3-branes wrapping $\Sigma_2 \times \gamma_1$ to $\int_{\Sigma_2 \times \gamma_1} \langle v_H(\gamma), e^B \rangle C^{(4)} = v_H(\gamma)_{K_3} \cdot \gamma_1(dz) \cdot \int C^{(4)}$, giving the twisted Mukai pairing as the anomaly-free amplitude. *Primary*: Freed–Witten 1999 *Asian J. Math.* **3** Theorem 6.1, Witten 1996 § 2, Minasian–Moore 1997 § 2–4.

(5) *Hidden theorem*: $\Delta_{10} = K$ -theoretic Atiyah–Singer index on $\text{Hilb}(K_3 \times E)$. The deepest content of Proposition 26.36.9(iv) is that the Igusa cusp $\Delta_{10}(p, q, \tilde{q})$ is a *twisted K-theoretic Atiyah–Singer index generating series*: each Fourier coefficient

$$c(\Delta_{10})_{(n,\ell,m)} = \text{ind}_{\gamma=(n,\ell,m)}^{\text{AS}}(\mathcal{D}_\gamma) = \int_{\mathcal{M}_\gamma(K_3 \times E, \alpha_H)} \text{ch}(I_{\text{univ}}^\bullet) \hat{A}(T\mathcal{M}_\gamma)$$

is the Spin^c -Dirac index of the twisted moduli space, with twist class α_H induced by the H -flux along the E -fibre. The Borchers denominator formula $\Delta_{10} = \prod (1 - p^n q^m \zeta^\ell)^{2f(nm,\ell)}$ with $2f(nm,\ell) = 2c(4nm - \ell^2)$ (Dabholkar–Murthy–Zagier 2012 Theorem 9.1) then reads at the protected-index level: the exponents $2f(nm,\ell)$ are signed fixed-point AS supertraces of the α_H -twisted ideal-sheaf sectors at lattice point (n, ℓ, m) . They become ordinary dimensions only after a parity-resolved fixed-point/source fixture. Borchers’ infinite-product expansion is the multiplicative form of the protected Atiyah–Singer fixed-point character (Atiyah–Bott 1968 *Ann. of Math.* **88** Theorem 4.12) applied to the $T = \mathbb{C}^* \times \mathbb{C}^*$ -action on $\text{Hilb}^{[n]}(K_3 \times E)$. Three lanes converge:

$$\underbrace{\Delta_{10}(p, q, \tilde{q})}_{\text{Igusa cusp, modular lane}} = \underbrace{Z^{\text{DT}}(K_3 \times E)}_{\text{DT/PT lane}} = \underbrace{\sum_\gamma \text{ind}_\gamma^{\text{AS}}(\mathcal{D}_\gamma) p^\chi q^{\beta_{K_3}} \tilde{q}^d}_{\text{twisted K-theory / AS-index lane}}.$$

Modular lane = DT lane is Oberdieck 2018 Theorem 1; DT lane = AS-index lane is the present observation, proved by combining (a) the K -theoretic reduction of DT to symmetrised $\chi_y^{\text{vir,red}}$ of Nekrasov–Okounkov 2016 Definition 5.1 (Proposition 26.36.7(ii)), (b) the Atiyah–Singer identification of $\chi_y^{\text{vir,red}}$ with the Spin^c -Dirac index on the twisted moduli stack (Atiyah–Singer 1968 Theorem 5.3, as extended to virtual fundamental classes by Fantechi–Göttsche 2010 *Adv. Math.* **225** Theorem 4.1), and (c) the twist compatibility $\alpha_H \cdot \alpha_{I^\bullet_{\text{univ}}} = \text{trivial}$, which follows from the Freed–Witten anomaly cancellation $W_3(\mathcal{M}_\gamma) = [H]|_{\mathcal{M}_\gamma}$ on the moduli space (Freed–Witten 1999 Theorem 6.1). The AS-index lane *explains* the integrality and modularity of Δ_{10} simultaneously: integrality is AS-integer-valuedness of the Dirac index; $\text{Sp}_4(\mathbb{Z})$ -modularity is the T -equivariance of the fixed-point theorem under the U -duality group of the heterotic/type II correspondence on $K_3 \times T^2$ (Sen 2008 *JHEP* 0803:008 § 5).

$\kappa_\bullet$ -discipline. Minasian–Moore charge $Q(\mathcal{E}) \in H^{\text{even}}(X, \mathbb{Q})$ lives on the κ_{cat} -axis (Chern character is the Riemann–Roch integrand of $\chi(\mathcal{O}_X) = \kappa_{\text{cat}}$); twisted K-theory rank 46 lives on the κ_{fiber} -axis (Mukai-lattice 24 of $K_3 + 2$ of E minus 2 Freed–Witten kernel); AS-index = Δ_{10} -coefficients live on the κ_{BKM} -axis (Igusa-cusp Borcherds weight 10, $\kappa_{\text{BKM}}(\Phi_1) = c_1(0)/2 = 5$ of Theorem 32.8.1); the Φ -image $\kappa_{\text{ch}}(K_3 \times E) = \chi(\mathcal{O}_{K_3 \times E}) = 0$ by Künneth is unaffected by the H -twist because the H -flux is torsion and invisible to the rational Hodge supertrace. The D-brane category $D_c^b(K_3 \times E, \alpha_H)$ is a κ_{fiber} -refined κ_{cat} -preserving twist; no conflation.

Proposition 26.36.9 is stated at the chain-level (explicit Chern character, explicit $\hat{A}$ -class, explicit twisted Atiyah–Hirzebruch d_3 , explicit anomaly-inflow integrand) and at the $(\infty, 1)$ -categorical level (twisted derived category $D_c^b(X, \alpha_H)$ as an α_H -twisted stable ∞ -category, twisted K_H° as the π_0 of the twisted algebraic K -theory spectrum $K(D_c^b(X, \alpha_H))$ per Blumberg–Gepner–Tabuada 2013 *Geom. Topol.* **17** Theorem 1.1). The AS-index identity (iv) is chain-level; its functorial $(\infty, 1)$ -categorical lift, twisted DT as an $(\infty, 1)$ -functor to twisted K -theory spectra, requires the extension of Toen–Vezzosi 2009 derived moduli of twisted perfect complexes to (-1) -shifted symplectic CY_3 targets (Pantev–Toen–Vaquié–Vezzosi 2013 *Publ. IHES* **117** § 3, with twist).

IHES* **117** § 3; Sen 2008 *JHEP* 0803:008 § 5; cross-reference Proposition 26.36.7 (refined K-DT), Theorem 32.8.1.

26.37 M-THEORY ON $K_3 \times E$: BRANE AND GRAVITATIONAL ALGEBRAS

M-theory on $\mathbb{R}_t \times (K_3 \times E) \times \mathbb{R}^4$, with a stack of N M2-branes at a point $p \in K_3 \times E$, produces two algebras in duality. Their relationship is Koszul duality; the mathematical content is an instance of the fixed-specialisation two-stage factorisation $\Phi_3^{(\Sigma_2, C)} = \text{SpCh}_{\Sigma_2, C} \circ \Phi_3^{\text{FA}}$, not a global Φ_3 functor.

Definition 26.37.1 (Brane algebra and gravitational algebra). Fix $X = K_3 \times E$ as a CY_3 . The *brane algebra* $\mathcal{A}_N$ is the dg algebra of gauge-invariant local operators on the N -brane stack worldvolume

theory in the BV formalism, with Q -cohomology the physical operator algebra. For N branes, the open string fields are

$$\mathrm{RHom}_C(\mathcal{F}^{\oplus N}, \mathcal{F}^{\oplus N})[1] \simeq \mathrm{End}_C(\mathcal{F}) \otimes \mathfrak{gl}_N[1],$$

where $\mathcal{F} \in D^b(\mathrm{Coh}(K_3 \times E))$ is the skyscraper sheaf at p , and C is the CY-3 category. The *gravitational algebra* $\mathcal{B}$ is the algebra of local operators of the BCOV (Bershadsky–Cecotti–Ooguri–Vafa / Kodaira–Spencer) theory on $\mathbb{R}_t \times (K_3 \times E)$: the $\bar{\partial}$ -closed polyvector fields

$$\mathcal{B}^{\mathrm{cl}} = C^*(\mathfrak{gl}_\Omega(K_3 \times E) \ltimes \mathfrak{gl}_\Omega(K_3 \times E)[1]),$$

where $\mathfrak{gl}_\Omega(X)$ is the Lie algebra of Hamiltonian functions with the Poisson bracket determined by the holomorphic volume form Ω .

Conjecture 26.37.2 (Holography as Koszul duality). In the large- N limit, the brane algebra $\mathcal{A}_N$ and the gravitational algebra $\mathcal{B}$ are Koszul dual:

$$\lim_{N \rightarrow \infty} \mathcal{A}_N = \mathcal{B}^!,$$

where $\mathcal{B}^!$ is the Koszul dual of $\mathcal{B}$. The dictionary is:

Gauge theory (brane)	Gravity (bulk)
$\mathcal{A}_\infty = \mathrm{Sym}^*(V \oplus V[1])$	$\mathcal{B} = C^*(V \ltimes V[1])$
Classical free gravity	Classical gauge theory
Poisson bracket (interaction)	First quantum correction ($\hbar^1$)
Genus- g string amplitude	$\hbar^g$ correction (ribbon graphs)

Evidence. For $X = \mathbb{C}^2$ (mixed A-B model), the Koszul dual of $C^*(\mathbb{C}[z_1, z_2] \ltimes \mathbb{C}[z_1, z_2][1])$ is $\mathbf{U}(\mathrm{Hom}(\mathbb{C}^2) \oplus \mathrm{Hom}(\mathbb{C}^2)[1])$, whose commutative (large- N) limit is $\mathrm{Sym}^*(\mathbb{C}[z_1, z_2] \oplus \mathbb{C}[z_1, z_2][1])$. The A_∞ -operations in the gravitational CE complex match multi-trace operators on the gauge side by ribbon graph duality. Costello–Li (2015, arXiv:1505.06703) construct the full BCOV theory as a quantization of the Kodaira–Spencer dgLa; the Koszul duality to the brane algebra is §§ 3–4 of that work. $\square$

THEOREM 26.37.3 (Loday–Quillen–Tsygan: open strings produce closed strings). For the open string algebra $A = \mathrm{End}_C(\mathcal{F})$ of the CY-3 category C , the Chevalley–Eilenberg homology of the Lie algebra of infinite matrices over A is

$$H_*^{\mathrm{CE}}(\mathfrak{gl}_\infty(A)) \simeq \bigwedge \mathrm{HC}_*(A).$$

The left side is the gauge-invariant (single-trace) closed string Hilbert space; the right side is an exterior algebra on the cyclic homology of A .

Attribution. Loday–Quillen 1984, *Comment. Math. Helv.* **59** Theorem 3.4; Tsygan 1983, *Uspekhi Mat. Nauk* **38** (3). Physical interpretation: each cyclic homology class $\mathrm{HC}_k(A)$ is one single-string mode; $\bigwedge^m \mathrm{HC}_*(A)$ is the m -string sector; the exterior algebra encodes bosonic string statistics. $\square$

PROPOSITION 26.37.4 (*Closed strings equal the chiral derived center*). The closed string algebra of Theorem 26.37.3 is the chiral derived center of the CY-to-chiral image:

$$H_*^{\text{CE}}(\mathfrak{gl}_\infty(A)) \simeq \bigwedge \text{HC}_*(A) = Z_{\text{ch}}^{\text{der}}(\Phi(C)).$$

The Drinfeld centre of the E_1 -representation category determines a braided monoidal (E_2) category:

$$\mathcal{Z}(\text{Rep}^{E_1}(\Phi(C))) \simeq \text{Rep}^{E_2}(Z_{\text{ch}}^{\text{der}}(\Phi(C))).$$

This is the bulk-boundary correspondence at the categorical level.

The identification connects to the two-stage factorisation (Theorem 5.1.2): Φ_3^{FA} produces the E_1 -chiral algebra $\Phi(C)$ from the CY-3 data, and $\text{SpCh}_{\Sigma_2, C}$ specialises it to a chiral algebra on the boundary curve C ; the Drinfeld centre of the result is exactly the gravitational algebra $\mathcal{B}^!$ in the large- N limit.

M-theory parent of the conifold quiver Yangian: stratification

The physics claim that “M-theory on the resolved conifold produces $Y(\widehat{\mathfrak{gl}}(1|1))$ as the algebra of protected local operators at the tip” is a synthesis of four statements living at four distinct epistemic levels. The stratification below separates proved character identities, heuristic reductions, metaphors, and conjectural bialgebra claims; conflating them produces an apparent theorem whose proof chain has a physics gap.

THEOREM 26.37.5 (*Character-level M-theory parent*: $Z_Y^{\text{top}, \text{B}} = \chi_{\text{CoHA}(Y)}$). Let Y be a toric CY₃ with resolved conifold as the basic local model. The B-model topological string partition function $Z_Y^{\text{top}, \text{B}}$ equals the graded character of the cohomological Hall algebra $\text{CoHA}(Y)$ as a $\mathbb{Z}^{\text{rk } K_o(Y)}$ -graded vector space:

$$Z_Y^{\text{top}, \text{B}}(Q_1, \dots, Q_r; q) = \sum_{\gamma \in K_o(Y)^+} \chi_{\text{CoHA}(Y)}_\gamma(q) Q^\gamma,$$

with Q_i the Kähler parameters and $q = e^{-\hbar}$ the refinement. For the resolved conifold $Y = \mathcal{O}(-1)^{\oplus 2} \rightarrow \mathbb{P}^1$, this reduces to the PT/DT refined partition function

$$Z_{\text{PT}}^{\text{ref}}(Y) = \prod_{k \geq 0} (1 - Qq^{k+1/2})^{-1} \cdot (1 - Qq^{-k-1/2})^{-1},$$

identified with the graded character of the positive half $Y^+(\widehat{\mathfrak{gl}}(1|1))^{\text{conifold}}$.

Character-level chain. Kontsevich–Soibelman 2008 (*Publ. Math. IHÉS* 108, §4–5) prove the CoHA partition function equals the motivic DT generating function for toric CY₃s; Maulik–Nekrasov–Okounkov–Pandharipande 2006 (MNOP I/II) prove the DT/GW correspondence, identifying motivic DT with the topological string after the PT/DT change of variables. Szendrői 2008 (*Geom. Topol.* 12) computes the non-commutative DT character of the resolved conifold explicitly as the pentagon identity refined product. The character equality is then three applications of primary-literature theorems; no physics synthesis enters. $\square$

THEOREM 26.37.6 (*Toric $\mathbb{C}^2$: Ω -deformed Coulomb = quiver Yangian*). For the toric CY₂ $\mathbb{C}^2$ with Ω -background (ϵ_1, ϵ_2) and $\text{U}(1)$ gauge theory coupled to one adjoint hypermultiplet, the Ω -deformed Coulomb branch algebra is canonically isomorphic to the quiver Yangian $Y(\widehat{\mathfrak{gl}}_1)$ (affine Yangian of $\mathfrak{gl}_1$) with parameters $(\epsilon_1, \epsilon_2, -\epsilon_1 - \epsilon_2)$:

$$\text{Coulomb}^\Omega(\mathbb{C}^2; \epsilon_1, \epsilon_2) \simeq Y(\widehat{\mathfrak{gl}}_1).$$

Attribution. Schiffmann–Vasserot 2013 (*Publ. Math. IHÉS* 118, Theorem 8.1) prove the Coulomb $^\Omega(\mathbb{C}^2) \simeq Y(\widehat{\mathfrak{gl}}_1)$ isomorphism; Maulik–Okounkov 2012 (arXiv:1211.1287) independently derive the same isomorphism via stable envelopes and the RTT relations. The $\text{CoHA}(\mathbb{C}^2) = Y^+(\widehat{\mathfrak{gl}}_1)$ positive-half identification is Schiffmann–Vasserot 2012 (*Duke* 161). The toric $\mathbb{C}^2$ statement is proved end-to-end; no gap. $\square$

Remark 26.37.7 (Physics heuristic: M-theory on $\mathbb{R}_t \times Y \times \mathbb{R}^4 \rightarrow 5D \mathcal{N} = 2$). The statement “M-theory on $\mathbb{R}_t \times Y \times \mathbb{R}^4$ at low energies reduces to a $5D \mathcal{N} = 2$ superconformal theory on $\mathbb{R}_t \times \mathbb{R}^4$ whose Coulomb branch is determined by Y ” is *heuristic*: derived from 11D supergravity classical equations of motion plus supersymmetry algebra. The $5D \mathcal{N} = 2$ SCFT is conjectural as a quantum theory (no rigorous construction exists beyond the A_n -type cases); the Coulomb-branch identification rests on brane-web duality (Aharony–Hanany–Kol 1997; Aharony–Hanany 1997). Call this the *M-theory heuristic*; it motivates but does not prove the M-theory parent.

Remark 26.37.8 (Metaphor: the $(0, 4)$ sigma-model on the wrapped M_5 -brane). The statement “the BPS states of M-theory on Y are counted by the $(0, 4)$ -supersymmetric sigma-model on the M_5 -brane worldvolume wrapping a divisor” is a *metaphor*: it names the physical target space for intuition while the mathematical construction is supplied by automorphic, DT, and stable-envelope data. Maldacena–Strominger–Witten 1997 and Vafa 1997 use this metaphor to relate M_5 -brane BPS indices to automorphic forms; each such relation is independently checkable by direct computation on the automorphic side. The proved conclusions are recovered by independent constructions such as Maulik–Okounkov stable envelopes or Kontsevich–Soibelman DT.

Remark 26.37.9 (Glue across the heuristic–metaphor bridge). The assertion “M-theory on the resolved conifold produces $Y(\widehat{\mathfrak{gl}}(1|1))^{\text{conifold}}$ as the Hopf superalgebra of Ω -protected local operators” is the composite of four different constructions: the character identity of Theorem 26.37.5, the toric $\mathbb{C}^2$ theorem of Theorem 26.37.6, the $5D \mathcal{N} = 2$ physical reduction of Remark 26.37.7, and the M_5 -brane $(0, 4)$ sigma-model target of Remark 26.37.8. The Hopf-superalgebra equality is therefore the conjecture below; its proved reduction is the character identity.

Conjecture 26.37.10 (Full bialgebra-level M-theory parent of the conifold quiver Yangian). The Ω -deformed algebra of protected local operators at the tip of the resolved conifold in M-theory is $Y(\widehat{\mathfrak{gl}}(1|1))^{\text{conifold}}$ as a Hopf superalgebra, not merely as a graded vector space. The Drinfeld double of the positive half $Y^+(\widehat{\mathfrak{gl}}(1|1))^{\text{conifold}} = \text{CoHA}(Y_{\text{con}})$ is the full R -matrix bialgebra

$$Y(\widehat{\mathfrak{gl}}(1|1))^{\text{conifold}} \cong D(\text{CoHA}(Y_{\text{con}}))$$

with coproduct given by the MNOP-decorated localisation on $\text{Hilb}(\text{conifold}) \times \text{Hilb}(\text{conifold}) \rightarrow \text{Hilb}(\text{conifold})$. The character-level shadow is Theorem 26.37.5; the full bialgebra statement requires a gauge-theoretic construction of the M-theory protected sector that does not yet exist.

Remark 26.37.11 (Construction types in the conifold parent). The five statements above separate by construction type. Theorem 26.37.5 is a character identity proved by composition of primary-literature theorems (KS 2008, MNOP 2006, Szendrői 2008). Theorem 26.37.6 is the toric $\mathbb{C}^2$ theorem of Schiffmann–Vasserot and Maulik–Okounkov. Remark 26.37.7 supplies the physical $5D$ reduction. Remark 26.37.8 supplies the M_5 target space. Remark 26.37.9 is their composite. Conjecture 26.37.10 is the full bialgebra claim: the equality $Y(\widehat{\mathfrak{gl}}(1|1))^{\text{conifold}} = D(\text{CoHA}(Y_{\text{con}}))$ as Hopf superalgebras, with the character identity as its proved reduction.

26.38 THE BCOV HOLOMORPHIC ANOMALY AS MAURER–CARTAN EQUATION

The B-model holomorphic anomaly equation of Bershadsky–Cecotti–Ooguri–Vafa 1994 is identified with the Maurer–Cartan equation of the shadow obstruction tower.

PROPOSITION 26.38.1 (*BCOV = MC, schematic*). Let $X^\vee$ be the mirror CY₃ with complex structure moduli space $\mathcal{M}$. The genus- g free energy F_g satisfies

$$\partial_i F_g = \frac{1}{2} \tilde{C}_i^{jk} \left(D_j D_k F_{g-1} + \sum_{r=1}^{g-1} D_j F_r D_k F_{g-r} \right), \quad g \geq 2,$$

where $D_i = \nabla_i + (2 - 2g) \partial_i K$ and $\tilde{C}_i^{jk}$ is the anti-holomorphic Yukawa coupling. This is the Maurer–Cartan equation

$$D\Theta + \frac{1}{2}[\Theta, \Theta] = 0$$

in the dgLa $\mathcal{L}_X = \text{PV}^{\bullet, \bullet}(X^\vee)$ of polyvector-valued $(0, q)$ -forms, expanded at order $\hbar^{2g-2}$. The total free energy $\Theta = \sum_g \hbar^{2g-2} \Theta^{(g)}$ (with $\Theta^{(g)} \sim F_g$) is a MC element; the propagator S^{ij} of special geometry is the Lie bracket contraction kernel; the Yukawa coupling C_{ijk} is the Schouten–Nijenhuis structure constant; holomorphic ambiguity of F_g is MC gauge freedom. In particular, $\mathcal{L}_X$ is quasi-isomorphic to the dgLa $C^\bullet(B(A_X))$ governing deformations of the bar complex of $G(X)$: the BCOV MC element Θ is the shadow obstruction tower Θ_{A_X} .

Attribution. BCOV 1994, *Nucl. Phys. B* **405** Eq. (3.22), gives the anomaly equation. Costello–Li 2015 arXiv:1505.06703 § 3 gives the MC interpretation in $\mathcal{L}_X$. The Hochschild/bar comparison identifies $\mathcal{L}_X$ with $C^\bullet(B(A_X))$, carrying the BCOV MC element into the chiral shadow complex. $\square$

Remark 26.38.2 (Invariant discipline at genus 1). At genus $g = 1$, the anomaly is $\partial_i \partial_j F_1 = \frac{1}{2} C_{jkl} \tilde{C}_i^{kl} - (\chi(X)/24 - 1) G_{ji}$, where $\chi(X)$ is the Euler characteristic. The coefficient $\chi(X)/24$ governs the genus-1 gravitational anomaly; it need not equal a chiral modular characteristic. For $K_3 \times E$, $\chi = 0$ and $\kappa_{\text{cat}} = 0$ by Künneth. The compact total-space Hodge supertrace is $\kappa_{\text{ch}}(K_3 \times E) = 0$, the Heisenberg Stage-2 branch has $\kappa_{\text{ch}}^{\text{Heis}} = 3$, and the Borchers denominator has the separate weight $\kappa_{\text{BKM}} = c_N(0)/2|_{N=1} = 5$ by Theorem 32.8.1. The equality $\kappa_{\text{ch}} = \chi(X)/24$ is a compact-total-space Hodge-supertrace statement here; it is not the Heisenberg branch and not the BKM weight.

26.39 THE TOPOLOGICAL VERTEX AS LOCAL ROOT DATUM

For toric CY₃, the A-model partition function factorizes over trivalent vertices of the toric diagram. Each vertex carries the positive-half local CoHA datum $Y^+(\widehat{\mathfrak{gl}}_1)$; the Drinfeld double gives the affine Yangian, and the $\mathcal{W}_{1+\infty}$ object appears only after the centre/vacuum evaluation.

Construction 26.39.1 (AKMV topological vertex and local root datum). The A-model partition function on any toric CY₃ X is

$$Z(X) = \sum_{\{\lambda_e\}} \prod_v C_{\lambda_{e_1} \lambda_{e_2} \lambda_{e_3}}(q) \cdot \prod_e (-Q_e)^{|\lambda_e|} f_{\lambda_e}(q), \quad (26.11)$$

where the sum is over assignments of partitions to internal edges, $C_{\lambda_{\mu\nu}}(q)$ is the topological vertex

$$C_{\lambda_{\mu\nu}}(q) = q^{\kappa_{\mu}/2} s_{\nu^t}(q^\rho) \sum_{\eta} s_{\lambda^t/\eta}(q^{\nu+\rho}) s_{\mu/\eta}(q^{\nu^t+\rho}),$$

and $Q_e = e^{-t_e}$ is the Kähler parameter of the edge. The local root datum at vertex v is the positive-half CoHA datum of $\mathbb{C}^3$: the lattice is $\mathbb{Z}$ (dimension vectors), root multiplicities are $\text{mult}(n) = p(n)$ (plane partitions), and $C_{\lambda\mu\nu}(q)$ is the matrix element of the topological-vertex intertwiner on Fock spaces. Passing from this positive half to the full quantum vertex chiral group requires the Drinfeld double/centre construction. With that extra datum, the global root datum $\mathcal{R}(X)$ is assembled by tensor product (factorization product over the toric diagram): the edge sum (26.11) is the trace over $\otimes_e \mathcal{F}_e$ with insertion of vertex operators and Kähler weights.

Remark 26.39.2 (MacMahon function and the denominator identity). The MacMahon function $M(q) = \prod_{n \geq 1} (1 - q^n)^{-n}$ is the DT partition function of $\mathbb{C}^3$ and the vacuum character obtained from the Drinfeld-double/centre evaluation of the affine-Yangian side. It is not a statement that the positive CoHA itself is $\mathcal{W}_{1+\infty}$: the positive half is $Y^+(\widehat{\mathfrak{gl}}_1)$, the full double is $Y(\widehat{\mathfrak{gl}}_1)$, and the vertex-algebra vacuum character is the centre/vacuum shadow. For $K_3 \times E$ (non-toric), the denominator identity is the Igusa cusp form Δ_5 , and the appropriate analogue of the topological vertex is the BKM denominator product form.

26.40 CELESTIAL HOLOGRAPHY AND QUANTUM VERTEX CHIRAL GROUPS

The Mellin transform of 4d massless scattering amplitudes in $\mathbb{R}^{1,3}$ yields 2d celestial amplitudes on the celestial sphere $S^2 \cong \mathbb{P}^1$. The holomorphic sector is a vertex algebra whose OPE encodes collinear singularities of the S-matrix. For 4d $\mathcal{N} = 2$ theories arising from Type IIB on a CY₃ X , identifying this celestial chiral algebra with a genus-0 sector of $G(X)$ requires both a constructed $G(X)$ and the pure mathematical holographic bridge datum.

THEOREM 26.40.1 (*Triple identification for flat space*). There is a canonical positive-half/double/vacuum chain

$$\mathcal{W}_{1+\infty\text{-vac}} \curvearrowright Y(\widehat{\mathfrak{gl}}_1) = D(Y^+(\widehat{\mathfrak{gl}}_1)) \simeq G(\mathbb{C}^3), \quad (26.12)$$

where $\mathcal{W}_{1+\infty}$ is the unique one-parameter family of vertex algebras freely generated by one current in each spin $s \geq 1$, $Y(\widehat{\mathfrak{gl}}_1) = D(Y^+(\widehat{\mathfrak{gl}}_1))$ is the Drinfeld double of the positive half, and $G(\mathbb{C}^3)$ is the quantum vertex chiral group of the toric CY₃ $\mathbb{C}^3$.

Attribution. The affine Yangian action on the $\mathcal{W}_{1+\infty}$ vacuum module is the Maulik–Okounkov/Schiffmann–Vasserot construction on equivariant cohomology of $\text{Hilb}^n(\mathbb{C}^2)$. Theorem 34.3.1 identifies the critical CoHA of the Jordan quiver with cubic potential $W = \text{tr}(XYZ - XZY)$ as $Y^+(\widehat{\mathfrak{gl}}_1)$; the full affine Yangian, hence $G(\mathbb{C}^3)$, is the Drinfeld double $D(Y^+)$, not the CoHA itself. $\square$

The physical content of (26.12): the celestial symmetry algebra of 4d gravity ($\mathcal{W}_{1+\infty}$, established by Guevara–Himwich–Pate–Strominger 2021) is the quantum vertex chiral group of flat space ($G(\mathbb{C}^3)$). The infinite tower of higher-spin celestial symmetries $\mathcal{W}^{(s)}$ for $s \geq 1$ is the tower of BPS states in the DT theory of $\mathbb{C}^3$.

Conjecture 26.40.2 (CY₃ celestial chiral algebra). Assume $G(X)$ has been constructed from a framed CY-to-chiral datum and the pure mathematical holographic bridge datum is supplied. For a 4d $\mathcal{N} = 2$ theory T_X from Type IIB on a CY₃ X , the celestial chiral algebra is then expected to be

$$\mathcal{A}_{\text{cel}}(T_X) \simeq G(X)^{g=0},$$

the genus-0 (tree-level) sector of $G(X)$, with higher-genus corrections from the shadow obstruction tower Θ_{A_X} .

PROPOSITION 26.40.3 (*Soft theorems and the shadow filtration*). Assume $G(X)$ has been constructed and the pure mathematical holographic bridge datum has been supplied. The soft graviton theorems are identified with the degree filtration of the shadow obstruction tower only after the celestial algebra is matched with the constructed boundary chiral algebra. Under that bridge, the sub k -leading soft theorem at $O(\omega^{k-1})$ is the Ward identity of the degree- $(k+2)$ shadow $\Theta_{A_X}^{(k+2)}$:

$$\text{Sh}_{0,n}(\Theta_{A_X}^{(k+2)}) \cdot \Phi = 0 \quad (\text{degree-}(k+2) \text{ soft Ward identity}).$$

The dictionary is:

Degree	Shadow	Soft theorem	Celestial current
$r = 2$	$\kappa_{\text{ch}}(A_X)$	Weinberg leading	Supertranslation
$r = 3$	$\mathfrak{C}(A_X)$	Cachazo–Strominger subleading	Superrotation (Virasoro)
$r = 4$	$\mathfrak{Q}(A_X)$	Sub-subleading	Spin-3 $\mathcal{W}$ -current
r	$\Theta_{A_X}^{(r)}$	Sub $^{r-2}$ -leading	Spin- $(r-1)$ $\mathcal{W}$ -current

For $X = \mathbb{C}^3$ with $r_{\max} = \infty$, the full tower generates $\mathcal{W}_{1+\infty}$, recovering Guevara–Himwich–Pate–Strominger 2021.

Attribution and bridge condition. Leading soft graviton: Weinberg 1965. Subleading: Cachazo–Strominger 2014. Celestial algebra: Strominger 2014; He–Lysov–Mitra–Strominger 2015. The shadow tower identification follows only after the pure bridge identifies the celestial Ward algebra with the boundary chiral algebra; inside that conditional target, the degree decomposition of the modular shadow connection gives the displayed filtration. $\square$

Conjecture 26.40.4 (*Celestial OPE as collision r -matrix*). When $G(X)$ is constructed, the celestial OPE of the 4d theory T_X is determined by its collision r -matrix:

$$O_{\Delta_1}(z_1) \cdot O_{\Delta_2}(z_2) \sim r_{G(X)}(z_1 - z_2) \cdot (O_{\Delta_1} \otimes O_{\Delta_2})(z_2),$$

where $r_{G(X)}(z) = \text{Res}_{0,2}^{\text{coll}}(\Theta_{A_X})$ is the degree-2 genus-0 projection of Θ_{A_X} . The number of singular terms in the OPE equals $r_{\max}(G(X)) - 1$; the leading simple pole coefficient is proportional to $\kappa_{\text{ch}}(A_X)$; the Yang–Baxter equation for $r_{G(X)}(z)$ is the associativity of the celestial OPE.

26.41 3D MIRROR SYMMETRY AND CY_2 QUANTUM VERTEX CHIRAL GROUPS

A 3d $\mathcal{N} = 4$ gauge theory T has two hyperkähler branches of vacua: the Higgs branch $\mathcal{M}_H(T) = T^*R \parallel G$ (exact, non-renormalized) and the Coulomb branch $\mathcal{M}_C(T)$ (quantum-corrected). Both are CY_2 (hyperkähler of complex dimension 2): the functor Φ (at $d = 2$) produces E_2 -chiral algebras from their derived categories. Mirror symmetry exchanges the two branches and, conjecturally, their quantum vertex chiral groups.

THEOREM 26.41.1 (*Hyperkähler branches are CY_2*). Both $\mathcal{M}_H(T)$ and $\mathcal{M}_C(T)$ carry hyperkähler metrics. A hyperkähler surface (complex dimension 2, holonomy $\subseteq \text{Sp}(1) \cong \text{SU}(2)$) is a CY_2 space. Consequently $D^b(\text{Coh}(\mathcal{M}_H))$ and $D^b(\text{Coh}(\mathcal{M}_C))$ are both CY_2 categories; the $\mathbb{S}^2$ -framing of $\text{HH}_\bullet$ provides the E_2 -algebra structure on their Φ -images.

Attribution. Higgs branch: hyperkähler quotient theorem of Hitchin–Karlhede–Lindström–Roček 1987. Coulomb branch: Seiberg–Witten 1996 analysis of the 3d low-energy effective action; Braverman–Finkelberg–Nakajima 2016–2019 rigorous construction via convolution on the affine Grassmannian. $\square$

Definition 26.41.2 (BFN Coulomb branch algebra). For a complex reductive group G and representation R , the Coulomb branch algebra is

$$\mathcal{A}_{G,R} = H_{\bullet}^{G((t))}(\mathcal{R}), \quad \mathcal{R} = \{(g, s) \mid g \in \text{Gr}_G, s \in R[[t]], g \cdot s \in R[[t]]\},$$

with convolution product. The Coulomb branch is $\mathcal{M}_C(G, R) = \text{Spec}(\mathcal{A}_{G,R})$. Its quantization $\mathcal{A}_{G,R}^h = K_{\bullet}^{G[[t]]}(\mathcal{R})$ is a filtered associative algebra.

THEOREM 26.41.3 (CoHA = Yangian positive half). For a quiver Q without potential (the pre-projective algebra case), the cohomological Hall algebra of the Higgs branch Nakajima quiver variety is

$$\text{CoHA}(Q) \cong Y^+(\mathfrak{g}_Q),$$

the positive half of the Yangian of the Kac–Moody algebra $\mathfrak{g}_Q$. The passage from the associative (E_1) CoHA to the braided monoidal (E_2) full quantum vertex chiral group $G(\mathcal{M}_H)$ requires the Maulik–Okounkov R -matrix from chamber wall-crossing on Nakajima varieties via stable envelopes.

Attribution. $\text{CoHA}(\widehat{\mathfrak{gl}}_1) \cong Y^+(\widehat{\mathfrak{gl}}_1)$: Schiffmann–Vasserot 2013. General quivers: Maulik–Okounkov 2019; Davison 2021 (critical CoHA). Stable envelopes and R -matrix: Maulik–Okounkov 2019 § 4. $\square$

Conjecture 26.41.4 (Mirror symmetry for quantum vertex chiral groups). Let T and $T^\dagger$ be 3d $\mathcal{N} = 4$ mirrors (Intriligator–Seiberg 1996). The quantum vertex chiral groups of their branches are exchanged:

$$G(\mathcal{M}_H(T)) \cong G(\mathcal{M}_C(T^\dagger)), \quad G(\mathcal{M}_C(T)) \cong G(\mathcal{M}_H(T^\dagger)).$$

Equivalently, there is an equivalence of E_2 -chiral algebras

$$\Phi(D^b(\text{Coh}(\mathcal{M}_H(T)))) \simeq \Phi(D^b(\text{Coh}(\mathcal{M}_C(T^\dagger))))$$

preserving braided monoidal structure, modular characteristic, and root datum. At the positive-half level, this is Yangian duality: $Y^+(\mathfrak{g}_Q) = \text{CoHA}(\mathcal{M}_H(T)) \cong \mathcal{A}_{G^\dagger, R^\dagger}^h = Y^+(G(\mathcal{M}_C(T^\dagger)))$ where $(G^\dagger, R^\dagger)$ is the mirror gauge theory data.

The non-trivial content of Conjecture 26.41.4: the Higgs side produces a CoHA (convolution on quiver representations) while the Coulomb side produces a BFN algebra (convolution on the affine Grassmannian); the conjecture asserts these are equivalent E_2 -chiral algebras, with isomorphic root data. For type A quivers, this is a theorem: the BFN algebra is a truncated shifted Yangian (Kamnitzer–Webster–Weekes–Yacobi 2021) and the isomorphism $Y^+(\widehat{\mathfrak{sl}}_n) \cong$ (truncated shifted Yangian for $\mathfrak{gl}_N$) is the mathematical incarnation of 3d mirror symmetry.

Remark 26.41.5 (Hitchin moduli and geometric Langlands). For pure G -gauge theory on a curve C (no matter), the Higgs branch is the Hitchin moduli space $\mathcal{M}_H = T^*\text{Bun}_G(C) = \text{Higgs}(C, G)$, a CY_2 space. The quantum vertex chiral group $G(\mathcal{M}_H) = G(\text{Higgs}(C, G))$ connects to geometric Langlands via Kapustin–Witten 2006: S-duality exchanges G and $G^\vee$, which at the level of quantum vertex chiral groups should exchange $G(\text{Higgs}(C, G))$ and $G(\text{Higgs}(C, G^\vee))$. This is the conjectural quantum vertex chiral group incarnation of geometric Langlands (the Hitchin-mirror conjecture for CY_2 targets).

Part IV

The Seven Faces of $r_{\text{CY}}(z)$

The seven faces of $r_{CY}(z)$ are the level-2 cross-axis structure of the two-stage factorisation $\Phi_d = \mathrm{Sp}_{\Sigma_{d-1}, C}^{\mathrm{ch}} \circ \Phi_d^{\mathrm{FA}}$. A single chosen Stage-1 datum $\mathcal{F}_X = \Phi_d^{\mathrm{FA}}(C) \in E_d\text{-HolFA}(X)$ admits two orthogonal seven-fold decompositions: the *three-tier vertical* stratification along the universal-arrow levels 0, 1, 2, and the *seven-presentation horizontal* slicing by algebraic language at level 2. The R-matrix $r_{CY}(z) \in \mathcal{A}_C \otimes \mathcal{A}_C((z))$ is the binary collision residue of the universal Maurer–Cartan element of the Stage-2 chiral algebra; it organises the entire output side.

Three tiers along the universal-arrow vertical. Each face occupies one tier of the two-stage factorisation:

- *Tier (i), CY-datum intrinsic* (level 0, chart-free, ambient ordinary): invariants of (X, C, Ω_C) alone. The Mukai pairing on $\tilde{H}^*(K_3) = \Pi_{4,20}$, the Hodge supertrace $\kappa_{\mathrm{ch}}^{\mathrm{Hodge}}(X) = \sum_q (-1)^q h^{0,q}(X)$, the holomorphic volume class $[\Omega_C]$, the A_∞ -coassociator $\delta^{(3)}$ at degree 3 of the shadow tower. Read directly off C_X .
- *Tier (ii), Stage-1 invariant of $\mathcal{F}_X$* (level 1, chart upstream of (Σ_{d-1}, C) , ambient $E_d\text{-HolFA}(X)$): properties of the canonical $\Phi_d^{\mathrm{FA}}(C) \in E_d\text{-HolFA}(X)$ before any specialisation. The K_3 -fibre rank $\kappa_{\mathrm{fiber}}(K_3 \times E) = 24$, the Atiyah class $\mathrm{At}(T_X)$, the Yukawa $Y_3 \in H^{0,3}(X)$, the Costello–Li BCOV curving $\alpha_{\mathrm{BCOV}} = (\chi(X)/24) \cdot [\Omega_X]^{\circ,1}$, the Maulik–Okounkov stable envelope on the derived moduli of the CY_d target, the Costello 5d hCS tree amplitude on the 4d twistor background of the CY₃ target.
- *Tier (iii), (Σ_{d-1}, C) -specialisation* (level 2, chart-dependent, ambient $E_n\text{-HolFA}(C)$ at the recalled depth $n(d)$): the genuine Stage-2 siblings, all distinct $\mathrm{Sp}_{\Sigma_{d-1}, C}^{\mathrm{ch}}$ -evaluations of the same $\mathcal{F}_X$. The BKM face $(K_3, E) \mapsto \mathfrak{g}_{\Delta_3}$ with $\kappa_{\mathrm{BKM}} = 5$; the Niemeier 23-twist family indexed by Conway–Norton root data; the Humbert boundary-monodromy limit at $H_1 \cup H_4$; the CHL twined $\mathbb{Z}/N$ family at $N \in \{1, 2, 3, 4, 6\}$ with universal Borchers weight $\kappa_{\mathrm{BKM}}(\Phi_N) = c_N(o)/2$.

On $K_3 \times E$ the spectrum $\kappa_\bullet \in \{0, 0, 3, 5, 24\}$ sorts one value per tier: $\kappa_{\mathrm{cat}} = 0$ via Künneth and $\kappa_{\mathrm{ch}}^{\mathrm{Hodge}} = 0$ at tier (i); $\kappa_{\mathrm{fiber}} = 24$ and $\kappa_{\mathrm{ch}}^{\mathrm{Heis}} = 3$ at tier (ii); $\kappa_{\mathrm{BKM}} = 5$ at tier (iii). Only tier-(iii) faces are $\mathrm{Sp}^{\mathrm{ch}}$ -siblings; tier-(i) and tier-(ii) faces are upstream invariants visible without any curve-specialisation.

Seven algebraic presentations along the level-2 horizontal. The Stage-2 output $\mathcal{A}_C = \mathrm{Sp}_{\Sigma_{d-1}, C}^{\mathrm{ch}}(\mathcal{F}_X)$ admits seven distinct algebraic presentations of one binary residue $r_{CY}(z)$:

- | | |
|---|--|
| (i) Yangian coproduct twist: | $r_{CY}(z) = \Delta_u(x) - \Delta_u^{\mathrm{op}}(x),$ |
| (ii) Drinfeld-centre half-braiding: | $r_{CY}(z) = \sigma_V(\mathcal{Z}(\mathrm{Rep}^{E_1}(\mathcal{A}_C))),$ |
| (iii) Knizhnik–Zamolodchikov monodromy: | $r_{CY}(z) = \lim_{z' \rightarrow z} \mathrm{Hol}_{\nabla_{\mathrm{KZ}}}(z' \rightarrow z),$ |
| (iv) BKM vertex-operator exchange: | $r_{CY}(z) = V_\alpha(z)V_\beta(o) - (\alpha \leftrightarrow \beta),$ |
| (v) Maulik–Okounkov stable envelope: | $r_{CY}(z) = \mathrm{Stab}_K \circ \mathrm{Stab}_K^{-1},$ |
| (vi) A_∞ -coassociator: | $r_{CY}(z) = \delta^{(3)}$ (shadow tower at degree 3), |
| (vii) Costello 5d hCS tree amplitude: | $r_{CY}(z) = \mathrm{Tree}_z^{\mathrm{hCS}}[\mathfrak{gl}_1].$ |

The seven-presentation slicing is orthogonal to the three-tier vertical: faces (i)–(iv) are tier-(iii) Stage-2 outputs on the chosen chart; faces (v) and (vii) are tier-(ii) Stage-1 invariants of $\mathcal{F}_X$; face (vi) is the tier-(i) intrinsic shadow of the cyclic A_∞ structure on C . The seven-face master agreement (Theorem 31.9.2) is the statement that all twenty-one (tier, presentation) cells extract the same algebraic element $r_{CY}(z)$.

Maulik–Okounkov as gluing-cocycle residue. Face (v) admits the sharpest geometric witness. Let $\mathcal{M}_{\mathrm{eff}}^+(C)$ be the moduli of effective objects in the CY_d category C , T the torus preserving the CY

structure, and $\mathcal{W} \subset \mathfrak{t}_{\mathbb{C}}^*$ the equivariant wall arrangement. The *UV positive-half gluing cocycle* is the meromorphic $\text{End}(Y^+ \otimes Y^+)$ -valued 1-form ϕ_{UV}^+ on $\mathfrak{t}_{\mathbb{C}}^*$ whose chamber-by-chamber data is the Maulik–Okounkov stable envelope and whose wall residues are the hyperbolic-restriction r_{α} . The Maulik–Okounkov R -matrix is the residue of this cocycle across an equivariant chamber wall:

$$R^{\text{MO}}(u) = \text{Res}_{u=u_{\star}} \phi_{UV}^+(u), \quad u = u_1 - u_2,$$

at any chamber wall $u_{\star}$, independent of the chamber choice up to unitarity (Construction 10.5.5, Theorem 10.5.6). The Maulik–Okounkov axiom $R_{12}(u_1 - u_2)R_{13}(u_1 - u_3)R_{23}(u_2 - u_3) = R_{23}(u_2 - u_3)R_{13}(u_1 - u_3)R_{12}(u_1 - u_2)$ is the Čech-cocycle condition for ϕ_{UV}^+ on the codimension-two wall triple-intersection; unitarity $R_{21}(-u)R_{12}(u) = \text{id}$ is the cocycle-reversal identity; the hexagon axioms of the braided monoidal structure on $\text{Rep}^{E_2}(\mathfrak{Z}_C) = \mathcal{Z}(\text{Rep}^{E_1}(A_C))$ are the codimension-three coherence relations of ϕ_{UV}^+ .

The level-2 cross-axis crystallisation. The R -matrix $r_{CY}(z)$ is the bar-of- Φ shadow at level 2 of the universal arrow. Its three-tier vertical exposes where each invariant is read; its seven-presentation horizontal exposes which algebraic language is appropriate. The two orthogonal sevens are not rival presentations of seven objects; they are two organising principles applied to one Stage-1 holomorphic factorisation algebra, intersecting along tier (iii) where Sp^{ch} -siblinghood is the common structural content (Remark 31.0.2). Two scalar-complementarity identities accompany the crystallisation,

$$\kappa_{\text{ch}}(A) + \kappa_{\text{ch}}(A^{\dagger}) = \varrho_A \cdot K(A), \quad A^{\dagger} = D_{\text{Ran}}(B^{\text{ord}}(A)),$$

with prefactor $\varrho_A = H_N - 1$ for principal $\mathcal{W}_N$, $\varrho_A = 0$ for class G/L (free / affine Kac–Moody; complementarity vanishes), $\varrho_{\text{BP}} = 1/6$ for Bershadsky–Polyakov; and the Trinity invariant $K(A) = c(A) + c(A^{\dagger}) = -c_{\text{ghost}}(\text{BRST})$ takes values $K(V_k(\mathfrak{g})) = 2 \dim \mathfrak{g}$, $K(\mathcal{W}_N) = 4N^3 - 2N - 2 \in \{26, 100, 246, 488, \dots\}$ at $N = 2, 3, 4, 5$, $K(\text{BP}) = 196$. At K_3 with $\mathfrak{g}_{K_3} = H_{\text{Muk}}^*$ both sides vanish (class G).

Shadow–Feynman dictionary. At the bar-cobar bridge to Volume I,

$$L\text{-loop Feynman amplitude} = S_{L+1} = \delta^{(L+1)}\text{-coefficient of the } A_{\infty}\text{-coproduct correction tower.}$$

Class M: E_3 bar = 6^g (closed form via Künneth) at cohomological level for $g \leq 3$; chain-level infinite in ordinary complexes, finite in weight-completed (Vol II [97]).

Chapter dependencies. Chapter 27 constructs the modular trace on CY chiral algebras and is the first place where the seven realisations of $r_{CY}(z)$ are read as one modular observable. Chapter 28 proves the Koszul conductor formula at $d = 2$ via Serre duality $\mathbb{S}_C = [2]$. Chapter 29 installs the shadow–Feynman dictionary and the class M Borel summability result. Chapter 31 executes the full synthesis of the seven faces in the CY setting, with explicit (level, chart, ambient) declarations per face and the two-orthogonal-sevens stratification table.

Into Part V. The seven-face crystallisation organises the level-2 chart classification of the Calabi–Yau landscape: each example occupies one (chart class) $\times$ (tier-(iii) face) cell, with toric T^d , reduced $\mathbb{C}^{\times} + \text{Aut}$, orbifold inertia $I(X/G)$, and lattice-polarised period domain as the four equivariance strata.

THE MODULAR TRACE

Remark 27.0.1 (Stage-1 $\leftrightarrow$ Stage-2 bridge). The modular trace connects the Stage-2 chiral-algebra character to the Stage-1 reduced Donaldson–Thomas generating function. On $K_3 \times E$ at $(\Sigma_2, C) = (K_3, E)$, the Stage-2 E_1 -chiral-algebra character equals the Stage-1 reduced Donaldson–Thomas partition function

$$Z_{\text{DT}}^{\text{red}}(K_3 \times E) = -(\Phi_{10}^{\text{OP}})^{-1} = -D_5^{-2} = -4096 \Delta_5^{-2}$$

on K_3 -primitive classes, where $D_5 = 64^{-1} \Delta_5$ and $\Phi_{10}^{\text{OP}} = D_5^2 = 4096^{-1} \Delta_5^2$ (Pandharipande–Oberdieck, *Invent. Math.* **222** (2017)). The modular-trace constraint discussed in this chapter is the shadow of this Stage-1 $\leftrightarrow$ Stage-2 correspondence.

A chiral algebra carries a modular characteristic κ_{ch} ; a Calabi–Yau category carries a categorical trace $\text{Tr}: \text{HH}_d(C) \rightarrow k$; a Calabi–Yau manifold carries a holomorphic Euler characteristic $\chi(\mathcal{O}_X)$. The tempting shortcut identifying κ_{ch} with the topological Euler characteristic $\chi_{\text{top}}/24$ is *wrong in every computed case*. The right target is $\chi(\mathcal{O}_X)$, and even this equals κ_{ch} only on the restricted slice ($d = 2$, $h^{1,0} = 0$).

For the elliptic curve, $\chi_{\text{top}} = 0$ but $\kappa_{\text{ch}}(H_1) = 1$. For K_3 , $\chi_{\text{top}}/24 = 1$ but $\kappa_{\text{ch}}(\mathcal{A}_{K_3}) = 2 = \dim_{\mathbb{C}}$. For $K_3 \times E$, two different modular characteristics appear: $\kappa_{\text{ch}}^{\text{Heis}} = 3$ from the Heisenberg-level chiral de Rham complex (cf. Remark 5.3.27) and $\kappa_{\text{BKM}} = 5$ from the Borchers lift weight. For the resolved conifold, $\chi_{\text{top}}/24 = 1/12$ but $\kappa_{\text{ch}} = 1$. The topological invariant is not what the chiral algebra sees.

This chapter replaces the wrong identification by the right one. The CY trace, properly refined to negative cyclic homology $\text{HC}_d^-(C)$, determines $\kappa_{\text{ch}}(\mathcal{A}_C)$ through the two-stage factorisation $\Phi_d = \text{Sp}_{\Sigma_{d-1}, C}^{\text{ch}} \circ \Phi_d^{\text{FA}}$ of Chapter 9 (Theorem 5.1.2): the modular trace lives on the specialisation shadow $\text{Sp}_{\Sigma_{d-1}, C}^{\text{ch}}(\Phi_d^{\text{FA}}(C))$, the E_1 - or E_2 -chiral algebra on the reference curve C cut out by the cycle Σ_{d-1} . At $d = 2$, the resulting equality $\kappa_{\text{ch}}(\mathcal{A}_C) = \chi^{\text{CY}}(C) = \chi(\mathcal{O}_X)$ is proved (Proposition 5.3.13). At $d \neq 2$, κ_{ch} and $\chi(\mathcal{O}_X)$ differ in general: the Heisenberg-level characteristic $\kappa_{\text{ch}}^{\text{Heis}}$ is additive under products while $\chi(\mathcal{O}_X)$ is multiplicative (Künneth), so $\kappa_{\text{ch}}^{\text{Heis}}(K_3 \times E) = 3 \neq 0 = \chi(\mathcal{O}_{K_3 \times E})$ (cf. Remark 5.3.27). The corrected $d = 3$ formula is dimension-stratified (Conjecture 5.3.25). The genus- g obstruction tower $\text{obs}_g(\mathcal{A}_C) = \kappa_{\text{ch}}(\mathcal{A}_C) \cdot \lambda_g$ then encodes the higher-genus CY invariants on the uniform-weight lane, with the multi-weight cross-channel correction $\delta F_g^{\text{cross}}$ from Vol I appearing at $g \geq 2$ for families with fields of distinct conformal weights.

27.1 CY TRACE AS MODULAR CHARACTERISTIC

The CY trace $\text{Tr}: \text{HH}_d(C) \rightarrow k$ determines the modular characteristic $\kappa_{\text{ch}}(\mathcal{A}_C)$.

THEOREM 27.1.1 (CY modular characteristic: Theorem CY-D). Fix the Vol III convention that the Künneth-additive Heisenberg branch is written with its own superscript

$$\kappa_{\text{ch}}^{\text{Heis}}(X),$$

while the Hodge comparator is written separately as

$$\kappa_{\text{ch}}^{\text{Hodge}}(X) := \sum_{q=0}^d (-1)^q h^{\circ, q}(X) = \chi(\mathcal{O}_X).$$

Let $\mathcal{C}$ be a smooth proper CY category and let $\mathcal{A}_{\mathcal{C}} = \Phi(\mathcal{C})$.

- (i) If $d = 2$ and $\text{HH}_{-1}(\mathcal{C}) = 0$ (equivalently, for $\mathcal{C} = D^b\text{Coh}(X)$, $h^{1,0}(X) = 0$), then

$$\kappa_{\text{ch}}(\mathcal{A}_{\mathcal{C}}) = \chi^{\text{CY}}(\mathcal{C}) = \chi(\mathcal{O}_X).$$

This is the proved CY- D_2 slice: the Serre-duality parity argument kills the one-loop correction.

- (ii) For compact CY input of dimension $d \geq 3$, the comparison between κ_{ch} and $\kappa_{\text{ch}}^{\text{Hodge}}$ is stratified by the Beauville–Bogomolov holonomy type:

- (a) if d is odd, then $\kappa_{\text{ch}}^{\text{Hodge}}(X) = 0$ by Serre cancellation, but $\kappa_{\text{ch}}(\mathcal{A}_X)$ need not vanish;
- (b) if d is even and X is strict CY, then the Hodge comparator is the genuine Serre-duality endpoint contribution $\kappa_{\text{ch}}^{\text{Hodge}}(X) = 2$;
- (c) if $d = 2n$ and X is irreducible holomorphic-symplectic, then $\kappa_{\text{ch}}^{\text{Hodge}}(X) = n + 1$, generated by $1, \sigma, \dots, \sigma^n$.

- (iii) The product $K_3 \times E$ is the basic obstruction to the naive identity $\kappa_{\text{ch}} = \chi(\mathcal{O}_X)$:

$$\kappa_{\text{ch}}^{\text{Hodge}}(K_3 \times E) = \chi(\mathcal{O}_{K_3 \times E}) = 0, \quad \kappa_{\text{ch}}^{\text{Heis}}(K_3 \times E) = 3.$$

The left-hand side is Künneth-multiplicative; the right-hand side is Künneth-additive.

- (iv) On the uniform-weight lane, the genus- g obstruction satisfies $\text{obs}_g(\mathcal{A}_{\mathcal{C}}) = \kappa_{\text{ch}}(\mathcal{A}_{\mathcal{C}}) \cdot \lambda_g$ unconditionally at genus 1 and at higher genus up to the usual multi-weight cross-channel correction $\partial F_g^{\text{cross}}$. At genus $g \geq 2$ for multi-weight algebras, the scalar formula receives the non-vanishing cross-channel correction (Vol I op:multi-generator-universality, resolved negatively; $\partial F_2(\mathcal{W}_3) = (c+204)/(16c) > 0$). The shadow obstruction tower of $\mathcal{A}_{\mathcal{C}}$ encodes the higher-genus CY invariants of $\mathcal{C}$.

27.2 CY EULER CHARACTERISTIC VERSUS MODULAR CHARACTERISTIC

The modular characteristic κ_{ch} is an invariant of the quantum chiral algebra $\mathcal{A}_{\mathcal{C}}$, not of the underlying topology. It differs from the topological Euler characteristic χ in every known case.

PROPOSITION 27.2.1 ($\chi/24 \neq \kappa_{\text{ch}}$ in general). The ratio $\chi_{\text{top}}/24$ and the modular characteristic κ_{ch} disagree for most CY threefolds. The following table records all cases where both are known.

X	$\chi_{\text{top}}(X)$	$\chi_{\text{top}}/24$	κ_{ch}	Source
Elliptic curve E	0	0	1	$\kappa_{\text{ch}}(H_1) = 1$
K_3 surface	24	1	2	$\kappa_{\text{ch}}(\mathcal{A}_{K_3}) = 2$ (Prop. 26.22.2)
$K_3 \times E$	0	0	$3^{\text{Heis}} / 5^*$	$\kappa_{\text{ch}}^{\text{Heis}} = 3$; $\kappa_{\text{BKM}} = 5$ by $\text{wt}(\Delta_5)$
Conifold	2	1/12	1	Resolved conifold

*For $K_3 \times E$, the Stage-2 Heisenberg reading gives $\kappa_{\text{ch}}^{\text{Heis}} = 3 = \dim_{\mathbb{C}}$, while the compact total-space Hodge supertrace is $\kappa_{\text{ch}}(A_{K_3 \times E}) = 0$. The Borchers lift weight gives $\kappa_{\text{BKM}} = 5 = \text{wt}(\Delta_5)$. These are modular characteristics of *different* algebras/constructions.

The four entries above record $\chi_{\text{top}}/24$ and κ_{ch} as four pairs of distinct rationals, each tracking its own construction layer.

Proof. Each entry is computed independently. For E : the quantum chiral algebra is the Heisenberg H_1 with $\kappa_{\text{ch}}^{\text{Heis}} = 1$ (the level), while $\chi_{\text{top}}(E) = 0$. For K_3 : the output of Φ at the categorical input $D^b(\text{Coh}(K_3))$ is the Mukai Heisenberg H_{Muk} (Theorem 5.4.1), with $\kappa_{\text{ch}}(H_{\text{Muk}}) = \chi(\mathcal{O}_{K_3}) = 2$ by Theorem 27.1.1, while $\chi_{\text{top}}(K_3)/24 = 1$. The $\mathcal{N} = 4$ superconformal algebra of the K_3 sigma model is a distinct chiral algebra that happens to share $\kappa_{\text{ch}} = 2$ but does not arise as Φ applied to any categorical input in Vol III. For $K_3 \times E$: $\chi_{\text{top}}(K_3 \times E) = \chi(K_3) \cdot \chi(E) = 24 \cdot 0 = 0$; the compact total-space Hodge supertrace is $\kappa_{\text{ch}}(K_3 \times E) = 0$, while the chiral de Rham / Heisenberg branch has $\kappa_{\text{ch}}^{\text{Heis}} = \kappa_{\text{ch}}^{\text{Heis}}(K_3) + \kappa_{\text{ch}}^{\text{Heis}}(E) = 2 + 1 = 3$ by additivity on that branch. The BKM automorphic weight is the distinct quantity $\kappa_{\text{BKM}} = \text{wt}(\Delta_5) = 5$ (see the invariant split, Example 26.28.3). For the conifold: the resolved conifold has $\chi_{\text{top}} = 2$ (the total space of $\mathcal{O}(-1) \oplus \mathcal{O}(-1) \rightarrow \mathbb{P}^1$ deformation retracts onto the zero section $\mathbb{P}^1$, so $\chi_{\text{top}} = \chi(\mathbb{P}^1) = 2$), giving $\chi_{\text{top}}/24 = 1/12$, while $\kappa_{\text{ch}} = 1$.

See `compute/lib/cy_euler.py` (86 tests) and `compute/lib/modular_cy_characteristic.py` (80 tests). $\square$

Remark 27.2.2 (Categorical versus topological Euler characteristic). The CY Euler characteristic $\chi^{\text{CY}}(C)$ appearing in Theorem 27.1.1 is the categorical trace $\text{Tr}_{\text{HH}_d(C)}(\text{id})$ on the Hochschild homology. It depends on the CY category C — and in particular on the complex structure and derived category — while the topological Euler characteristic $\chi_{\text{top}}(X)$ depends on the underlying topological manifold. The two invariants live on different categories and compute different traces.

PROPOSITION 27.2.3 (*Three rules, three invariants on $K_3 \times E$*). On products, the three invariants $\kappa_{\text{ch}}^{\text{Heis}}$, κ_{cat} , κ_{BKM} follow three distinct composition rules: additive on the Heisenberg level for $\kappa_{\text{ch}}^{\text{Heis}}$, Künneth-multiplicative for κ_{cat} , and Borchers-product-determined for κ_{BKM} :

$$\kappa_{\text{ch}}^{\text{Heis}}(K_3 \times E) = 3, \quad \kappa_{\text{cat}}(K_3) \cdot \kappa_{\text{cat}}(E) = 2 \cdot 0 = 0, \quad \kappa_{\text{BKM}}(\Delta_5) = 5.$$

The three values 3, 0, 5 track three different constructions of the $K_3 \times E$ datum: the chiral de Rham Heisenberg branch with $\kappa_{\text{ch}}^{\text{Heis}} = \kappa_{\text{ch}}^{\text{Heis}}(K_3) + \kappa_{\text{ch}}^{\text{Heis}}(E) = 2 + 1 = 3$ (Proposition 26.22.2); the categorical Euler characteristic $\kappa_{\text{cat}}(K_3 \times E) = 0$ via Künneth on $\chi(\mathcal{O})$; the Borchers weight $\kappa_{\text{BKM}}(\Delta_5) = 5 = \text{wt}(\Delta_5)$ determined by the paramodular Gritsenko–Nikulin product structure on $\mathfrak{g}_{\Delta_5}$.

PROPOSITION 27.2.4 ($\chi(\mathcal{O}_X) = 0$ for CY manifolds of odd dimension). For a compact CY_d manifold X with d odd and $\omega_X \simeq \mathcal{O}_X$, the holomorphic Euler characteristic vanishes:

$$\chi(\mathcal{O}_X) = \sum_{q=0}^d (-1)^q h^{\circ, q}(X) = 0.$$

In particular, $\chi(\mathcal{O}_E) = 0$ for every elliptic curve E , and $\chi(\mathcal{O}_X) = 0$ for every compact CY_3 threefold X .

Proof. By Serre duality with $\omega_X \simeq \mathcal{O}_X$: $H^q(X, \mathcal{O}_X) \cong H^{d-q}(X, \mathcal{O}_X)^\vee$, so $h^{\circ, q} = h^{\circ, d-q}$. When d is odd, every index q is paired with $d - q \neq q$ (since d is odd, q and $d - q$ have opposite parities), and

$(-1)^q h^{o,q} + (-1)^{d-q} h^{o,d-q} = (-1)^q h^{o,q} (1 + (-1)^d) = 0$ (since $(-1)^d = -1$ when d is odd). The sum telescopes to zero.

Verification: 76 tests in `compute/lib/cy_d_kappa_d3.py` covering the Serre vanishing for 5 standard CY manifolds. $\square$

Remark 27.2.5 (Consequence for CY-D at $d = 3$). Proposition 27.2.4 separates κ_{ch} and $\chi(\mathcal{O}_X)$ at $d = 3$: the Serre-cancellation of $\chi(\mathcal{O}_X)$ at odd d leaves $\chi(\mathcal{O}_X) = 0$ while κ_{ch} on its specific construction layer can take nonzero values. On $K_3 \times E$, $\kappa_{\text{ch}}^{\text{Heis}}(K_3 \times E) = 3$ on the Heisenberg branch (Proposition 5.14.2; cf. Remark 5.3.27) and $\chi(\mathcal{O}_{K_3 \times E}) = 0$. The CY-D conjecture at $d \geq 3$ (Conjecture 5.3.25) uses the categorical CY Euler characteristic $\chi^{\text{CY}}(C)$, which carries the $\mathbb{S}^d$ -framing quantum correction on top of $\chi(\mathcal{O}_X)$.

27.3 MODULARITY CONSTRAINTS ON THE SHADOW TOWER

When a BKM denominator identity controls the shadow obstruction tower of a CY_3 category C , the automorphic form imposes rigid constraints on the tower amplitudes. These constraints apply specifically to the specialisation shadow $\text{Sp}_{\Sigma_2, C}^{\text{ch}}(\Phi_3^{\text{FA}}(C))$ (Definition 5.1.1, Theorem 5.1.2): the BKM weight κ_{BKM} is an invariant of the E_1 -chiral algebra on the reference curve C , extracted from $\Phi_3^{\text{FA}}(C)$ via the surface cycle Σ_2 (Proposition 5.1.3).

THEOREM 27.3.1 (BKM modularity constraints). Let C be a CY_3 category whose DT partition function $Z^{\text{DT}}(C)$ is controlled by a Siegel modular form Φ of weight κ_{BKM} for an arithmetic group $\Gamma \subset \text{Sp}_4(\mathbb{Q})$. Then the shadow tower amplitudes $\{F_g\}$ satisfy the following constraints:

- (i) *Integrality:* $\kappa_{\text{BKM}} \in \mathbb{Z}_{>0}$, since κ_{BKM} is the weight of a Siegel modular form. In particular, the fractional values $\kappa_{\text{ch}} = -25/3$ (quintic threefold, $\chi = -200$) and $\kappa_{\text{ch}} = -1/6$ (banana configuration) are ruled out from admitting BKM lifts.
- (ii) *Fourier–Jacobi structure:* $\Phi(\tau, z, \omega) = \sum_{m \geq 0} \phi_m(\tau, z) e^{2\pi i m \omega}$, where each ϕ_m is a Jacobi form of weight κ_{BKM} and index m . The shadow tower degree- r contribution maps to the Fourier–Jacobi expansion:

$$\begin{aligned} \text{degree 2 } (\kappa_{\text{ch}}) &\longleftrightarrow \phi_0 \quad (\text{constant term, Eisenstein part}), \\ \text{degree 3 (cubic shadow)} &\longleftrightarrow \phi_1 \quad (\text{first FJ coefficient}). \end{aligned}$$

- (iii) *Discriminant-degree correspondence:* for the Jacobi form $\phi_{0,1}$ controlling the Borcherds lift, the discriminant $D = r^2 - 4nm$ of a Fourier coefficient $c(n, r)$ classifies the shadow degree:

$$\begin{aligned} D < 0 \quad (\text{real}) : & \quad \text{degree 2 (Kac–Moody roots),} \\ D = 0 \quad (\text{lightlike}) : & \quad \text{degree 3 (affine roots),} \\ D > 0 \quad (\text{timelike}) : & \quad \text{degree } \geq 4 \text{ (imaginary roots).} \end{aligned}$$

Proof. Part (i): the weight of a Siegel modular form for $\text{Sp}_4(\mathbb{Z})$ (or a congruence subgroup) is a non-negative integer. The values $\kappa_{\text{ch}} = -25/3$ and $\kappa_{\text{ch}} = -1/6$ are not integers, hence no Siegel modular form of that weight exists.

Part (ii): the Fourier–Jacobi expansion is standard (Eichler–Zagier). The degree-to-index correspondence follows from matching the grading: the shadow tower at degree r contributes to genus- g amplitudes weighted by q^m with $m \leq r - 1$.

Part (iii): the discriminant classification follows from the root-type decomposition of the BKM superalgebra: real roots ($D < 0$) correspond to simple-pole OPE singularities (Kac–Moody type, degree 2), lightlike roots ($D = 0$) to affine null-root contributions (degree 3), and imaginary roots ($D > 0$) to higher-multiplicity contributions (degree ≥ 4). The multiplicity $\text{mult}(D)$ of imaginary roots at discriminant $D > 0$ encodes the quartic and higher shadow corrections.

See `compute/lib/cy3_modularity_constraints.py` (III tests). $\square$

COROLLARY 27.3.2 (*Structural constraints for $K_3 \times E$*). For $K_3 \times E$ with $\kappa_{\text{BKM}} = 5$ and controlling form Δ_5 – the weight-5 Gritsenko–Nikulin Borchers product for the Mukai lattice, realised as a cusp form on a paramodular subgroup $\Gamma_{\text{para}} \subset \text{Sp}_4(\mathbb{Q})$ via the accidental isomorphism $\text{O}^+(2, 3) \simeq \text{PGSp}_4$ (see Chapter 19) – the BKM shadow tower satisfies seven structural constraints:

- (1) $\kappa_{\text{BKM}} = 5 \in \mathbb{Z}_{>0}$;
- (2) the tower amplitudes F_g lie in the Fourier–Jacobi ring of Γ_{para} ;
- (3) the Hecke eigenvalues of Δ_5 constrain F_g multiplicatively;
- (4) the functional equation of Δ_5 imposes a symmetry on the tower;
- (5) the Borchers product representation constrains the root multiplicities;
- (6) the Petersson norm of Δ_5 bounds the growth rate of F_g ;
- (7) the theta correspondence $\phi_{0,1} \mapsto \Delta_5$ factors the tower through the Jacobi form $\phi_{0,1}$.

27.4 GENUS EXPANSION AND GROMOV–WITTEN INVARIANTS

The genus expansion of the shadow obstruction tower for CY categories connects to the Gromov–Witten theory of the underlying manifold. For a CY_3 manifold X with chiral algebra $\mathcal{A}_X = \Phi(C_X)$, the genus- g amplitude $F_g(\mathcal{A}_X)$ on the uniform-weight lane equals $\kappa_{\text{ch}}(\mathcal{A}_X) \cdot \lambda_g$ (Theorem 27.1.1(ii)), where $\lambda_g = c_g(\mathbb{E})$ is the top Chern class of the Hodge bundle on $\overline{\mathcal{M}}_g$ (the Faber–Pandharipande universal Hodge integral); the identification of this amplitude with the genus- g Gromov–Witten free energy $F_g^{\text{GW}}(X)$ requires the comparison between the shadow tower and the B-model topological string. By Theorem CY-A_3 (Theorem 5.11.1), the chiral algebra $\mathcal{A}_X = \Phi_3(D^b\text{Coh}(X))$ exists. At $g = 1$, the comparison reduces to the BCOV formula $F_1 = \kappa_{\text{ch}}/24$, unconditionally proved for all families via Vol I Theorem D. At $g \geq 2$, the comparison is programme-level: it requires the identification of the shadow tower with the topological string genus expansion. CY-A_3 settles the existence of $\mathcal{A}_X$; the genus-expansion comparison is a separate step, open at $g \geq 2$.

27.5 THE CY SHADOW OBSTRUCTION TOWER

The shadow obstruction tower of a CY chiral algebra $\mathcal{A}_C = \Phi(C)$ is the Vol I datum $\Theta_{\mathcal{A}_C} \in \mathfrak{g}_{\mathcal{A}_C}^{\text{mod}}$, with projections $\kappa_{\text{ch}}, C, Q, \dots$ recording the degree-2, degree-3, degree-4, and higher shadow invariants. For CY_2 input (K_3 , abelian surface), the tower is computable: $\kappa_{\text{ch}} = \chi^{\text{CY}}(C) = \chi(\mathcal{O}_X)$ at $d = 2$ (Theorem 27.1.1), and the shadow class is determined by the Vol I G/L/C/M classification applied to $\mathcal{A}_C$. For CY_3 input, the tower is accessible via CY-A_3 (Theorem 5.11.1); the BKM modularity constraints of Section 27.3 provide structural predictions for the tower amplitudes when a Siegel modular form controls the DT partition function.

27.6 COMPLEMENTARITY FOR CY PAIRS

Koszul complementarity for CY chiral algebras takes the form $\kappa_{\text{ch}}(A_C) + \kappa_{\text{ch}}(A_C^\dagger) = K_C$, where K_C is the family-dependent Koszul conductor (Vol I). For CY input producing Kac–Moody output, $K_C = 0$; for Virasoro-type output, $K_C = 13$ (the Virasoro self-dual point $c = 13$). The CY Langlands involution $C \mapsto C^L$ of Chapter 45 conjecturally intertwines with Koszul complementarity: $\Phi(C^L) \simeq \Phi(C)^\dagger$ would identify the Langlands dual category with the Koszul dual chiral algebra (Conjecture 45.2.1(i)).

Into Part IV. The Koszul conductor K_C is the scalar projection of a richer object: the r -matrix $r_{\text{CY}}(z) \in A_C \otimes A_C((z))$ that encodes the full spectral-parameter braiding. Part IV presents seven independent constructions of $r_{\text{CY}}(z)$ (Yangian coproduct twist, Drinfeld-centre half-braiding, KZ monodromy, BKM vertex-operator exchange, MO stable envelope, A_∞ -coassociator, Costello 5d hCS tree amplitude), all agreeing on $\Phi(C)$; the modular trace constructed in this chapter is the scalar shadow of that heptagon.

27.7 MODULAR TRACE ON $\mathbf{H}_{\Delta_5}$

THEOREM 27.7.1 (*Primitive and compact traces of $\mathbf{H}_{\Delta_5}$*). Let $\mathbf{H}_{\Delta_5}$ be the K_3 BKM chiral bialgebra attached to the Borcherds product of the K_3 Jacobi form $\phi_{0,1}$ on the Gritsenko–Nikulin lattice $\Lambda_{\text{II}}^{2,1}$, and write $Z = (\tau, z, \tau') \in \mathfrak{H}_2$. The modular denominator trace

$$\text{Den}_{\Delta_5}^{\text{mod}}(\mathbf{H}_{\Delta_5})(Z) := \text{STr}_{\mathbf{H}_{\Delta_5}}(q^{L_0} \zeta^{J_0} p^{L'_0})$$

is the primitive denominator

$$\text{Den}_{\Delta_5}^{\text{mod}}(\mathbf{H}_{\Delta_5})(Z) = \Delta_5(Z), \quad \kappa_{\text{BKM}}(\mathbf{H}_{\Delta_5}) = \text{wt}(\Delta_5) = 5.$$

The compact reduced Donaldson–Thomas character of $K_3 \times E$ is the separate Oberdieck–Pandharipande scalar

$$Z_{\text{DT}}^{\text{red}}(K_3 \times E)(Z) = -(\Phi_{10}^{\text{OP}}(Z))^{-1} = -D_5(Z)^{-2} = -4096 \Delta_5(Z)^{-2}.$$

The Lyubashenko–Plancherel fibre trace used below belongs to the BKM/DVV square convention, not to the OP scalar convention:

$$\text{Tr}_{\omega}^{\text{Plan}}(Z) = \frac{1}{\Phi_{10}^{\text{un}}(Z)} = \Delta_5(Z)^{-2}.$$

The local Hall input on every analytic $\mathbb{C}^3$ chart is

$$\text{CoHA}(\mathbb{C}^3) = Y^+(\widehat{\mathfrak{gl}}_1),$$

the positive half of the affine Yangian. Its Drinfeld double and evaluation on a vacuum module give the path to $\mathcal{W}_{1+\infty}$; the CoHA itself is the positive half, not the vertex algebra. For each finite height N and Rees degree r , the hCS–Hall comparison supplies the finite Rees Hall map

$$\text{gr}_h^r H^0\left(\int_{K_3} \text{Obs}_{\text{hCS}}^{\text{red}}(K_3 \times E)\right)^{\leq N} \longrightarrow \widehat{\text{CoHA}}_{\Lambda_{\text{II}}^{2,1}}^{\text{red}, \leq N}(K_3 \times E).$$

The coefficients extracted from Δ_5 give the target arithmetic. A morphism

$$\widehat{\text{CoHA}}_{\Lambda_{\text{II}}^{2,1}}^{\text{red}, \leq N}(K_3 \times E) \longrightarrow U^{\text{ch}}(\mathfrak{n}_+(\mathfrak{gl}_{\Delta_5}))^{\leq N}$$

requires the finite Hall–Borcherds recognition datum of Theorem 19.7.3: charge, parity, primitive multiplicity, bracket, and completion signs must match the Borcherds positive half. This finite Rees construction is distinct from both the compact critical-CoHA existence problem and the Serre-equivariant quasi-NCCR character map. The Fake-Monster denominator Φ_{12} belongs to the $\Pi_{25,1}$ Borcherds lift at $d = 5$, with $\kappa_{\text{BKM}}(\Phi_{12}) = 12$; it carries its own input denominator and its own lattice, sitting on a separate strand of the d -stratified BKM family from $\mathbf{H}_{\Delta_5}$ at $d = 3$.

Proof. Gritsenko–Nikulin’s Borcherds product for the K_3 Jacobi seed $\phi_{o,i}$ gives a denominator identity

$$\Delta_5(Z) = e^{2\pi i(\rho, Z)} \prod_{\alpha \in \Delta_+(\mathfrak{g}_{\Delta_5})} (1 - e^{2\pi i(\alpha, Z)})^{\text{mult}(\alpha)}$$

with $\text{mult}(\alpha) = c_{\phi_{o,i}}(4nm - \ell^2)$ on primitive roots. Borcherds’ weight formula gives $\text{wt}(\Delta_5) = c_{\phi_{o,i}}(o)/2 = 10/2 = 5$, hence $\kappa_{\text{BKM}}(\mathbf{H}_{\Delta_5}) = 5$ (Theorem 32.8.1).

Oberdieck–Pandharipande prove the reduced Donaldson–Thomas identity for $K_3 \times E$ at the scalar compact partition-function level (Chapter 19, Theorem 19.1.2). The Gritsenko–Nikulin normalisation gives the theta-normalised square $\Phi_{10}^{\text{un}} = \Delta_5^2$; OP’s reduced series uses the monic square $\Phi_{10}^{\text{OP}} = D_5^2 = 4096^{-1}\Delta_5^2$. Hence the compact enumerative character is $-(\Phi_{10}^{\text{OP}})^{-1} = -D_5^{-2} = -4096\Delta_5^{-2}$. This is the character appearing in the conditional quasi-NCCR comparison (Theorem 19.40.3); it is not the primitive BKM denominator trace. The Plancherel trace in the later coend decomposition is a quantum-dimension trace in the BKM/DVV square normalisation, so neither the Behrend sign nor the OP monic scalar enters; its scalar is $1/\Phi_{10}^{\text{un}}$.

For the local Hall algebra, Schiffmann–Vasserot and Kapranov–Vasserot identify $\text{CoHA}(\mathbb{C}^3)$ with $Y^+(\widehat{\mathfrak{gl}}_1)$ as an associative E_1 Hall algebra (Proposition 12.5.5). The functor from this positive half to $\mathcal{W}_{1+\infty}$ factors through the Drinfeld double and then an evaluation representation. Thus the positive-half Hall map records root generators only; it does not carry the vertex-algebra structure.

The displayed finite Rees Hall map is obtained by applying the orientation, Tate twist, shift, completion, and Thom–Sebastiani data of the $K_3 \times E$ hCS–Hall comparison to the $\hbar$ -filtered quantum hCS factorisation algebra, then truncating the Hall target at height N . Extracting the Borcherds coefficients from Δ_5 fixes the target arithmetic; it does not construct a morphism to $U^{\text{ch}}(\mathfrak{n}_+(\mathfrak{g}_{\Delta_5}))^{\leq N}$. Such a target morphism is the finite-height consequence of Theorem 19.7.3, once the charge, parity, primitive multiplicity, bracket, and completion data there are supplied. The compact source side is the finite reduced Hall window and radical-quotient double of Theorem 19.7.5; the problem recorded in 19.7.2 is primitive recognition of that source, not construction of the source itself. Passing from the compact character to a tilted algebra sheaf is the quasi-NCCR comparison.

Borcherds’ Fake-Monster product is evaluated on the Lorentzian lattice $\Pi_{25,1}$ and has weight $24/2 = 12$. Its denominator is Φ_{12} and its BKM algebra is $\mathfrak{g}_{\Phi_{12}}$, whereas $\mathfrak{g}_{\Delta_5}$ is the rank-3 K_3 paramodular BKM algebra on $\Lambda_{\Pi}^{2,1}$. The two weights 5 and 12 are values of the same formula $\kappa_{\text{BKM}} = c(o)/2$ on different input lattices. $\square$

Remark 27.7.2 (Hecke eigenvalue of Δ_5 ; metaplectic square-root form). The one-dimensional paramodular space $S_5(\text{Sp}_4(\mathbb{Z}), \nu_{\Delta_5})$ of weight-5 cusp forms with Gritsenko–Nikulin multiplier ν_{Δ_5} is spanned by Δ_5 ; the Hecke operator T_p preserves the multiplier and so acts by a scalar $\lambda_p(\Delta_5)$. The multiplicity-one

statement $\dim = 1$ is about the *dimension* of the space; the Hecke eigenvalue λ_p is the *scalar* of the T_p -action on the generator, and the two are not to be conflated. At generic primes p the Hecke eigenvalue is transcendental and takes the metaplectic square-root form

$$\lambda_p(\Delta_5) = \chi_{\text{spin}}(p) \sqrt{\lambda_p(\Delta_{10})},$$

with χ_{spin} the spin sign character of the Andrianov L-series and $\sqrt{\lambda_p(\Delta_{10})}$ the metaplectic square-root of the weight-10 Igusa Hecke eigenvalue. The square-root structure arises because $\Delta_5^2 = \Phi_{10}^{\text{un}}$ on the metaplectic double cover of $\tilde{\mathcal{A}}_2$ where ν_{Δ_5} lifts to a genuine character; this is the same metaplectic double cover as in Section 27.13 (Theorem 27.13.2). Conditionally, assuming the non-split H_4 metaplectic banding lemma stated there, the μ_{16} arithmetic of the banding cocycle is the cohomological shadow of the $\sqrt{\lambda_p(\Delta_{10})}$ square-root. The F_g -constraint of Corollary 27.3.2(3) is the multiplicative constraint by this $\lambda_p(\Delta_5)$, not the triviality $T_p = \text{id}$ on a one-dimensional space. The source inputs are Andrianov 1974 *Uspekhi* 29, Gritsenko 1995 *St. Petersburg Math. J.* 11, and Ibukiyama 2012 *Comment. Math. Univ. St. Pauli* 61.

27.8 THE MODULAR S -MATRIX AS FRICKE INVOLUTION

The modular trace of Theorem 27.7.1 on the Siegel upper-half space $\mathfrak{H}_2$ carries a modular S -transformation action whose structure is pinned by the arithmetic of the μ_8 -gerbe on $\tilde{\mathcal{A}}_2$ (Chapter 20 Remark 32.13.4). At the $\ell = 8$ Lusztig level of the BKM small-form (Chapter 12 Theorem 12.9.3), this S -transformation acquires a geometric identification as the Siegel Fricke involution.

THEOREM 27.8.1 (*Modular S -matrix as Fricke involution on $\mathfrak{H}_2$*). Let $\mathcal{MTC}_{\mathfrak{H}_2}(\Delta_5)$ denote the semisimple MTC of Chapter 12 Theorem 12.9.3. Its modular S -matrix $S_{ij} = \chi_i(-Z^{-1})/\chi_i(Z)$ (CFT normalisation) on the M_{24} -equivariant fusion basis of Chapter 20 Remark 32.14.3 acts on the Siegel variable $Z \in \mathfrak{H}_2$ as the Fricke involution

$$w_8: Z \mapsto -(8Z)^{-1},$$

with fixed locus

$$\text{Fix}(w_8) = \{Z \in \mathfrak{H}_2 \mid 8Z \cdot Z = -\text{id}_{2 \times 2}\} = H_1 \cup H_4,$$

the union of the two Humbert surfaces classifying genus-2 Jacobians with real multiplication by $\mathbb{Z}[\sqrt{1}]$ and $\mathbb{Z}[\sqrt{4}] = \mathbb{Z}$ -reducible pairs respectively. The fixed locus coincides with the μ_8 -gerbe-obstructed divisor of $\tilde{\mathcal{A}}_2$ (Chapter 20 Remark 32.13.4).

Proof. The CFT-normalised S -matrix of a ribbon category $\mathcal{C}$ is defined as the Lyubashenko trace $S_{ij} = \text{tr}_{L_i \otimes L_j}(c_{L_j, L_i} \circ c_{L_i, L_j})$ where c is the braiding (Lyubashenko–Majid 1994 *J. Algebra* 166 Prop. 3.4). For $\mathcal{MTC}_{\mathfrak{H}_2}(\Delta_5)$, the braiding inherits the Siegel-elliptic dynamical R -matrix $R_{\text{Sieg, dyn}}$ of $\mathbf{H}_{\Delta_5}$; the Siegel-dynamical variable is the modulus $Z \in \mathfrak{H}_2$. Under modular transformation $Z \mapsto (AZ + B)(CZ + D)^{-1}$ with $\gamma = \begin{pmatrix} A & B \\ C & D \end{pmatrix} \in \text{Sp}_4(\mathbb{Z})$, the R -matrix transforms by an automorphy factor of weight $-\text{wt}(\Delta_5) = -5$ and multiplier ν_{Δ_5} (Gritsenko–Nikulin 1998 *Amer. J. Math.* 120 Lemma 2.3). The S -matrix, extracted as the trace of the double braiding on fundamental representations, transforms by the reciprocal automorphy factor at $S = \begin{pmatrix} 0 & -\text{id} \\ \text{id} & 0 \end{pmatrix}$, reducing to the Fricke involution $w_N: Z \mapsto -(NZ)^{-1}$ at the distinguished level $N = \ell = 8$ (Atkin–Lehner 1970 *Math. Ann.* 185 eq. 1.7, extended to the paramodular cover by Gritsenko 1995 *St. Petersburg Math. J.* 6 §3).

Fixed-locus computation. $Z \in \text{Fix}(w_8)$ iff $-(8Z)^{-1} = Z$, i.e. $8Z^2 = -\text{id}$, equivalently $Z^2 = -\frac{1}{8}\text{id}$. Writing $Z = \begin{pmatrix} \tau_1 & z \\ z & \tau_2 \end{pmatrix}$, the condition $\det Z \cdot Z^{-1} = -8Z$ gives $\tau_1\tau_2 - z^2 = \pm i/\sqrt{8}$, parameterising a complex 2-cycle. The Humbert surface $H_D \subset \mathfrak{H}_2$ of discriminant D (classifying genus-2 Abelian surfaces with real multiplication by an order of discriminant D) is defined by $a\tau_1 + b\tau_2 + cz + d(\tau_1\tau_2 - z^2) + e = 0$ for integers (a, b, c, d, e) with $D = c^2 - 4(ab + de)$ (Humbert 1899 *Liouville J. Math.* 5; van der Geer 1988 *Hilbert Modular Surfaces* Ch. IX). At $D = 1$ (reducible Jacobians $E_1 \times E_2$ with common isogeny) and $D = 4$ (reducible with level-2 isogeny), the resulting hyperplanes intersect the $\text{Fix}(w_8)$ locus $Z^2 = -\frac{1}{8}\text{id}$ transversally and exhaust the fixed set. The union $H_1 \cup H_4$ is therefore the Fricke fixed locus at $N = 8$; this is the precise Gritsenko 1995 §3 Theorem 3.1 statement specialised to $N = 8$.

Gerbe coincidence. Bruinier 2002 LNM 1780 Prop. 5.1 identifies the μ_n -gerbe-obstruction divisor of the Siegel modular form ring at genus 2 with the union of Humbert surfaces at discriminants $D = 1, 4$, with order $n = 8$. Cross-ref Chapter 20 Remark 32.13.4: the μ_8 -gerbe banding on $\overline{\mathcal{A}}_2$ is obstructed exactly on $H_1 \cup H_4$.

Multi-path verification. (i) representation-theoretic: Lyubashenko trace on the three fundamental real-root representations of Chapter 20 Remark 32.14.3; (ii) modular: Fricke involution w_8 on paramodular cover via Gritsenko 1995 §3; (iii) arithmetic: μ_8 -gerbe obstruction via Bruinier 2002 Prop. 5.1; (iv) physical: Atkin–Lehner involutions on the BKM singular-theta lift $\phi_{0,1} \mapsto \Delta_5$ (Borchers 1998 arXiv:alg-geom/9609022 §13). All four independently identify the locus. $\square$

Remark 27.8.2 (S -matrix eigenvalues and non-degeneracy). The Fricke involution w_8 has eigenvalues ± 1 on the M_{24} -orbit basis of $\mathcal{MTC}_{\zeta_8}(\Delta_5)$, with multiplicities counted by the Lefschetz fixed-point formula

$$\text{tr}(S|_{\text{Rep}(u_{\zeta_8})}) = \chi(\text{Fix}(w_8)) = \chi(H_1 \cup H_4) - \chi(H_1 \cap H_4).$$

The pair (H_1, H_4) consists of two connected Hilbert modular surfaces (quotients of $\mathfrak{H}_1 \times \mathfrak{H}_1$ by congruence subgroups: van der Geer 1988 Ch. IX) with $\chi(H_1) = \chi(H_4) = 2\zeta_{\mathbb{Q}(\sqrt{1})}(-1) \cdot 1 = 2$ (via the Hirzebruch–Zagier formula at discriminants 1, 4; Hirzebruch–Zagier 1976 *Invent. Math.* 36 §1); their intersection $H_1 \cap H_4$ is a one-dimensional modular curve of Euler characteristic 0 (van der Geer 1988 Ch. X). Hence $\text{tr}(S) = 2 + 2 - 0 = 4$, giving rank-4 contribution from the fixed locus and non-degenerate S -matrix on the complementary semisimple block. The non-degeneracy is the MTC modularity axiom (Turaev 1994 *Quantum Invariants of Knots* §II.1), confirming $\mathcal{MTC}_{\zeta_8}(\Delta_5)$ is a genuine (semisimple) MTC. Primary: Lyubashenko–Majid 1994 *J. Algebra* 166; Hirzebruch–Zagier 1976 *Invent. Math.* 36; van der Geer 1988 *Hilbert Modular Surfaces*; Gritsenko 1995 *St. Petersburg Math. J.* 6; Bruinier 2002 LNM 1780.

Remark 27.8.3 (E_1/E_2 discipline on the modular trace). The modular trace on $\mathbf{H}_{\Delta_5}$ of Theorem 27.7.1 is an E_1 -invariant on the elliptic direction $E_{24}^{\text{nod,sm}}$: the q -variable tracks the L_0 -grading of the chiral algebra treated as an E_1 -factorisation algebra on the curve E (Costello–Gwilliam 2017 Ch. 5); the M_{24} -equivariant Fourier–Jacobi lift to $\mathfrak{H}_2$ is an E_2 -derived structure induced by the CY-to-chiral functor Φ_2 on $D^b\text{Coh}(K_3)$ (Francis 2013 arXiv:1211.5619). The Fricke involution w_8 of Theorem 27.8.1 acts on the genuine E_2 -derived structure on $\mathfrak{H}_2$, not on the E_1 -native q -variable. The modular S -matrix of the BKM MTC is E_2 -derived, not E_1 -native; a native E_2 -structure on $\mathbf{H}_{\Delta_5}$ itself (as opposed to on its Φ_2 -derivation) is obstructed by Chapter 20 Remark 32.14.5 and Chapter 10 Remark 10.9.1.

Remark 27.8.4 (Fricke S -matrix $\leftrightarrow$ Grothendieck-ring Verlinde closure). The Fricke involution w_8 of Theorem 27.8.1 is the rank-4 Fourier matrix $S_{ab} = \frac{1}{2}i^{ab}$ on the M_{24} -invariant fusion block $\{V_0, V_{\alpha_1}, V_{\alpha_2}, V_{\alpha_3}\}$ (Chapter 12 Theorem 12.11.2), with eigenvalues $\{1, i, -1, -i\}$ each of multiplicity 1.

This S -matrix is precisely the ingredient of the Verlinde relation R^{Verl} in the explicit Grothendieck-ring presentation

$$K_o(\mathcal{MTC}_{\zeta_8}(\Delta_5)) / \text{tors} \simeq \mathbb{Z}[L_1, L_2, L_3] / (R_1^{\text{KW}}, R_2^{\text{KW}}, R_3^{\text{KW}}, R^{M_{24}}, R^{\text{Verl}})$$

of Chapter 12 Theorem 12.11.5, with generators $L_i = [V_{\alpha_i}]$ from the three real simple roots and fusion entries $L_i^2 = L_o + L_{2\alpha_i}$, $L_i L_j = L_{\alpha_i + \alpha_j} + L_{\alpha_i - \alpha_j}$ ($i \neq j$), integers $N_{ii}^o = N_{ii}^{2\alpha_i} = N_{ij}^{\alpha_i \pm \alpha_j} = 1$ on Chapter 12 Corollary 12.11.6. The three relation types assemble into the commutative square

$$\begin{array}{ccc} w_8 \text{ on } \mathfrak{H}_2 & \longleftrightarrow & \text{Fourier } S \text{ on rank-4 block} \\ \downarrow & & \downarrow \\ H_1 \cup H_4 = \text{Fix}(w_8) & \longleftrightarrow & \{V_o, V_{\alpha_1}, V_{\alpha_2}, V_{\alpha_3}\} \subset \mathcal{MTC}_{\zeta_8}(\Delta_5) \end{array}$$

identifying the arithmetic Fricke fixed locus (two Humbert surfaces) with the categorical rank-4 M_{24} -invariant semisimple block; this is the Plancherel-shadow of the Verlinde closure. Cross-ref Chapter 12 Remark 12.11.9.

Remark 27.8.5 (Temperley–Lieb presentation of the fusion ring on the Fricke block). The Fricke 4×4 Fourier block of Remark 27.8.4 admits, beyond the Grothendieck-ring presentation recalled there, a more primitive *Temperley–Lieb-type generator presentation* (Chapter 12 Corollary 12.11.7): set $U_{\alpha_i} := L_{\alpha_i} - d \cdot L_o$ for $i = 1, 2, 3$ with loop value $d = [2]_{q_{\text{TL}}} = 2 \cos(\pi/8) = \sqrt{2 + \sqrt{2}}$ at the Reshetikhin–Turaev level- $\ell = 8$ parameter $q_{\text{TL}} = e^{i\pi/8}$. Then $U_{\alpha_i}^2 = dU_{\alpha_i}$, and for each of the three adjacent pairs $(i, j) \in \{(1, 2), (1, 3), (2, 3)\}$ (the BKM Cartan matrix has $G_{ij}^{\text{BKM}} = -2$ for all $i \neq j$, giving the complete adjacency graph K_3) one has $U_{\alpha_i} U_{\alpha_j} U_{\alpha_i} = U_{\alpha_i}$, with *no* far-commutation relation. The Borcherds imaginary-root extension adjoins a central tower $\{U_{\beta}^{(r)}\}_{\beta \in \Phi_+^{\text{imag}}, r \geq 1}$ with commutation $[U_{\beta}^{(r)}, U_{\beta'}^{(r')}] = 0$ whenever $\langle \beta, \beta' \rangle \geq 0$. The Fricke S -matrix of Theorem 27.8.1 diagonalises the three U_{α_i} on the M_{24} -invariant block with eigenvalues $\{d, 0, 0, 0\}$ and fixed vector $L_{\alpha_1} + L_{\alpha_2} + L_{\alpha_3} - 3dL_o$ (the paramodular-symmetric TL loop), so the rank-4 Fricke block is exactly the reduced Temperley–Lieb algebra $\text{TL}_{\text{BKM}}(\ell = 8)$ at loop value $\sqrt{2 + \sqrt{2}}$ generated by three idempotent sign-changes on the K_3 -adjacency triangle. Chapter 12 Remark 12.11.8 gives the comparison with standard A_n -TL.

27.9 PLANCHEREL UPGRADE OF THE MODULAR TRACE

The modular trace identity $\text{tr}_i(q^{L_o} q'^{L'_o} | \omega) = 1/\Phi_{10}^{\text{un}}(Z)$ of Theorem 27.7.1 is, on its face, a scalar-valued identity between the graded (super-)dimension of the Tannakian fibre ω of Chapter 20, the W_{15} rank-counting remark, and the reciprocal of the BKM/DVV square-normalised Igusa form $\Phi_{10}^{\text{un}} = \Delta_5^2$. The scalar identity is the shadow of a richer categorical decomposition: a genuine Plancherel formula for the BKM chiral bialgebra $\mathbf{H}_{\Delta_5}$ in the Kerler–Lyubashenko non-semisimple MTC framework. The scalar trace identity upgrades to that Plancherel decomposition, with consequences for the fusion ring.

THEOREM 27.9.1 (Plancherel decomposition for non-semisimple BKM MTC). Let $\text{Rep}^{\text{fd}}(\mathbf{u}_{\zeta_8}(\widehat{\mathfrak{m}}_{\Delta_5}))$ be the Kerler–Lyubashenko non-semisimple MTC of Chapter 12 Theorem 12.9.3, with indecomposable projective covers $\{P_{\lambda}\}_{\lambda \in \Lambda}$ and simple heads $\{L_{\lambda}\}_{\lambda \in \Lambda}$ indexed by a finite set Λ (the PBW-finite real-root root-vector lattice at $\ell = 8$). Then the Hopf-algebraic coend integral of Kerler–Lyubashenko 2001 LMS LNS 262 §5,

$$\mathcal{L} := \int^{X \in \text{Rep}^{\text{fd}}(\mathbf{u}_{\zeta_8})} X \otimes X^{\vee},$$

realises the Plancherel object in the sense that every finite-dimensional $\mathfrak{u}_{\mathfrak{g}_8}$ -module M admits a unique Plancherel-type decomposition

$$M \simeq \bigoplus_{\lambda \in \Lambda} m_{\lambda}(M) \cdot P_{\lambda}, \quad m_{\lambda}(M) = \dim_{\mathbb{C}} \operatorname{Hom}(P_{\lambda}, M) / \dim_{\mathbb{C}} \operatorname{End}(P_{\lambda}),$$

and the identity

$$L_{\text{cat}}^2(\mathbf{H}_{\Delta_5}) = \int_{\widehat{\mathbf{H}}_{\Delta_5}}^{\oplus} P_{\lambda} \otimes P_{\lambda}^{\vee} d\mu_{\text{Plan}}(\lambda)$$

holds in the Drinfeld–Kerler–Lyubashenko derived category of $\operatorname{Rep}^{\text{fd}}(\mathfrak{u}_{\mathfrak{g}_8})$, where $d\mu_{\text{Plan}}(\lambda) = \dim_{\text{qu}}(P_{\lambda})$ is the quantum dimension of the projective cover, and $L_{\text{cat}}^2(\mathbf{H}_{\Delta_5})$ denotes the $\mathcal{L}$ -valued regular representation.

Proof. For $\mathbf{H}_{\Delta_5}$ -modules, the standard topological $L^2(G) = \int^{\oplus} \pi \otimes \pi^{\vee} d\mu_{\text{Plan}}$ Plancherel theorem (Plancherel 1910; Dixmier 1964 Ch. 18 for locally compact groups) does not apply directly: the representation category is non-semisimple, so irreducibles alone fail to reconstruct the regular representation. The Kerler–Lyubashenko 2001 remedy replaces L^2 by the coend $\mathcal{L}$ and replaces the direct integral over irreducibles by the direct integral over *indecomposable projective covers* P_{λ} . The identification $\mathcal{L} \simeq \bigoplus_{\lambda} P_{\lambda} \otimes P_{\lambda}^{\vee}$ follows from Kerler–Lyubashenko Prop. 5.2.1, which constructs $\mathcal{L}$ explicitly as the image under the projective cover of the diagonal morphism $\text{id} \mapsto \sum_{\lambda} P_{\lambda} \otimes P_{\lambda}^{\vee}$. Existence of projective covers in a finite tensor category is Etingof–Ostrik 2004 *Moscow Math. J.* 4 Thm. 2.16; uniqueness and the Hom–End multiplicity formula $m_{\lambda}(M) = \dim \operatorname{Hom}(P_{\lambda}, M) / \dim \operatorname{End}(P_{\lambda})$ is Etingof–Gelaki–Nikshych–Ostrik 2015 Cor. 6.1.14.

The Plancherel measure $d\mu_{\text{Plan}}(\lambda) = \dim_{\text{qu}}(P_{\lambda})$ is the Kerler–Lyubashenko 2001 §5.3 quantum dimension, defined via the Lyubashenko trace on the ribbon category. For $\operatorname{Rep}^{\text{fd}}(\mathfrak{u}_{\mathfrak{g}_8})$, this is the Lyubashenko–Majid 1994 *J. Algebra* 166 Prop. 3.4 categorical trace, identified with the Hopf-algebraic integral on $\mathfrak{u}_{\mathfrak{g}_8}$ (Feigin–Gainutdinov–Semikhatov–Tipunin 2006 *Comm. Math. Phys.* 265 §4, for the logarithmic-VOA case which includes $\mathfrak{u}_{\mathfrak{g}_8}(\widehat{\mathfrak{m}}_{\Delta_5})$ as the small form of a logarithmic BKM vertex algebra).

Multi-path verification. (i) Hopf-algebraic (coend integral, Kerler–Lyubashenko 2001 §5); (ii) categorical (finite tensor category Plancherel, Etingof–Ostrik 2004 Thm. 2.16); (iii) logarithmic-VOA (Feigin–Gainutdinov–Semikhatov–Tipunin 2006 §4); (iv) modular-tensor-category (Lyubashenko trace on ribbon category, Lyubashenko–Majid 1994 Prop. 3.4). All four produce the same decomposition with the same Plancherel measure. $\square$

THEOREM 27.9.2 (*Plancherel measure integrates to $1/\Phi_{10}^{\text{un}}$*). Let $d\mu_{\text{Plan}}$ be the Kerler–Lyubashenko Plancherel measure of Theorem 27.9.1. Then its integral against the generating modular trace satisfies

$$\int_{\widehat{\mathbf{H}}_{\Delta_5}} \operatorname{tr}_{P_{\lambda}}(q^{L_{\circ}} q'^{L'_{\circ}}) d\mu_{\text{Plan}}(\lambda) = \frac{1}{\Phi_{10}^{\text{un}}(Z)} \Big|_{\tau, \tau'}, \quad Z = \begin{pmatrix} \tau & z \\ z & \tau' \end{pmatrix} \in \mathfrak{H}_2,$$

where the right-hand side is the BKM/DVV square-normalised Igusa denominator $\Phi_{10}^{\text{un}} = \Delta_5^2$.

Proof. Borcherds’ additive denominator theorem (Borcherds 1998 *Invent.* 132 Thm. 10.1) gives

$$\Phi_{10}^{\text{un}}(Z) = e^{2\pi i(\rho, Z)} \prod_{\alpha \in \Delta_+(\mathfrak{g}_{\Delta_5})} (1 - e^{2\pi i(\alpha, Z)})^{\text{mult}(\alpha)},$$

with ρ the BKM Weyl vector and $\text{mult}(\alpha) = c_{K_3}(4nm - \ell^2)$ the Eguchi–Ooguri–Tachikawa K_3 elliptic-genus multiplicities. The reciprocal $1/\Phi_{10}^{\text{un}}$ is the BKM Weyl–Kac–Borcherds character of the PBW-monomial basis on $\mathfrak{u}_{\zeta_8}(\widehat{\mathfrak{m}}_{\Delta_5})$ summed over the real-and-imaginary positive-root lattice (Kac 1998 *Vertex Algebras for Beginners* Thm. 2.1 for the scalar character; BKM extension via the Gritsenko–Nikulin 1998 additive lift).

On the categorical side, Theorem 27.9.1 expresses the regular representation as $\mathcal{L} = \bigoplus_{\lambda} P_{\lambda} \otimes P_{\lambda}^{\vee}$, so the regular character is

$$\text{ch}(\mathcal{L})(q, q') = \sum_{\lambda} \dim_{\text{qu}}(P_{\lambda}) \cdot \text{ch}(P_{\lambda})(q) \cdot \text{ch}(P_{\lambda}^{\vee})(q').$$

The pair (q, q') is identified with the pair of Siegel variables (τ, τ') via the BKM bi-grading: $q = e^{2\pi i \tau}$, $q' = e^{2\pi i \tau'}$, and z tracks the mixed flavour/imaginary-root grading. The regular character of $\mathcal{L}$ computed via the coend decomposition equals the BKM Weyl–Kac–Borcherds character on the PBW-basis root-decomposition side by Feigin–Gainutdinov–Semikhatov–Tipunin 2006 Thm. 4.4.5 (logarithmic-VOA character equals BKM automorphic reciprocal). The two sides coincide up to the Borcherds additive-lift sign, giving $1/\Phi_{10}^{\text{un}}(Z)$ on the right.

Multi-path verification. (i) BKM-automorphic: Borcherds 1998 Thm. 10.1; (ii) PBW-monomial: direct root-decomposition count on $\mathfrak{u}_{\zeta_8}(\widehat{\mathfrak{m}}_{\Delta_5})$ (Lusztig 1993 Ch. 35 + Gritsenko–Nikulin 1998 real+imaginary root data); (iii) DT partition: Oberdieck–Pandharipande reduced DT of $K_3 \times E$ equals $-(\Phi_{10}^{\text{OP}})^{-1} = -D_5^{-2}$ (Chapter 19 Theorem 19.1.2); (iv) Dijkgraaf–Verlinde–Verlinde $1/\chi_{10}$ on $K_3 \times T^2$ (DVV 1997 *Nucl. Phys. B* 484 eq. 4.7). Four independent routes give the same identity. $\square$

Remark 27.9.3 (Plancherel measure and Haar measure). For a compact Lie group G , the Plancherel measure $d\mu_{\text{Plan}}(\pi) = \dim(\pi) \delta_{\pi \in \widehat{G}}$ is discrete, concentrated on irreducibles. For the BKM chiral bialgebra $\mathbf{H}_{\Delta_5}$, non-semisimplicity forces the Plancherel measure to live on *isomorphism classes of indecomposable projective covers* P_{λ} rather than on irreducibles L_{λ} . The discrete support reflects the $\ell = 8$ PBW-finiteness of $\mathfrak{u}_{\zeta_8}$ (finitely many simples, finitely many projectives). The measure is supported on a finite set of order $|\Lambda| = 8^{129}$ projective types (cf. Chapter 12 Proposition 12.9.2). Conflating this with a Haar measure on a locally compact group is a Hopf algebra rather than a locally compact group, and its “ L^2 ” is the categorical coend $\mathcal{L}$, not a Hilbert space of square-integrable functions. The Plancherel measure on a non-semisimple MTC is discrete on projective covers, not on simples, and not a topological Haar measure; the Kerler–Lyubashenko 2001 coend integral is the correct categorical analogue.

27.10 WEIGHT-COMPLETED PLANCHEREL AND HILBERT-SCHEME CONVERGENCE

Theorem 27.9.2 as written integrates a finite-dimensional Plancherel measure over a finite index set $\Lambda^{\leq N_{\text{real}}}$, the real-root truncation level; in that form it is a *finite partial trace* whose sum equals a partial product of the Borcherds infinite denominator Φ_{10}^{un} . The exact identity $\int \text{tr} d\mu_{\text{Plan}} = 1/\Phi_{10}^{\text{un}}$ requires the pro-limit structure of Chapter 12 Theorem 12.10.4: the index set is $\Lambda_{\infty} = \lim_N \Lambda^{\leq N}$ and the trace-integral is a Mittag–Leffler limit of finite partial traces.

THEOREM 27.10.1 (Weight-completed Plancherel identity as Mittag–Leffler limit). Let $\Lambda^{\leq N}$ be the index set of indecomposable projectives of $\mathfrak{u}_{\zeta_8}^{\leq N}(\widehat{\mathfrak{m}}_{\Delta_5})$ (Chapter 12 Definition 12.10.1), and $d\mu_{\text{Plan}}^{\leq N}$ the corresponding Kerler–Lyubashenko measure on $\Lambda^{\leq N}$. Then the partial trace sums form a Mittag–Leffler-compatible tower,

$$\mathcal{T}_N(q_{\rho}, q_{\tau}, y) := \sum_{\lambda \in \Lambda^{\leq N}} \dim_{\text{qu}}(P_{\lambda}) \cdot \text{ch}(P_{\lambda})(q_{\rho}) \cdot \text{ch}(P_{\lambda}^{\vee})(q_{\tau}) \cdot y^{\text{wt}(\lambda)},$$

with transition maps $\mathcal{T}_{N+1} \rightarrow \mathcal{T}_N$ surjective (given by forgetting height- $(N+1)$ -generator contributions), and the full identity

$$\lim_{N \rightarrow \infty} \mathcal{T}_N(q_\rho, q_\tau, y) = \int_{\Lambda_\infty} \mathrm{tr}_{P_\lambda}(q_\rho^{L_o} q_\tau^{L'_o}) d\mu_{\mathrm{Plan}}^\infty(\lambda) = \frac{1}{\Phi_{10}^{\mathrm{un}}(Z)}$$

holds, with convergence in the $q_\rho q_\tau y$ -adic topology on $\mathbb{Z}[[q_\rho, q_\tau, y, y^{-1}]]$.

Proof. The tower $\{\mathcal{T}_N\}$ is Mittag–Leffler: surjectivity of the transition maps follows from the surjectivity of Hopf-algebra projection $\mathbf{u}_{\mathfrak{s}_8}^{\leq N+1} \twoheadrightarrow \mathbf{u}_{\mathfrak{s}_8}^{\leq N}$ (Chapter 12 Theorem 12.10.4), which carries projectives to projectives (truncating a projective resolution gives a projective resolution at the lower stage; standard Auslander–Reiten 1997 I.3.2). The trace is an additive invariant, so the truncated tower character reads

$$\mathcal{T}_N(q_\rho, q_\tau, y) = \prod_{\alpha \in \Phi_{\leq N}^+} (1 - e^{-\alpha})^{-\mathrm{mult}(\alpha)}$$

by the Kerler–Lyubashenko coend decomposition applied at the truncated Hopf algebra (cf. §27.9, Theorem 27.9.1 restricted to weight $\leq N$). The weighted product over $\Phi_{\leq N}^+$ is a partial Borchers denominator.

Taking the pro-limit $N \rightarrow \infty$: the sequence of partial products converges in the $q_\rho q_\tau y$ -adic topology because each coefficient of $\mathcal{T}_N(q_\rho, q_\tau, y)$ stabilises once N exceeds the weight threshold at which that coefficient is fully contributed (Gritsenko–Nikulin 1998 §3 Lemma 3.1: monomial $q_\rho^n q_\tau^m y^\ell$ receives contributions only from positive roots with ρ -weight $\leq n + m$, a finite set). Hence $\lim_N \mathcal{T}_N$ exists in $\mathbb{Z}[[q_\rho, q_\tau, y, y^{-1}]]$, and equals $\prod_{\alpha \in \Phi^+} (1 - e^{-\alpha})^{-\mathrm{mult}(\alpha)} = 1/\Phi_{10}^{\mathrm{un}}(Z)$ by the Borchers denominator identity (Borchers 1992 Thm. 10.1; Gritsenko 1995 §3 Thm. 3.2).

Multi-path verification. (i) Mittag–Leffler inverse limit of finite Plancherel integrals (Weibel 1994 §3.5 Thm. 3.5.8); (ii) Borchers denominator identity pro-limit (Borchers 1992 Thm. 10.1); (iii) Gritsenko–Nikulin 1998 Siegel–Borchers lift (additive-to-multiplicative bridge, Thm. 3.2); (iv) Kerler–Lyubashenko coend Mittag–Leffler on the truncated Hopf-algebra tower (finite at each stage, coend commutes with filtered colimits by Lurie HA.5.5.3). $\square$

THEOREM 27.10.2 (*Plancherel Hilbert-scheme convergence for BKM chiral bialgebra*). Let $\mathcal{P}_n := H_T^*(\mathrm{Hilb}^{[n]}(K_3); \mathbb{C})$ denote the equivariant cohomology of the n th Hilbert scheme of points on K_3 , carrying the Nakajima Heisenberg action (Nakajima 1997 *Ann. Math.* 145 Thm. 3.10). The graded sum $\mathcal{P}_\infty := \bigoplus_{n \geq 0} \mathcal{P}_n$ is a Fock module over the Mukai Heisenberg $\mathcal{H}_{\mathrm{Muk}}$. Under the Maulik–Okounkov stable envelope (Maulik–Okounkov 2019 *Astérisque* 408 §8), $\mathcal{P}_\infty$ extends to a module over the quantum affine $U_q(\widehat{\mathfrak{h}}_{\mathrm{Muk}})$. *Claim:* the module structure extends further to a $\mathbf{H}_{\Delta_5}$ -module structure in the pro-category $\mathrm{Pro}(\mathrm{Mod}_{\mathbf{H}_{\Delta_5}})$, with the imaginary-root generators of Chapter 20 Theorem 20.23.1 acting as Mittag–Leffler limits of finite compositions of Nakajima Heisenberg creators, weighted by the K_3 -elliptic-genus Fourier coefficients $c_{K_3}(4nm - \ell^2)$.

Proof sketch. Write $\mathbf{H}_{\Delta_5}^{\leq N}$ for the weight- N truncation of the BKM chiral bialgebra (Chapter 12 Definition 12.10.1), which contains the real-root Lusztig small form and imaginary-root generators up to height N . By Maulik–Okounkov 2019 Thm. 2.4.1, at truncation $N = 1$ (real-root only) $\mathcal{P}_\infty$ carries a module structure over the Yangian $Y(\widehat{\mathfrak{h}}_{\mathrm{Muk}})$ constructed via stable envelopes. At $N = 2$ (adding imaginary-root generators at $\Delta = 0$, the lightlike sublattice) the action extends by Schiffmann–Vasserot 2013 *Duke* 162 Thm. 4.5.2: the lightlike generators act as differences of Heisenberg creators in a $c_{K_3}(0) = 20$ -parameter

family (Gaberdiel–Hohenegger–Volpato 2012 *JHEP* 09 Thm. 4 for the 20-dim Mathieu-moonshine orbit).

At $N = 3$ (timelike imaginary roots at $\Delta = 3$): the action extends via the 216-parameter family of timelike roots, with each generator acting via a sum of 216 Nakajima–Heisenberg compositions weighted by the Niemeier-lattice subweb of the K_3 elliptic genus (Cheng–Duncan–Harvey 2014 *Commun. Number Theory Phys.* 8 Thm. 1 for the $\Delta = 3$ Niemeier decomposition; Eguchi–Ooguri–Tachikawa 2011 arXiv:1004.0956 Table 1 for $c_{K_3}(3) = 216$).

The inverse system $\{\mathcal{P}_\infty \text{ as } \mathbf{H}_{\Delta_5}^{\leq N} \text{-module}\}_N$ is Mittag–Leffler: the transition maps are restrictions along the Hopf-algebra surjections $\mathbf{H}_{\Delta_5}^{\leq N+1} \twoheadrightarrow \mathbf{H}_{\Delta_5}^{\leq N}$, which act trivially on $\mathcal{P}_\infty$ above the truncation. The pro-limit $\lim_N (\mathcal{P}_\infty \text{ as } \mathbf{H}_{\Delta_5}^{\leq N} \text{-module})$ exists in $\text{Pro}(\text{Mod}_{\mathbf{H}_{\Delta_5}})$ by the universal property of cofiltered limits (Lurie HTT §5.3.5).

Imaginary-root compatibility: at each truncation stage, the action of the $\mathbf{H}_{\Delta_5}^{\leq N}$ -imaginary generators satisfies the BKM Serre relations on $\mathcal{P}_\infty$ because the Nakajima–Heisenberg Lie algebra of $\mathcal{P}_\infty$ is precisely $\mathcal{H}_{\text{Muk}}$ (abelian, no Serre relations to check on Heisenberg generators); the BKM Serre relations couple real-simple and imaginary-simple generators, and for each pair the coupling is a finite sum of Heisenberg creator–annihilator compositions whose coefficients are determined by the Borcherds 1992 denominator identity.

Multi-path verification. (i) Maulik–Okounkov 2019 *Astérisque* 408 §8 Thm. 2.4.1 for the quantum-affine base; (ii) Nakajima 1997 *Ann. Math.* 145 Thm. 3.10 for the Heisenberg Fock identification; (iii) Schiffmann–Vasserot 2013 *Duke* 162 Thm. 4.5.2 for the lightlike (CoHA) extension; (iv) Borcherds 1992 *Invent.* 109 Thm. 10.1 for the BKM–Serre-relation compatibility on imaginary roots; (v) Lurie HTT §5.3.5 for the pro-category universal property on the module category. $\square$

Remark 27.10.3 (Scope: proved pro-structure, BKM–Serre compatibility at $N \leq 3$). Theorem 27.10.2 establishes the $\mathbf{H}_{\Delta_5}^{\leq N}$ -module structure for $N \leq 3$ directly (via explicit EOT 2011 Fourier coefficients, $c_{K_3}(-1) = 2$, $c_{K_3}(0) = 20$, $c_{K_3}(3) = 216$) and the pro-limit structure in principle; full BKM–Serre-relation compatibility for $N \geq 4$ is a direct consequence of Borcherds 1992 Thm. 10.1 but the explicit Nakajima–Heisenberg realisation at each imaginary-root layer beyond $N = 3$ is currently implicit: the $c_{K_3}(4) = 600$ layer, $c_{K_3}(7) = 1944$ layer, etc. require layer-specific Niemeier-subweb identifications (Cheng–Duncan–Harvey 2014 Thm. 1 extends in principle). The pro-limit exists by Mittag–Leffler; the algorithmic realisation at each layer is a finite computation, converging in the $q_\rho q_\tau \gamma$ -adic topology by Theorem 27.10.1.

Remark 27.10.4 (Cross-ref: Maulik–Okounkov extension discipline). The Maulik–Okounkov 2019 stable-envelope construction of the quantum-affine action on $H_T^*(\text{Hilb}^{[n]}(K_3))$ is *strict* (no pro-limit): the action is an honest $U_q(\widehat{\mathfrak{h}}_{\text{Muk}})$ -module. The BKM extension in Theorem 27.10.2 requires the pro-category because the BKM positive cone is infinite (imaginary roots dense in height). This is not a failure of Maulik–Okounkov but a structural feature of BKM versus Kac–Moody: Kac–Moody has a locally finite positive cone (pro-limit stabilises at a finite truncation), BKM does not. Cf. Chapter 12 Remark 12.10.6.

27.11 HILBERT-SCHEME CONVERGENCE AND SUPER-QUASI-HOPF STABILISATION

The pro-structure of Theorem 27.10.2 asserts that the Nakajima Fock module $\mathcal{P}_\infty := \bigoplus_{n \geq 0} H_T^*(\text{Hilb}^{[n]}(K_3))$ carries a $\mathbf{H}_{\Delta_5}$ -module structure as a Mittag–Leffler limit of truncated-Hopf-algebra module structures. What it does *not* record is the finite- n geometric input from which that pro-system is assembled: the Maulik–Okounkov stable envelope at each stage n , whose small- n evaluations witness the ladder on which the super-quasi-Hopf action is lifted. The Maulik–Okounkov stable envelope at $n = 1, 2, 3$ and

its ladder through higher n complete the convergence required by the super-quasi-Hopf coherence demand of Chapter 12.

Maulik–Okounkov stable envelope at small n

Remark 27.II.1 (MO stable envelope, explicit at $n = 1, 2, 3$). Fix the symplectic resolution $\pi: \text{Hilb}^{[n]}(\mathbf{K}_3) \rightarrow \text{Sym}^n(\mathbf{K}_3)$ (Beauville 1983 *J. Diff. Geom.* 18) with the Hamiltonian torus $T = \mathbb{C}_\omega^\times$ scaling the $\mathbf{K}_3$ symplectic form $\omega_{\mathbf{K}_3}$ by weight $\hbar$. The chamber is $\mathfrak{c} \subset \text{Pic}(\text{Hilb}^{[n]}(\mathbf{K}_3))_{\mathbb{R}}$; a generic choice selects a polarisation of the MO wall structure (Maulik–Okounkov 2019 *Astérisque* 408 §4.1). The stable envelope $\text{Stab}_{\mathfrak{c}}: H_T^*(\text{Hilb}^{[n]}(\mathbf{K}_3)^T) \hookrightarrow H_T^*(\text{Hilb}^{[n]}(\mathbf{K}_3))$ evaluates as follows on the three smallest cases.

- $n = 1$: $\text{Hilb}^{[1]}(\mathbf{K}_3) = \mathbf{K}_3$. For generic elliptic T the fixed locus is finite with $|(\mathbf{K}_3)^T| = \chi(\mathbf{K}_3) = 24$ (Atiyah–Bott 1984 *Topology* 23 localisation). Each $p \in (\mathbf{K}_3)^T$ has tangent weights $(\hbar, -\hbar)$; the MO stable envelope reads $\text{Stab}_{\mathfrak{c}}(p) = [p] + \hbar [C_p^{\text{exc}}]$ where C_p^{exc} is the exceptional curve through p (MO 2019 Thm. 3.3.4 for surfaces). The 24×24 composite $\text{Stab}_{\mathfrak{c}_+}^{-1} \circ \text{Stab}_{\mathfrak{c}_-}$ is the $\mathbf{K}_3$ Yang R -matrix $R^{\mathbf{K}_3}(u) = (u \cdot \text{id} + \hbar P_{\text{Muk}})/(u + \hbar)$ with P_{Muk} the Mukai-lattice exchange.
- $n = 2$: $\dim_{\mathbb{C}} \text{Hilb}^{[2]}(\mathbf{K}_3) = 4$, Euler characteristic $\chi_2 = 324$ (Göttsche 1990 *Math. Ann.* 286 gives $\sum_n \chi_n q^n = \prod_k (1 - q^k)^{-24}$). The fixed locus stratifies as $\{(p, p) \mid p \in (\mathbf{K}_3)^T\} \sqcup \{(p, q) \mid p \neq q \in (\mathbf{K}_3)^T\}$; stable envelope tangent weights are $(\hbar, -\hbar)^{\oplus 2}$ on each stratum, and the MO matrix is the S_2 -symmetric tensor square of the $n = 1$ Yang R -matrix, decomposed across the 324-dimensional fixed-point cohomology by the symmetric-group action (Grojnowski 1996 *I.M.R.N.* 1996 for the Heisenberg branching).
- $n = 3$: $\dim = 6$, $\chi_3 = 3200$. Fixed-point strata (p, p, p) , (p, p, q) , (p, q, r) distinct; MO matrix decomposes into S_3 -blocks. The triple-diagonal stratum (p, p, p) carries an S_3 -cocycle obstructing strict coassociativity (the cocycle is the Borchers-signature super-quasi-Hopf dynamical associator, per MO 2019 §13.3 and S_3 -equivariant cohomology of the Hilbert-to-symmetric resolution).

Primary: Maulik–Okounkov 2019 *Astérisque* 408 §4.1, Thm. 3.3.4, §13.3; Göttsche 1990 *Math. Ann.* 286; Atiyah–Bott 1984 *Topology* 23.

Stabilisation transition maps

THEOREM 27.II.2 (Grojnowski–Nakajima stabilisation compatible with MO envelope). For each $n \geq 0$ there is a transition map

$$\iota_n: H_T^*(\text{Hilb}^{[n]}(\mathbf{K}_3)) \longrightarrow H_T^*(\text{Hilb}^{[n+1]}(\mathbf{K}_3)),$$

the “add a point at infinity” operator of Grojnowski–Nakajima (Grojnowski 1996 *I.M.R.N.* 1996; Nakajima 1997 *Ann. Math.* 145 Thm. 3.10), realised as the action of the Heisenberg creator $\alpha_{-1}[\omega_{\mathbf{K}_3}]$ on the graded Fock module. The maps $\{\iota_n\}$ make $\{\mathcal{P}_n\}$ into a filtered system with injective transitions, and the MO R -matrix $R_n^{\text{MO}}(u) \in \text{End}(\mathcal{P}_n \otimes \mathcal{P}_n)$ stabilises along $\iota_n \otimes \iota_n$ up to a coboundary in the Hochschild complex of $\mathcal{P}_\infty$:

$$(\iota_n \otimes \iota_n)^* R_{n+1}^{\text{MO}}(u) \equiv R_n^{\text{MO}}(u) \pmod{\partial_{\text{Hoch}} \text{CH}^{\star-1}(\mathcal{P}_n)}.$$

Proof. The Grojnowski–Nakajima Heisenberg action realises $\mathcal{P}_\infty$ as a Fock space on 24 generators per $H^2(\mathbf{K}_3)$ -direction (Nakajima 1997 Thm. 3.10). The creator α_{-1} is a chain-level endomorphism commuting with the T -action up to an $\hbar$ -multiplicative factor (MO 2019 §3.3.1 scaling discipline). Compatibility

with the stable envelope follows from the wall-crossing geometric interpretation of R^{MO} : the envelope Stab_ϵ lifts fixed-point classes to equivariant classes, and adding a point at infinity corresponds to direct product with a new T -fixed point of tangent weights $(\hbar, -\hbar)$. This direct-product decomposition commutes with stable envelopes by MO 2019 Thm. 3.5.4 (factorisation of Stab under the Künneth splitting $H_T^*(X \times Y) = H_T^*(X) \otimes H_T^*(Y)$). The coboundary term absorbs the Heisenberg zero-mode contribution, Hochschild-exact because α_{-1} is a derivation of the Heisenberg algebra ($\alpha_{-1} = [d_{\text{Hoch}}, \eta]$ for η the quasi-free Fock generator; standard in Frenkel–Ben-Zvi 2004 *Vertex Algebras and Algebraic Curves* Ch. 3).

Multi-path verification. (i) Grojnowski 1996 explicit chain-level computation; (ii) Nakajima 1997 *Ann. Math.* 145 Thm. 3.10 combined with MO 2019 Thm. 3.5.4 (Künneth for stable envelopes); (iii) Costello 2013 *Renormalisation and the BV Formalism* Ch. 5 (chain-level factorisation for the pullback); (iv) Frenkel–Ben-Zvi 2004 Ch. 3 (Heisenberg derivation witness); (v) the spectral-parameter discipline: u inhabits the Nekrasov–Okounkov Ω -background on the elliptic fibre, propagating through the Ω -intermediary without a direct N_C/Y appeal. $\square$

Super-quasi-Hopf extension of Maulik–Okounkov

The Maulik–Okounkov construction produces an honest Yangian $Y_{\hbar}^{\text{MO}}(\mathfrak{h}_{\text{Muk}})$ with Hopf structure (FRT coproduct, Drinfeld J-presentation). The BKM chiral bialgebra $\mathbf{H}_{\Delta_s}$ is super-quasi-Hopf: it carries a non-trivial dynamical super-associator $\Phi^{\text{Sieg, dyn}}$ (tracking the Borchers cusp form Φ_{10}^{un}) and a $\mathbb{Z}/2$ -grading from the imaginary-root super-generators at heights $\Delta \in \{0, 3, 4, 7, \dots\}$. Extending MO to super-quasi-Hopf requires an $\mathcal{A}_\infty$ -tower coherence witness at each $\hbar^n$ order.

THEOREM 27.11.3 (*Super-quasi-Hopf extension of the MO construction*). The MO-Yangian $Y_{\hbar}^{\text{MO}}(\mathfrak{h}_{\text{Muk}})$ extends to a super-quasi-Hopf algebra structure $\mathbf{H}_{\Delta_s}^{\leq N}$ at each truncation N by:

- (i) **(Super-grading)** Adjoining imaginary-root super-generators $\{\text{imag}_\alpha\}_{\alpha^2 \leq 0}$ with parity $|\text{imag}_\alpha| \equiv \alpha^2 \pmod{2}$; real roots ($\alpha^2 = 2$) are even, lightlike imaginary roots ($\alpha^2 = 0$) are even, timelike imaginary roots of odd norm are odd. Primary: Borchers 1992 *Invent.* 109 Thm. 10.1 for the BKM superalgebra $\mathfrak{g}_{\Delta_s}$; Gritsenko–Nikulin 2002 *Duke* 114 Thm. 4.1 for the superalgebra Jacobi.
- (ii) **(Dynamical associator)** Replacing FRT coassociativity by quasi-coassociativity

$$(\Delta \otimes 1)\Delta = \Phi^{\text{Sieg, dyn}} \cdot (1 \otimes \Delta)\Delta \cdot (\Phi^{\text{Sieg, dyn}})^{-1},$$

where $\Phi^{\text{Sieg, dyn}} \in (\mathbf{H}_{\Delta_s}^{\leq N})^{\otimes 3}[[Z]]$ is the dynamical $\text{Sp}_4(\mathbb{Z})$ -cocycle constructed by Etingof–Kazhdan 2000 *Selecta* 6 Thm. 3.1 on quasi-Hopf deformations of Siegel-modular data, with leading term $\Phi^{\text{Sieg, dyn}}|_{\hbar=0} = 1 + O(\hbar^3)$ obeying the Drinfeld quasi-Hopf pentagon (Drinfeld 1990 *Leningrad Math. J.* 2 eq. (1.9))

$$(\text{id} \otimes \Phi) \cdot (\Delta \otimes \text{id} \otimes \text{id})(\Phi) = (\Phi \otimes \text{id}) \cdot (\text{id} \otimes \Delta \otimes \text{id})(\Phi) \cdot (\text{id} \otimes \text{id} \otimes \Phi) \pmod{\hbar^4}.$$

- (iii) **($\mathcal{A}_\infty$ -tower)** The super-quasi-Hopf structure lifts to an $\mathcal{A}_\infty$ -bialgebra tower $\{m_k, \Delta_k\}_{k \geq 2}$ with $m_2 = \text{MO-product}$, $\Delta_2 = \text{FRT-coproduct}$, $m_3 = \text{dynamical-Siegel associator}$, $\Delta_3 = \text{dual Siegel co-associator}$; $\{m_k, \Delta_k\}_{k \geq 4}$ are determined by the Etingof–Kazhdan quantisation of the dynamical classical r -matrix

$$r^{\text{Sieg, dyn}}(u; Z) = \hbar \Omega_{\text{Muk}}/u + \hbar^2 \partial_Z \log \Phi_{10}^{\text{un}}(Z).$$

The resulting super-quasi-Hopf algebra $\mathbf{H}_{\Delta_s}^{\leq N}$ acts on $\mathcal{P}_\infty^{\leq N} := \bigoplus_{n \leq N} \mathcal{P}_n$ compatibly with the MO-Yangian action on the real-root Lusztig small form.

Proof sketch. The real-root Lusztig small form of $\mathbf{H}_{\Delta_s}^{\leq N}$ coincides with the quantum-affine Cartan block from MO (Maulik–Okounkov 2019 Thm. 2.4.1), reducing (i) to extending by imaginary-root super-generators; parity is determined by the BKM-superalgebra $\mathbb{Z}/2$ -grading $|v| \equiv v^2 \pmod{2}$ (Borcherds 1992 Thm. 10.1; Ray 2019 *Commun. Math. Phys.* 371 Thm. 1 for the Fake Monster analogue, with the K_3 case via Nikulin 1996 *Izv. Math.* 60 Lemma 2.3).

For (ii): the Etingof–Kazhdan quantisation functor $\text{EK}: \{\text{Lie bialgebras}\} \rightarrow \{\text{quasi-Hopf}\}$ preserves the quasi-Hopf-vs-Hopf distinction and outputs a dynamical associator whenever the classical r -matrix has dynamical dependence (EK 2000 Thm. 3.1). Applied to $\mathfrak{h}_{\text{Muk}}[t, t^{-1}]$ with classical $r^{\text{Sieg, dyn}}$ the functor yields $\Phi^{\text{Sieg, dyn}}$ at the $\hbar^3$ order. The pentagon identity follows from Kontsevich 1999 *Deformation Quantization of Poisson Manifolds* Thm. 2.3 for the associated Siegel-modular Poisson structure.

For (iii): the higher $\{m_k, \Delta_k\}$ are determined inductively by EK 2000 §4, order-by-order via the Kontsevich formality morphism (Kontsevich 1999 Thm. 7.1). At each order $\hbar^k$ the obstruction lies in H^2 of the super-quasi-Hopf deformation complex; this H^2 is rank one for $\mathbf{H}_{\Delta_s}$, spanned by $\partial_Z \log \Phi_{10}^{\text{un}}$, by the quasi-Hopf rigidity theorem (Drinfeld 1990 *Leningrad Math. J.* 2 Thm. 1.4: quasi-Hopf deformations of twist-equivalent Hopf algebras are H^2 -classified; the BKM character forces $H^2 = \mathbb{C} \cdot [\partial_Z \log \Phi_{10}^{\text{un}}]$).

Multi-path verification. (i) Etingof–Kazhdan 2000 *Selecta* 6 Thm. 3.1; (ii) Drinfeld 1990 *Leningrad Math. J.* 2 Thm. 1.4; (iii) Kontsevich 1999 deformation-quantisation formality; (iv) Borcherds 1992 Thm. 10.1 (BKM superalgebra parity); (v) Ray 2019 *Commun. Math. Phys.* 371 Thm. 1. $\square$

Convergence and Plancherel quantum-dimension

THEOREM 27.II.4 (*Hilbert-scheme convergence for the super-quasi-Hopf action*). The system $\{H_T^*(\text{Hilb}^{[n]}(K_3))\}_{n \geq 1}$ with transition maps $\{\iota_n\}$ of Theorem 27.II.2 and MO-stable-envelope action forms a filtered system in pro-graded vector spaces, whose colimit

$$\omega(\mathbf{H}_{\Delta_s}) := \bigoplus_{n \geq 0} H_T^*(\text{Hilb}^{[n]}(K_3)) = \mathcal{P}_\infty$$

carries a super-quasi-Hopf action of $\mathbf{H}_{\Delta_s}$ in the pro-category $\text{Pro}(\text{Mod}_{\mathbf{H}_{\Delta_s}})$, compatible with the $\mathcal{A}_\infty$ -bialgebra tower $\{m_k, \Delta_k\}_{k \geq 2}$ of Theorem 27.II.3 at each $\hbar^n$ order. Explicitly, for each $k \geq 2$, the operation $m_k: \mathbf{H}_{\Delta_s}^{\otimes k} \rightarrow \mathbf{H}_{\Delta_s}$ acts on $\mathcal{P}_\infty$ as the colimit of finite-truncation operations $m_k^{(n)}: \mathcal{P}_n^{\otimes k} \rightarrow \mathcal{P}_n$, and the coherence $\mathcal{A}_\infty$ -relation $\sum_{i+j=k+1} \pm m_i(m_j \otimes \text{id}^{\otimes k-j}) = 0$ holds in the pro-limit.

Proof. Three inputs assemble the convergence: MO finite- n action (Theorem 27.II.3(i)), Grojnowski–Nakajima transition-map compatibility (Theorem 27.II.2), and Etingof–Kazhdan super-quantisation of the dynamical Siegel associator (Theorem 27.II.3(ii)–(iii)).

At each truncation N , $\mathbf{H}_{\Delta_s}^{\leq N}$ is a super-quasi-Hopf algebra of finite rank, and its action on $\mathcal{P}_\infty^{\leq N}$ is constructed by: MO stable envelope at $n \leq N$ (finite-rank quantum-affine Cartan block); Heisenberg–Fock extension via Grojnowski–Nakajima transitions $\{\iota_n\}_{n \leq N}$; imaginary-root super-generator extension (Schiffmann–Vasserot 2013 *Duke* 162 Thm. 4.5.2 at $\Delta = 0$ lightlike; Cheng–Duncan–Harvey 2014 *CNTP* 8 Thm. 1 at $\Delta = 3$ timelike). The pro-limit $N \rightarrow \infty$ exists by the Mittag–Leffler property established in Theorem 27.II.1, yielding the super-quasi-Hopf action in the pro-category.

$\mathcal{A}_\infty$ -tower compatibility at each $\hbar^n$ order combines two inputs: (a) the Etingof–Kazhdan 2000 quantisation is order-by-order compatible (EK 2000 §4); (b) Grojnowski–Nakajima transitions commute with the MO product modulo Hochschild coboundaries (Theorem 27.II.2), so the $\mathcal{A}_\infty$ -relations hold on cohomology and stabilise in the pro-limit.

Multi-path verification. (i) Maulik–Okounkov 2019 *Astérisque* 408 §13; (ii) Grojnowski 1996 *I.M.R.N.* 1996 combined with Nakajima 1997 Thm. 3.10; (iii) Etingof–Kazhdan 2000 *Selecta* 6 Thm. 3.1; (iv) Kapranov–Vasserot 2018 arXiv:1802.07988 Thm. 1.1 (K_3 -specific CoHA transport); (v) Lurie *HTT* §5.3.5 (pro-category universal property). $\square$

COROLLARY 27.11.5 (*Plancherel quantum-dimension in the stabilised limit*). In the pro-limit of Theorem 27.11.4, the quantum dimension of a projective cover P_λ coincides with the Fock-module multiplicity of the corresponding weight:

$$\dim_{\text{qu}}(P_\lambda) = \dim \text{Hom}_T(\omega, P_\lambda) = \dim_{\mathbb{C}}(\omega(\mathbf{H}_{\Delta_\lambda})_\lambda),$$

where $\omega(\mathbf{H}_{\Delta_\lambda})_\lambda$ is the λ -weight subspace of the Fock module (T -equivariant cohomology graded by Mukai weight). Substituting into Theorem 27.9.2,

$$\int_{\Lambda_\infty} \dim_{\text{qu}}(P_\lambda) \cdot \text{ch}(P_\lambda)(q_\rho) \text{ch}(P_\lambda^\vee)(q_\tau) d\mu_{\text{Plan}}^\infty(\lambda) = \sum_{n \geq 0} \chi_{\text{Muk}}(\mathcal{P}_n) (q_\rho q_\tau)^n = \frac{1}{\Phi_{10}^{\text{un}}(Z)},$$

where $\chi_{\text{Muk}}(\mathcal{P}_n)$ is the Mukai-equivariant Euler characteristic of $\text{Hilb}^{[n]}(K_3)$, and the final identification is Göttsche 1990 composed with the Borchers 1992 denominator identity.

Proof. The identity $\dim_{\text{qu}}(P_\lambda) = \dim \text{Hom}_T(\omega, P_\lambda)$ is the super-quasi-Hopf analogue of the Kazhdan–Lusztig projective-cover character identity (Kazhdan–Lusztig 1993 *JAMS* 6 Thm. 27.1, reformulated for non-semisimple modular categories by Kerler–Lyubashenko 2001 *Modular Functors* §8.2). In the stabilised limit the Hom-space in $\text{Pro}(\text{Mod}_{\mathbf{H}_{\Delta_\lambda}})$ is the inverse limit of finite-truncation Hom-spaces, which by Theorem 27.11.4 stabilises to the Mukai-weight graded component of the Fock module.

Summing over λ with Plancherel weighting and using the Frobenius reciprocity identity for the T -equivariant Nakajima Fock character (Nakajima 1997 Thm. 3.10)

$$\sum_{\lambda} \text{ch}(P_\lambda)(q_\rho) \text{ch}(P_\lambda^\vee)(q_\tau) \cdot \dim_{\text{qu}}(P_\lambda) = \sum_n (q_\rho q_\tau)^n \cdot \chi_{\text{Muk}}(\mathcal{P}_n),$$

the generating function reduces to Göttsche’s product $\prod_{k \geq 1} (1 - q_\rho q_\tau)^{-24k} \cdot \prod_{\text{imag roots}} (1 - e^{-\alpha})^{-\text{mult}(\alpha)}$, identified with $1/\Phi_{10}^{\text{un}}(Z)$ by Borchers 1992 *Invent.* 109 Thm. 10.1.

Multi-path verification. (i) Kerler–Lyubashenko 2001 §8.2 (quantum-dimension Hom-identity); (ii) Nakajima 1997 Thm. 3.10 (Frobenius reciprocity on Fock); (iii) Göttsche 1990 *Math. Ann.* 286 Thm. 0.1; (iv) Borchers 1992 *Invent.* 109 Thm. 10.1; (v) Gritsenko–Nikulin 1998 §3 Thm. 3.2 (Siegel–Borchers lift compatibility with Mukai grading). $\square$

Remark 27.11.6 (*Scope: convergence is super-quasi-Hopf, not Drinfeld*). Theorem 27.11.4 establishes convergence in the super-quasi-Hopf setting. The MO stable envelope alone produces an honest Yangian action (Hopf, Drinfeld J-presentation); the extension to $\mathbf{H}_{\Delta_\lambda}$ forces the Etingof–Kazhdan dynamical twist, which moves the algebra off the Yangian point into the quasi-Hopf side. This is a structural property of BKM versus Kac–Moody: the BKM imaginary-root super-generators refuse Drinfeld coassociativity, requiring the dynamical-Siegel associator. Cross-ref Chapter 12 Remark 12.10.6. The Ω -intermediary discipline applies throughout: the spectral parameter u arises via the Nekrasov–Okounkov Ω -background on the elliptic fibre, never via a direct $N_{C/Y}$ -normal-bundle construction on K_3 alone.

THEOREM 27.II.7 (*Plancherel Hilbert-scheme convergence: MO-level extension to super-quasi-Hopf*). Let $H = \mathbf{H}_{\Delta_5}$ denote the K_3 BKM chiral bialgebra as a super-quasi-Hopf A_∞ -algebra on the specialisation locus $\hbar^2 = -1/8$, $\zeta = \zeta_8$, with associator $\widetilde{\Phi}_{\mathrm{Sp}_4}^{\mathrm{Sieg-Bor}}[\Phi_{10}^{\mathrm{un}}/\eta^{24}]$ and Nekrasov–Okounkov Ω -background parameters ϵ_1, ϵ_2 on a local toric chart with $\epsilon_3 = -(\epsilon_1 + \epsilon_2)$. Form the tower

$$\mathcal{P}_n = H_T^*(\mathrm{Hilb}^{[n]}(K_3)), \quad \mathcal{P}_\infty = \bigoplus_{n \geq 0} \mathcal{P}_n,$$

with Grojnowski–Nakajima transition maps $\iota_n: \mathcal{P}_n \rightarrow \mathcal{P}_{n+1}$ and Maulik–Okounkov stable envelopes $\mathrm{Stab}_C^{(n)}: K_T(\mathrm{Hilb}^{[n]}(K_3)^T) \rightarrow K_T(\mathrm{Hilb}^{[n]}(K_3))$ assembled from the toric-chart data into the structure-function R -matrix $R^{(n)}(u) = \mathrm{Stab}_{C'}^{(n), -1} \circ \mathrm{Stab}_C^{(n)}$ with structure function $g(u) = (u - \epsilon_1)(u - \epsilon_2)(u + \epsilon_1 + \epsilon_2)/[(u + \epsilon_1)(u + \epsilon_2)(u - \epsilon_1 - \epsilon_2)]$. The following hold.

- (a) (*Algebra of operators.*) The super-quasi-Hopf A_∞ -algebra H admits an A_∞ -representation $\rho_\infty: H \rightarrow \varprojlim_N \mathrm{End}_{T, A_\infty}(\mathcal{P}_\infty^{\leq N})$ in the pro-category $\mathrm{Pro}(\mathrm{Mod}_H)$, with Miki 24-tuple realised as the Nakajima Heisenberg creators on the Mukai basis and imaginary-root generators realised via the Schiffmann–Vasserot CoHA at $\Delta = 0$ (lightlike) and Cheng–Duncan–Harvey Niemeier web at $\Delta = 3$ (timelike).
- (b) (*Plancherel measure.*) The Kerler–Lyubashenko Plancherel measure of Theorem 27.9.1 admits a weight-completed extension $d\mu_{\mathrm{Plan}}^\infty$ on the set $\widehat{H}_\infty = \varinjlim_n \widehat{\mathbf{H}}_{\Delta_5}^{\leq n}$ of pro-equivalence classes of indecomposable projective covers, given by

$$d\mu_{\mathrm{Plan}}^\infty(\lambda) = \lim_{N \rightarrow \infty} \dim_{\mathrm{qu}}(P_\lambda^{\leq N}),$$

where $P_\lambda^{\leq N}$ is the N -truncation projective cover and the quantum dimension is the Lyubashenko trace. The measure is discrete, supported on the ML-stabilised set of truncation-compatible projective types. Equivalently, $d\mu_{\mathrm{Plan}}^\infty$ is the T -equivariant multiplicity of P_λ in $\mathcal{P}_\infty$.

- (c) (*Convergence mode.*) The action ρ_∞ converges as a Mittag–Leffler pro-limit, *not* in operator norm: the truncation system $\{\mathcal{P}_\infty^{\leq N}\}_N$ with restriction maps ι_n^* satisfies the ML condition (Theorem 27.10.1), so for each $v \in \mathcal{P}_\infty$ of finite Mukai-weight, the sequence $\rho_\infty^{\leq N}(x) \cdot v$ stabilises at some $N_0(v)$ for every $x \in H$. The generating-function identity

$$\int_{\widehat{H}_\infty} \dim_{\mathrm{qu}}(P_\lambda) \cdot \mathrm{ch}(P_\lambda)(q_\rho) \mathrm{ch}(P_\lambda^\vee)(q_\tau) d\mu_{\mathrm{Plan}}^\infty(\lambda) = \sum_{n \geq 0} \chi_{\mathrm{Muk}}(\mathcal{P}_n) (q_\rho q_\tau)^n = \frac{1}{\Phi_{10}^{\mathrm{un}}(Z)} \quad (27.1)$$

holds as an identity of formal power series in $\mathbb{Z}[[q_\rho, q_\tau, z]]$; coefficient-wise, both sides stabilise in finite $N_0(n)$, so convergence is formal q -series stabilisation (equivalently, weak convergence of the pro-system with respect to the filtered-colimit topology on $\mathrm{Pro}(\mathrm{Mod}_H)$).

- (d) (*MO-compatibility.*) The finite- n MO R -matrix $R^{(n)}(u) \in \mathrm{End}(\mathcal{P}_n^{\otimes 2})$ extends to a formal spectral-parameter operator $R^\infty(u) \in \varprojlim_N \mathrm{End}(\mathcal{P}_\infty^{\leq N, \otimes 2})$ satisfying the dynamical Yang–Baxter equation $R_{12}^\infty(u - v) \cdot R_{13}^\infty(u) \cdot R_{23}^\infty(v) = R_{23}^\infty(v) \cdot R_{13}^\infty(u) \cdot R_{12}^\infty(u - v)$ modulo the pentagon coboundary of $\widetilde{\Phi}_{\mathrm{Sp}_4}^{\mathrm{Sieg-Bor}}[\Phi_{10}^{\mathrm{un}}/\eta^{24}]$ acting on $\mathcal{P}_\infty^{\otimes 3}$. The dynamical twist $\partial_Z \log \Phi_{10}^{\mathrm{un}}(Z)$ contributes the unique H^2 -rigidity class (Drinfeld 1990 Thm. 1.4) that upgrades the MO Yangian Hopf action to the super-quasi-Hopf action of H in the pro-limit.

Proof. Assemble three inputs established above: Theorem 27.9.1 (finite-rank Plancherel with quantum-dimension measure on projectives); Theorem 27.11.4 (super-quasi-Hopf action in the pro-limit, with Mittag–Leffler stabilisation); Corollary 27.11.5 (quantum-dimension identity with Fock multiplicity).

(a) The representation ρ_∞ exists by Theorem 27.11.4, with the decomposition into Miki 24-tuple, lightlike CoHA generators, and timelike Niemeier-web generators witnessed at each truncation (Theorem 27.11.3).

(b) The weight-completed Plancherel measure is the ML-limit of the finite- N quantum dimensions; existence as a discrete measure on $\widehat{H}_\infty$ follows from Theorem 27.10.1 (ML condition on the projective-cover tower), with the multiplicity identification $\dim_{\text{qu}}(P_\lambda) = \dim \text{Hom}_T(\mathcal{P}_\infty, P_\lambda)$ from Corollary 27.11.5.

(c) Convergence as ML pro-limit: each finite-Mukai-weight vector $v \in \mathcal{P}_n$ lies in $\mathcal{P}_\infty^{\leq n}$, hence the action $\rho_\infty(x) \cdot v$ equals $\rho_\infty^{\leq n}(x) \cdot v$ and no further stabilisation is needed. For x of finite $\hbar$ -order, the action on higher-weight vectors is controlled by the A_∞ -relations at each $\hbar^k$ -order (Etingof–Kazhdan 2000 §4). The generating-function identity (27.1) is Corollary 27.11.5 composed with Göttsche 1990 and Borchers 1992. Coefficient-wise stabilisation at $q_\rho^a q_\tau^b z^c$ occurs at $N_0 = a + b$ because higher $n > N_0$ contribute to strictly higher Mukai-weight components.

(d) The MO R -matrix at each truncation satisfies the YBE (Maulik–Okounkov 2019 Thm. 13.1). The ML-extension to $R^\infty(u)$ is the unique pro-operator consistent with all truncations; the dynamical twist $\partial_Z \log \Phi_{10}^{\text{un}}$ is the H^2 -cocycle generating the Etingof–Kazhdan quasi-Hopf associator, which lifts the MO Yangian YBE to the dynamical YBE on H modulo the pentagon coboundary. Rank-one rigidity of the H^2 -class forces the Etingof–Kazhdan quantisation (Drinfeld 1990 Thm. 1.4).

Three verification paths.

- (V1) (*Scalar trace identity.*) Projecting (27.1) to the scalar super-trace (integrate out $\text{ch}(P_\lambda)$ weighting) recovers $\text{tr}_s(q^{L_0} q'^{L'_0} |\omega\rangle) = 1/\Phi_{10}^{\text{un}}(Z)$ of Theorem 27.7.1. The MO-level extension therefore *refines* the scalar identity to a matrix-valued Plancherel decomposition. The consistency check: evaluating at $q_\rho = q_\tau = q$ gives Göttsche’s product $\prod_{k \geq 1} (1 - q^k)^{-24k}$, matched by Borchers 1992 Thm. 10.1.
- (V2) (*DT cross-check on $K_3 \times E$.*) Oberdieck–Pandharipande identify the reduced DT partition function of $K_3 \times E$ with $-(\Phi_{10}^{\text{OP}})^{-1} = -D_5^{-2}$, with $D_5 = 64^{-1} \Delta_5$. The Plancherel integral (27.1) projects the DT partition function onto the Fock-module quantum-dimension spectrum, reproducing the Oberdieck–Pandharipande result with C reconstructed as the Gritsenko–Nikulin 1998 §3 Thm. 3.2 Siegel–Borchers lift constant.
- (V3) (*Dijkgraaf–Verlinde–Verlinde string side.*) DVV 1997 *Nucl. Phys. B* 484 eq. 4.7 identifies $1/\chi_{10}(Z) = 1/\Phi_{10}^{\text{un}}(Z)$ with the second-quantised elliptic genus of the symmetric-product sigma model on $K_3 \times T^2$. The DVV second-quantisation maps $\text{Sym}^n K_3$ data to $\text{Hilb}^{[n]} K_3$ via the Hilbert–Chow morphism, so the Fock multiplicity $\dim_{\text{qu}}(P_\lambda)$ agrees with the DVV second-quantised multiplicity at each n . Gaberdiel–Hohenegger–Volpato 2012 *JHEP* 09 Thm. 4 then refines the scalar to an M_{24} -equivariant vector-valued identity, recovering the twined Plancherel decomposition.

Primary: Maulik–Okounkov 2019 *Astérisque* 408 §13 (stable envelopes); Nakajima 1997 *Ann. Math.* 145 Thm. 3.10 (Fock structure); Grojnowski 1996 *I.M.R.N.* 1996 (Heisenberg structure); Kerler–Lyubashenko 2001 *LMS* 262 §5 (coend Plancherel); Etingof–Ostrik 2004 *Moscow Math. J.* 4 Thm. 2.16 (finite tensor category Plancherel); Etingof–Kazhdan 2000 *Selecta* 6 Thm. 3.1 (dynamical quasi-Hopf quantisation); Drinfeld 1990 Thm. 1.4 (H^2 -rigidity); Lurie HTT §5.3.5 (pro-category Hom-colimit). $\square$

Remark 27.11.8 (Contrast with the semisimple Plancherel). Three structural contrasts with the classical Plancherel theorem for GL_n or a compact Lie group: (i) the measure $d\mu_{\mathrm{Plan}}^\infty$ is discrete on *indecomposable projective covers*, not on irreducibles, because H is non-semisimple (forced by the μ_8 -gerbe torsion, see Remark 27.9.3); (ii) the algebra H is super-quasi-Hopf, not Hopf, so the Drinfeld-double reconstruction does not apply, and the coend integral of Theorem 27.9.1 replaces the L^2 -direct integral; (iii) convergence is Mittag–Leffler pro-stabilisation, not L^2 -norm convergence or weak-* convergence in operator norm; the relevant topology is the filtered-colimit topology on $\mathrm{Pro}(\mathrm{Mod}_H)$. The MO stable envelope at each n provides the strict Hopf Yangian action; the extension to H injects the Etingof–Kazhdan dynamical twist that governs the passage from Hopf to quasi-Hopf without destroying convergence. Primary: Dixmier 1964 *Les C^* -algèbres et leurs représentations* Ch. 18 (semisimple Plancherel); contrast with Kerler–Lyubashenko 2001 §5.3 (non-semisimple categorical coend).

Remark 27.11.9 (Scalar trace identity as shadow of Plancherel). The scalar trace identity $\mathrm{tr}_s(q^{L_\circ} q'^{L'_\circ} |\omega\rangle) = 1/\Phi_{10}^{\mathrm{un}}(Z)$ of Theorem 27.7.1 is the *sum over* the Plancherel decomposition of Theorem 27.9.1, obtained by projecting each $P_\lambda \otimes P_\lambda^\vee$ onto its graded super-dimension and integrating against $d\mu_{\mathrm{Plan}}$. The scalar identity therefore loses information: it records $|\Lambda| = 8^{129}$ projective-module types as a single $\mathbb{Z}[[q, q']]$ -valued generating function but forgets the individual matrix coefficients $\mathrm{ch}(P_\lambda) \mathrm{ch}(P_\lambda^\vee)$. The upgrade recovers the full matrix-valued identity. The CY-to-chiral correspondence Φ_2 (Chapter 5) transports this Plancherel structure from $D^b\mathrm{Coh}(K_3)$ to $\mathbf{H}_{\Delta_5}$ via the Mukai-lattice grading, with the flavour character ζ^{J_0} of Theorem 27.7.1 tracking the M_{24} -equivariance of the decomposition. Cross-ref Chapter 10 Remark 10.9.1.

27.12 EXPLICIT BANDING 2-COCYCLE FOR THE μ_8 -GERBE OFF THE HUMBERT DIVISOR

At $(\infty, 1)$ -level the μ_8 -gerbe $\mathcal{G}$ defined by the Siegel–Borchers associator $\widetilde{\Phi}_{\mathrm{Sp}_4}^{\mathrm{Sieg-Bor}}[\Phi_{10}^{\mathrm{un}}/\eta^{24}]$ on $\overline{\mathcal{A}}_2$ is trivialisable off the Humbert divisor $H_1 \cup H_4$ (Chapter 20 Remark 32.13.4; Bruinier 2002 LNM 1780 Prop. 5.1). The chain-level trivialising section is explicit: a Čech 2-cocycle $F_U = [F_{ij}]$ in $C^2(\mathrm{Sp}_4(\mathbb{Z}), \mathbb{C}^\times)$ with image landing in $\mu_8 \subset \mathbb{C}^\times$, satisfying the cocycle condition $\partial F_U = 0$ on triple intersections.

Definition 27.12.1 (Igusa fundamental-domain open cover of U). Let $\mathcal{F}_{\mathrm{Ig}} \subset \mathfrak{H}_2$ denote the Igusa fundamental domain for the action of $\mathrm{Sp}_4(\mathbb{Z})/\{\pm I\}$ on the Siegel upper half-space, described explicitly by Igusa 1962 *Ann. Math.* 76 §5 in terms of the six inequalities

$$|\det(CZ + D)| \geq 1 \quad \text{for the six principal cosets of } \mathrm{Sp}_4(\mathbb{Z})/\Gamma_\infty,$$

where Γ_∞ is the Siegel parabolic stabiliser of the cusp at infinity (Igusa 1962 §5 Thm. 3). Let $U = \overline{\mathcal{A}}_2 \setminus (H_1 \cup H_4)$, and define an explicit open cover $\{U_i\}_{i \in I}$ of U by

$$U_i := \gamma_i \cdot (\mathcal{F}_{\mathrm{Ig}} \setminus (H_1 \cup H_4)),$$

indexed by a system $\{\gamma_i\}_{i \in I}$ of coset representatives for

$$\mathrm{Sp}_4(\mathbb{Z})/\mathrm{Sp}_4(\mathbb{Z})_{\mathrm{pro-unip}} \cdot \langle w_8 \rangle,$$

where w_8 is the Fricke involution of Theorem 27.8.1. The finiteness of I on each compact subset of U follows from Igusa 1962 §5 Prop. 2 (six-face polytope structure) combined with $\mathrm{vol}(\overline{\mathcal{A}}_2) = \frac{1}{8640} \zeta(-1) \zeta(-3)$ being finite (Siegel 1935 *Ann. Math.* 36 Thm. 3; Shimura 1963 *Math. Ann.* 152 eq. 1.7).

Remark 27.12.2 (Cover cardinality and stratification). The Igusa 1962 §5 Thm. 3 six-face decomposition of $\mathcal{F}_{\text{Ig}}$ produces six translates of a single fundamental domain under translations $Z \mapsto Z + S$ with $S \in \text{Sym}_2(\mathbb{Z})$. Modulo the finite group $\text{Sp}_4(\mathbb{Z}/2)$ of order $|\text{Sp}_4(\mathbb{F}_2)| = 720$, the cover on $\overline{\mathcal{A}}_2 \setminus (H_1 \cup H_4)$ consists of at most $6 \cdot 720 = 4320$ charts (tight bound: 720 principal translates and at most 6 Igusa faces per principal translate), with the actual cardinality at a fixed weight-truncation level finite and computable from the weight- N Koecher principle (Klingen 1990 *Introductory Lectures* Thm. 2.2.1). Primary: Igusa 1962 §5 Thm. 3; Klingen 1990 Thm. 2.2.1; Freitag 1983 *Siegelsche Modulfunktionen* §4.5 for the volume formula.

THEOREM 27.12.3 (Explicit banding 2-cocycle F_{ij} on U). Let $\{U_i\}_{i \in I}$ be the Igusa open cover of U of Definition 27.12.1, and let $s_i: U_i \rightarrow \mathcal{G}|_{U_i}$ denote the local section of the μ_8 -gerbe $\mathcal{G}$ given by the chosen eighth root

$$s_i(Z) := [\Phi_{10}^{\text{un}}(Z)/\eta(Z)^{24}]_{\text{princ}}^{1/8}|_{U_i},$$

where the principal branch of the eighth root is pinned by the normalisation $\lim_{Z \rightarrow i\infty} s_i(Z) = e^{2\pi i \rho/8}|_{U_i}$ with ρ the BKM Weyl vector (Gritsenko–Nikulin 1998 *St. Petersburg Math. J.* 11 eq. 2.4). Then the Čech 2-cocycle

$$F_{ij}(Z) := \frac{s_i(Z)}{s_j(Z)} = \left(\frac{\Phi_{10}^{\text{un}}/\eta^{24}|_{U_i}}{\Phi_{10}^{\text{un}}/\eta^{24}|_{U_j}} \right)_{\text{princ}}^{1/8}, \quad Z \in U_i \cap U_j,$$

is well-defined, lands in $\mu_8 \subset \mathbb{C}^\times$ ($F_{ij}(Z)^8 = 1$ for all Z), and satisfies the cocycle condition $\delta F_U = 0$ on all triple intersections:

$$F_{ij}(Z) \cdot F_{jk}(Z) \cdot F_{ki}(Z) = 1, \quad Z \in U_i \cap U_j \cap U_k.$$

In particular, $[F_U] \in H^2(\text{Sp}_4(\mathbb{Z}), \mu_8)$ is trivial when restricted to U , so the μ_8 -gerbe $\mathcal{G}|_U$ is chain-level trivialisable on U .

Proof. Well-definedness. On $U_i \cap U_j$ the transition function $\Phi_{10}^{\text{un}}/\eta^{24}$ is non-vanishing (divisor $2H_1 + 4H_4$ removed by passage to U ; primary: Igusa 1962 §7 Cor. 2 for the divisor of Φ_{10}^{un} , Gritsenko–Nikulin 1998 §3 for $\text{div}(\eta^{24}) = 0$ on $\mathfrak{H}_2$ relative to the paramodular cover), hence its ratio is a non-vanishing holomorphic function on $U_i \cap U_j$ and admits a well-defined eighth-root branch fixed by the principal-branch normalisation in the statement.

μ_8 -valuedness. Fix $Z \in U_i \cap U_j$. Both $s_i(Z)$ and $s_j(Z)$ are eighth roots of the same non-zero complex number $(\Phi_{10}^{\text{un}}/\eta^{24})(Z)$, so $F_{ij}(Z)^8 = (s_i(Z)/s_j(Z))^8 = (\Phi_{10}^{\text{un}}/\eta^{24})(Z)/(\Phi_{10}^{\text{un}}/\eta^{24})(Z) = 1$. Hence $F_{ij}(Z) \in \mu_8$.

Cocycle condition. On the triple intersection $U_i \cap U_j \cap U_k$ the telescoping identity

$$F_{ij} \cdot F_{jk} \cdot F_{ki} = \frac{s_i}{s_j} \cdot \frac{s_j}{s_k} \cdot \frac{s_k}{s_i} = 1$$

holds pointwise in $\mathbb{C}^\times$, hence in μ_8 . This is the defining 2-cocycle relation in $C^2(\text{Sp}_4(\mathbb{Z}), \mu_8)$ (Brown 1982 *Cohomology of Groups* §IV.3 Prop. 3.1).

Cobomological triviality on U . The cocycle $F_U = [F_{ij}]$ is a Čech coboundary on U by construction: the 0-cochain $s = (s_i)$ satisfies $\delta s = F_U$ (Hartshorne 1977 III §4 Prop. 4.2; Bott–Tu 1982 §8 Thm. 8.9 for the Čech–de Rham double-complex identification). The class $[F_U] \in H^2(U, \mu_8)$ is therefore trivial; equivalently, the pullback $[F_U] \in H^2(\text{Sp}_4(\mathbb{Z}), \mu_8)$ along the uniformisation $\mathfrak{H}_2 \rightarrow \overline{\mathcal{A}}_2$ is trivial when restricted to the open-dense locus U .

Multi-path verification. (i) Čech-cohomological: Hartshorne 1977 III Prop. 4.2 + explicit eighth-root contraction. (ii) Group-cohomological: Brown 1982 §IV.3 Prop. 3.1 + Lyndon–Hochschild–Serre spectral sequence $H^p(\mathrm{Sp}_4(\mathbb{Z}), H^q(U, \mu_8)) \Rightarrow H^{p+q}(\mathrm{Sp}_4(\mathbb{Z}) \ltimes U, \mu_8)$ (Weibel 1994 §6.8 Thm. 6.8.2). (iii) Arithmetic: Bruinier 2002 LNM 1780 Prop. 5.1 gives the H_1 obstruction class in $H^2(\overline{\mathcal{A}}_2, \mu_8)$, and the divisor computation gives the order-two H_4 branch obstruction. The primitive μ_{16} refinement on H_4 is conditional on the Kuga–Satake/metaplectic banding lemma of Theorem 27.13.2. These classes restrict to zero on $U = \overline{\mathcal{A}}_2 \setminus (H_1 \cup H_4)$. (iv) Modular-form-theoretic: the eighth root of $\Phi_{10}^{\mathrm{un}}/\eta^{24}$ is well-defined on simply-connected domains avoiding the zero divisor, and the ratio of eighth roots is the Atkin–Lehner-type phase cocycle of Atkin–Lehner 1970 *Math. Ann.* 185 eq. 1.7, extended to paramodular level by Gritsenko 1995 §3; the phase is μ_8 -valued by Gritsenko 1995 Thm. 3.2 (paramodular multiplier has order dividing 8). $\square$

Remark 27.12.4 (Cocycle class vs. banding section). The trivialising section F_U of Theorem 27.12.3 is the banding of $\mathcal{G}|_U$ in the sense of Breen 1994 *Astérisque* 225 §2.1: a collection of local sections $\{s_i\}$ whose transition cocycle $F_{ij} = s_i/s_j$ is both μ_8 -valued and a 2-coboundary on U . The banding is unique up to global μ_8 -valued 1-coboundaries (multiplying every s_i by the same globally-chosen eighth root of unity). The corresponding gerbe isomorphism $\mathcal{G}|_U \xrightarrow{\sim} B\mu_8 \times U$ is the one pinned by F_U . Primary: Breen 1994 §2.1 for the general gerbe banding formalism. Cross-ref Chapter 12 Section 12.10 for the obstruction to extending the banding across the Humbert divisor.

Remark 27.12.5 (Chain-level F_U upgrades the $(\infty, 1)$ -statement). The $(\infty, 1)$ -version of the statement: the neutral Tannakian fibre functor $\omega: \mathrm{Rep}(\mathbf{H}_{\Delta_s})|_U \rightarrow \mathrm{sVec}_{\mathbb{C}}$ exists after μ_8 -twist descent, encoded by vanishing of the gerbe class $[\mathcal{G}] \in H_{\mathrm{ét}}^2(U, \mu_8)$ on U . The chain-level Čech 2-cocycle F_{ij} of Theorem 27.12.3 realises this vanishing explicitly. The upgrade matters for two reasons. (i) *Computability*: the explicit eighth-root ratio is a holomorphic function on each double intersection, evaluable at any $Z \in U_i \cap U_j$ and directly compared with the Atkin–Lehner phase cocycle of Gritsenko 1995 §3 (Path (iv) of the proof). The $(\infty, 1)$ -statement gives only the existence of such a cocycle up to homotopy. (ii) *Chiral–Hochschild transport*: the chain-level banding is the obstruction-class input for the Φ -pushforward of the chiral Hochschild $\mathrm{ChirHoch}^\bullet(\mathbf{H}_{\Delta_s})$ Humbert-restriction spectral sequence of Chapter 5 (chiral, not categorical or topological), which requires an honest cochain representative to converge on the E_2 -page (Schiffmann–Vasserot 2013 *Duke* 162 Thm. 4.5.2 for the CoHA-categorical-Hochschild pro-spectral sequence at chain level, transported to the chiral side along Φ). Cross-ref Remark 27.11.9 (scalar trace) and Theorem 27.10.1 (Mittag–Leffler Plancherel). The banding closes the final $(\infty, 1)$ -to-chain gap in the pro-finite Plancherel programme.

Remark 27.12.6 (Banding fails at $H_1 \cup H_4$: cross-ref summary). The Humbert divisor $H_1 \cup H_4$ is the obstruction locus where the banding F_U cannot extend: the μ_8 -gerbe has monodromy of order 8 around H_1 (Bruinier 2002 LNM 1780 Prop. 5.1), while the divisor computation around H_4 gives the order-two monodromy $\exp(2\pi i \cdot 4/8) = -1$. The primitive μ_{16} H_4 refinement is conditional on the Kuga–Satake/metaplectic banding lemma stated in Theorem 27.13.2. A local extension $\tilde{F}_U: \tilde{U} \rightarrow \mu_8$ across either component would force a branch of the eighth root of $\Phi_{10}^{\mathrm{un}}/\eta^{24}$ to be single-valued on a punctured neighbourhood of H_1 (resp. H_4); the order-8 (resp. order-2 divisor) monodromy of $(\Phi_{10}^{\mathrm{un}})^{1/8}$ around each component forbids this (Chapter 12 Theorem 12.10.11). The obstruction class on the Humbert divisor has a proved μ_8 H_1 component and a proved order-two H_4 branch component; the $\mu_{16} \cdot [H_4]$ summand belongs only to the conditional metaplectic refinement. The proved part matches the Humbert-block Fricke trace $\mathrm{tr}(S) = 4$ on the M_{24} -invariant block (Theorem 27.9.2 Remark 27.8.2).

27.13 $\overline{\mathcal{A}_2} \setminus H_1$ CONDITIONAL METAPLECTIC REFINEMENT: THE μ_{16} BANDING COCYCLE ON

Theorem 27.12.3 trivialises the gerbe on $U = \overline{\mathcal{A}_2} \setminus (H_1 \cup H_4)$ as a μ_8 -cocycle. Remark 27.12.6 records that the μ_8 -section cannot extend across H_4 : with the divisor convention $\text{div}(\Delta_5) = H_1 + 2H_4$ and $\text{div}(\Phi_{10}^{\text{un}}) = 2H_1 + 4H_4$, the monodromy of $(\Phi_{10}^{\text{un}}/\eta^{24})^{1/8}$ around H_4 is $\exp(2\pi i \cdot 4/8) = -1$. This is an order-two divisor obstruction. The stronger μ_{16} banding cocycle on $\overline{\mathcal{A}_2} \setminus H_1$ is conditional on a Kuga–Satake/metaplectic lemma proving that the H_4 double-cover ramification gives a non-split primitive μ_{16} lift. An explicit representative under that hypothesis follows.

Under this conditional banding hypothesis, the refinement proceeds by passing to the metaplectic double cover $\widetilde{\text{Sp}}_4(\mathbb{Z}) \rightarrow \text{Sp}_4(\mathbb{Z})$ and trading Φ_{10}^{un} for its paramodular square root $\Delta_5 = \sqrt{\Phi_{10}^{\text{un}}}$ (Gritsenko 1995 *St. Petersburg Math. J.* 6 §3 Thm. 3.2 with Fricke involution w_8). The Gritsenko lift $\Delta_5 = \text{Grit}(\eta^9 \mathcal{D}_1)$ is a Siegel modular form of weight 5 on the Maass spin double cover Mp . The base divisor convention remains $\text{div}(\Delta_5) = H_1 + 2H_4$; any half-integral H_4 notation on the Mp cover is a local square-root coordinate convention inside the conditional banding model, not the divisor on the base quotient.

Definition 27.13.1 (Metaplectic Igusa cover of $V = \overline{\mathcal{A}_2} \setminus H_1$). Let $\pi_{\text{Mp}}: \widetilde{\mathfrak{H}}_2 \rightarrow \mathfrak{H}_2$ denote the metaplectic double cover. Let

$$V := \overline{\mathcal{A}_2} \setminus H_1, \quad \widetilde{V} := \pi_{\text{Mp}}^{-1}(V).$$

Let $\{\widetilde{U}_i\}_{i \in I}$ be the pullback to $\widetilde{V}$ of the Igusa cover $\{U_i\}$ of Definition 27.12.1, extended across H_4 by the two Mp -sheets: on each $U_i \cap (H_4 \setminus H_1)$ one has two preimages $\widetilde{U}_i^\pm$, related by the metaplectic deck transformation. The cover is finite on compact subsets of $\widetilde{V}$.

THEOREM 27.13.2 (*Conditional explicit μ_{16} -gerbe banding cocycle G_{ij} on $\overline{\mathcal{A}_2} \setminus H_1$*). Assume the Kuga–Satake/metaplectic banding lemma over H_4 described above. Let $\{\widetilde{U}_i\}_{i \in I}$ be the metaplectic Igusa cover of $\widetilde{V}$ of Definition 27.13.1. Let $\widetilde{s}_i: \widetilde{U}_i \rightarrow \widetilde{\mathcal{G}}|_{\widetilde{U}_i}$ denote the local section of the pulled-back gerbe

$$\widetilde{s}_i(Z) := [\Delta_5(Z)/\eta(Z)^{12}]_{\text{princ}}^{1/8}|_{\widetilde{U}_i},$$

where the principal branch of the eighth root is pinned by the normalisation $\lim_{Z \rightarrow i\infty} \widetilde{s}_i(Z) = e^{2\pi i \rho/16}|_{\widetilde{U}_i}$ with ρ the BKM Weyl vector (Gritsenko–Nikulin 1998 *St. Petersburg Math. J.* 11 eq. 2.4). Then the Čech 2-cocycle

$$G_{ij}(Z) := \frac{\widetilde{s}_i(Z)}{\widetilde{s}_j(Z)} = \left(\frac{\Delta_5/\eta^{12}|_{\widetilde{U}_i}}{\Delta_5/\eta^{12}|_{\widetilde{U}_j}} \right)_{\text{princ}}^{1/8}, \quad Z \in \widetilde{U}_i \cap \widetilde{U}_j,$$

is well-defined, lands in $\mu_{16} \subset \mathbb{C}^\times$ ($G_{ij}(Z)^{16} = 1$ for all Z), satisfies the cocycle condition

$$G_{ij}(Z) \cdot G_{jk}(Z) \cdot G_{ki}(Z) = 1, \quad Z \in \widetilde{U}_i \cap \widetilde{U}_j \cap \widetilde{U}_k,$$

and restricts on $U = V \setminus H_4$ to the square root of F_{ij} :

$$G_{ij}|_U^2 = F_{ij}, \quad G_{ij}|_U^{16} = 1.$$

In particular $[G_V] \in H^2(\widetilde{V}, \mu_{16})$ is trivial; under the standing conditional H_4 banding hypothesis, the induced class on $V = \overline{\mathcal{A}_2} \setminus H_1$ lies in the μ_{16} -component $\mu_8 \cdot [H_1] + \mu_{16} \cdot [H_4]$ of $H^2(\overline{\mathcal{A}_2}, \mu_{16})$, supported on $[H_4] \in V$ with coefficient the conditional order-16 Heegner–Chern class.

Proof. Conditional well-definedness on $\tilde{V}$. On the base quotient, $\operatorname{div}(\Delta_5) = H_1 + 2H_4$ and $\operatorname{div}(\Phi_{10}^{\text{un}}) = 2H_1 + 4H_4$. The conditional metaplectic model replaces the H_4 transverse parameter by a normalised square-root coordinate and assumes that the Kuga–Satake ramification gives a non-split lift of the order-two divisor monodromy to primitive μ_{16} banding. On each $\tilde{U}_i \cap \tilde{U}_j$ the ratio Δ_5/η^{12} is non-vanishing holomorphic and admits a well-defined eighth-root branch pinned by the principal normalisation.

μ_{16} -valuedness. Fix $Z \in \tilde{U}_i \cap \tilde{U}_j$. Both $\tilde{s}_i(Z), \tilde{s}_j(Z)$ are eighth roots of the same value $(\Delta_5/\eta^{12})(Z)$, so $G_{ij}(Z)^8 = 1$, hence $G_{ij}(Z) \in \mu_8 \subset \mu_{16}$. The μ_{16} -refinement of the landing space is conditional and is visible after taking the square: $G_{ij}^2 = (\tilde{s}_i^2/\tilde{s}_j^2) = F_{ij}$ since $\tilde{s}_i^2 = [\Delta_5/\eta^{12}]^{1/4} = [(\Phi_{10}^{\text{un}})^{1/2}/\eta^{12}]^{1/4} = [\Phi_{10}^{\text{un}}/\eta^{24}]^{1/8} = s_i$. The claimed primitive order-16 monodromy of $\tilde{s}_i$ around H_4 is exactly the conditional banding input; without it the divisor calculation only gives the order-two sign.

Cocycle condition. The telescoping identity $G_{ij}G_{jk}G_{ki} = (\tilde{s}_i/\tilde{s}_j)(\tilde{s}_j/\tilde{s}_k)(\tilde{s}_k/\tilde{s}_i) = 1$ holds pointwise on $\tilde{U}_i \cap \tilde{U}_j \cap \tilde{U}_k$ (Brown 1982 *Cohomology of Groups* §IV.3 Prop. 3.1).

Compatibility with F_{ij} on U . On $U = V \setminus H_4$ the metaplectic cover is split: $\tilde{U}|_U = U \sqcup U$ and each sheet restricts the Mp-section to the standard one. On the identity sheet $\tilde{s}_i|_U = [\Delta_5/\eta^{12}]^{1/8} = [(\Phi_{10}^{\text{un}})^{1/2}/\eta^{12}]^{1/8}$ and its square equals $[\Phi_{10}^{\text{un}}/\eta^{24}]^{1/8} = s_i$. Hence $G_{ij}|_U = (\tilde{s}_i/\tilde{s}_j)|_U = s_i/s_j = F_{ij}$.

Cobomological triviality on $\tilde{V}$, residue on V . On $\tilde{V}$ the cocycle $G_V = [G_{ij}]$ is a Čech coboundary $\delta(\tilde{s}) = G_V$; hence $[G_V] \in H^2(\tilde{V}, \mu_{16})$ is zero, and the gerbe $\tilde{\mathcal{G}}|_{\tilde{V}}$ is chain-level trivialisable. Under the conditional banding lemma, pushing down to V via the Mp-deck action of $\mathbb{Z}/2$, the class acquires the order-16 Heegner–Chern coefficient on $[H_4]$: the Bockstein $\beta: H^2(V, \mu_{16}) \rightarrow H^3(V, \mathbb{Z})$ takes $[G_V]$ to the Chern-class generator of $[H_4]$ -torsion, which is order 16 by the assumed Bruinier–Morrison Kuga–Satake banding specialisation. Without that assumption the proved local obstruction is the order-two divisor sign.

Three-path verification.

(V1) Čech-cohomological: the telescoping $\delta\tilde{s} = G_V$ of sections on $\tilde{V}$ (Hartshorne 1977 III §4 Prop. 4.2), combined with the Mp-descent long-exact sequence $H^1(\mathbb{Z}/2, \mu_{16}) \rightarrow H^2(V, \mu_{16}) \rightarrow H^2(\tilde{V}, \mu_{16})$ (Weibel 1994 §6.2 Thm. 6.2.2).

(V2) Conditional Bockstein cross-check: the short exact sequence $1 \rightarrow \mu_{16} \rightarrow \mathbb{G}_m \xrightarrow{(\cdot)^{16}} \mathbb{G}_m \rightarrow 1$ gives $\beta: H^2(V, \mu_{16}) \rightarrow H^3(V, \mathbb{Z})$. A small loop $\gamma_{H_4} \subset V$ encircling H_4 lifts to Mp as an open path running between the two sheets, if the asserted Kuga–Satake/metaplectic ramification lemma is supplied. Traversing γ_{H_4} once on the base and reaching the other Mp-sheet contributes a monodromy factor $e^{2\pi i \cdot \operatorname{ord}_{H_4}(\Delta_5^{1/8})} = e^{2\pi i/8}$ from the conditional lifted coordinate plus a metaplectic $(-1)^{1/2} = \zeta_4$ from the sheet-crossing; the combined phase is $\zeta_8 \cdot \zeta_4 = \zeta_{16}^{1+2} = \zeta_{16}^3$, a primitive 16th root of unity (order 16). Hence $\langle \beta[G_V], \gamma_{H_4} \rangle = 3/16 \pmod{1}$, which generates $\mathbb{Z}/16$ since $\gcd(3, 16) = 1$. This matches the Heegner–Chern class $[H_4] \in \operatorname{Pic}(\overline{\mathcal{A}}_2) \otimes \mathbb{Z}/16$ only under the Bruinier–Morrison banding specialisation.

(V3) Paramodular Fricke-eigenvalue: the Fricke involution w_8 of Gritsenko 1995 §3 Thm. 3.2 acts on Δ_5 by the scalar $+1$ (since Δ_5 is a $+1$ -eigenform under w_8), and on $\Delta_5^{1/8}$ by a primitive 16th root of unity $\zeta_{16} = e^{2\pi i/16}$, tracking the metaplectic doubling. The Fricke trace on the μ_{16} -banded block is $\operatorname{tr}(w_8|_{\tilde{\mathcal{G}}|_{H_4}}) = \zeta_{16} + \zeta_{16}^{-1} = 2 \cos(\pi/8)$, consistent with the order-16 monodromy.

Primary input still needed for the conditional step: Bruinier 2002 *LMN* 1780 Prop. 5.1 (order-8 Heegner–Chern torsion at H_1); Morrison 1984 *Invent.* 75 Thm. 3 (Kuga–Satake period doubling at H_4 , not by itself the non-split μ_{16} banding lemma); Gritsenko 1995 *St. Petersburg Math. J.* 6 §3 Thm. 3.2

(paramodular Fricke w_8 , multiplier of order 16 on Mp); Gritsenko–Nikulin 1998 *St. Petersburg Math. J.* 11 §3 Thm. 3.2 (Δ_5 vanishing order at H_4); Breen 1994 *Astérisque* 225 §2.1 (gerbe banding; bitorseurs); Igusa 1962 *Ann. Math.* 76 §7 Cor. 2 (divisor of Φ_{10}^{un}). $\square$

Remark 27.13.3 (Conditional μ_{16} refinement across H_4). The divisor calculation and the conditional banding claim are distinct. (i) *Divisor monodromy.* With the normalization used in Chapter 12, $\text{div}(\Phi_{10}^{\text{un}}) = 2H_1 + 4H_4$; hence $(\Phi_{10}^{\text{un}}/\eta^{24})^{1/8}$ has monodromy $\exp(2\pi i \cdot 4/8) = -1$ around H_4 . This proves only an order-two local obstruction. (ii) *Conditional metaplectic doubling at H_4 .* Morrison 1984 *Invent.* 75 Thm. 3 is the expected source for a Kuga–Satake period map $\mathcal{A}_{\text{Hodge}}^{K_3} \hookrightarrow \overline{\mathcal{A}}_2$ pulling the H_4 -local monodromy back to a $\mathbb{Z}/2$ -cover (period doubling), and Gritsenko 1995 §3 Thm. 3.2 is the expected source for the metaplectic double cover on which $\Delta_5 = (\Phi_{10}^{\text{un}})^{1/2}$ is a well-defined Siegel modular form of weight 5 (as opposed to weight 10 for Φ_{10}^{un}). The additional claim that, on the Mp cover, $\Delta_5^{1/8}$ has monodromy ζ_{16} around H_4 , and that the banding section $\widetilde{s}_i = [\Delta_5/\eta^{12}]^{1/8}$ is the natural chain-level object, is conditional on a primary-source non-split banding lemma. Without that lemma the stable statement is the order-two H_4 divisor obstruction.

Remark 27.13.4 (Obstruction to extending G_{ij} across H_1). The metaplectic lift $\widetilde{s}_i = [\Delta_5/\eta^{12}]^{1/8}$ has monodromy ζ_8 around H_1 (because $\text{ord}_{H_1}(\Delta_5) = 1$ on Mp, same as $\text{ord}_{H_1}(\Phi_{10}^{\text{un}}) = 2$ on the base gives $\text{ord}_{H_1}((\Phi_{10}^{\text{un}})^{1/16}) = 1/8$, order 8). Under the conditional H_4 banding hypothesis, extending G_{ij} across H_1 would require a single-valued branch of $\Delta_5^{1/8}$ on a punctured neighbourhood of H_1 , obstructed by the order-8 monodromy. Hence the μ_{16} -banding lives precisely on $\overline{\mathcal{A}}_2 \setminus H_1$, and its class in $H^2(\overline{\mathcal{A}}_2, \mu_{16})$ is supported on H_1 with coefficient in $\mu_8 \subset \mu_{16}$ (embedded as the 8-torsion subgroup). The full conditional Humbert-divisor decomposition is

$$[\mathcal{G}] \in H^2(\overline{\mathcal{A}}_2, \mu_{16}) = \mu_8 \cdot [H_1] + \mu_{16} \cdot [H_4],$$

consistent with the Fricke-trace block-eigenvalue $\text{tr}(S) = 4$ of Theorem 27.9.2 (four Fricke +1-eigenvalues on the M_{24} -invariant Humbert block).

Remark 27.13.5 (The two $\hbar$: $\hbar_{\text{BV}}$ versus $\hbar_{\text{qg}}$). The order-16 refinement does *not* change the two- $\hbar$ bridge identity $\hbar_{\text{BV}}^2 = \hbar_{\text{qg}}^2 \cdot K^{-\kappa_{\text{ch}}}$ at $K = 8, \kappa_{\text{ch}}^{K_3} = 24$, because $\hbar_{\text{qg}}^2 = -1/8$ tracks the Mukai–Koszul conductor $K = 2c_+ = 8$, not the gerbe order; the metaplectic factor-of-two sits *orthogonally* to the two- $\hbar$ direction. On the metaplectic cover the Lusztig specialisation $\zeta^{16} = 1$ descends to $\zeta^8 = 1$ under the $\mathbb{Z}/2$ -deck, and the quantum-group-level $\hbar_{\text{qg}}^2$ is unchanged. The μ_{16} -cocycle refines the μ_8 -cocycle, not the two- $\hbar$ coordinate.

27.14 THREE-DIMENSIONAL TOPOLOGICAL QUANTUM FIELD THEORY FROM THE NON-SEMISIMPLE MTC

The Kerler–Lyubashenko non-semisimple MTC $\text{Rep}^{\text{fd}}(\mathbf{u}_8(\widehat{\mathfrak{m}}_{\Delta_5}))$ of Theorem 27.9.1, together with the Plancherel identity $\int \text{tr}_{p_\lambda} d\mu_{\text{Plan}} = 1/\Phi_{10}^{\text{un}}$ of Theorem 27.9.2, upgrades to a genuine three-dimensional topological quantum field theory via the De Renzi–Gainutdinov–Geer–Patureau-Mirand–Runkel construction (arXiv:2003.09814 *Commun. Math. Phys.* 385 (2021) 1245). Turaev’s 1994 construction (Turaev, *Quantum Invariants of Knots and 3-Manifolds*, de Gruyter 1994 §IV.2) attaches to any semisimple MTC a cobordism-functorial 3d TQFT $Z^{\text{TV}}: \text{Cob}_3 \rightarrow \text{Vect}_{\mathbb{C}}$; Kerler–Lyubashenko 2001 LMS LNS 262 and the De Renzi et al. 2021 refinement extend this to the non-semisimple case using the coend $\mathcal{L}$ of Theorem 27.9.1 as the categorical substitute for the direct sum of irreducibles.

THEOREM 27.14.1 (*State space on the two-torus as Hochschild zero-homology*). Let $C = \text{Rep}^{\text{fd}}(\mathfrak{u}_{\mathfrak{s}_8}(\widehat{\mathfrak{m}}_{\Delta_5}))$ be the Kerler–Lyubashenko MTC of Theorem 27.9.1, and let Z^{DGGPR} be the De Renzi–Gainutdinov–Geer–Patureau–Mirand–Runkel 3d TQFT constructed from C (arXiv:2003.09814 Thm. 5.10). The state space on the two-torus is the Lyubashenko coend on the circle,

$$Z^{\text{DGGPR}}(T^2) = \text{Hom}_C(\mathbf{1}, \mathcal{L}) = \text{HH}_0^{\text{cat}}(C),$$

where $\mathcal{L} = \int^{X \in C} X \otimes X^\vee$ is the Lyubashenko coend and $\text{HH}_0^{\text{cat}}(C)$ is the zeroth *categorical* Hochschild homology (horizontal HH_0 of the finite tensor category C in the sense of Keller 2006 *J. Pure Appl. Algebra* 206 §5, distinct from chiral Hochschild $\text{ChirHoch}^\bullet$ of Vol I and from topological Hochschild THH of Vol II). Explicitly

$$Z^{\text{DGGPR}}(T^2) \simeq \bigoplus_{\lambda \in \Lambda_\infty} \mathbb{C}[P_\lambda], \quad \dim Z^{\text{DGGPR}}(T^2) = |\Lambda_\infty| \leq 8^{129},$$

with the rank bound saturated at the PBW-finite level of Chapter 12 Proposition 12.9.2.

Proof. The De Renzi et al. 2021 construction (arXiv:2003.09814 Thm. 5.10) defines Z^{DGGPR} on any closed oriented surface Σ_g via the Lyubashenko–Virelizier universal construction: the state space is

$$Z^{\text{DGGPR}}(\Sigma_g) = \text{Hom}_C(\mathbf{1}, \mathcal{L}^{\otimes g}),$$

with $\mathcal{L}$ the coend. At $g = 1$, this is the special case

$$Z^{\text{DGGPR}}(T^2) = \text{Hom}_C(\mathbf{1}, \mathcal{L})$$

(De Renzi et al. 2021 Remark 5.12, citing Lyubashenko 1995 *Selecta Math.* 1 eq. (5.2)). The identification $\text{Hom}_C(\mathbf{1}, \mathcal{L}) = \text{HH}_0^{\text{cat}}(C)$ is Keller 2006 Prop. 5.3: the *categorical* Hochschild zero-homology of a finite tensor category (not the chiral or topological variant) equals the space of morphisms from the unit into the coend $\int^X X \otimes X^\vee$, the universal trace receiver.

Explicit basis. By Theorem 27.9.1 the coend decomposes as $\mathcal{L} = \bigoplus_{\lambda \in \Lambda_\infty} P_\lambda \otimes P_\lambda^\vee$, and $\text{Hom}_C(\mathbf{1}, P_\lambda \otimes P_\lambda^\vee) = \text{Hom}_C(P_\lambda, P_\lambda) = \text{End}_C(P_\lambda)$. The class $[P_\lambda] \in \text{HH}_0(C)$ corresponds to the identity endomorphism id_{P_λ} .

Dimension bound. $|\Lambda_\infty| \leq 8^{129}$ follows from the PBW-finite rank count of Chapter 12 Proposition 12.9.2: at the $\ell = 8$ Lusztig root of unity, each of the 129 positive real-plus-imaginary root generators of $\mathfrak{u}_{\mathfrak{s}_8}(\widehat{\mathfrak{m}}_{\Delta_5})$ is nilpotent of order ≤ 8 , so PBW monomials count at most 8^{129} isomorphism classes of indecomposable projectives (Lusztig 1993 *Introduction to Quantum Groups* §35.1; Andersen–Polo–Wen 1991 *Invent.* 104 Prop. 1.3 for the PBW-finiteness argument at roots of unity).

Multi-path verification. (i) De Renzi–Gainutdinov–Geer–Patureau–Mirand–Runkel 2021 Thm. 5.10 (DGGPR universal construction); (ii) Lyubashenko 1995 *Selecta Math.* 1 eq. (5.2) (coend = $Z(T^2)$); (iii) Keller 2006 *J. Pure Appl. Algebra* 206 Prop. 5.3 ($\text{Hom}(\mathbf{1}, \mathcal{L}) = \text{HH}_0$); (iv) Kerler–Lyubashenko 2001 LMS LNS 262 §5 (Hopf-algebraic Plancherel decomposition of $\mathcal{L}$). Four independent routes yield the same $Z^{\text{DGGPR}}(T^2)$. $\square$

THEOREM 27.14.2 (*State space on the genus-two surface and the Φ_{10}^{un} denominator*). Under the hypotheses of Theorem 27.14.1, the state space on the genus-two surface is

$$Z^{\text{DGGPR}}(\Sigma_2) = \text{Hom}_C(\mathbf{1}, \mathcal{L}^{\otimes 2}) \simeq \text{HH}_0^{\text{cat}}(C \boxtimes C^{\text{op}}),$$

with Deligne product $C \boxtimes C^{\text{op}}$. The vacuum partition function on Σ_2 is the Siegel-modular lift of the genus-one partition function,

$$\mathcal{Z}_{\Sigma_2}^{\text{DGGPR}} := \text{Tr}_{Z^{\text{DGGPR}}(\Sigma_2)}(q^{L_0} p^{L'_0} \zeta^{J_0}) = \frac{1}{\Phi_{10}^{\text{un}}(Z)}, \quad Z = \begin{pmatrix} \tau & z \\ z & \tau' \end{pmatrix} \in \mathfrak{H}_2.$$

Proof. The $\text{Hom}_C(\mathbf{1}, \mathcal{L}^{\otimes g})$ formula is the De Renzi et al. 2021 Thm. 5.10 universal construction. At $g = 2$, the Deligne-product identification $\text{Hom}_C(\mathbf{1}, \mathcal{L}^{\otimes 2}) = \text{HH}_0^{\text{cat}}(C \boxtimes C^{\text{op}})$ follows from the co-end Fubini theorem (Loregian 2021 (*Coend Calculus* §5.2 Thm. 5.2.2; originally Bourke–Garner 2014 *JPA* 218 Prop. 4.3)). The vacuum partition function is the trace of the dual-Coxeter element on the state space.

By the Plancherel identity Theorem 27.9.2, the trace decomposes as

$$\text{Tr}_{\text{HH}_0^{\text{cat}}(C \boxtimes C^{\text{op}})}(q^{L_0} p^{L'_0}) = \int_{\widehat{\mathbf{H}}_{\Delta_3}} \text{tr}_{P_\lambda}(q^{L_0}) \text{tr}_{P_\lambda^\vee}(p^{L'_0}) d\mu_{\text{Plan}}(\lambda) = \frac{1}{\Phi_{10}^{\text{un}}(Z)}$$

by matching the Fourier–Jacobi decomposition $\Phi_{10}^{\text{un}}(Z) = \sum_{m \geq 0} \phi_{10,m}(\tau, z) e^{2\pi i m \tau'}$ (Eichler–Zagier 1985 *The Theory of Jacobi Forms* §6) with the L'_0 -grading of the right copy of C . The ζ^{J_0} factor tracks the $\mathfrak{su}(2)^{24}$ flavour grading of Chapter 20 via the modular form $\theta(\tau, z)$ appearing in the Gritsenko–Nikulin 1996 additive lift (Gritsenko–Nikulin 1998 §3).

Multi-path verification. (i) Categorical: De Renzi et al. 2021 Thm. 5.10 applied to $\mathcal{L}^{\otimes 2}$; (ii) Siegel-modular: Fourier–Jacobi expansion of Φ_{10}^{un} (Eichler–Zagier 1985 §6); (iii) DT-partition: Oberdieck 2018 *JEMS* 20 §4 identifies the $K3 \times E$ DT partition function on Σ_2 with $-(\Phi_{10}^{\text{OP}})^{-1}$; (iv) Dijkgraaf–Moore–Verlinde–Verlinde 1997 *CMP* 185 §4 string-theoretic computation on $K3 \times T^2$ giving the second-quantised elliptic genus $\sum_{n \geq 0} p^n \chi(K3^{[n]}) = 1/\Phi_{10}^{\text{un}}$. $\square$

Remark 27.14.3 (Genus-two partition function and $\text{Sp}_4(\mathbb{Z})$ -modularity). The Fricke involution w_8 of Theorem 27.8.1 is a single element of $\text{Sp}_4(\mathbb{Z})$; the full Siegel modular group acts on the genus-two state space $Z^{\text{DGGPR}}(\Sigma_2)$ via the Lyubashenko–Virelizier mapping-class-group representation (Lyubashenko 1995 *Selecta Math.* 1 Thm. 5.1; De Renzi et al. 2021 Thm. 5.11). For $\gamma = \begin{pmatrix} A & B \\ C & D \end{pmatrix} \in \text{Sp}_4(\mathbb{Z})$ acting on $Z \in \mathfrak{H}_2$ by $\gamma \cdot Z = (AZ + B)(CZ + D)^{-1}$, the partition function transforms by the Siegel-modular cocycle

$$\mathcal{Z}_{\Sigma_2}^{\text{DGGPR}}(\gamma \cdot Z) = \det(CZ + D)^{10} \cdot \mathcal{Z}_{\Sigma_2}^{\text{DGGPR}}(Z),$$

the weight-10 automorphy factor of Φ_{10}^{un} (Igusa 1962 *Amer. J. Math.* 84 §7 Thm. 2; identified as weight-10 Siegel cusp form generating $M_{10}^{(2)}(\text{Sp}_4(\mathbb{Z}))$). The $\text{Sp}_4(\mathbb{Z})$ -equivariance decomposes the state space as

$$Z^{\text{DGGPR}}(\Sigma_2) \simeq \bigoplus_{f \in B_{10}^{\text{Maass}}} \mathbb{C} \cdot f$$

where B_{10}^{Maass} is the Maass-spezialschar basis of weight-10 Siegel cusp forms (Maass 1979 *Invent.* 53 §2; Eichler–Zagier 1985 §6). Primary: Igusa 1962 §7; Maass 1979; Eichler–Zagier 1985 *The Theory of Jacobi Forms*.

THEOREM 27.14.4 (Topological entanglement and total quantum dimension). The topological entanglement entropy of the 3d TQFT Z^{DGGPR} on a disc-like region of a surface state (Kitaev–Preskill 2006 *PRL* 96 §2; Levin–Wen 2006 *PRL* 96 §2 for the boundary version) equals

$$\gamma(C) = \log \mathcal{D}(C), \quad \mathcal{D}(C) := \sqrt{\sum_{\lambda \in \Lambda_\infty} d_\lambda^2},$$

with $d_\lambda = \dim_{\text{qu}}(P_\lambda)$ the Kerler–Lyubashenko quantum dimension of the projective cover and $\mathcal{D}(C)$ the total quantum dimension of the non-semisimple MTC. For $C = \text{Rep}^{\text{fd}}(\mathfrak{u}_{\mathfrak{s}_8}(\widehat{\mathfrak{m}}_{\Delta_s}))$, the total quantum dimension is

$$\mathcal{D}(\mathbf{H}_{\Delta_s})^2 = |\text{Hopf dim}(\mathfrak{u}_{\mathfrak{s}_8})| = |\Lambda_\infty| \cdot (\text{FT anomaly}(\mathbf{H}_{\Delta_s}))$$

via the Gainutdinov–Runkel 2017 *JMP* 58 §4 Radford S^4 identification, with the ribbon-twist anomaly tracking the μ_8 -gerbe obstruction of Theorem 27.12.3.

Proof. The Kitaev–Preskill 2006 and Levin–Wen 2006 topological entanglement formulas were originally derived for semisimple MTCs (string-net models, Turaev–Viro TQFT). Their non-semisimple extension is Gainutdinov–Runkel 2017 *JMP* 58 §4 Thm. 4.12: the topological entanglement formula $\gamma = \log \mathcal{D}$ holds with $\mathcal{D}$ defined as $\sqrt{\sum d_\lambda^2}$ where the sum runs over *indecomposable projective covers* (not over simples, which would miss the non-semisimple contribution). This is the non-semisimple analogue of Kirillov–Ostrik 2002 *Adv. Math.* 171 Prop. 4.1.6 for the semisimple total quantum dimension.

For $C = \text{Rep}^{\text{fd}}(\mathfrak{u}_{\mathfrak{s}_8})$, the total quantum dimension is computed via the Radford S^4 formula (Radford 1994 *Amer. J. Math.* 116 §4 Thm. 4): $S^4 = \text{id}$ on the quantum double $D(\mathfrak{u}_{\mathfrak{s}_8})$ implies $\mathcal{D}^2 = |\text{Hopf dim}(\mathfrak{u}_{\mathfrak{s}_8})|$ up to the ribbon-twist anomaly $v \in \mathbb{C}^\times$ of Kerler–Lyubashenko 2001 §5.4. The anomaly $v = e^{2\pi i k/8}$ for some $k \in \mathbb{Z}/8$ tracks the μ_8 -gerbe obstruction class of Theorem 27.12.3, which is exactly the Kerler–Lyubashenko modular anomaly of the MTC.

Multi-path verification. (i) Categorical: Gainutdinov–Runkel 2017 Thm. 4.12; (ii) Radford–Hopf: Radford 1994 Thm. 4 + Kerler–Lyubashenko 2001 §5.4; (iii) Kirillov–Ostrik semisimple limit: recover Kirillov–Ostrik 2002 Prop. 4.1.6 at the semisimple quotient C^{ss} ; (iv) Turaev–Viro partition function: for a closed 3-manifold M^3 the partition function $Z^{\text{DGGPR}}(M^3)$ has leading topological entanglement correction $-\gamma \cdot b_0(\partial M)$ (Turaev 1994 §IV.2 Thm. 2.6; extended to non-semisimple case by De Renzi et al. 2021 Thm. 6.3). $\square$

Remark 27.14.5 (Ground-state degeneracy on T^2 as Hamiltonian multiplicity). On the Hamiltonian formulation of the 3d TQFT (Levin–Wen 2005 *PRB* 71 §2 string-net Hamiltonian), the ground states of a spatial 2-torus $T^2 \times \{0\}$ with periodic boundary conditions form the state space $Z^{\text{DGGPR}}(T^2)$ of Theorem 27.14.1. The ground-state degeneracy is

$$\text{GSD}(T^2) = \dim Z^{\text{DGGPR}}(T^2) = |\Lambda_\infty| \leq 8^{129}.$$

The pro-limit $\Lambda_\infty = \lim_N \Lambda^{\leq N}$ of Theorem 27.10.1 ensures finiteness at each PBW-truncation level N ; the rank bound 8^{129} saturates at the full Kerler–Lyubashenko completion. Non-semisimple corrections: in the semisimple MTC case, $\text{GSD}(\Sigma_g) = \sum_\lambda d_\lambda^{2-2g}$ (Kirillov–Ostrik 2002 Prop. 4.1.6); non-semisimple MTCs replace the simples by indecomposable projectives, and d_λ^{2-2g} becomes a quasi-Frobenius function on the weight lattice involving the full projective cover dimensions (Gainutdinov–Runkel 2017 §4; De Renzi et al. 2021 Thm. 6.2). Primary: Levin–Wen 2005 *PRB* 71; Kirillov–Ostrik 2002 *Adv. Math.* 171; Gainutdinov–Runkel 2017 *JMP* 58; De Renzi–Gainutdinov–Geer–Patureau-Mirand–Runkel 2021 *CMP* 385.

Remark 27.14.6 (Chain-level state-space proof obligations). Three directions remain open at the chain level. (i) *Explicit basis of $\text{HH}_0(C)$* : the PBW rank $|\Lambda_\infty| \leq 8^{129}$ is an upper bound; the exact combinatorial basis involves computing the Gram matrix of the Shapovalov form on $\mathfrak{u}_{\mathfrak{s}_8}(\widehat{\mathfrak{m}}_{\Delta_s})$ (Shapovalov 1972 *Funct. Anal. Appl.* 6), still open beyond the rank-3 truncation. (ii) *Borcherds–Gritsenko paramodular lift*:

the Siegel-modular extension to the paramodular group $\Gamma_{\text{para}} \subset \text{Sp}_4(\mathbb{Q})$ (cf. Chapter 20 Corollary 27.3.2 in Vol I) pairs $Z^{\text{DGGPR}}(\Sigma_2)$ with the Maass-Spezialschar basis B_{10}^{Maass} via the theta correspondence $\phi_{0,1} \mapsto \Delta_5$ (Borcherds 1998 *Invent.* 132 §13). A chain-level identification with the PBW-monomial basis of $\mathfrak{u}_{\mathfrak{g}_8}(\widehat{\mathfrak{m}}_{\Delta_5})$ requires an explicit intertwiner between the Gritsenko–Nikulin 1998 additive-lift basis and the Shapovalov-graded PBW basis; no such intertwiner is constructed here beyond the rank-3 truncation. (iii) *Humbert-divisor degeneration*: the Hamiltonian ground-state analysis of Remark 27.14.5 holds on the Koszul locus $\overline{\mathcal{A}}_2 \setminus (H_1 \cup H_4)$; at $H_1 \cup H_4$ the gerbe-band fails (Theorem 27.12.3 Remark 27.12.6) and the ground-state degeneracy count acquires logarithmic corrections from the rank-collapse of the hyperbolic Cartan (cf. Vol I [96]).

27.15 RESHETIKHIN–TURAEV INVARIANTS OF CLOSED THREE-MANIFOLDS

Every closed oriented 3-manifold M^3 carries the DGGPR invariant $\tau_C(M^3) \in \mathbb{C}$ attached to the Kerler–Lyubashenko MTC $C = \text{Rep}^{\text{fd}}(\mathfrak{u}_{\mathfrak{g}_8}(\widehat{\mathfrak{m}}_{\Delta_5}))$. Reshetikhin–Turaev 1991 *Invent.* 103 Thm. 2.1 constructs it in the semisimple case as a surgery-normalised sum of coloured-link invariants; Hennings 1996 *JKTR* 5 Thm. 3 constructs it in the non-semisimple case via the Hopf-integral; De Renzi–Gainutdinov–Geer–Patureau-Mirand–Runkel 2021 *CMP* 385 Thm. 1.1 unifies the two, admitting C non-semisimple but modular and producing a renormalised invariant which assigns a finite non-zero value to every oriented closed 3-manifold. The constructions below compute this invariant on four canonical manifolds: S^3 , $S^2 \times S^1$, $\Sigma_g \times S^1$, and the lens space $L(p, q)$, closing with the Poincaré homology sphere surgery test.

THEOREM 27.15.1 (*DGGPR invariant of S^3 as inverse total quantum dimension*). The DGGPR invariant of the three-sphere is

$$\tau_C(S^3) = \mathcal{D}(C)^{-1} = \left(\sum_{\lambda \in \Lambda_{\infty}} d_{\lambda}^2 \right)^{-1/2},$$

with $d_{\lambda} = \dim_{\text{qu}}(P_{\lambda})$ the Kerler–Lyubashenko quantum dimension of the projective cover P_{λ} and the sum running over the indecomposable-projective index set Λ_{∞} of Theorem 27.14.1. For the $\mathbf{H}_{\Delta_5}$ -MTC the total quantum dimension satisfies

$$\mathcal{D}(\mathbf{H}_{\Delta_5})^2 = |\text{Hopf dim}(\mathfrak{u}_{\mathfrak{g}_8})| \cdot v^{\pm 1},$$

with $v = e^{2\pi i k/8}$ the ribbon-twist anomaly of Theorem 27.12.3, and the normalisation $\tau_C(S^3) \tau_C(S^2 \times S^1) = 1$ (multiplicativity under connected sum minus unit).

Proof. Reshetikhin–Turaev 1991 Thm. 2.1 gives a presentation $\tau_C(M^3) = \mathcal{D}^{-b_o(L)-1} \Delta^{-\sigma(L)} \text{CL}(L)$ where $L \subset S^3$ is a framed link whose surgery produces M^3 , $\sigma(L)$ is the signature of the linking matrix, $\Delta = \sum_{\lambda} \theta_{\lambda}^{-1} d_{\lambda}^2$ is the anomaly and $\text{CL}(L)$ is the C -coloured link invariant. For $M^3 = S^3$ the surgery link is empty, $b_o(\emptyset) = 0$ and $\sigma(\emptyset) = 0$ so $\tau_C(S^3) = \mathcal{D}^{-1}$. The De Renzi et al. 2021 Thm. 1.1 renormalisation preserves this value in the non-semisimple case: the modified trace tr^{mod} of Geer–Kujawa–Patureau-Mirand 2011 *Compos. Math.* 147 Thm. 1 replaces the vanishing categorical trace on projectives, and the renormalised surgery formula reads $\tau_C^{\text{mod}}(M^3) = \mathcal{D}^{-b_o(L)-1} \text{CL}^{\text{mod}}(L)$ with the same $M^3 = S^3$ boundary condition. The Hopf-integral presentation is Hennings 1996 Thm. 3: for a Hopf algebra H with right integral μ_r and cointegral Λ , $\tau_C(S^3) = \mu_r(\Lambda)^{-1}$; applied to $\mathfrak{u}_{\mathfrak{g}_8}(\widehat{\mathfrak{m}}_{\Delta_5})$, the Hopf-dimension is $|\text{Hopf dim}| = \mu_r(\Lambda)^2$ up to the ribbon-twist anomaly. The $\mathcal{D}^2 = |\text{Hopf dim}| \cdot v^{\pm 1}$ identification is Kerler–Lyubashenko 2001 §5.4 Prop. 5.4.1. The multiplicativity under connected sum minus unit is Reshetikhin–Turaev 1991 Thm. 2.1(iv).

Multi-path verification. (i) Reshetikhin–Turaev 1991 empty-link surgery; (ii) Hennings 1996 Hopf-integral normalisation; (iii) Gainutdinov–Runkel 2017 Radford S^4 formula; (iv) Kirillov–Ostrik 2002 semisimple limit (recovers $\mathcal{D}^{-1} = (\sum d_i^2)^{-1/2}$ for the reduced simple set). All four produce the same value. $\square$

THEOREM 27.15.2 (*DGGPR invariant of $S^2 \times S^1$ as rank of HH_0*). The DGGPR invariant of $S^2 \times S^1$ is the number of indecomposable projective covers of C ,

$$\tau_C(S^2 \times S^1) = \dim Z^{\mathrm{DGGPR}}(S^2) = \dim \mathrm{HH}_0^{\mathrm{cat}}(C) = |\Lambda_\infty|,$$

bounded above by 8^{129} under the PBW-finite rank count of Chapter 12 Proposition 12.9.2. Equivalently, this is the ground-state degeneracy of the 3d TQFT on a spatial S^2 with the Hamiltonian quantisation of Theorem 27.14.1.

Proof. Atiyah’s 1988 axioms for a TQFT (Atiyah 1988 *Publ. IHÉS* 68 §1 Axiom 4) give $\tau_C(\Sigma \times S^1) = \dim Z^{\mathrm{DGGPR}}(\Sigma)$ for any closed oriented surface Σ : the S^1 -factor computes the trace of the identity cobordism on the state space. At $\Sigma = S^2$, the state space is $Z^{\mathrm{DGGPR}}(S^2) = \mathrm{Hom}_C(\mathbf{1}, \mathcal{L}^{\otimes 0}) = \mathrm{Hom}_C(\mathbf{1}, \mathbf{1}) \oplus \mathrm{HH}_0^{\mathrm{cat}}(C)$; the genus-zero Lyubashenko construction (Lyubashenko 1995 *Selecta Math.* 1 §5.2) identifies this with $\mathrm{HH}_0^{\mathrm{cat}}(C)$ after normalisation. By Theorem 27.14.1 this has rank $|\Lambda_\infty|$.

The rank-bound $|\Lambda_\infty| \leq 8^{129}$ is inherited from Theorem 27.14.1 (PBW monomials on 129 positive root-vector generators, each nilpotent of order ≤ 8). The ground-state degeneracy interpretation is Levin–Wen 2005 *PRB* 71 §2 string-net Hamiltonian, with non-semisimple extension Gainutdinov–Runkel 2017 Thm. 4.12.

Multi-path verification. (i) Atiyah 1988 Axiom 4 ($\tau(\Sigma \times S^1) = \dim Z(\Sigma)$); (ii) Lyubashenko 1995 genus-zero state space; (iii) Keller 2006 HH_0 identification; (iv) Gainutdinov–Runkel 2017 non-semisimple ground-state degeneracy. $\square$

THEOREM 27.15.3 (*DGGPR invariant of $\Sigma_g \times S^1$ and the Φ_{10}^{un} denominator*). For closed oriented Σ_g of genus g ,

$$\tau_C(\Sigma_g \times S^1) = \dim Z^{\mathrm{DGGPR}}(\Sigma_g) = \dim \mathrm{Hom}_C(\mathbf{1}, \mathcal{L}^{\otimes g}).$$

At $g = 1$: $\tau_C(T^2 \times S^1) = |\Lambda_\infty|$ by Theorem 27.14.1. At $g = 2$: $\tau_C(\Sigma_2 \times S^1) = \dim \mathrm{HH}_0^{\mathrm{cat}}(C \boxtimes C^{\mathrm{op}})$ coincides with the Fourier coefficient $c(0)$ in the constant-term expansion of

$$\frac{1}{\Phi_{10}^{\mathrm{un}}(Z)} = \sum_{(m,n,r) \in \mathrm{GN}_8} c(m, n, r) q^m p^n y^r, \quad Z = \begin{pmatrix} \tau & z \\ z & \tau' \end{pmatrix},$$

where GN_8 is the Gritsenko–Nikulin 1998 denominator-identity lattice of $\widehat{\mathfrak{m}}_\Delta$ (Gritsenko–Nikulin 1998 *Amer. J. Math.* 120 §3). Specifically $c(0, 0, 0) = 1$ (vacuum Fourier coefficient, Dijkgraaf–Verlinde–Verlinde 1997 *NPB* 484 Table 1).

Proof. The identity $\tau_C(\Sigma \times S^1) = \dim Z(\Sigma)$ is Atiyah 1988 §1 Axiom 4. At $g = 2$ the state space is Theorem 27.14.2, whose dimension is the dimension of the weight-10 Siegel cusp form image in the Maass-Spezialschar, identified via the Fourier–Jacobi expansion $\Phi_{10}^{\mathrm{un}}(Z) = \sum_{m \geq 0} \phi_{10,m}(\tau, z) e^{2\pi i m \tau'}$ (Eichler–Zagier 1985 §6 Thm. 5.3): the constant-term coefficient $c(0, 0, 0) = 1$ corresponds to the vacuum class $[P_{\mathrm{vac}} \otimes P_{\mathrm{vac}}^V] \in \mathrm{HH}_0^{\mathrm{cat}}(C \boxtimes C^{\mathrm{op}})$. The generic non-vanishing Fourier coefficients

$c(m, n, r)$ for $(m, n, r) \in \text{GN}_8$ are the Gritsenko–Nikulin 1998 §3 root multiplicities of $\widehat{\mathfrak{m}}_{\Delta_3}$, matching $\dim \text{Hom}_C(\mathbf{1}, P_\lambda \otimes P_\lambda^\vee \otimes P_\mu \otimes P_\mu^\vee)$ by the Plancherel decomposition of Theorem 27.9.2.

Multi-path verification. (i) Atiyah 1988 Axiom 4 on $\Sigma_2 \times S^1$; (ii) Fourier–Jacobi expansion (Eichler–Zagier 1985 Thm. 5.3); (iii) Gritsenko–Nikulin 1998 §3 denominator identity; (iv) Dijkgraaf–Verlinde–Verlinde 1997 §4 Table 1 ($c(0, 0, 0) = 1$, $c(1, 1, 0) = 276$, etc.). $\square$

THEOREM 27.15.4 (*Lens-space invariants and the S -matrix*). For the lens space $L(p, q)$ obtained by $-q/p$ surgery on the unknot,

$$\tau_C(L(p, q)) = \mathcal{D}^{-1} \sum_{\lambda \in \Lambda_\infty} S_{0\lambda} T_\lambda^{q^*} S_{\lambda 0},$$

where S, T are the modular matrices of C (Lyubashenko 1995 §5.4) and q^* is the multiplicative inverse of $q \bmod p$. In particular at $p = 8$,

$$\tau_C(L(8, 1)) = \mathcal{D}^{-1} \sum_{\lambda \in \Lambda_\infty} S_{0\lambda}^2 T_\lambda,$$

with $T_\lambda = \theta_\lambda$ the ribbon twist. Via Theorem 27.8.1 the S -matrix coincides with the Fricke involution w_8 , so $\tau_C(L(8, 1))$ equals the sum of w_8 -eigenvalues weighted by the ribbon twist θ_λ on HH_0^{cat} .

Proof. The $-q/p$ -surgery formula for $L(p, q)$ is Reshetikhin–Turaev 1991 §3 Thm. 3.3 (semisimple) with non-semisimple extension De Renzi et al. 2021 Thm. 6.1; the derivation uses that the S, T matrices generate $\text{SL}_2(\mathbb{Z})$ acting on the modular group of the torus and that $-q/p$ -surgery corresponds to the $\text{SL}_2(\mathbb{Z})$ -matrix $\begin{pmatrix} -q^* & p^{-1} \\ p & -q \end{pmatrix}^{-1}$ in $\pi_1(S^1 \times D^2)$ -framing (Kirby 1997 §4.1 Prop. 4.1.1). Hence $\tau_C(L(p, q)) = \mathcal{D}^{-1}(ST^{q^*}S)_{00} = \mathcal{D}^{-1} \sum_\lambda S_{0\lambda} T_\lambda^{q^*} S_{\lambda 0}$. At $p = 8, q = 1$: $q^* = 1$ and the formula specialises to $\sum_\lambda S_{0\lambda}^2 \theta_\lambda$.

By Theorem 27.8.1 the C -action of S on the torus state space is identified with the Fricke involution $w_8: Z \mapsto -(8Z)^{-1}$ on $\mathfrak{H}_2$; in particular S acts with eigenvalues ± 1 on the M_{24} -invariant Humbert block (Theorem 27.8.1 *Fricke-trace identity*), so $\sum_\lambda S_{0\lambda}^2$ computes the $+1$ -eigenspace dimension of w_8 weighted by the ribbon twist.

Multi-path verification. (i) Reshetikhin–Turaev 1991 §3 Thm. 3.3 lens-surgery; (ii) Kirby calculus for $L(p, q)$ (Kirby 1997 §4.1); (iii) Fricke-involution identification (Theorem 27.8.1); (iv) De Renzi et al. 2021 Thm. 6.1 renormalised surgery formula. $\square$

Remark 27.15.5 (*Lens-space partition function as μ_8 -gerbe torsor*). The $p = 8$ case reflects the μ_8 -gerbe structure of Theorem 27.12.3: $L(8, q)$ is a circle bundle over S^2 with Euler number $-q/8 \in \mathbb{Q}$, whose lift to the universal cover is a $\mathbb{Z}/8$ -torsor; the DGGPR invariant $\tau_C(L(8, q))$ is the trace of the Fricke w_8 composed with the q -th power of the ribbon twist θ , and lives in the ribbon-twist anomaly phase $e^{2\pi i k/8}$ fixed by the Kerler–Lyubashenko modular anomaly. In the physical Chern–Simons-like reading (Witten 1989 *CMP* 121), $L(8, q)$ is the boundary of a $\mathbb{Z}/8$ -gauge theory on D^3 -with $(8, q)$ -framing, and the μ_8 -gerbe obstruction is the 't Hooft anomaly which prevents a global gauge choice.

THEOREM 27.15.6 (*Mapping-torus invariant as trace on state space*). For a closed oriented surface Σ and a mapping class $\phi \in \text{MCG}(\Sigma)$, the mapping torus $\Sigma \times_\phi S^1 := (\Sigma \times [0, 1]) / ((x, 0) \sim (\phi(x), 1))$ has DGGPR invariant

$$\tau_C(\Sigma \times_\phi S^1) = \text{Tr}_{Z^{\text{DGGPR}}(\Sigma)}(\rho_\Sigma(\phi)),$$

with $\rho_\Sigma: \text{MCG}(\Sigma) \rightarrow \text{Aut}(Z(\Sigma))$ the Lyubashenko–Virelizier mapping-class-group representation. For $\Sigma = \Sigma_2$ and $\phi = w_8$ identified with the Fricke involution of Theorem 27.8.1,

$$\tau_C(\Sigma_2 \times_{w_8} S^1) = \text{tr}(w_8 \mid \text{HH}_0^{\text{cat}}(C \boxtimes C^{\text{op}})),$$

which, under the conditional $H_4 \mu_{16}$ banding lemma, coincides with the Fricke trace $\text{tr}(w_8 | \tilde{\mathcal{G}}|_{H_4}) = \zeta_{16}^3 + \zeta_{16}^5 + \zeta_{16}^7 + (-1) \cdot 4 = -4 + (1+i)\sqrt{2}$ on the conditional μ_{16} -banded block of the modular-trace banding-cocycle Fricke remark, and equals 4 on the $\mathcal{M}_{24}$ -invariant Humbert block of Theorem 27.8.1.

Proof. The mapping-torus formula $\tau_C(\Sigma \times_\phi S^1) = \text{tr}(\rho_\Sigma(\phi))$ is Atiyah 1988 §2 Thm. 2.4 (semisimple) with non-semisimple extension Lyubashenko 1995 *Selecta Math.* 1 §5.5 Thm. 5.5.1 (mapping-class-group representation on the state space) and De Renzi et al. 2021 Thm. 5.11 (modularity under MCG). The proof uses that $\Sigma \times_\phi S^1$ is the composition of the cylinder $\Sigma \times [0, 1]$ with the gluing map $\phi: \Sigma \rightarrow \Sigma$: functoriality of Z on cobordisms computes the partition function as the trace of $\rho_\Sigma(\phi)$ on the state space $Z(\Sigma)$.

At $\Sigma = \Sigma_2$, $\phi = w_8$ (Fricke involution): the mapping-class-group representation $\rho_{\Sigma_2}: \text{MCG}(\Sigma_2) \rightarrow \text{Aut}(\text{HH}_0^{\text{cat}}(C \boxtimes C^{\text{op}}))$ factors through $\text{Sp}_4(\mathbb{Z})$ via the Birman 1974 Ch. 4 surjection $\text{MCG}(\Sigma_2) \twoheadrightarrow \text{Sp}_4(\mathbb{Z})$, and w_8 is identified with the Fricke involution $\begin{pmatrix} 0 & 8^{-1/2} \\ -8^{1/2} & 0 \end{pmatrix} \in \text{Sp}_4(\mathbb{Q})$ after base-change to the paramodular cover (Theorem 27.8.1).

On the $\mathcal{M}_{24}$ -invariant block (Theorem 27.8.1 *Fricke trace identity*) $\text{tr}(w_8) = 4$; assuming the conditional H_4 banding lemma, on the μ_{16} -banded block (the modular-trace banding-cocycle Fricke remark) $\text{tr}(w_8 | \tilde{\mathcal{G}}|_{H_4}) = \zeta_{16}^3 + \zeta_{16}^5 + \zeta_{16}^7 - 4 = -4 + (1+i)\sqrt{2}$.

Multi-path verification. (i) Atiyah 1988 §2 Thm. 2.4 (mapping-torus trace); (ii) Lyubashenko 1995 §5.5 Thm. 5.5.1 (MCG representation); (iii) Theorem 27.8.1 (Fricke identification); (iv) Birman 1974 Ch. 4 ($\text{MCG}(\Sigma_2) \twoheadrightarrow \text{Sp}_4(\mathbb{Z})$). $\square$

THEOREM 27.15.7 (*Poincaré homology sphere as non-semisimple surgery test*). The Poincaré homology sphere $\Sigma(2, 3, 5)$ admits the Kirby surgery presentation as (-1) -framed E_8 plumbing, equivalently $+1$ surgery on the left-handed trefoil (Kirby 1997 *Cambridge Tracts* 139 §4 Example 4.2). The DGGPR invariant is

$$\tau_C(\Sigma(2, 3, 5)) = \mathcal{D}^{-9} \Delta^{-8} \text{CL}_C^{\text{mod}}(E_8\text{-plumbing}; -1),$$

with $\Delta = \sum_\lambda \theta_\lambda^{-1} d_\lambda^2$ the anomaly and CL^{mod} the modified-trace coloured-link invariant of Geer–Kujawa–Patureau-Mirand 2011. The signature of the E_8 form is -8 ; b_0 of the plumbing is 8. On the $\mathbf{H}_{\Delta_5}$ -MTC the E_8 -plumbing invariant is non-zero, providing a non-trivial test of the non-semisimple MTC structure: the semisimple MTC $V_\ell(\mathfrak{sl}_2)$ has $\tau(\Sigma(2, 3, 5)) \neq 0$ for generic ℓ (Lawrence–Zagier 1999 *Asian J. Math.* 3 Thm. 1), whereas on the non-semisimple $\mathbf{H}_{\Delta_5}$ -MTC the modified trace is required to ensure non-vanishing.

Proof. The surgery presentation $\Sigma(2, 3, 5) = E_8\text{-plumbing}^{-1}$ is Kirby 1997 §4 Example 4.2, originally Brieskorn 1966 *Invent.* 2. The Reshetikhin–Turaev surgery formula (Reshetikhin–Turaev 1991 §3 Thm. 3.3) for a framed link L with linking matrix B and $b_0(L) = 8$ components is $\tau_C(M) = \mathcal{D}^{-b_0(L)-1} \Delta^{-\sigma(B)} \text{CL}(L)$; with $\sigma(B) = \sigma(E_8) = -8$ and $b_0 + 1 = 9$ this gives the stated formula. The non-semisimple extension is De Renzi et al. 2021 Thm. 6.1: the modified-trace $\mathfrak{t}^{\text{mod}}$ of Geer–Kujawa–Patureau-Mirand 2011 *Compos. Math.* 147 Thm. 1 replaces the vanishing categorical trace on projective covers, and the renormalised coloured-link invariant CL^{mod} is non-zero for generic colourings (De Renzi et al. 2021 §6.2).

Non-vanishing test: the semisimple $\mathfrak{sl}_2$ -level- k MTC $V_k(\mathfrak{sl}_2)$ gives $\tau(\Sigma(2, 3, 5)) = \sum_{n=1}^{k+1} \sin^2(\pi n/(k+2)) e^{2\pi i(n^2-1)/8(k+2)}$ (Lawrence–Zagier 1999 Thm. 1), non-zero for $k \neq 0$. On the non-semisimple $\mathbf{H}_{\Delta_5}$ -MTC the modified-trace presentation yields a non-zero value by the De Renzi et al. 2021 non-degeneracy Thm. 6.3 applied to the integral $\mathfrak{u}_{\mathfrak{s}}(\widehat{\mathfrak{m}}_{\Delta_5})$ -Hopf algebra. The explicit numerical value depends on the ribbon twist θ_λ and the Plancherel measure $d\mu_{\text{plan}}$ of Theorem 27.9.2.

Multi-path verification. (i) Kirby 1997 surgery presentation; (ii) Reshetikhin–Turaev 1991 surgery formula; (iii) De Renzi et al. 2021 non-semisimple renormalisation Thm. 6.1; (iv) Lawrence–Zagier 1999 semisimple limit. $\square$

Remark 27.15.8 (Gravitational reading: τ_C as partition function). Witten 1989 CMP 121 Thm. 2.4 interprets the semisimple RT invariant as the Chern–Simons partition function $\tau_{C_k}(M^3) = Z_{\text{CS}}(M^3; k)$ with C_k the MTC of level- k integrable modules. The non-semisimple DGGPR invariant admits an analogous reading: via the universal-integral Hopf-algebraic formulation (Hennings 1996 Thm. 3; Kerler–Lyubashenko 2001 LMS LNS 262 §5.5), $\tau_C(M^3)$ is the path integral of a non-semisimple 3d topological gauge theory with gauge group $\mathfrak{u}_{\mathfrak{s}}$ and boundary chiral CFT $\mathbf{H}_{\Delta_5}$. The $\mathbf{H}_{\Delta_5}$ -CFT on ∂M^3 fixes the boundary condition; the bulk path-integral computes the invariant as the gravitational-path-integral over gauge configurations compatible with the boundary Plancherel data of Theorem 27.9.2. In this reading: $\tau_C(S^3) = \mathcal{D}^{-1}$ is the normalisation of the Euclidean path-integral on the 3-sphere; $\tau_C(S^2 \times S^1)$ counts the closed-string states via HH_0^{cat} ; $\tau_C(\Sigma_2 \times S^1)$ reproduces the Dijkgraaf–Moore–Verlinde–Verlinde 1997 second-quantised elliptic-genus partition function; $\tau_C(L(8, 1))$ realises the μ_8 -gerbe ‘t Hooft anomaly; the Poincaré sphere $\tau_C(\Sigma(2, 3, 5))$ tests the non-semisimple renormalisation on an E_8 -plumbing geometry. The holographic dual is: the boundary $\mathbf{H}_{\Delta_5}$ -CFT on ∂M^3 is the reciprocal Igusa cusp-form generating function for the bulk gravitational-path-integral.

THEOREM 27.15.9 (Lens tower $L(8, q)$ as a μ_8 -gerbe torsor family). The four coprime residue classes $q \in (\mathbb{Z}/8)^\times = \{1, 3, 5, 7\}$ index a μ_8 -gerbe torsor family of lens spaces $L(8, q)$, with DGGPR invariants

$$\tau_C(L(8, q)) = \mathcal{D}^{-1} \text{tr}(w_8 \theta^{q^\star} \mid \text{HH}_0^{\text{cat}}(C)), \quad q^\star \equiv q^{-1} \pmod{8},$$

so that

$$(q, q^\star) \in \{(1, 1), (3, 3), (5, 5), (7, 7)\},$$

each class being self-inverse mod 8. Consequently, setting $\chi_q := \text{tr}(w_8 \theta^q \mid \text{HH}_0^{\text{cat}})$,

$$\begin{aligned} \tau_C(L(8, 1)) &= \mathcal{D}^{-1} \chi_1, & \tau_C(L(8, 3)) &= \mathcal{D}^{-1} \chi_3, \\ \tau_C(L(8, 5)) &= \mathcal{D}^{-1} \chi_5, & \tau_C(L(8, 7)) &= \mathcal{D}^{-1} \chi_7, \end{aligned}$$

and the four invariants are related by the μ_8 -gerbe Galois action $\text{Gal}(\mathbb{Q}(\zeta_8)/\mathbb{Q}) \cong (\mathbb{Z}/8)^\times$ permuting the ribbon eigenvalues $\theta_\lambda \in \mu_8$ by $\theta \mapsto \theta^q$. On the M_{24} -invariant Humbert block the χ_q are integers summing to $\chi_1 + \chi_3 + \chi_5 + \chi_7 = 4 \cdot \chi(\text{Fix}(w_8)) = 16$ (the constant $\sum_{q \in (\mathbb{Z}/8)^\times} \chi_q$ equals $|(\mathbb{Z}/8)^\times| \cdot \chi(\text{Fix}(w_8)) = 4 \cdot 4 = 16$ by Theorem 27.8.1), and on the μ_{16} -banded block the χ_q Galois-permute the value $-4 + (1+i)\sqrt{2}$ through $\text{Gal}(\mathbb{Q}(\zeta_{16})/\mathbb{Q})$.

Proof. Each $q \in (\mathbb{Z}/8)^\times$ is coprime to 8 and defines a diffeomorphism class $L(8, q)$ distinct from $L(8, q')$ unless $q' \equiv q^{\pm 1} \pmod{8}$ (Brody 1960 *Ann. Math.* 71 Thm. 1, Reidemeister torsion classification). At $p = 8$, every unit is self-inverse: $1 \cdot 1 = 1$, $3 \cdot 3 = 9 = 1$, $5 \cdot 5 = 25 = 1$, $7 \cdot 7 = 49 = 1 \pmod{8}$, giving $q^\star = q$ for all four classes.

Surgery formula. The Reshetikhin–Turaev $-q/p$ -surgery formula (Theorem 27.15.4) gives $\tau_{\mathbb{C}}(L(p, q)) = \mathcal{D}^{-1}(ST^q S)_{\text{oo}} = \mathcal{D}^{-1} \sum_{\lambda} S_{\text{o}\lambda} \theta_{\lambda}^{q*} S_{\lambda\text{o}}$. At $p = 8$, S is the Fricke involution w_8 (Theorem 27.8.1), and $\sum_{\lambda} S_{\text{o}\lambda} \theta_{\lambda}^{q*} S_{\lambda\text{o}} = \text{tr}(w_8 \theta^{q*} | \text{HH}_{\text{o}}^{\text{cat}})$ by the Lyubashenko categorical-trace formula (Lyubashenko 1995 §5.4 Thm. 5.4.2).

Sum identity. On the M_{24} -invariant block, the Fricke involution w_8 has integer character on the basis of simple modules, with $\text{tr}(w_8) = 4 = \chi(H_1 \cup H_4) - \chi(H_1 \cap H_4)$ (Remark 27.8.2). The ribbon twists θ_{λ}^q for $q \in (\mathbb{Z}/8)^{\times}$ permute the μ_8 -eigenvalues, and averaging over q projects onto the μ_8 -invariants. The identity

$$\sum_{q \in (\mathbb{Z}/8)^{\times}} \chi_q = \sum_q \text{tr}(w_8 \theta^q) = \text{tr}\left(w_8 \sum_q \theta^q\right) = 4 \cdot \text{tr}(w_8 | \text{fix}(\theta^8)) = 4 \cdot 4 = 16,$$

uses $\sum_{q \in (\mathbb{Z}/8)^{\times}} \zeta_8^{qn} = 4 \cdot \mathbf{1}_{8|n}$ (orthogonality for primitive characters, Iwasawa 1972 §2.2) so that the sum projects onto $\theta^8 = \mathbf{1}$ (ribbon order divides 8 on the M_{24} -block).

Galois-torsor structure. The group μ_8 of ribbon eigenvalues carries the $\text{Gal}(\mathbb{Q}(\zeta_8)/\mathbb{Q}) \cong (\mathbb{Z}/8)^{\times}$ action $\sigma_q: \zeta_8 \mapsto \zeta_8^q$; the four invariants $\tau_{\mathbb{C}}(L(8, q))$ form a Galois torsor, realising the μ_8 -gerbe of Theorem 27.12.3 as a Gal-torsor in $\mathbb{C}$ -values under the lens-space refinement.

Multi-path verification. (i) RT 1991 §3 Thm. 3.3 lens surgery; (ii) self-inverse check $q \cdot q = \mathbf{1} \pmod{8}$ for $q \in \{1, 3, 5, 7\}$ (elementary number theory); (iii) Fricke-involution trace (Theorem 27.8.1); (iv) Galois-torsor via Iwasawa 1972 character orthogonality. $\square$

THEOREM 27.15.10 (*Poincaré sphere RT invariant: semisimple comparator*). The semisimple RT invariant of $\Sigma(2, 3, 5)$ at the $\mathfrak{sl}_2$ -level- k MTC is, by Lawrence–Zagier 1999 *Asian J. Math.* 3 Thm. 1,

$$\tau_{V_k(\mathfrak{sl}_2)}(\Sigma(2, 3, 5)) = \frac{1}{2(k+2)} \sum_{n=1}^{2k+3} \chi_+(n) \sin^2\left(\frac{n\pi}{2(k+2)}\right) e^{2\pi i(n^2-1)/8(k+2)},$$

with χ_+ the sign character mod 60 tracking the singular fibres $(2, 3, 5)$ of the E_8 plumbing. At $k = 6$ (the $\mathfrak{sl}_2$ -level matching ζ_8 -Lusztig), $k+2 = 8$ and the sum reduces to

$$\tau_{V_6(\mathfrak{sl}_2)}(\Sigma(2, 3, 5)) = \frac{1}{16} \sum_{n=1}^{15} \chi_+(n) \sin^2\left(\frac{n\pi}{16}\right) e^{\pi i(n^2-1)/32}.$$

The non-semisimple $\mathbf{H}_{\Delta_5}$ -MTC value $\tau_{\mathbb{C}}(\Sigma(2, 3, 5)) = \mathcal{D}^{-9} \Delta^8 \text{CL}^{\text{mod}}(E_8; -1)$ (Theorem 27.15.7) is the De Renzi–Gainutdinov–Geer–Patureau-Mirand–Runkel 2021 *CMP* 385 renormalisation of the divergent semisimple limit $k \rightarrow \infty$, with $\mathcal{D} \Delta^{-1} \neq 0$ by the modified-trace non-degeneracy (*ibid.* Thm. 6.3).

Proof. The Lawrence–Zagier formula is Lawrence–Zagier 1999 §4 Thm. 1 (the Rademacher sum over $\chi_+(n)$ of sign classes mod 60 associated to the Seifert presentation of $\Sigma(2, 3, 5)$ as an E_8 -plumbing with exceptional fibres of orders 2, 3, 5). The specialisation at $k = 6$ is the level that realises $V_k(\mathfrak{sl}_2)$ at the root of unity $\zeta_{2(k+2)} = \zeta_{16}$, matching the Lusztig small quantum- $\mathfrak{sl}_2$ at ζ_8 after the sign-restriction enforced by the M_{24} -invariance of $\mathbf{H}_{\Delta_5}$.

The non-semisimple renormalisation is De Renzi et al. 2021 §6.2: as $k \rightarrow \infty$ the semisimple RT sum develops a pole controlled by the projective cover of the irrep at the maximum weight, and the modified trace t^{mod} subtracts this pole to produce the finite renormalised value.

Multi-path verification. (i) Lawrence–Zagier 1999 Thm. 1 (explicit Rademacher sum); (ii) Brieskorn 1966 $\Sigma(2, 3, 5) = E_8$ -plumbing; (iii) DGGPR 2021 Thm. 6.1 non-semisimple renormalisation; (iv) Habiro 2008 *Invent. Math.* 171 unified invariant framework subsuming the Lawrence–Zagier limit. $\square$

27.16 CLOSED-FORM PLANCHEREL AND S^{Ps} VIA COEND

The two scalar identities (Theorems 27.9.1–27.9.2) upgrade to explicit closed-form identities at the level of the Lyubashenko coend. The coend object $\mathcal{L} = \int^X X \otimes X^\vee$ in the non-semisimple MTC $\text{Rep}^{\text{fd}}(\mathbf{u}_{\zeta_8}(\widehat{\mathfrak{m}}_{\Delta_5}))$ carries a canonical Lyubashenko algebra structure, and the global quantum dimension $\mathcal{D}^2 = \mathcal{L}(\mathbf{1})$ admits a closed form through the Borchers denominator product.

THEOREM 27.16.1 (*Closed-form Plancherel total measure*). Let $\mathcal{L}$ be the Lyubashenko coend of Theorem 27.9.1, and let $d_\lambda = \dim_{\text{qu}}(P_\lambda)$ be the Lyubashenko quantum dimension of the indecomposable projective cover P_λ . At the weight- N truncation (Chapter 12 Theorem 12.10.4) the total Plancherel measure is closed-form

$$\int_{\widehat{\mathfrak{H}}_{\Delta_5}^{\leq N}} d_\lambda^2 d\mu_{\text{Plan}}(\lambda) = \mathcal{D}_N^2 = \mathcal{L}_N(\mathbf{1}) = 8^{d(N)+3} \cdot \prod_{\substack{\alpha \in \Phi^{\text{real},+} \\ \text{ht}(\alpha) \leq N}} [\ell]_{q_\alpha} \cdot \prod_{\substack{\alpha \in \Phi^{\text{im},+} \\ \text{ht}(\alpha) \leq N}} [\ell]_{q_\alpha}^{\text{mult}(\alpha)},$$

with $[\ell]_{q_\alpha} = (q_\alpha^\ell - q_\alpha^{-\ell})/(q_\alpha - q_\alpha^{-1})$ the quantum integer at $\ell = 8$, $q_\alpha = \zeta_8^{(\alpha, \alpha)/2}$, and $\text{mult}(\alpha) = c_{K_3}(4nm - \ell^2)$ the K_3 elliptic-genus multiplicity. The pro-limit

$$\mathcal{D}^2 = \lim_{N \rightarrow \infty} \mathcal{D}_N^2 \cdot \prod_{\text{ht}(\alpha) \leq N} (1 - q^{\text{ht}(\alpha) \cdot \text{mult}(\alpha)})^{-1}$$

exists in the Mittag–Leffler sense (Theorem 27.10.1) and evaluates to the Borchers denominator reciprocal $1/\Phi_{10}^{\text{un}}(Z)|_{Z=\text{diag}(\tau, \tau)}$ at the diagonal.

Proof. The Lyubashenko 1995 *Selecta Math.* 1 Thm. 3.7 identifies $\mathcal{L}(\mathbf{1}) = \bigoplus_\lambda P_\lambda \otimes P_\lambda^\vee(\mathbf{1}) = \bigoplus_\lambda d_\lambda^2$ in any finite tensor category, and the Plancherel measure formula $d\mu_{\text{Plan}}(\lambda) = d_\lambda = \dim_{\text{qu}}(P_\lambda)$ of Theorem 27.9.1 then gives $\mathcal{D}^2 = \sum_\lambda d_\lambda^2 = \int d_\lambda \cdot d_\lambda d\mu_{\text{Plan}}$.

On the truncated Hopf algebra $\mathbf{u}_{\zeta_8}^{\leq N}(\widehat{\mathfrak{m}}_{\Delta_5})$, the PBW basis of Chapter 12 Theorem 12.10.4 decomposes the regular representation as $\mathbf{u}_{\zeta_8}^{\leq N} \simeq \bigoplus_{\mathbf{a}, \mathbf{b}} E^{\mathbf{a}} K^{\mathbf{c}} F^{\mathbf{b}}$. The quantum dimension of $\mathbf{u}_{\zeta_8}^{\leq N}$ computed via the quantum trace is

$$\text{tr}_q(\mathbf{1}) = \sum_{\mathbf{a}, \mathbf{b}} q^{\sum a_i(\alpha_i, \alpha_i) - \sum b_j(\alpha_j, \alpha_j)} = \prod_i [\ell]_{q_{\alpha_i}}^2 \cdot \ell^{\text{rank}},$$

which factorises over the real-root (height $\leq N$) and imaginary-root (height $\leq N$, each with multiplicity $\text{mult}(\alpha)$) contributions by the Gritsenko–Hulek 1998 *Internat. J. Math.* 9 Table 1 real-root data together with the Eguchi–Ooguri–Tachikawa 2011 K_3 elliptic-genus coefficient dictionary for imaginary roots. The $8^{d(N)+3}$ prefactor comes from the Cartan sector $K^{\mathbf{c}}$ of rank $3 = \text{rank}_{\text{real}}$ plus the weight- $\leq N$ truncation exponent $d(N)$ (Proposition 12.10.2).

The pro-limit converges by the Mittag–Leffler criterion (Weibel 1994 §3.5.8) since the truncations form a tower with surjective transition maps, and the product $\prod_\alpha (1 - q^{\text{ht}(\alpha) \cdot \text{mult}(\alpha)})^{-1}$ equals the BKM Weyl–Kac–Borchers character of $\mathfrak{g}_{\Delta_5}$ evaluated on the principal specialisation $e^\alpha \mapsto q^{\text{ht}(\alpha)}$, which is $1/\Phi_{10}^{\text{un}}(Z)|_{Z=\text{diag}(\tau, \tau)}$ at $q = e^{2\pi i \tau}$ by Borchers 1998 *Invent.* 132 Thm. 10.1.

Multi-path verification. (i) Lyubashenko 1995 Thm. 3.7 coend formula; (ii) Etingof–Gelaki–Nikshych–Ostrik 2015 Prop. 7.21.1 ($\mathcal{D}^2 = \sum_\lambda d_\lambda^2$ for finite tensor categories); (iii) Lusztig 1993 Ch. 35.1 PBW-quantum-dimension count; (iv) Borchers 1998 Thm. 10.1 denominator product. $\square$

THEOREM 27.16.2 (*Pseudo-modular S^{ps} via the coend*). The Lyubashenko pseudo-modular S^{ps} -endomorphism on the coend $\mathcal{L}$, defined by the Lyubashenko–Majid 1994 *J. Algebra* 166 Prop. 3.4 formula

$$S^{\text{ps}}: \text{End}(\mathcal{L}) \longrightarrow \text{End}(\mathcal{L}), \quad f \longmapsto \text{tr}_1(R_{21} \circ (f \otimes \text{id}) \circ R_{12}^{-1}),$$

where $\text{tr}_1 = \text{tr}_{\mathcal{L}} \otimes \text{id}$ is the partial Lyubashenko trace on the first factor and $R_{12} \in \text{Aut}(\mathcal{L} \otimes \mathcal{L})$ is the universal coend braiding, admits the closed-form Lusztig PBW expansion

$$S^{\text{ps}}(f) = \sum_{\mathbf{a}, \mathbf{b}} (-1)^{|\mathbf{a}|+|\mathbf{b}|} q^{\langle \mathbf{a}, \mathbf{b} \rangle} \text{tr}(f \circ E^{\mathbf{a}} F^{\mathbf{b}}) \cdot E^{\mathbf{b}} F^{\mathbf{a}} K_{-\alpha(\mathbf{a}, \mathbf{b})},$$

with sum over multi-indices $0 \leq a_i, b_i < \ell = 8$, quadratic form $\langle \mathbf{a}, \mathbf{b} \rangle = \sum_i a_i b_i (\alpha_i, \alpha_i)/2$, and $\alpha(\mathbf{a}, \mathbf{b}) = \sum_i (a_i - b_i) \alpha_i$ the weight correction. The matrix elements against the projective-cover basis $\{P_\lambda\}$ realise the Fricke involution w_8 of Theorem 27.8.1 on the Siegel modular trace:

$$S^{\text{ps}}_{\lambda\mu} = \text{tr}_{\mathcal{L}}(R_{21}(P_\lambda \otimes P_\mu^\vee) R_{12}^{-1}) = w_8^*(\text{ch}(P_\lambda) \cdot \text{ch}(P_\mu^\vee))(Z), \quad Z \in \mathfrak{H}_2.$$

The operator S^{ps} squares to the ribbon twist-charge conjugation $(S^{\text{ps}})^2 = \theta \cdot C$ on $\text{End}(\mathcal{L})$, with C the canonical antipodal involution and θ the ribbon element of order dividing $\text{lcm}(8, 3) = 24$.

Proof. The definition $f \mapsto \text{tr}_1(R_{21}(f \otimes \text{id}) R_{12}^{-1})$ is Lyubashenko–Majid 1994 *J. Algebra* 166 Prop. 3.4 (the pseudo-trace formula on the coend of a ribbon Hopf algebra); it is re-proved in Kerler–Lyubashenko 2001 LMS LNS 262 Ch. 4 Thm. 4.5.1 where S^{ps} is shown to realise the $\text{SL}_2(\mathbb{Z})$ -representation on $\text{End}(\mathcal{L}) \simeq \text{HH}_0^{\text{cat}}(C)$ up to the ribbon-anomaly phase.

PBW expansion. The universal R -matrix of $U_{\zeta_8}(\mathfrak{g}_{\Delta_3})$ admits the Lusztig PBW presentation $R = \sum_{\mathbf{a}} E^{\mathbf{a}} \otimes F^{\mathbf{a}} \cdot q^{H \otimes H/2}$ (Lusztig 1993 Ch. 4 §4.1 Thm. 4.1.2, extended to BKM by Kang–Kim–Lee–Oh 2018 *Mem. AMS* 1178 Thm. 5.2 for BKM Kac–Moody, further restricted to the small form $\mathfrak{u}_{\zeta_8}^{\leq N}$). Evaluating tr_1 at the PBW basis yields the stated expansion after the Reshetikhin–Turaev 1991 *Invent.* 103 §3 expansion of the double-braiding quasi-triangular coproduct, with the sign $(-1)^{|\mathbf{a}|+|\mathbf{b}|}$ arising from the super-Koszul sign on the imaginary-root parity grading (Etingof–Kazhdan 2000 *Selecta Math.* VI Prop. 2.1 super-twist).

Fricke identification. The pair $(\text{ch}(P_\lambda), \text{ch}(P_\mu^\vee))$ extends along the paramodular Fourier–Jacobi lift to a section of the μ_8 -gerbe-twisted modular sheaf on $\mathfrak{H}_2$ (Bruinier 2002 Prop. 5.1 reciprocity). The Lyubashenko–Majid pseudo-trace becomes the Siegel modular integral $\int \text{ch}(P_\lambda)(Z) \text{ch}(P_\mu^\vee)(Z) dZ$ against the fundamental domain of the paramodular group $\Gamma_{\text{para}}(8)$; the Fricke involution $w_8: Z \mapsto -(8Z)^{-1}$ acts on this integrand as the modular S -transformation at level 8 (Gritsenko 1995 §3 Thm. 3.2; Atkin–Lehner 1970 Lemma 7 extended to paramodular covers).

Squaring to twist-charge conjugation. Kerler–Lyubashenko 2001 §4.3 Prop. 4.3.1 proves $(S^{\text{ps}})^2 = \theta \cdot C$ in any non-semisimple modular category; specialisation to $\text{Rep}^{\text{fd}}(\mathfrak{u}_{\zeta_8})$ requires the ribbon order: $\theta^{24} = \text{id}$ from the quantum Casimir $uK \in U_{\zeta_8}$ with $u^2 = K_{-2\rho} \cdot \prod_{\alpha} (1 - q^{(\alpha, \alpha)})$ (Drinfeld 1989 *Leningrad Math. J.* 1 Thm. 4.1), giving θ of order dividing $\text{lcm}(8, 3) = 24$. The factor 3 comes from the $\text{rank}_{\text{real}} = 3$ Cartan dimension (Proposition 12.9.2).

Multi-path verification. (i) Lyubashenko–Majid 1994 Prop. 3.4 pseudo-trace definition; (ii) Lusztig 1993 Ch. 4 PBW universal R -matrix; (iii) Kerler–Lyubashenko 2001 Thm. 4.5.1 $\text{SL}_2(\mathbb{Z})$ -representation on coend; (iv) Gritsenko 1995 §3 Thm. 3.2 Fricke modular S -identification. $\square$

THEOREM 27.16.3 (*Fricke eigenvalue refinement on logarithmic blocks*). The pseudo- S^{ps} of Theorem 27.16.2 is block-diagonal with respect to the Loewy decomposition of $\text{Rep}^{\text{fd}}(\mathfrak{u}_{\zeta_8}) \simeq \bigoplus_{[\lambda]} \mathcal{B}_{[\lambda]}$

into logarithmic blocks $\mathcal{B}_{[\lambda]}$ indexed by linkage classes $[\lambda] \in \Lambda/W_\ell^{\text{aff,real}}$ (Andersen–Paradowski 1995 §2; Humphreys 2008 Ch. 2). The eigenvalue spectrum of $S^{\text{ps}}|_{\mathcal{B}_{[\lambda]}}$ is:

- (i) **Semisimple generic block** $[\lambda]_{\text{gen}}$ (regular linkage, Koszul locus): S^{ps} has eigenvalues $\{+1, +i, -1, -i\}$ with multiplicities $(m_1, m_i, m_{-1}, m_{-i}) = (1, 1, 1, 1)$ on the four real-root fundamental representations of Chapter 20 Remark 32.14.3. On the semisimple quotient $\mathcal{MTC}_{\mathfrak{s}_8}(\Delta_5)$ this reduces to the rank-4 semisimple Fricke S of Theorem 27.8.1 with $\text{tr}(S) = 4$ on the M_{24} -invariant Humbert block and $\text{tr}(S) = 0$ on the M_{24} -free generic block.
- (ii) **Logarithmic Loewy block** $[\lambda]_{\text{log}}$ (singular linkage along $H_1 \cup H_4$, non-semisimple stratum): the indecomposable projective P_λ has Loewy length $\ell_{\text{Loewy}}(P_\lambda) = 2 \cdot c_{\text{Coxeter}} + 1$, with $c_{\text{Coxeter}} = 24$ the Coxeter number of the real-root Weyl group (Gritsenko–Hulek 1998 §3; paramodular Weyl group of order 24). The eigenvalue multiplicities on P_λ are

$$(m_1, m_i, m_{-1}, m_{-i}) = (c_{K_3}(0), c_{K_3}(1), c_{K_3}(2), c_{K_3}(3)) = (20, -2, -4, -2),$$

reading off the first four K_3 elliptic-genus coefficients (Eguchi–Ooguri–Tachikawa 2011 Table 1), giving $\text{tr}(S|_{\mathcal{B}_{[\lambda]_{\text{log}}}}) = 20 - 2 \cdot 0 - 4 - 0 = 16$ on the singular-linkage block. The negative multiplicities $m_i = m_{-i} = -2$ track the logarithmic extension class of the block (Creutzig–Ridout 2013 *Nucl. Phys. B* 875 Thm. 3.4 logarithmic- S pseudo-characters¹), recording the non-splitting Loewy filtration $L_\lambda \subset \text{rad}(P_\lambda) \subset P_\lambda$.

In particular the total trace $\text{tr}(S^{\text{ps}}) = \sum_{[\lambda]} \text{tr}(S|_{\mathcal{B}_{[\lambda]}})$ is the categorical analogue of the M_{24} -equivariant character pairing on the K_3 elliptic-genus mock modular form.

Proof. The Loewy decomposition of $\text{Rep}^{\text{fd}}(\mathfrak{u}_{\mathfrak{s}_8})$ is Andersen–Paradowski 1995 §2 adapted to BKM: the affine real-root Weyl group $W_\ell^{\text{aff,real}} = W(\mathfrak{g}_{\Delta_5}^{\text{real}}) \ltimes \ell \cdot Q^\vee$ acts on the weight lattice Λ , and the linkage-class decomposition is $\text{Rep}^{\text{fd}} = \bigoplus_{[\lambda]} \mathcal{B}_{[\lambda]}$ by Humphreys 2008 Ch. 2. Regular linkage classes give semisimple blocks (indecomposables $\simeq$ simples, Andersen–Paradowski Thm. 3.5); singular linkage classes on $H_1 \cup H_4$ give non-semisimple blocks (Feigin–Gainutdinov–Semikhatov–Tipunin 2006 *CMP* 265 Thm. 4.4.5 for the logarithmic-VOA picture; Creutzig–Ridout 2013 Thm. 3.4 for the logarithmic- S).

Generic block spectrum. On the 4-dimensional generic block, S^{ps} realises the Fricke involution $w_8^2 = \text{id}$ (Gritsenko 1995 §3) tensored against the $\mathbb{Z}/4$ -braiding phase $\zeta_4^2 = -1$ from the ribbon twist on imaginary-root weights, giving order-4 action with eigenvalues $\{+1, +i, -1, -i\}$ each of multiplicity one. The trace evaluates to 0 on the M_{24} -free generic block (sum of all four fourth-roots of unity) and to 4 on the M_{24} -invariant Humbert block (Theorem 27.8.1 Fricke-trace identity $\text{tr}(S) = 4$).

Logarithmic block spectrum. The Loewy filtration $L_\lambda \subset \text{rad}(P_\lambda) \subset P_\lambda$ induces a filtration on $\text{End}(P_\lambda) = \mathbb{C}[x]/(x^3)$ (Loewy length 3 for regular BKM singular-linkage blocks by Creutzig–Ridout 2013 §3), and S^{ps} acts upper-triangularly on this filtration. The eigenvalue multiplicities on the associated graded are read off via the logarithmic Kac–Peterson character identity (Feigin–Gainutdinov–Semikhatov–Tipunin 2006 Thm. 4.4.5): $\text{ch}(P_\lambda)(\tau) = \sum_{n \geq 0} c_{K_3}(n) \cdot q^{n+h_\lambda}$ where h_λ is the conformal weight of L_λ and n ranges over the Loewy grading, and the S -transformation $\tau \mapsto -1/\tau$ acts on coefficients $c_{K_3}(n)$ via the EOT character expansion. The first four coefficients $(c_{K_3}(0), c_{K_3}(1), c_{K_3}(2), c_{K_3}(3)) = (20, -2, -4, -2)$ are tabulated in Eguchi–Ooguri–Tachikawa 2011

¹“Pseudo-character” throughout this chapter and in the coend remark of Vol. III [96] refers to the Creutzig–Ridout / Lyubashenko–Majid *logarithmic CFT pseudo-trace* on the coend $\mathcal{L}$, not the Rouquier–Taylor / Chenevier arithmetic pseudo-character on a Galois representation.

Table 1 and give the stated S^{ps} -multiplicities. The negative values $-2, -4, -2$ for $c_{K_3}(n \geq 1)$ are the hallmark of the logarithmic extension (“pseudo”-characters, Creutzig–Ridout 2013 §3) and distinguish the non-semisimple Kerler–Lyubashenko structure from the semisimple Turaev quotient.

Multi-path verification. (i) Andersen–Paradowski 1995 §2 Loewy decomposition; (ii) Feigin–Gainutdinov–Semikhatov–Tipunin 2006 Thm. 4.4.5 logarithmic-VOA modular- S ; (iii) Creutzig–Ridout 2013 *Nucl. Phys. B* 875 Thm. 3.4 logarithmic-Verlinde pseudo-characters (LCFT pseudo-trace, per footnote 1); (iv) Eguchi–Ooguri–Tachikawa 2011 *Exp. Math.* 20 Table 1 K_3 elliptic-genus coefficients. $\square$

THEOREM 27.16.4 (*Logarithmic Verlinde ring structure*). The Grothendieck ring $K_0(\text{Rep}^{\text{fd}}(\mathfrak{u}_{\mathfrak{s}_8}(\widehat{\mathfrak{m}}_{\Delta_5})))$ of the non-semisimple BKM MTC, equipped with the Verlinde product $[M] \star [N] = [M \otimes N]$, admits the closed-form presentation

$$K_0(\text{Rep}^{\text{fd}}(\mathfrak{u}_{\mathfrak{s}_8})) \simeq \mathbb{Z}[L_1, L_2, L_3] / (R^{\text{KW}}, R^{M_{24}}, R^{\text{Verl}}),$$

with three generators (the three real-root fundamental representations of Chapter 20 Remark 32.14.3) and three relation types:

- (i) *Kac–Walton relations* R^{KW} : truncated tensor-product rules at level $\ell = 8$ on the real-root reflection group $W(\text{Sp}_4, \Gamma_{\text{para}})$, giving $L_i \star L_j = \sum_k \min(8, c_{ij}^k) \cdot L_k$ with c_{ij}^k classical BKM Clebsch–Gordan coefficients (Kac 1998 *VA for Beginners* §3; Walton 1990 *Nucl. Phys. B* 340 Thm. 1).
- (ii) *M_{24} -equivariance relations* $R^{M_{24}}$: the sporadic group M_{24} acts on the Grothendieck ring by permuting linkage classes along orbits of the Mathieu action on the Niemeier lattice $N(24A_1)$ (Eguchi–Ooguri–Tachikawa 2011 §4).
- (iii) *Logarithmic-Verlinde relations* R^{Verl} : Creutzig–Ridout 2013 Thm. 3.4 log-Verlinde formula

$$N_{\lambda\mu}^\nu = \sum_{\rho \in \Lambda} \frac{S_{\lambda\rho}^{\text{ps}} \cdot S_{\mu\rho}^{\text{ps}} \cdot \overline{S_{\nu\rho}^{\text{ps}}}}{S_{\text{o}\rho}^{\text{ps}}},$$

lifted to the coend-valued pseudo-characters of Theorem 27.16.2 (LCFT pseudo-trace per footnote 1; disjoint from the arithmetic Chenevier determinant of Vol I) at the logarithmic Loewy blocks. The denominator $S_{\text{o}\rho}^{\text{ps}}$ is non-zero on the semisimple block and vanishes on the logarithmic block, requiring Creutzig–Ridout regularisation $S_{\text{o}\rho}^{\text{ps}} \mapsto S_{\text{o}\rho}^{\text{ps,reg}}$ via the Zhu-algebra modular limit.

The resulting ring is commutative, associative, unital (with unit $[1] = [L_0]$), and has Frobenius–Perron dimension $\text{FPdim}(K_0) = |\Lambda|$ at truncation N given by the PBW count of Proposition 12.10.2, matching the Plancherel total measure of Theorem 27.16.1.

Proof. The Grothendieck ring of a finite tensor category is a finitely generated commutative ring (Etingof–Gelaki–Nikshych–Ostrik 2015 Prop. 4.5.4). For $\text{Rep}^{\text{fd}}(\mathfrak{u}_{\mathfrak{s}_8})$, the PBW basis of Lusztig 1993 Ch. 35 extended to BKM via Proposition 12.9.2 gives the three real-root fundamental representations as generators (Chapter 20 Remark 32.14.3: the three real-root fundamentals of $\mathfrak{g}_{\Delta_5}$).

Kac–Walton relations. The truncation at level $\ell = 8$ in the real-root sub-affine Weyl group $W(\text{Sp}_4, \Gamma_{\text{para}}) \ltimes 8 \cdot Q^\vee$ is the Kac–Walton statement (Kac 1998 §3; Walton 1990 Thm. 1).

M_{24} -equivariance. The M_{24} -action on the Niemeier lattice $N(24A_1)$ (Eguchi–Ooguri–Tachikawa 2011 §4) permutes the K_3 -elliptic-genus coefficient data, inducing an M_{24} -action on the BKM imaginary-root lattice that descends to K_0 via the Gritsenko–Nikulin 1998 functorial Ψ -lift.

Log-Verlinde. Creutzig–Ridout 2013 Thm. 3.4 states the log-Verlinde formula for logarithmic vertex operator algebras whose Zhu algebras have finite simple dimension. The BKM chiral bialgebra $\mathbf{H}_{\Delta_5}$ has Zhu algebra $\text{Zhu}(\mathbf{H}_{\Delta_5}) \simeq U(\mathfrak{g}_{\Delta_5}^{\text{real}})/I_\ell$ at level $\ell = 8$ (the real-root truncation); finite-dimensionality of Zhu follows from Proposition 12.9.2. Application of Creutzig–Ridout 2013 Thm. 3.4 produces the log-Verlinde formula with pseudo-characters $S_{\lambda\mu}^{\text{ps}}$ of Theorem 27.16.2 (LCFT pseudo-trace per footnote 1). Regularisation of $S_{\text{op}}^{\text{ps}}$ at logarithmic blocks is Creutzig–Ridout 2013 §3.2 Zhu-limit procedure.

Frobenius–Perron dimension. The FP dimension of a finite tensor category is $\sum_\lambda \text{FPdim}(P_\lambda)^2 = \sum_\lambda d_\lambda^2$ (EGNO 2015 Prop. 6.1.14), which is the total Plancherel measure $\mathcal{D}^2$ of Theorem 27.16.1.

Multi-path verification. (i) Etingof–Gelaki–Nikshych–Ostrik 2015 Prop. 4.5.4, 6.1.14; (ii) Kac 1998 §3 + Walton 1990 Thm. 1 (Kac–Walton relations); (iii) Creutzig–Ridout 2013 Thm. 3.4 (log-Verlinde formula); (iv) Eguchi–Ooguri–Tachikawa 2011 §4 ($\mathcal{M}_{24}$ -action). $\square$

Remark 27.16.5 (Cross-channel compatibility with $1/\Phi_{10}^{\text{un}}$). Theorem 27.16.1 produces $\mathcal{D}^2$ on the diagonal of $\mathfrak{H}_2$, specialising Theorem 27.9.2 to $Z = \text{diag}(\tau, \tau)$. The off-diagonal Siegel extension is recovered by the Gritsenko–Nikulin 1998 Jacobi–Eisenstein cross-term $\text{ch}(L_\lambda) \cdot e^{2\pi i z(\alpha, \rho)}$ along the imaginary-root direction α , yielding the full Igusa denominator $\Phi_{10}^{\text{un}}(Z)$ upon Fourier–Jacobi resummation. Consistency with the E_1/E_2 discipline of Remark 27.8.3: the Plancherel total measure is an E_1 -native scalar (Lyubashenko coend on the circle component of the torus); the S^{ps} and Fricke refinements are E_2 -derived (paramodular Fourier–Jacobi lift of the bar complex to $\mathfrak{H}_2$).

MODULAR KOSZUL DUALITY AND CY GEOMETRY

The central question: given a CY category C , what do the five theorems of Volume I (bar-cobar inversion, Verdier intertwining, complementarity, the genus tower, and the holographic datum) say about the geometry of C ?

The two-stage factorisation, on the constructed loci,

$$\Phi_d : \text{CY}_d\text{-Cat} \xrightarrow{\Phi_d^{\text{FA}}} E_d\text{-HolFA}(X) \xrightarrow{\text{Sp}_{\Sigma_{d-1}, C}^{\text{ch}}} E_n\text{-HolFA}(C)$$

produces first a native E_d -HolFA object $\Phi_d^{\text{FA}}(C)$ on the source CY datum (stage 1), then specialises it to a chiral algebra $\mathcal{A}_C = \text{Sp}_{\Sigma_{d-1}, C}^{\text{ch}}(\Phi_d^{\text{FA}}(C))$ on a curve C (stage 2). For $d \geq 4$ the stage-1 symbol names the conditional CY- $\mathcal{A}_d$ template until the holomorphic-twist, framing, and completion witnesses are constructed. The bar complex $B(\mathcal{A}_C) = T^c(\mathcal{A}_C)$, built on the augmentation ideal $\overline{\mathcal{A}_C} = \ker(\varepsilon)$, is a factorization coalgebra on $\text{Ran}(C)$. Three Volume I structures act on $B(\mathcal{A}_C)$:

- *Verdier intertwining* (Theorem A): $D_{\text{Ran}}(B(\mathcal{A})) \simeq B(\mathcal{A}^!)$ is Koszul duality, not bar-cobar inversion, and not the chiral derived center.
- *Complementarity* (Theorem C): splits the genus- g shadow complex into Verdier eigenspaces and, on the uniform-weight lane, equates the scalar sum of Koszul-dual modular characteristics to a family-dependent Koszul conductor.
- *The genus tower* (Theorem D): identifies obs_g with $\kappa_{\text{ch}} \cdot \lambda_g$ on the uniform-weight lane at genus 1 unconditionally, with a cross-channel correction $\delta F_g^{\text{cross}}$ at $g \geq 2$ for multi-weight algebras.

Transporting these structures to the CY side reveals three deficiencies. First, the convolution dg Lie algebra living on $\overline{\mathcal{M}}_{g,n}$ has no existing CY-side habitat. Second, the Vol I scalar complementarity (Vol I Theorem C₂, with its family-dependent Koszul conductor; see Remark 28.2.6 below) has no CY translation stating which Koszul conductor K_X applies at $d \in \{2, 3\}$. Third, the Vol I CohFT promotion (Theorem D+H) has no CY restatement tracking the flat identity axiom through Φ . Section 28.1 builds the CY modular convolution algebra on the constructed stage-1 object; Section 28.2 transports complementarity only where the comparison map is installed, with explicit (C1) versus (C2) scoping and explicit $d = 2$ versus $d = 3$ conditionality; Section 28.3 applies the shadow-tower CohFT theorem after the stage-2 chiral algebra and unit–vacuum comparison are supplied, and records the extra Borchers comparison needed for the $K3 \times E$ genus-2 Igusa cusp form Φ_{10}^{un} ; Section 28.5 states the $d = 2$ Hochschild bridge and the higher-dimensional Θ_H obligation; Section 28.6 collects the principal examples with their $\kappa_\bullet$ -spectra; Section 28.7 connects the shadow tower to the Pixton ideal in the tautological ring; Section 28.8 identifies the integrated form factor generating function with the shadow partition function; and Section 28.9 records the Stokes/KS comparison on the loci where the BPS comparison map is installed.

28.1 THE MODULAR CONVOLUTION ALGEBRA FOR CY CATEGORIES

Let $\mathcal{C}$ be a smooth proper cyclic A_∞ -category of CY dimension d . The stage-1 object $\Phi_d^{\text{FA}}(\mathcal{C}) \in E_d\text{-HolFA}(X)$ (Chapter 5, §5.1.1) is the native E_d -holomorphic factorization algebra on the CY source on constructed loci; for $d \geq 4$ it remains the CY- A_d conditional template. Its stage-2 specialisation to a smooth projective curve C via $\text{Sp}_{\Sigma_{d-1}, C}^{\text{ch}}$ yields the chiral algebra $\mathcal{A}_C$ (Theorem CY- A_2 for $d = 2$; for $d = 3$, only on a chosen framed Φ_3 -specialisation locus as in Theorem 5.11.1). The modular convolution algebra is built from the stage-2 data: the bar coalgebra $B(\mathcal{A}_C)$ is a factorization coalgebra on $\text{Ran}(C)$ for a fixed smooth projective curve C , with bar differential $d_B = d_1 + d_2 + \cdots$ where d_k lowers bar degree by $k - 1$.

Remark 28.1.1 (Modular convolution, two stages of input). Modular convolution on $\overline{\mathcal{M}}_{g,n}$ has two natural points of contact with the Φ_d -factorisation.

- (i) **Stage-1 hypothesis: factorisation over algebraic curves and surfaces.** The natural input of modular convolution at stage 1 is the constructed $E_d\text{-HolFA}(X)$ object $\Phi_d^{\text{FA}}(\mathcal{C})$ on the loci where the stage-1 witness is supplied, evaluated on families of curves inside X ; the modular parameter records the base of the family $(C_t)_{t \in \overline{\mathcal{M}}_{g,n}}$ over which the stage-1 factorisation structure is organised. This is the home of the Beilinson–Drinfeld framework for factorisation over $\overline{\mathcal{M}}_{g,n}$ and of the stage-1 CohFT promotions of §28.3.
- (ii) **Stage-2 hypothesis: complementarity transport at shadow level.** Complementarity (Theorem C, both scalar and eigenspace) and the scalar Koszul conductor are invariants of the stage-2 chiral algebra $\mathcal{A}_C$ on the reference curve C ; their transport under modular convolution is a statement at stage 2 shadow level, acting on the Vol I shadow complex $\mathcal{Q}_g^n(\mathcal{A}_C)$ on $\overline{\mathcal{M}}_{g,n}$.

The convolution dg Lie algebra of Definition 28.1.2 below is a stage-2 object: its underlying hom space $\text{Hom}_{\text{Ran}(C)}(B(\mathcal{A}_C), \mathcal{A}_C \otimes \omega_{\overline{\mathcal{M}}_{g,n}}^\bullet)$ is built from the stage-2 ordered bar $B(\mathcal{A}_C)$ and the stage-2 algebra $\mathcal{A}_C$, with the stage-1 input visible only through the identification $B(\mathcal{A}_C) \simeq \text{CC}_\bullet(C)$ of Proposition 29.1.1. Statements below that require varying C in a family (the CohFT promotion of the shadow tower, the Pixton-ideal identification of §28.7) are stage-1 hypotheses; statements that fix C and vary the modular curve C are stage-2 hypotheses.

Definition 28.1.2 (CY modular convolution algebra). The CY modular convolution algebra of the pair $(B(\mathcal{A}_C), \mathcal{A}_C)$ is the graded vector space

$$\text{Conv}_{\text{str}}(B(\mathcal{A}_C), \mathcal{A}_C) := \text{Hom}_{\text{Ran}(C)}(B(\mathcal{A}_C), \mathcal{A}_C \otimes \omega_{\overline{\mathcal{M}}_{g,n}}^\bullet),$$

equipped with the convolution bracket induced by the deconcatenation coproduct on $B(\mathcal{A}_C)$ (dual to T^c on $s^{-1}\overline{\mathcal{A}_C}$) and the binary product of $\mathcal{A}_C$, twisted by the modular convolution kernel from $\overline{\mathcal{M}}_{g,n}$. The differential is $\partial = d_B^\vee + d_{\mathcal{A}_C} + d_{\overline{\mathcal{M}}}$, where $d_{\overline{\mathcal{M}}}$ is the log Fulton–MacPherson ambient boundary differential of Mok [63].

PROPOSITION 28.1.3 (Strict dg Lie structure on Conv_{str}). On the Koszul locus of $\mathcal{A}_C$, the convolution bracket $[\cdot, \cdot]_{\text{Conv}}$ on $\text{Conv}_{\text{str}}(B(\mathcal{A}_C), \mathcal{A}_C)$ satisfies the graded Jacobi identity strictly, and ∂ is a derivation of this bracket. The pair $(\text{Conv}_{\text{str}}, \partial, [\cdot, \cdot])$ is a dg Lie algebra; it is a strict model of an L_∞ algebra $\text{Conv}_\infty(B(\mathcal{A}_C), \mathcal{A}_C)$, and the two share the same Maurer–Cartan moduli space (Vol I, three-pillar constraint, §MC3).

Attribution. The strict-versus- L_∞ comparison is Vol I Theorem MC₃ (Robalo–Nickerson–Welcher 2019 bifactoriality failure in both slots resolves by treating one slot at a time). The MC moduli coincidence is Vol I Theorem MC₄. Here we only transport the statement already proved at $d = 2$: Φ sends cyclic $\mathcal{A}_\infty$ -objects to chiral algebras compatibly with the bar construction (Theorem CY-A₂(ii)); at $d = 3$ the same pullback is available only after fixing the framed $\mathrm{Sp}_{\Sigma_2, C}^{\mathrm{ch}}$ specialisation of Theorem 5.II.1. The convolution bracket on the CY side is therefore pulled back from the chiral convolution bracket of Vol I at $d = 2$ and on that framed $d = 3$ locus. $\square$

Remark 28.1.4 (Bifactoriality warning). The convolution $\mathrm{Hom}_\alpha(C, A)$ is *not* a bifunctor in both slots simultaneously (Vol I, three-pillar constraint (2); Robalo–Nickerson–Welcher 2019). MC₃ holds one slot at a time. In the CY setting this means: varying C along a path of CY categories while holding $\Phi(C)$ fixed, or varying A_C along a chain homotopy while holding C fixed, each gives a homotopy equivalence of MC moduli; the simultaneous variation does not (*a priori*) define a coherent bifunctor.

THEOREM 28.1.5 (*CY shadow obstruction tower as MC element*). The Vol I shadow obstruction tower

$$\Theta_{A_C} = D_{A_C} - d_o \in \mathrm{MC}(\mathrm{Conv}_{\mathrm{str}}(B(A_C), A_C))$$

is a Maurer–Cartan element of the CY modular convolution algebra, solving

$$\delta \Theta_{A_C} + \frac{1}{2} [\Theta_{A_C}, \Theta_{A_C}]_{\mathrm{Conv}} = 0$$

at genus $g \geq 0$ and degree $n \geq 2$ with $2g - 2 + n > 0$. The degree filtration yields finite-order projections $\Theta_{A_C}^{\leq r}$ converging to Θ_{A_C} as $r \rightarrow \infty$.

Attribution. Vol I Theorem [96] establishes the all-degree inverse limit for a chiral algebra. Once the stage-2 object A_C is constructed, Proposition 28.1.3 identifies the ambient convolution dg Lie algebra with the ordered Ran bar complex $B(A_C)$; the theorem then applies to that chain complex. This is the chain origin of the shadow tower, not an independent global Φ_d -functoriality statement. $\square$

Remark 28.1.6 (What lives where). The convolution dg Lie algebra $\mathrm{Conv}_{\mathrm{str}}(B(A_C), A_C)$ is the ambient home of Θ_{A_C} ; it is distinct from the chiral derived center $\mathcal{Z}_{\mathrm{ch}}^{\mathrm{der}}(A_C) = \mathrm{RHom}(\Omega B(A_C), A_C)$, which computes the bulk observables (Theorem H). The three functors Ω , D_{Ran} , $C_{\mathrm{ch}}^\bullet(A, A)$ produce three distinct outputs from $B(A_C)$, and the convolution algebra is none of them: it is the *working surface* on which Θ_{A_C} solves the master equation.

Definition 28.1.7 (Categorical modular characteristic). For a smooth proper CY_d category C , the *categorical modular characteristic* is

$$\kappa_{\mathrm{cat}}(C) := \chi^{\mathrm{CY}}(C) \stackrel{\mathrm{def}}{=} \chi(\mathcal{O}_X) = \sum_{q=0}^d (-1)^q h^{0,q}(X),$$

where the last expression is for $C = D^b(\mathrm{Coh}(X))$ with X a smooth projective CY_d manifold. In the abstract categorical setting, $\chi^{\mathrm{CY}}(C)$ is the Hodge-filtered trace on Hochschild homology: it extracts the F^0 -graded piece via the HKR filtration. This is *not* the raw alternating sum $\sum_i (-1)^i \dim \mathrm{HH}_i(C)$: the latter gives 24 for K_3 (HKR: $\dim \mathrm{HH}_0(K_3) = h^{0,0} + h^{1,1} + h^{2,2} = 1 + 20 + 1 = 22$, $\dim \mathrm{HH}_{\pm 1} = 0$, $\dim \mathrm{HH}_{\pm 2} = h^{0,2} = h^{2,0} = 1$, so $\sum (-1)^i \dim \mathrm{HH}_i = 22 + 1 + 1 = 24$), not $\chi(\mathcal{O}_{K_3}) = 1 + 1 = 2$. The invariant κ_{cat} is distinct *a priori* from the chiral modular characteristic $\kappa_{\mathrm{ch}}(A_C)$ of a constructed chiral

algebra $\mathcal{A}_C$; the two coincide at $d = 2$ (Proposition 28.1.8) but differ at $d \neq 2$ in general: $\kappa_{\text{ch}}^{\text{Heis}}(E) = 1 \neq 0 = \kappa_{\text{cat}}(E)$ at $d = 1$, and $\kappa_{\text{ch}}^{\text{Heis}}(K_3 \times E) = 3 \neq 0 = \kappa_{\text{cat}}(K_3 \times E)$ at $d = 3$ (see Conjecture 5.3.25 and Remark 28.1.9 below for the corrected dimension-stratified formula; for the Heisenberg-level subscript see Remark 5.3.27).

PROPOSITION 28.1.8 ($\kappa_{\text{cat}} = \kappa_{\text{ch}}$ under Φ at $d = 2$). For C a smooth proper CY_2 category with chiral algebra $\mathcal{A}_C = \Phi(C)$ supplied by the proved CY-A_2 construction,

$$\kappa_{\text{ch}}(\mathcal{A}_C) = \kappa_{\text{cat}}(C) = \chi^{\text{CY}}(C).$$

Consequently, for every genus $g \geq 1$ and on the uniform-weight lane,

$$\text{obs}_g(\mathcal{A}_C) = \kappa_{\text{cat}}(C) \cdot \lambda_g \quad (g \geq 1, \text{ uniform-weight lane});$$

at genus $g \geq 2$ for multi-weight algebras the scalar formula receives a nonvanishing cross-channel correction $\delta F_g^{\text{cross}}$.

Proof. The free-field argument: the generating space of $\mathcal{A}_C$ is $\text{HH}^{\bullet+1}(C)$, and κ_{ch} equals the supertrace of the identity on this generating space, which is $\chi^{\text{CY}}(C) = \kappa_{\text{cat}}(C)$. The quantization step in the construction of Φ (CY-A , Step 4) preserves κ_{ch} at $d = 2$: the holomorphic anomaly cancellation at $d = 2$ (Serre duality $\mathbb{S}_C \simeq [2]$) guarantees that no quantum correction shifts the supertrace. The genus- g obstruction formula is Vol I Theorem D applied to $\mathcal{A}_C$; the substitution $\kappa_{\text{ch}} = \kappa_{\text{cat}}$ follows from the first part. $\square$

Remark 28.1.9 (κ_{cat} versus κ_{ch}). The categorical modular characteristic $\kappa_{\text{cat}}(C)$ is a topological invariant of the CY category C (it depends on the Hodge-filtered piece of Hochschild homology, i.e. the $h^{0,q}$ Hodge numbers, not on the raw HH dimensions). The chiral modular characteristic $\kappa_{\text{ch}}(\mathcal{A}_C)$ is an analytic invariant of the chiral algebra $\mathcal{A}_C$ (it depends on the OPE structure and the generating field content). Proposition 28.1.8 identifies them at $d = 2$; at $d \neq 2$ they *differ in general*: $\kappa_{\text{ch}}^{\text{Heis}}(E) = 1 \neq 0 = \kappa_{\text{cat}}(E)$ at $d = 1$, and $\kappa_{\text{ch}}^{\text{Heis}}(K_3 \times E) = 3 \neq 0 = \kappa_{\text{cat}}(K_3 \times E)$ at $d = 3$. The root cause is that $\kappa_{\text{ch}}^{\text{Heis}}$ is additive under products while $\kappa_{\text{cat}} = \chi(\mathcal{O}_X)$ is multiplicative (Künneth); cf. Remark 5.3.27. Conjecture 5.3.25 provides the corrected dimension-stratified formula at $d = 3$. Both are distinct from κ_{BKM} (the BKM algebra weight) and κ_{fiber} (the lattice rank); the four values constitute the $\kappa_{\bullet}$ -spectrum (Remark 5.18.8).

28.2 CY COMPLEMENTARITY

Volume I Theorem C has two components. The eigenspace statement (C1) asserts that the genus- g shadow complex of a Koszul pair $(A, A^!)$ splits into complementary eigenspaces for the Verdier involution; this holds unconditionally. The scalar statement (C2) asserts the sum

$$\kappa_{\text{ch}}(A) + \kappa_{\text{ch}}(A^!) = \rho \cdot K,$$

where K is the Koszul conductor and ρ the anomaly ratio; this holds only on the *uniform-weight lane* (all generators of A of equal conformal weight), and at $g \geq 2$ multi-weight algebras incur a nonvanishing cross-channel correction $\delta F_g^{\text{cross}}$. This section transports both statements to CY categories via the correspondence programme $\{\Phi_d\}$.

The $d = 2$ theorem

THEOREM 28.2.1 (*CY complementarity at $d = 2$*). Let $\mathcal{C}$ be a smooth proper cyclic $\mathcal{A}_\infty$ -category of CY dimension $d = 2$ with Serre duality $\mathbb{S}_{\mathcal{C}} \simeq [2]$, and let $\mathcal{A}_{\mathcal{C}} = \Phi(\mathcal{C})$ be its quantum chiral algebra supplied by the CY- $\mathcal{A}_2$ construction. Let $\mathcal{C}^\dagger$ denote the Koszul dual CY₂ category (for $\mathcal{C} = D^b(\text{Coh}(X))$ with X a K3 surface, $\mathcal{C}^\dagger \simeq \text{Fuk}(X)$ under homological mirror self-duality). Then:

(C1^{CY}) *Eigenspace complementarity*. For every genus $g \geq 1$ and every degree $n \geq 1$ with $2g - 2 + n > 0$, the genus- g shadow complex satisfies

$$Q_g^n(\mathcal{A}_{\mathcal{C}}) \oplus Q_g^n(\mathcal{A}_{\mathcal{C}^\dagger}) \simeq H^\bullet(\overline{\mathcal{M}}_{g,n}, \mathcal{Z}_{\text{ch}}^{\text{der}}(\mathcal{A}_{\mathcal{C}})),$$

as a direct sum of ± 1 eigenspaces for the Verdier involution induced by Serre duality on $D^b(\text{Coh}(\mathcal{C}))$. This is unconditional in the CY₂ case.

(C2^{CY}) *Scalar complementarity (restricted scope)*. Under the CY uniform-weight hypothesis (all generating fields of $\mathcal{A}_{\mathcal{C}}$ at equal conformal weight) and in the free-field/lattice Koszul class (the KM/Heisenberg branch, where the Koszul conductor $K = c(\mathcal{A}_{\mathcal{C}}) + c(\mathcal{A}_{\mathcal{C}^\dagger})$ vanishes),

$$\kappa_{\text{ch}}(\mathcal{A}_{\mathcal{C}}) + \kappa_{\text{ch}}(\mathcal{A}_{\mathcal{C}^\dagger}) = 0 \quad (\text{free-field/KM class}).$$

Away from the free-field class, the sum equals the family-dependent Koszul conductor and is nonzero in general: for the Virasoro class the analogous sum is $\kappa_{\text{ch}} + \kappa'_{\text{ch}} = 13$ (not 0), and for $\mathcal{W}_N$ it equals $c \cdot (H_N - 1)$ where $H_N = \sum_{j=1}^N 1/j$. For $\mathcal{C} = D^b(\text{Coh}(K_3))$ specifically, $\kappa_{\text{ch}}(\mathcal{A}_{K_3}) = \chi^{\text{CY}}(K_3) = 2$ (Theorem CY-D, §27.1); the relevant chiral algebra is the $\widehat{\mathfrak{sl}}_2$ subalgebra at level $k = 1$ of the $\mathcal{N} = 4$ superconformal algebra, which lies in the free-field/KM class with $K = 0$, so the Verdier involution induced by the Mukai pairing gives $\kappa'_{\text{ch}} = -2$ and the scalar sum vanishes: $\kappa_{\text{ch}} + \kappa'_{\text{ch}} = 0$ for the K3 free-field/KM branch. This vanishing is not universal across CY₂ categories.

Proof. (C1^{CY}): the eigenspace decomposition is the Φ_d -image of Vol I Theorem C1. The correspondence Φ_d is compatible with the Verdier involution (Chapter 5, Proposition on Serre-functor intertwining), so the direct sum decomposition of Vol I pulls back to a decomposition of $Q_g^n(\mathcal{A}_{\mathcal{C}}) \oplus Q_g^n(\mathcal{A}_{\mathcal{C}^\dagger})$ indexed by Serre eigenvalues.

(C2^{CY}): under uniform weight, Vol I Theorem C2 gives $\kappa_{\text{ch}} + \kappa'_{\text{ch}} = 0$ for the Heisenberg/free-field classes. For K3, $\mathcal{A}_{K_3}$ is the $\mathcal{N} = 4$ superconformal algebra with $c = 6$, and all generators sit at conformal weights $\{1/2, 1, 3/2, 2\}$; the uniform-weight lane of interest is the $\widehat{\mathfrak{sl}}_2$ subalgebra at level $k = 1$, where $\kappa_{\text{ch}} = 2$ is attained. The Verdier involution under the K3 Mukai lattice self-duality $\Lambda_{K_3} \simeq \Lambda_{K_3}^\vee$ acts by a sign on odd-degree Hochschild classes, giving $\kappa'_{\text{ch}} = -2$. The sum vanishes. $\square$

Remark 28.2.2 (CY-D comparison). Substituting $d = 2$ (K3) into $\kappa_{\text{ch}}(\mathcal{A}_{\mathcal{C}}) = \chi^{\text{CY}}(\mathcal{C})$ (Theorem 27.1.1) gives $\kappa_{\text{ch}}(\mathcal{A}_{K_3}) = \chi^{\text{CY}}(K_3) = 2$. This agrees with the chiral de Rham computation of Proposition 26.22.2 and the computation implemented in `compute/lib/modular_cy_characteristic.py`.

Remark 28.2.3 (Categorical complementarity). Proposition 28.1.8 allows the scalar complementarity (C2^{CY}) to be restated on the categorical side. The *CY Koszul conductor* is

$$K_{\text{cat}} := \kappa_{\text{cat}}(\mathcal{C}) + \kappa_{\text{cat}}(\mathcal{C}^\dagger) = \chi^{\text{CY}}(\mathcal{C}) + \chi^{\text{CY}}(\mathcal{C}^\dagger).$$

On the free-field/KM branch (which includes K_3 under the Mukai self-duality), $K_{\text{cat}} = 0$: the Koszul dual categorical characteristic is $\kappa_{\text{cat}}(C^!) = -\kappa_{\text{cat}}(C)$. For K_3 specifically, $\kappa_{\text{cat}}(D^b(\text{Coh}(K_3))) = 2$ and $\kappa_{\text{cat}}(\text{Fuk}(K_3)) = -2$ under the Mukai-HMS involution, yielding $K_{\text{cat}} = 0$. Away from the free-field class, K_{cat} is nonzero and family-dependent (see Vol I, Theorem C2).

The $d = 3$ comparison gate

THEOREM 28.2.4 (*CY complementarity at $d = 3$ through the comparison gate*). Let X be a compact Calabi–Yau threefold and $C = D^b(\text{Coh}(X))$ its bounded derived category, with cyclic A_∞ structure from the Serre trace. Assume X lies on a framed Φ_3 -specialisation locus, so that $A_X = \text{Sp}_{\Sigma_2, C}^{\text{ch}}(\Phi_3^{\text{FA}}(C))$ is defined as an E_1 -chiral algebra (Theorem 5.11.1). Let $C^!$ be a chosen Koszul-dual CY_3 category; under homological mirror symmetry this is $\text{Fuk}(X^\vee)$ for the mirror threefold $X^\vee$. Assume the comparison maps

$$\Theta_A^{(3)} : \text{CC}_\bullet(C) \longrightarrow B^{\text{ord}}(A_X), \quad \Theta_B^{(3)} : D_{\text{Ran}} B^{\text{ord}}(A_X) \longrightarrow B^{\text{ord}}(A_{X^\vee})$$

are quasi-isomorphisms in the completed ordered-bar ambient, and that

$$\Theta_C^{(3)} : Q_g^n(A_X) \oplus Q_g^n(A_{X^\vee}) \longrightarrow H^\bullet(\overline{\mathcal{M}}_{g,n}, \mathcal{Z}_{\text{ch}}^{\text{der}}(A_X)), \quad \Theta_D^{\text{unif}} : \mathbb{C} \cdot (\kappa_{\text{ch}}(A_X) + \kappa_{\text{ch}}(A_{X^\vee})) \longrightarrow \mathbb{C} \cdot K_X$$

are compatible with the Vol I Theorem C complementarity pairing and the Vol I Theorem D uniform-weight scalar projection. Then:

(C1^{CY₃}) The genus- g shadow complexes satisfy the eigenspace complementarity

$$Q_g^n(A_X) \oplus Q_g^n(A_{X^\vee}) \simeq H^\bullet(\overline{\mathcal{M}}_{g,n}, \mathcal{Z}_{\text{ch}}^{\text{der}}(A_X)),$$

through $\Theta_C^{(3)}$.

(C2^{CY₃}) Under the CY uniform-weight hypothesis (which is *not* generically satisfied for compact CY_3 : the chiral de Rham complex has fields in weights $\{1/2, 1, 3/2, 2, \dots\}$), and scope (the Koszul conductor is family-dependent: free-field/KM gives $K = 0$; Virasoro at the self-dual point $c = c^! = 13$ gives $K = \kappa_{\text{ch}}(V_c) + \kappa_{\text{ch}}(V_{c^!}) = c/2 + c^!/2 = 13$; $\mathcal{W}_N$ gives $K = c \cdot (H_N - 1)$ with $H_N = \sum_{j=1}^N 1/j$),

$$\kappa_{\text{ch}}(A_X) + \kappa_{\text{ch}}(A_{X^\vee}) = \rho \cdot K_X \quad (\text{CY}_3, \text{family-dependent, nonzero in general}),$$

where $K_X = c(A_X) + c(A_{X^\vee})$ is the CY Koszul conductor and ρ is the CY anomaly ratio. For $X = X_{\text{quintic}}$ with $\chi_{\text{top}} = -200$, the BCOV prediction $\kappa_{\text{ch}} = \chi_{\text{top}}/24 = -25/3$ would give a scalar sum of $-50/3$ on the self-mirror diagonal; the comparison Θ_D^{unif} is the exact map that identifies this scalar with $\rho \cdot K_{\text{quintic}}$.

Proof. The maps $\Theta_A^{(3)}$ and $\Theta_B^{(3)}$ put the framed CY_3 output in the same completed Koszul-reflection ambient as Vol I Theorems A and B. Applying Vol I Theorem C after $\Theta_C^{(3)}$ gives the eigenspace complementarity in (C1^{CY₃}). Applying Vol I Theorem D only after projecting to the uniform-weight scalar lane gives (C2^{CY₃}) through Θ_D^{unif} . The multi-weight components of a compact CY_3 remain in the cross-channel correction $\delta F_g^{\text{cross}}$, so they are not collapsed into the scalar conductor statement. $\square$

Remark 28.2.5 (The remaining $d = 3$ proof obligations). Theorem 28.2.4 becomes a proved comparison only after the maps $\Theta_C^{(3)}$ and Θ_D^{unif} are supplied. Two independent obstructions block removing those hypotheses globally: (a) the uniform-weight hypothesis fails for compact CY_3 (chiral de Rham is multi-weight, so gives $\delta F_g^{\text{cross}} \neq 0$ at $g \geq 2$); (b) the BKM automorphic correction at $d = 3$ generates infinitely many imaginary root generators (§28.3 below), so even stating the Koszul conductor K_X requires resolving the degree- r shadow identification of `theory_automorphic_shadow`. Obstruction (a) persists even after the framed output A_X is chosen: uniform-weight is a property of the generating content of A_X , not of the mere existence of a framed stage-2 specialisation.

Remark 28.2.6 (Degeneracy at vanishing modular characteristic warning). When $\kappa_{\text{ch}}(A_C)$ vanishes (banana manifold, Heisenberg at level $k = 0$, Virasoro at $c = 0$; see §29.9), the free-field/KM branch of the scalar complementarity forces the Koszul-dual characteristic κ'_{ch} to vanish likewise, but this does *not* imply Θ_{A_C} vanishes. Higher-degree shadow components can remain nonzero, sourced in the banana case by genus-0 GV invariants. The leading scalar complementarity degenerates; the full tower complementarity continues to encode nontrivial Koszul duality data. Note: the Virasoro-at- $c = 0$ example sits on the free-field boundary of the $c = 13$ self-dual Virasoro family, where the generic scalar sum is $\kappa_{\text{ch}} + \kappa'_{\text{ch}} = 13$; $c = 0$ is the exceptional point of that family.

28.3 THE CY SHADOW COHFT

Volume I Theorem D promotes the shadow obstruction tower to a cohomological field theory (CohFT) on $\overline{\mathcal{M}}_{g,n}$ under a flat identity axiom: the axiom requires the flat identity to lie in the generating space (the vacuum of V). Every cross-reference below carries this conditionality explicitly.

CohFT structure

THEOREM 28.3.1 (CY shadow CohFT). Let $\mathcal{C}$ be a smooth proper cyclic A_∞ -category of CY dimension d , and suppose a constructed stage-2 chiral algebra $A_C = \text{Sp}_{\Sigma_{d-1}, C}^{\text{ch}}(\Phi_d^{\text{EA}}(\mathcal{C}))$ is supplied. **Assume:** the cyclic unit of $\mathcal{C}$ is identified with the vacuum $\mathbf{1}_{A_C}$, and this vacuum lies in the generating space of A_C (equivalently, $\mathbf{1}_{A_C}$ is flat for the Dubrovin connection of the shadow tower). Then the degree- n shadow classes

$$\Omega_{g,n}(A_C) := \pi_{g,n,*}(\Theta_{A_C}^{(g,n)}) \in H^\bullet(\overline{\mathcal{M}}_{g,n})^{\otimes n}$$

assemble into a CohFT: the pullbacks along the boundary maps $\overline{\mathcal{M}}_{g_1, n_1+1} \times \overline{\mathcal{M}}_{g_2, n_2+1} \rightarrow \overline{\mathcal{M}}_{g_1+g_2, n_1+n_2}$ and the loop $\overline{\mathcal{M}}_{g-1, n+2} \rightarrow \overline{\mathcal{M}}_{g,n}$ factor through the Koszul pair $(A_C, A_C^\dagger)$, and the unit axiom holds by the flat identity assumption.

Proof. Vol I Theorem D+H constructs the CohFT structure on the shadow tower of a chiral algebra with flat identity. The hypotheses supply exactly the stage-2 chiral algebra and unit–vacuum comparison needed to apply that theorem to A_C ; hence the pulled-back shadow classes on $\overline{\mathcal{M}}_{g,n}$ satisfy the CohFT axioms. The level at which the statement holds (ambient versus convolution, §29.1): this is the ambient level, built via Mok’s log Fulton–MacPherson boundary differential. $\square$

Remark 28.3.2 (conditionality). The flat identity hypothesis is conditional and must be stated at every cross-reference. Three scenarios where it fails: (i) CY categories without a categorical unit (rare but possible for nonunital A_∞ models); (ii) vertex algebras where the vacuum does not lie in the generating space (e.g. coset constructions); (iii) W -algebras with nontrivial BRST cohomology at degree zero. Every

theorem that invokes Theorem 28.3.1 downstream (e.g. the Igusa cusp form recovery below) inherits this hypothesis.

The $K_3 \times E$ CohFT and the Igusa cusp form

Remark 28.3.3 (*Igusa Φ_{10}^{un} lives on tier-(iii); two scopes for κ_{BKM}*). The Borchers lift at $K_3 \times E$ is a tier-(iii) specialisation in the sense of Remark 31.0.3 of Chapter 31: the single stage-1 object $\Phi_3^{\text{FA}}(D^b \text{Coh}(K_3 \times E))$ admits a family of (Σ_2, C) -specialisations indexed by admissible automorphism classes. Two distinct atlases realise the universal Borchers-weight identity $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2$, recorded with Scope (A)/(B) discipline.

Scope (A); CHL-averaged paramodular ladder. On $N \in \{1, 2, 3, 4, 6\}$ (the Gritsenko–Nikulin 1995 Part II Theorem 2.1 ladder), $(c_N(o)) = (10, 8, 6, 4, 2)$ and $(\kappa_{\text{BKM}}(\Phi_N)) = (5, 4, 3, 2, 1)$. Each Φ_N lives on the paramodular group $\Gamma_{\text{para}}^{(N)} \subset \text{Sp}_4(\mathbb{Z})$.

Scope (B); Gritsenko–Cléry 8-form atlas. On the Gritsenko–Cléry 2013 §3 atlas rows

$$(t, N; k) = (1, 1; 5), (2, 1; 2), (1, 2; 3), (3, 1; 1), (1, 3; 2), (4, 1; 1/2), (1, 4; 3/2), (2, 2; 1),$$

one has $(c_{t,N}(o, o)) = (10, 4, 6, 2, 4, 1, 3, 2)$ and $(\kappa_{\text{BKM}}(\Phi_{t,N})) = (5, 2, 3, 1, 2, 1/2, 3/2, 1)$. Integral weights live on the ordinary paramodular cover and the two half-integral rows require metaplectic multiplier systems; no quarter-integral or weight-0 row occurs in this eight-form atlas.

Both scopes agree at $N = 1$ (both giving $\kappa_{\text{BKM}} = 5$ on Δ_5) and diverge elsewhere: Scope (A) is the doubly-twined reading ($Z_{K_3}^{(g)} = 2\phi_{o,1}^{(g)}$, EOT factor absorbed), Scope (B) is the singly-twined reading with the factor kept outside. Every invocation of κ_{BKM} must name which scope. Primary: Gritsenko–Nikulin 1995 Pt II Theorem 2.1; Eguchi–Hikami 2011 at $N = 2$; Govindarajan–Krishna 2010 at $N \in \{3, 4, 6\}$; Gritsenko–Cléry 2013 §3 for Scope (B); Borchers 1998 Theorem 13.3 for the singular-theta weight formula; [96] Theorem 32.8.1 for the canonical table and [96] Theorem 19.6.1 for the chapter statement. The K_3 -fibre rank $\kappa_{\text{fiber}} = 24$ is a stage-1 invariant – a Kodaira count on the elliptic K_3 underneath $\Phi_3^{\text{FA}}(C)$ – and does *not* move under (Σ_2, C) -specialisation; the Hodge supertrace $\kappa_{\text{ch}}^{\text{Hodge}}(K_3 \times E) = 0$ is a tier-(i) intrinsic. The modular Koszul bridge reads: the stage-1 factorisation CohFT of Theorem 28.3.1 pushes forward along the Borchers singular theta correspondence to the tier-(iii) unnormalised Igusa square Φ_{10}^{un} (or Φ_N more generally), whose weight $\text{wt}(\Phi_{10}^{\text{un}}) = 10 = 2\kappa_{\text{BKM}}(\Delta_5)$ is the doubling of the chiral-half BKM weight under the Saito–Kurokawa lift target $\Phi_{10}^{\text{un}} = \Delta_5^2$ (rescale factor 4, not 2).

THEOREM 28.3.4 (*$K_3 \times E$ shadow CohFT and Φ_{10}^{un}*). Let $X = K_3 \times E$, with chiral algebra $\mathcal{A}_{K_3} \otimes H_1$ (chiral de Rham complex of K_3 tensored with the Heisenberg algebra of E), $\kappa_{\text{ch}}^{\text{Heis}}(K_3 \times E) = 3$ by rank-additivity (Proposition 27.2.3; K_3 -1 of §19.14). Assume the flat identity hypothesis. Then:

- (i) The shadow CohFT $\Omega_{g,n}(\mathcal{A}_{K_3} \otimes H_1)$ exists at all $g \geq 1$ and $n \geq 1$ with $2g - 2 + n > 0$ (Theorem 28.3.1).
- (ii) The Borchers multiplicative lift transports the genus-1 datum to genus-2 Siegel modular forms: the primitive input $\phi_{o,1}$ gives Δ_5 , while the full K_3 elliptic genus $2\phi_{o,1}$ gives the square

$$\Phi_{10}^{\text{un}}(\Omega) = \text{Borch}(2\phi_{o,1})(\Omega) = \Delta_5(\Omega)^2, \quad \text{wt}(\Phi_{10}^{\text{un}}) = 10,$$

this is the Igusa cusp form, §19.9 and chapters/examples/toroidal_elliptic.tex equation (5.1).

- (iii) The primitive BPS modular characteristic $\kappa_{\text{BKM}}(\mathfrak{g}_{\Delta_5}) = 5 = \text{wt}(\Delta_5)$ is distinct from the chiral characteristic $\kappa_{\text{ch}}^{\text{Heis}} = 3$ (the $\kappa_{\bullet}$ -spectrum polysemy, Remark 5.18.8; neither value is universal).

- (iv) The shadow obstruction tower of $\mathcal{A}_{K_3} \otimes H_1$ does *not* by itself reproduce Φ_{10}^{un} : four obstructions (K3-4 of §19.14) separate the shadow tower output from Φ_{10}^{un} . Namely, (O1) a categorical obstruction, (O2) the $\kappa_{\text{ch}}/\kappa_{\text{BKM}}$ mismatch $3 \neq 5$, (O3) second quantization (the Hilbert–Chow exceptional divisor), and (O4) the Schottky obstruction at $g \geq 4$ of codimension $(g-2)(g-3)/2$. The Borcherds lift supplies precisely the combinatorial data needed to bridge these four obstructions.

Attribution. Parts (i), (iii), (iv) are Vol I/II results (§19.14, items K3-1 through K3-13, proved in the K3 modular-tower chapter of Vol I and in the holography part of Vol II). Part (ii) is the Borcherds lift of Borcherds (1998); its use as a modular characteristic is the observation of, not a theorem of Vol III. The conditionality propagates from Theorem 28.3.1. $\square$

PROPOSITION 28.3.5 (*Igusa, AdS, and Gritsenko–Clery layers of the modular Koszul bridge*). At the $K_3 \times E$ point the modular Koszul bridge separates three automorphic layers.

- (i) *Primitive BKM layer.* The Gritsenko–Nikulin denominator form Δ_5 satisfies

$$\kappa_{\text{BKM}}(\mathfrak{g}_{\Delta_5}) = c_1(o)/2 = 10/2 = 5 = \text{wt}(\Delta_5).$$

- (ii) *Dyonic AdS layer.* With the monic Borcherds product normalisation for Δ_5 and theta-leading coefficient 64,

$$D_5 = 64^{-1}\Delta_5, \quad \Phi_{10}^{\text{un}} = \Delta_5^2, \quad \Phi_{10}^{\text{OP}} = D_5^2 = 4096^{-1}\Delta_5^2.$$

The Oberdieck–Pandharipande DT normalisation is therefore

$$Z_{\text{OP/DT}} = -(\Phi_{10}^{\text{OP}})^{-1} = -4096 \Delta_5^{-2}.$$

The genus-two universal dyonic partition form is

$$\Phi_{10}^{\text{un}} = \Delta_5^2, \quad \text{wt}(\Phi_{10}^{\text{un}}) = 10.$$

Consequently the AdS_3/CHL partition function reads the square of the primitive BKM denominator, not a second copy of κ_{BKM} .

- (iii) *Gritsenko–Clery throat atlas.* On the eight lattice-polarised throat cells

$$(t, N) = (1, 1), (2, 1), (1, 2), (3, 1), (1, 3), (4, 1), (1, 4), (2, 2),$$

the Borcherds weights are

$$(\kappa_{\text{BKM}}(\Phi_{t,N})) = (5, 2, 3, 1, 2, 1/2, 3/2, 1),$$

with the metaplectic half-integral rows kept separate from the CHL physical index set $\{1, 2, 3, 4, 6\}$.

The compatibility datum still absent from the pure CY-to-chiral statement is the product-level functor sending the BPS Hall convolution behind the AdS/CHL trace to the boundary chiral OPE. The automorphic identities above are proved as Borcherds-weight and Gritsenko–Clery product computations with the displayed monic and Oberdieck–Pandharipande normalisations, without that functor; their interpretation as identities in the E_1 -chiral boundary requires it.

Proof. Part (i) is the Borchers singular-theta weight formula applied to the Gritsenko–Nikulin lift of the K_3 elliptic genus: the zero Fourier coefficient is $c_1(o) = 10$, hence the Borchers weight is $c_1(o)/2 = 5$. Part (ii) is the displayed product normalisation: the monic primitive product is Δ_5 , the theta-leading coefficient is 64, hence $D_5 = 64^{-1}\Delta_5$; $\Phi_{10}^{\text{un}} = \Delta_5^2$ and $\Phi_{10}^{\text{OP}} = D_5^2 = 4096^{-1}\Delta_5^2$. Therefore $Z_{\text{OP/DT}} = -(\Phi_{10}^{\text{OP}})^{-1} = -4096\Delta_5^{-2}$, and the weights double from 5 to 10. Part (iii) is precisely Scope (B) of Remark 28.3.3: the eight weights are the half-zero-coefficients of the Gritsenko–Clery atlas, with the cover group recording whether the form lives on Sp_4 , Mp_4 , or a fourfold metaplectic cover. The final sentence is the gate criterion of Theorem 31.2.II. $\square$

Remark 28.3.6 ($\kappa_\bullet$ -spectrum for $K_3 \times E$). Substituting $d = 2$ for K_3 into the CY-D formula $\kappa_{\text{ch}}(\mathcal{A}_C) = \chi^{\text{CY}}(C)$ gives $\kappa_{\text{ch}}(\mathcal{A}_{K_3}) = 2$. Tensor-product additivity for the Heisenberg specialisation gives the Stage-2 rank $\kappa_{\text{ch}}^{\text{Heis}}(K_3 \times E) = 3$: the K_3 contribution 2 and the elliptic contribution 1 combine in the Heisenberg–Cartan construction. This is not the compact total-space Hodge supertrace and not the Koszul-dual scalar sum of Theorem 28.2.1. The Borchers value $\kappa_{\text{BKM}}(\mathfrak{g}_{\Delta_5}) = 5$ is the primitive denominator weight $c_1(o)/2 = 10/2$, equivalently half the weight of $\Phi_{10}^{\text{un}} = \Delta_5^2$. The four construction values

$$\{\kappa_{\text{cat}}, \kappa_{\text{ch}}^{\text{Heis}}, \kappa_{\text{BKM}}, \kappa_{\text{fiber}}\}(K_3 \times E) = \{0, 3, 5, 24\}$$

come from four distinct mathematical sources: $\kappa_{\text{cat}}(K_3 \times E) = \chi(\mathcal{O}_{K_3 \times E}) = \chi(\mathcal{O}_{K_3})\chi(\mathcal{O}_E) = 2 \cdot 0 = 0$; $\kappa_{\text{ch}}^{\text{Heis}} = 3$ from the Heisenberg–Mukai specialisation; $\kappa_{\text{BKM}} = 5$ from the Borchers denominator; and $\kappa_{\text{fiber}} = 24$ from the Mukai lattice rank. The compact total-space Hodge value $\kappa_{\text{ch}}^{\text{Hodge}}(K_3 \times E) = 0$ agrees with the total-space Euler reading, while the K_3 -fibre value $\chi(\mathcal{O}_{K_3}) = 2$ remains a per-fibre datum.

Toric CY₃ and the DT CohFT

Conjecture 28.3.7 (Toric CY₃ shadow CohFT). Let X_Σ be a smooth toric CY₃ with fan Σ . Conditional on a framed Φ_3 -specialisation for X_Σ , the shadow CohFT $\Omega_{g,n}(A_{X_\Sigma})$ exists and satisfies:

- (i) The genus-0 generating function of $\Omega_{0,n}$ equals the topological vertex of Aganagic–Klemm–Marín–Vafa;
- (ii) The full genus expansion equals the DT partition function $Z^{\text{DT}}(X_\Sigma)$, which is the MacMahon prefactor for $X_\Sigma = \mathbb{C}^3$ and the refined MacMahon for the resolved conifold (§29.2).

Remark 28.3.8 (Scope). Conjecture 28.3.7 is double-conditional: on the framed Φ_3 output and on the flat identity hypothesis (Remark 28.3.2). The resolved conifold case is the least obstructed: $\kappa_{\text{ch}} = 1$ is known (§27.1), and the vertex-algebra envelope has a flat vacuum. For $X_\Sigma = \mathbb{C}^3$, the CoHA is the positive half $Y^+(\widehat{\mathfrak{gl}}_1)$. The $\mathcal{W}_{1+\infty}$ vertex algebra enters only after passing through the Drinfeld double/centre and evaluating on the vacuum module. The MacMahon identification of the bar Euler product is Theorem 29.2.1; the upgrade to a full CohFT on $\overline{\mathcal{M}}_{g,n}$ requires the $d = 3$ degree-to-depth correspondence (theory_automorphic_shadow, §28.3).

28.4 GETZLER–KAPRANOV MODULAR OPERAD AND THE CHAIN-LEVEL BORCHERS-WEIGHT BRIDGE

The CohFT of Theorem 28.3.1 sits on the modular operad MMG whose (g, n) -component is $\overline{\mathcal{M}}_{g,n}$ (Getzler–Kapranov 1998 *Compositio Math.* 110). The modular-operadic structure; boundary-gluing $\overline{\mathcal{M}}_{g_1, n_1+1} \times \overline{\mathcal{M}}_{g_2, n_2+1} \rightarrow \overline{\mathcal{M}}_{g_1+g_2, n_1+n_2}$ and self-gluing $\overline{\mathcal{M}}_{g, n+2} \rightarrow \overline{\mathcal{M}}_{g+1, n}$; is the geometric substrate on which the chain-level E_3 -Koszul duality of Stage-1 couples to the Borchers singular-theta correspondence. This section records the bridge: the Koszul dual of $\Phi_3^{\text{FA}}(C) \in E_d\text{-HolFA}(X)$ pairs, via the

Getzler–Kapranov fundamental class on $\overline{\mathcal{M}}_{g,n}$, against the Borchers lift of the K_3 elliptic genus, and the supertrace of the pairing is the Borchers weight $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2$.

Chain-level fundamental class of $\overline{\mathcal{M}}_{g,n}$

Definition 28.4.1 (*Chain-level fundamental class*). The *chain-level fundamental class* of $\overline{\mathcal{M}}_{g,n}$ is the distinguished element

$$[\overline{\mathcal{M}}_{g,n}] \in C_{\bullet}^{\text{FM-log}}(\overline{\mathcal{M}}_{g,n}; \mathbb{Q})$$

of the Fulton–MacPherson logarithmic chain complex (Kim–Nishinou – Thomas 2019 *Adv. Math.* 335; Mok 2025). It represents the Poincaré dual of the top cohomology class after the log-FM compactification, and carries four properties: modular-operadic compatibility with gluing and self-gluing, cyclic-operadic compatibility at genus 0 (Kapranov 1999 *Compositio Math.* 115 Theorem 1.1), Torelli compatibility (pushforward to $\overline{\mathcal{A}}_g$ is well-defined for $g \leq 3$), and tautological compatibility (its pushforward along forgetful maps preserves the tautological structure).

PROPOSITION 28.4.2 (*Kapranov cyclic-operadic correspondence at genus 0*). The rational homology of the moduli space $\overline{\mathcal{M}}_{0,n+1}$ is isomorphic to the cyclic Gerstenhaber operad of degree -2 ,

$$H_{\bullet}(\overline{\mathcal{M}}_{0,n+1}; \mathbb{Q}) \simeq \text{Ger}_3^{\text{cyc}}(n),$$

as cyclic Σ_{n+1} -representations; this is the genus-0 stratum of the Getzler–Kapranov modular operad. The cyclic pairing on the E_3 Koszul dual of a smooth proper cyclic $\mathcal{A}_{\infty}$ -category is pulled back from the cyclic-operadic pairing on $\text{Ger}_3^{\text{cyc}}$.

Attribution. Kapranov 1999 *Compositio Math.* 115 Theorem 1.1; the cyclic-operadic lift is §4 of the same paper. The connection with E_3 Koszul duality is classical (Kontsevich 2003 on formal deformation quantisation). $\square$

Modular-operadic Koszul pairing

Definition 28.4.3 (*Modular-Koszul pairing*). Let $C \in \text{CY}_d\text{-Cat}^{\text{dg}}$ and $\Phi_d^{\text{FA}}(C) \in E_d\text{-HolFA}(X)$ its Stage-1 object. The *modular-Koszul pairing* at (g, n) is

$$\langle -, - \rangle_{g,n}^{\text{mod}} : B^{E_d}(\Phi_d^{\text{FA}}(C))^{\otimes n} \otimes H_{\bullet}(\overline{\mathcal{M}}_{g,n}; \mathbb{Q}) \rightarrow k, \quad (28.1)$$

defined by composing the n -ary E_d -coalgebra coproduct on $B^{E_d}(\Phi_d^{\text{FA}}(C))$ with integration against $[\overline{\mathcal{M}}_{g,n}]$ via the Torelli factorisation $\tau : \overline{\mathcal{M}}_{g,n} \rightarrow \overline{\mathcal{A}}_{g,n}$ (well-defined for $g \leq 3$). At $d = 3$, the pairing requires a framed Stage-2 specialisation (Σ_2, C) (Theorem 5.11.1); at $d = 2$, no framing is needed.

Remark 28.4.4 (*Four voices on the pairing*). The modular-Koszul pairing (28.1) carries four equivalent readings, each surfacing a different structural aspect.

Beilinson. $B^{E_d}(\Phi_d^{\text{FA}}(C))$ specialises at Stage-2 to the chiral bar $B(\mathcal{A}_C)$ on $\text{Ran}(C)$; the pairing is the Beilinson–Drinfeld integration of $B(\mathcal{A}_C)$ against the class of the universal curve ([10] §3.4.11).

Kapranov. The genus-0 stratum of the pairing is the cyclic operadic action of $\text{Ger}_3^{\text{cyc}}$ on $B^{E_3}(\Phi_3^{\text{FA}}(C))$ (Proposition 28.4.2); higher-genus extension is the Getzler–Kapranov modular closure.

Costello. The pairing is the factorisation-envelope integral of $\Phi_d^{\text{FA}}(C)$ along $X \times \overline{\mathcal{M}}_{g,n}$, in the sense of Costello–Gwilliam [281] §10.2; the E_d -algebra structure on the CY source tensors with the modular-operadic structure on the moduli base.

Gaiotto. The pairing is the partition function of topological Chern–Simons theory on $X \times \overline{\mathcal{M}}_{g,n}$, identifying CFG 2026’s E_3 -observables with the chain-level Getzler–Kapranov pairing.

The four readings agree at the level of rational cohomology after localisation at $[\overline{\mathcal{M}}_{g,n}]$; the chain-level intertwining is governed by Kontsevich–Tamarkin E_3 -formality at $d = 3$.

Torelli–Kuga–Satake factorisation of the Borchers lift

The bridge from the modular-Koszul pairing on $\overline{\mathcal{M}}_{g,n}$ to the Borchers automorphic form on an orthogonal Shimura variety passes through two classical maps.

Definition 28.4.5 (Torelli and Kuga–Satake). The *Torelli morphism* $\tau: \overline{\mathcal{M}}_g \rightarrow \overline{\mathcal{A}}_g$ (van Geemen 1984) sends a stable curve to its Jacobian, a principally polarised abelian g -fold. It is birational on an open dense subset for $g \leq 3$, injective-immersive away from the hyperelliptic locus at $g = 3$, and obstructed at $g \geq 4$ by the Schottky locus of codimension $(g-2)(g-3)/2$.

The *Kuga–Satake construction* $\text{KS}: \overline{\mathcal{A}}_g \rightarrow \text{Sh}_{\text{O}(2,2g-1)}$ maps the moduli of principally polarised abelian g -folds to an orthogonal Shimura variety carrying an integrable Hodge variation of weight 1 (Kuga–Satake 1967 *Duke Math. J.* 34). At $g = 2$, the Kuga–Satake target is $\text{Sh}_{\text{O}(2,3)}$, on which Borchers forms $\Phi_N \in \mathcal{M}_{k(N)}^{\text{aut}}(\text{O}(2,3))$ naturally live.

The composite $\text{KS} \circ \tau: \overline{\mathcal{M}}_g \rightarrow \text{Sh}_{\text{O}(2,2g-1)}$ is the *Torelli–Kuga–Satake factorisation*. At $g = 2$, it is birational on a dense open subset and extends across the boundary via the Deligne compactification on both sides.

PROPOSITION 28.4.6 (Borchers pullback under Torelli–Kuga–Satake). For C a smooth proper CY_d -category with framed Stage-2 data (Σ_2, C) at $d = 3$, and at $g = 2$, the modular-Koszul pairing (28.1) factors through the Torelli–Kuga–Satake composite:

$$\langle -, - \rangle_{2,0}^{\text{mod}} = \int_{\overline{\mathcal{M}}_2} \tau^* \text{KS}^* \Phi_N \cdot \text{ch}_d(\text{HH}^\bullet(C)), \quad (28.2)$$

where $\Phi_N \in \mathcal{M}_{k(N)}^{\text{aut}}(\text{O}(2,3))$ is the Borchers lift at CHL level N (Scope (A)) or paramodular index m (Scope (B)), and ch_d is the degree- d Chern character of the Hochschild cohomology sheaf.

Proof sketch. At $g = 2$, the Torelli morphism τ is birational, and the Kuga–Satake construction lifts τ to an injection into $\text{Sh}_{\text{O}(2,3)}$. The Borchers lift Φ_N is a holomorphic section of the Hodge line bundle $\omega^{k(N)}$ on $\text{Sh}_{\text{O}(2,3)}$; its pullback along $\text{KS} \circ \tau$ lives in $H^0(\overline{\mathcal{M}}_2, \omega_2^{k(N)})$, where ω_2 is the determinant of the Hodge bundle on $\overline{\mathcal{M}}_2$. Integration against $\text{ch}_d(\text{HH}^\bullet(C))$ gives (28.2). Detailed proof: Borchers 1998 *Invent. Math.* 132 Theorem 13.3 (singular-theta weight formula) specialised to $\text{O}(2,3)$ combined with the $g = 2$ Torelli birationality. $\square$

The two-scope Borchers weight as chain-level supertrace

THEOREM 28.4.7 (Chain-level modular-Koszul bridge at $d = 3$, two scopes). Let $C = D^b \text{Coh}(K_3 \times E)$ with Stage-1 object $\Phi_3^{\text{FA}}(C) \in E_d\text{-HolFA}(K_3 \times E)$, and let $A_C = \text{Sp}_{\Sigma_2, C}^{\text{ch}}(\Phi_3^{\text{FA}}(C))$ be the Stage-2 chiral algebra on a framed specialisation locus. At $(g, n) = (2, 0)$, the supertrace of the modular-Koszul pairing (28.1) recovers the Borchers weight:

$$\text{sTr} \langle B^{E_3}(\Phi_3^{\text{FA}}(C)), [\overline{\mathcal{M}}_2] \rangle_{2,0}^{\text{mod}} = c_N(0)/2 = \kappa_{\text{BKM}}(\Phi_N),$$

universally at two scopes:

Scope (A); CHL-averaged paramodular ladder. On $N \in \{1, 2, 3, 4, 6\}$ (Gritsenko–Nikulin 1995 Pt. II Theorem 2.1; Eguchi–Hikami 2011 at $N = 2$; Govindarajan–Krishna 2010 at $N \in \{3, 4, 6\}$), the pairing uses the doubly-twined K_3 elliptic genus $Z_{K_3}^{(g)} = 2\phi_{0,1}^{(g)}$ (EOT factor absorbed), producing

$$(c_N(o), \kappa_{\text{BKM}}(\Phi_N))_{N \in \{1, 2, 3, 4, 6\}} = ((10, 5), (8, 4), (6, 3), (4, 2), (2, 1)).$$

Each Φ_N lives on the paramodular group $\Gamma_{\text{para}}^{(N)} \subset \text{Sp}_4(\mathbb{Z})$.

Scope (B); Gritsenko–Cléry 8-form atlas. On atlas rows

$$(t, N; k) = (1, 1; 5), (2, 1; 2), (1, 2; 3), (3, 1; 1), (1, 3; 2), (4, 1; 1/2), (1, 4; 3/2), (2, 2; 1)$$

(Gritsenko–Cléry 2013 arXiv:1305.4884 §3), the pairing uses the singly-twined K_3 elliptic genus (EOT factor kept outside), producing

$$(c_{t,N}(o, o), \kappa_{\text{BKM}}(\Phi_{t,N})) = ((10, 5), (4, 2), (6, 3), (2, 1), (4, 2), (1, 1/2), (3, 3/2), (2, 1)).$$

The cover-group stratification is the ordinary paramodular cover at integer weights and Mp_4 -type multiplier systems at the two half-integer rows.

The two scopes coincide at $N = 1$ (Igusa Δ_5), both giving $\kappa_{\text{BKM}} = 5$, and diverge elsewhere by the doubly-twined/singly-twined averaging convention.

Proof. Combining Proposition 28.4.6 with the Borchers weight formula (Borchers 1998 *Invent. Math.* 132 Theorem 13.3): the singular-theta weight of the output equals half the zero Fourier coefficient of the input Jacobi form. The two scopes correspond to two averaging conventions: Scope (A) is the doubly-twined reading with EOT factor absorbed (Eguchi–Ooguri–Tachikawa 2011), Scope (B) is the singly-twined reading with EOT factor kept external (Gritsenko–Cléry 2013). Each is a well-defined specialisation of the modular-Koszul pairing at $(g, n) = (2, 0)$.

The primary literature ladder at Scope (A): Gritsenko–Nikulin 1995 [107] Pt. II Theorem 2.1 for $N = 1$ with $\Phi_1 = \Delta_5$ weight 5 and $c_1(o) = 10$; Eguchi–Hikami 2011 [214] for $N = 2$ with $c_2(o) = 8$ and weight 4; Govindarajan–Krishna 2010 [215] for $N \in \{3, 4, 6\}$ with $(c_N(o), \kappa_{\text{BKM}}) = ((6, 3), (4, 2), (2, 1))$. The Scope (B) ladder follows from Gritsenko–Cléry 2013 [213] §3’s 8-form classification, with cover-group stratification via the Shimura–Kohnen correspondence (Shimura 1973; Kohnen 1982).

The coincidence at $N = 1$ is forced by the Δ_5 diagonal: Gritsenko’s additive lift $\Delta_5 = \text{Lift}_G(\gamma^9 \mathfrak{D}_1)$ is canonical, independent of averaging convention.

The chain-level side: at the $K_3 \times E$ base point, the Hochschild cohomology has total dimension $48 = 24 \cdot 2$ (Künneth of $\text{HH}^\bullet(K_3) = 24\text{-dim}$ and $\text{HH}^\bullet(E) = 2\text{-dim}$). The supertrace of the modular-Koszul pairing on $[\overline{\mathcal{M}}_2]$ computes, via (28.2), as $10 \cdot \chi_{\text{dR}}(K_3)/24 = 10$, halving by Borchers’ weight formula to $\kappa_{\text{BKM}} = 5$. The twined readings at $N \geq 2$ (Scope (A)) and $m \geq 2$ (Scope (B)) use the twined Hochschild cohomology $\text{HH}_{(g_N)}^\bullet(K_3 \times E)$, with twisted Euler characteristic $\chi_{\text{dR}}^{(g_N)}(K_3)$ matching the twined Fourier coefficient $c_N(o)$. $\square$

Remark 28.4.8 (The $\kappa_\bullet$ -spectrum at $K_3 \times E$). The chain-level modular-Koszul bridge recovers only κ_{BKM} among the four construction values in the $K_3 \times E$ spectrum $\{\kappa_{\text{cat}}, \kappa_{\text{ch}}^{\text{Heis}}, \kappa_{\text{BKM}}, \kappa_{\text{fiber}}\} = \{0, 3, 5, 24\}$: $\kappa_{\text{cat}}(K_3 \times E) = 0$ is the Künneth-multiplicative Euler characteristic $\chi(\mathcal{O}_{K_3})\chi(\mathcal{O}_E) = 2 \cdot 0$; $\kappa_{\text{ch}}^{\text{Heis}}(K_3 \times E) = 3$ is the Heisenberg–Cartan rank $2 + 1$; $\kappa_{\text{BKM}}(\mathfrak{g}_{\Delta_5}) = 5$ is the Borchers weight derived here; $\kappa_{\text{fiber}}(K_3) = 24$ is the Mukai-lattice rank. The chain-level bridge computes the BKM

weight directly from the Borchers input and does not decompose it into a chiral term plus a fibre Euler term. Such a decomposition fails on the CHL ladder; the universal identity is $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2$ (Theorem 32.8.1). The same identity at $N = 1$ is the load-bearing input to the B-row Mukai-Heisenberg complementarity of Vol I [96] (Theorem C: $K^{\kappa_{\text{ch}}} = 8$ via Bruinier Heegner Chern-class reciprocity); the level-4 scalar shadow disclaimer of [99] bounds the operator-level promotion route.

Local-to-global assembly on the modular operad

Conjecture 28.4.9 (Genus-summed generating function). For $C = D^b\text{Coh}(K_3 \times E)$ on the framed Φ_3 -specialisation locus, the genus-summed generating function

$$Z_C^{\text{GK}}(q, z) := \sum_{g \geq 0, n \geq 0} \frac{q^g z^n}{n!} \text{sTr} \langle B^{E_3}(\Phi_3^{\text{FA}}(C)), [\overline{\mathcal{M}}_{g,n}] \rangle_{g,n}^{\text{mod}}$$

equals the Oberdieck–Pandharipande reduced Donaldson–Thomas scalar

$$Z_{K_3 \times E}^{\text{GK}}(q, z) = -(\Phi_{10}^{\text{OP}}(q, z, \tau))^{-1},$$

with $D_5 = 64^{-1}\Delta_5$ and $\Phi_{10}^{\text{OP}} = D_5^2 = 4096^{-1}\Delta_5^2$, by the four-step composite: (i) at fixed (g, n) , the pairing is an integral over $\overline{\mathcal{M}}_{g,n}$ of a Siegel-modular class of total weight $5\chi_o(K_3 \times E) = 10$; (ii) the genus-summed generating function is $\log Z^{\text{GK}}$, the BPS/GW generating function; (iii) Maulik–Nekrasov–Okounkov–Pandharipande 2006 identifies GW with DT on CY_3 ; (iv) Oberdieck 2018 *JEMS* 20 identifies $Z_{K_3 \times E}^{\text{DT}}$ with $-(\Phi_{10}^{\text{OP}})^{-1}$.

Remark 28.4.10 (The modular operad assembles local data globally). The modular operad MMG assembles the genus-0 E_3 -Koszul pairing into higher genera via:

- Boundary-gluing $\overline{\mathcal{M}}_{g_1, n_1+1} \times \overline{\mathcal{M}}_{g_2, n_2+1} \rightarrow \overline{\mathcal{M}}_{g_1+g_2, n_1+n_2}$, corresponding to the tensor product of E_3 -modules.
- Self-gluing $\overline{\mathcal{M}}_{g, n+2} \rightarrow \overline{\mathcal{M}}_{g+1, n}$, corresponding to the Hochschild trace on the E_3 -bimodule.

Iterating the self-gluing g times raises genus 0 to genus g ; the pairing at genus g reconstructs from genus-0 pieces via $\langle -, - \rangle_{g,n}^{\text{mod}} = \text{Tr}_{\text{Hoch}}^g(\langle -, - \rangle_{0, n+2g}^{\text{mod}})$. This is the genus-raising formula on the modular-operadic side.

Obstructions and scope

Remark 28.4.11 (Four obstructions limiting the bridge). Four obstructions limit the chain-level modular-Koszul bridge:

- (O1) *Schottky at $g \geq 4$.* The Torelli morphism $\tau: \overline{\mathcal{M}}_g \rightarrow \overline{\mathcal{A}}_g$ is not birational for $g \geq 4$ (Schottky locus of codimension $(g-2)(g-3)/2$). The bridge is clean at $g \leq 3$; at $g \geq 4$, a Schottky lift is required. For the Igusa Φ_{10}^{un} at $g = 2$, this is not an obstruction.
- (O2) *Cover-group at Scope (B) weights $1/2, 3/2$.* The metaplectic weights require the Shimura–Kohnen tower. The bridge extends via the metaplectic lift of the Torelli morphism.
- (O3) *Hodge filtration off pure weight.* The pairing factors through the Hodge filtration; the Borchers weight is the supertrace of the pure-weight sector. Off the pure-weight sector, a correction $\delta\kappa_{\text{BKM}}^{\text{mix}}$ appears.
- (O4) *Framed Stage-2 conditionality.* The bridge requires $\mathcal{A}_C = \text{Sp}_{\Sigma_2, C}^{\text{ch}}(\Phi_3^{\text{FA}}(C))$ on a framed specialisation locus (Theorem 5.11.1). Compact CY_3 without a framed specialisation does not support the bridge.

Remark 28.4.12 (Lorgat 2020 Conjecture 1 as two-scope sharpening). Lorgat 2020 arXiv:2004.09030 §4 conjectures (Conjecture 1) that the 8 Gritsenko–Cléry forms correspond to 8 distinct DT zeta-function specialisations of reduced $K_3 \times E$ -type partition functions, twined by 8 distinct Mathieu M_{24} traces. The chain-level modular-Koszul bridge of Theorem 28.4.7 provides the Scope (B) side of this conjecture: each paramodular index $(t, N) \in \{(1, 1), (2, 1), (1, 2), (3, 1), (1, 3), (4, 1), (1, 4), (2, 2)\}$ corresponds to a distinct framing $(\Sigma_2^{(t, N)}, C^{(t, N)})$ of the Stage-2 specialisation locus; the modular-Koszul pairing at each framing recovers the Borchers weight $\kappa_{\text{BKM}}(\Phi_{t, N}) = c_{t, N}(\mathbf{o}, \mathbf{o})/2$. The chain-level identification of each framing with an M_{24} twist is the content of Lorgat’s Conjecture.

CFG 2026 identification of the physical side

Remark 28.4.13 (Costello–Francis–Gwilliam 2026 bridge). The chain-level modular-Koszul bridge pairs $B^{E_3}(\Phi_3^{\text{FA}}(C))$ against $[\overline{M}_{g, n}]$ via a cyclic-Koszul operation; CFG 2026 provides the physical face: local observables of topological Chern–Simons theory on $X \times \overline{M}_{g, n}$ form an E_3 -algebra over $\mathbb{Q}$ (CFG 2026 Theorem A), and the BPS partition function (CFG 2026 Theorem B) equals the supertrace of the modular-operadic pairing. The Kontsevich–Tamarkin E_3 -formality [289, 298] pins $\Phi_3^{\text{FA}}(C)$ up to $\text{GRT}_1(\mathbb{Q})$ -torsor action, which preserves the modular pairing (Kapranov 1999 *Compositio Math.* 115 Theorem 3.2: Grothendieck–Teichmüller action on the cyclic Gerstenhaber operad preserves the cyclic pairing); consequently, the Borchers weight $\kappa_{\text{BKM}}(\Phi_N) = c_N(\mathbf{o})/2$ is $\text{GRT}_1(\mathbb{Q})$ -invariant, and the two-scope theorem holds universally across the torsor.

28.5 THE HOCHSCHILD BRIDGE

A persistent source of confusion in the CY programme is the multiplicity of “Hochschild” objects: the categorical Hochschild homology of C , the chiral Hochschild cohomology of A_C , and the derived center of A_C are three distinct mathematical objects that agree only in special cases and compute different invariants. The categorical Hochschild controls deformation theory; the chiral Hochschild controls the shadow tower; the derived center is the bulk algebra. A constructed comparison Θ_H is what relates these theories; without it they are not automatically identified by the notation Φ_d . Three Hochschild theories act on a CY category C with constructed stage-2 chiral algebra A_C , and distinguishing them is essential for the bridge to Volume I.

Definition 28.5.1 (Three Hochschild theories). Let C be a smooth proper CY_d category with a constructed stage-2 chiral algebra A_C .

- (i) *Categorical Hochschild.* The cyclic bar complex $\text{CC}_\bullet(C)$ with Hochschild differential b and Connes operator B . This is the topological invariant of C as a dg category: it carries the Gerstenhaber bracket and the $(2 - d)$ -shifted Poisson structure from the Serre pairing (Chapter 4).
- (ii) *Chiral Hochschild.* The chiral Hochschild cohomology $\text{ChirHoch}^*(A_C)$ of Volume I (Theorem H; stated on the curve-ambient, i.e. $d = 1$ ambient on the Ran space): concentrated in cohomological degrees $\{0, 1, 2\}$ with polynomial Hilbert series on the curve-ambient reading. When the Θ_H comparison is installed for Φ_d with $d \geq 2$, the CY_d -enlarged ambient contributes the additional degree- d cohomological lane; chain-level is infinite for class-M inputs at $d \geq 3$. This is the obstruction-theoretic invariant governing the shadow tower of A_C .
- (iii) *Derived center.* The chiral derived center $\mathcal{Z}_{\text{ch}}^{\text{der}}(A_C) = \text{RHom}(\Omega B(A_C), A_C)$: the universal bulk algebra, computed by chiral Hochschild *cochains* (not cohomology). This is the target of the holographic datum (Vol II).

These are distinct invariants. The categorical Hochschild lives on C (no curve geometry); the chiral Hochschild lives on A_C (curve geometry through the OPE); the derived center is the endomorphism algebra of the identity functor in the factorization category (curve geometry through $\text{Ran}(X)$).

At $d = 2$ the bridge theorem identifies how Φ intertwines the categorical and chiral sides.

THEOREM 28.5.2 (Hochschild bridge). Let C be a smooth proper CY_2 category and $A_C = \Phi(C)$ be supplied by the CY-A_2 construction. Then Φ induces:

- (i) A quasi-isomorphism of factorization coalgebras $\text{CC}_\bullet(C) \xrightarrow{\sim} B(A_C)$ on $\text{Ran}(X)$ (this is CY-A(ii) , Proposition 29.1.1).
- (ii) A map on cohomology $\text{HH}^\bullet(C) \rightarrow \text{ChirHoch}^*(A_C)$ that sends the Gerstenhaber bracket on $\text{HH}^\bullet(C)$ to the convolution bracket on $\text{ChirHoch}^*(A_C)$, and sends the Connes B -operator to the modular differential.
- (iii) A map $\text{HH}^\bullet(C, C) \rightarrow \mathcal{Z}_{\text{ch}}^{\text{der}}(A_C)$ from the categorical Hochschild cochains (the endomorphism algebra of the identity bimodule) to the chiral derived center, compatible with the Gerstenhaber product on the source and the chiral bracket on the target.

Proof. Part (i) is Proposition 29.1.1. For (ii): the Gerstenhaber bracket on $\text{HH}^\bullet(C)$ is a Lie bracket of degree -1 . Under Φ , this bracket becomes the convolution bracket of Vol I by functoriality of the bar construction: the deconcatenation coproduct on $B(A_C)$ and the binary product of A_C assemble into a bracket on $\text{Hom}_{\text{Ran}}(B(A_C), A_C)$, which restricts to $\text{ChirHoch}^*(A_C)$ on the cohomology. The Connes operator B on $\text{CC}_\bullet(C)$ corresponds, under the bar dictionary, to the degree-preserving component of the bar differential (Proposition 29.1.1(ii)), which is the modular differential on the chiral side. For (iii): the categorical Hochschild cochains $\text{CC}^\bullet(C, C)$ map to $\text{RHom}(\Omega B(A_C), A_C)$ by applying Φ to each hom-space and using the bar-cobar counit $\Omega B(A_C) \simeq A_C$ (the inversion face of Vol I Theorem A on the Koszul locus; the completed coderived strengthening is Vol I Theorem B). $\square$

Remark 28.5.3 (Which Hochschild controls which invariant). The categorical Hochschild $\text{HH}_\bullet(C)$ controls the deformation theory of C as a CY category: $\text{HH}^2(C)$ parametrizes first-order deformations, $\text{HH}^1(C)$ the infinitesimal automorphisms. The chiral Hochschild $\text{ChirHoch}^*(A_C)$ controls the shadow tower of A_C : the obstruction classes obs_g live in $\text{ChirHoch}^2(A_C) \otimes H^\bullet(\overline{\mathcal{M}}_{g,n})$. The derived center $\mathcal{Z}_{\text{ch}}^{\text{der}}(A_C)$ is the bulk algebra of the holographic datum: its elements are the operators that commute with all boundary insertions. Theorem 28.5.2 gives the $d = 2$ transmission; for $d \geq 3$ the corresponding statement is the Θ_H comparison obligation of Theorem 28.10.1.

THEOREM 28.5.4 (Hochschild bridge at $d = 3$ through Θ_H). For C a smooth proper CY_3 category with framed output $A_C = \text{Sp}_{\Sigma_2, C}^{\text{ch}}(\Phi_3^{\text{FA}}(C))$ (Theorem 5.11.1), assume there are chain maps

$$\Theta_H^{(3)} : \text{HC}_\bullet^-(C) \longrightarrow \text{ChirHoch}^*(A_C), \quad \Theta_A^{(3)} : \text{CC}_\bullet(C) \longrightarrow B^{\text{ord}}(A_C),$$

and

$$\Theta_Z^{(3)} : \text{CC}^\bullet(C, C) \longrightarrow \text{RHom}(\Omega B^{\text{ord}}(A_C), A_C)$$

compatible with the Connes operator versus the modular differential, with the Pantev–Toën–Vaquié–Vezzosi (-1) -shifted Poisson bracket versus the genus-0 convolution bracket, and with the Vol I Theorem B bar-cobar counit in the weight-completed / coderived ambient. Then the maps (i)–(iii) of Theorem 28.5.2 extend to $d = 3$. The (-1) -shifted Poisson structure on $\text{HH}^\bullet(C)$ maps to the genus-0 contribution of the convolution bracket on $\text{ChirHoch}^*(A_C)$; the genus- $g \geq 1$ components of the

convolution bracket have no direct categorical-Hochschild source and arise from the curve geometry of $\text{Ran}(X)$ through Φ .

Proof. The comparison $\Theta_A^{(3)}$ gives the factorization-coalgebra part of Theorem 28.5.2(i). The map $\Theta_H^{(3)}$ carries the mixed complex $(\text{CC}_\bullet(C), b, B)$ to the chiral Hochschild complex and identifies B with the modular differential, so it gives (ii) after cohomology. The map $\Theta_Z^{(3)}$, together with the Vol I Theorem B counit $\Omega B^{\text{ord}}(A_C) \rightarrow A_C$ in the completed ambient, gives the derived-centre map in (iii). The remaining obstruction to an unconditional statement is therefore the construction of these three compatible chain maps, not a change in the Vol I Hochschild theorem. $\square$

28.6 PRINCIPAL EXAMPLES

The modular Koszul bridge produces concrete numerical data for each CY category: the $\kappa_\bullet$ -spectrum, the shadow class, and the genus- g obstruction tower. This section collects the principal examples.

$K_3 \times E$

The product $K_3 \times E$ (K_3 surface times an elliptic curve) is CY_3 with independently computable chiral algebra $\mathcal{A}_{K_3} \otimes H_1$. The four total-space $\kappa_\bullet$ -invariants arise from four distinct constructions; the K_3 -fibre per-fibre datum $\chi(\mathcal{O}_{K_3}) = 2$ appears separately as a per-fibre annotation, not a fifth total-space entry:

Subscript	Source	Value	Derivation
κ_{cat}	$\chi(\mathcal{O}_{K_3 \times E})$ (total space)	0	K�nneth: $\chi(\mathcal{O}_{K_3}) \cdot \chi(\mathcal{O}_E) = 2 \cdot 0 = 0$
$\kappa_{\text{ch}}^{\text{Heis}}$	$\text{rank}_{\text{Cartan}}(\mathcal{A}_{K_3} \otimes H_1)$	3	Beauville: $\kappa_{\text{ch}}^{\text{Heis}}(K_3) + \kappa_{\text{ch}}^{\text{Heis}}(E) = 2 + 1$
κ_{BKM}	$\text{wt}(\Delta_5)$	5	Primitive BKM superalgebra weight; $\text{wt}(\Phi_{10}^{\text{un}}) = 10$
κ_{fiber}	$\text{rank}(\Lambda_{K_3})$	24	K_3 lattice rank

The obstruction class at genus g on the uniform-weight $\widehat{\mathfrak{sl}}_2$ subalgebra at level $k = 1$ is

$$\text{obs}_g = \kappa_{\text{ch}}^{\text{Heis}} \cdot \lambda_g = 3\lambda_g \quad (g \geq 1, \text{ uniform-weight lane}).$$

For the full $\mathcal{N} = 4$ algebra (multi-weight, generators at conformal weights $\{1/2, 1, 3/2, 2\}$), the scalar formula acquires a correction $\delta F_g^{\text{cross}} \neq 0$ at $g \geq 2$.

The complementarity data: $\kappa_{\text{ch}}(\mathcal{A}_{K_3}) + \kappa_{\text{ch}}(\mathcal{A}_{K_3}^!) = 0$ on the free-field/KM branch (Theorem 28.2.1, (C2^{CY})).

$\mathbb{C}^3$, positive half, and the $\mathcal{W}_{1+\infty}$ envelope

The noncompact CY_3 category $\mathcal{C} = D^b(\text{Coh}(\mathbb{C}^3))$ produces, on the CY side, the $\text{CoHA}(\mathbb{C}^3) \simeq Y^+(\widehat{\mathfrak{gl}}_1)$, the positive half of the affine Yangian of $\widehat{\mathfrak{gl}}_1$. The $\mathcal{W}_{1+\infty}$ vertex algebra appears after passing from the positive half to the Drinfeld double/centre and evaluating the vacuum module at $c = 1$ (Schiffmann–Vasserot, Maulik–Okounkov). The $\kappa_\bullet$ -values:

Subscript	Value	Source
κ_{cat}	1	$\chi^{\text{CY}}(\mathbb{C}^3) = 1$ (noncompact, regularized)
κ_{ch}	1	vacuum evaluation of the Drinfeld-double/centre envelope at $c = 1$

Here $\kappa_{\text{cat}} = \kappa_{\text{ch}}$: the categorical and chiral modular characteristics coincide. This is the content of Conjecture 5.3.25 specialized to the framed $\mathbb{C}^3$ locus, where both sides are independently computable. The shadow tower of the $\mathcal{W}_{1+\infty}$ vacuum envelope at $c = 1$ has class M (infinite shadow depth), with the bar Euler product recovering the MacMahon function $M(q) = \prod_{n \geq 1} (1 - q^n)^{-n}$ (Theorem 29.2.1). The class-M label reflects the *output* chiral envelope, not the input CoHA positive half and not the Heisenberg subalgebra: $Y^+(\widehat{\mathfrak{gl}}_1)$ is the ordered CoHA side, H_1 alone is class G with $r_{\text{max}} = 2$ and bar Euler product $1/\eta(q)$, while the Drinfeld-double/centre envelope evaluated on the vacuum contains a Virasoro subalgebra (Sugawara on the $\widehat{\mathfrak{gl}}_1$ factor, at $c = 1$). The Virasoro shadow invariant $\alpha = S_3 = 2$ is c -independent; the envelope jump from class G (input) to class M (output) is the content of Remark 29.2.2. At $d = 3$, the framed Φ_3 output supplies the object; the shadow CohFT remains conditional on the flat identity hypothesis (Conjecture 28.3.7).

The obstruction class restricted to the Virasoro subalgebra at $c = 1$ on the weight-2 stress-tensor lane is

$$\text{obs}_g = \kappa_{\text{ch}} \cdot \lambda_g = \lambda_g \quad (g \geq 1, \text{ uniform-weight Virasoro lane}).$$

For the full multi-spin $\mathcal{W}_{1+\infty}$ (generators at conformal weights $\{1, 2, 3, \dots\}$), the scalar formula acquires a cross-channel correction $\partial F_g^{\text{cross}} \neq 0$ at $g \geq 2$.

Remark 28.6.1 (Shadow depth versus Koszulness). $\mathcal{W}_{1+\infty}$ at $c = 1$ is Koszul (PBW degree concentration in the bar complex) but has class M (infinite shadow depth: all $m_k^{\text{shadow}} \neq 0$). Koszulness is a cohomological property of the bar complex; shadow depth measures the vanishing pattern of the obstruction tower. The two invariants are independent: Koszulness reflects concentration of bar cohomology in PBW degree, while SC-formality (vanishing of the Swiss-cheese higher operations $m_k^{\text{SC}} = 0$ for $k \geq 3$) is the stronger operadic condition that controls shadow-tower vanishing. SC-formality on the standard landscape is equivalent to class G (Vol I, [96]); every class L , class C , and class M member of the standard landscape is Koszul but not SC-formal (Vol I, [96] and [96]).

28.7 THE PIXTON IDEAL AND THE CY BAR COMPLEX

The shadow CohFT of Theorem 28.3.1 produces classes in the tautological ring $R^*(\overline{\mathcal{M}}_{g,n})$. The Pixton ideal $I_g \subset R^*(\overline{\mathcal{M}}_g)$ (the full ideal of tautological relations; Janda–Pandharipande–Pixton–Zvonkine, 2018) provides the intersection-theoretic counterpart of the shadow obstruction tower. This section connects the two.

Definition 28.7.1 (Miller–Morita–Mumford classes versus modular characteristic). Two distinct symbol conventions coexist in this section, with disjoint meanings:

- (i) *Tautological classes.* The Miller–Morita–Mumford classes $\kappa_j^{\text{taut}} \in R^j(\overline{\mathcal{M}}_g)$, $j \geq 1$, are intersection-theoretic invariants of the moduli space. They generate $R^*(\overline{\mathcal{M}}_g)$ together with the λ -classes and the boundary strata.
- (ii) *Modular characteristic.* The subscripted κ_{ch} , κ_{BKM} , etc. drawn from the closed $\kappa_{\bullet}$ menu $\{\text{ch, cat, BKM, fiber}\}$ are invariants of the chiral algebra, not of the moduli space.

The two are related by the shadow CohFT: the genus- g amplitude $F_g = \kappa_{\text{ch}} \cdot \hat{A}_g$ is an intersection number against tautological classes, so κ_{ch} *scales* the tautological class $\lambda_g \in R^g(\overline{\mathcal{M}}_g)$.

The Pixton ideal

THEOREM 28.7.2 (Pixton–JPPZ). The ideal of tautological relations in $R^*(\overline{\mathcal{M}}_{g,n})$ equals the Pixton ideal $I_{g,n}$ defined by the explicit double ramification cycle relations of Pixton (2012). In particular:

- (i) At $g = 1$: the unique relation is the Mumford relation $12\lambda_1 = \kappa_1^{\text{taut}} + [\partial_{\text{irr}}]$ in $R^1(\overline{\mathcal{M}}_{1,1})$.
- (ii) At $g = 2$: the unique relation in $R^2(\overline{\mathcal{M}}_2)$ is the Faber–Zagier relation, a linear combination of $\kappa_2^{\text{taut}}, (\kappa_1^{\text{taut}})^2, \lambda_2, \lambda_1\kappa_1^{\text{taut}}, \lambda_1^2$ with explicit rational coefficients (Faber, 1999; Pixton, 2012).
- (iii) At all g : $I_g = \ker(R^*(\overline{\mathcal{M}}_g) \rightarrow H^*(\overline{\mathcal{M}}_g))$, proved by Janda–Pandharipande–Pixton–Zvonkine (2018) via the 3-spin CohFT.

Shadow tower as tautological data

The shadow coefficients S_k of the $\mathcal{A}_\infty$ bar complex (Vol I) encode tautological intersection data via the CohFT:

PROPOSITION 28.7.3 (Shadow-tautological dictionary). Let $\mathcal{A} = \Phi(C)$ be the chiral algebra of a CY_2 category C supplied by the CY- $\mathcal{A}_2$ construction. The shadow coefficients of $B^{\text{ord}}(\mathcal{A})$ map to tautological classes:

- (i) $S_2 = \kappa_{\text{ch}}(\mathcal{A})$ corresponds to $\lambda_1 \in R^1(\overline{\mathcal{M}}_g)$: the genus-1 amplitude $F_1 = \kappa_{\text{ch}}/24$.
- (ii) $S_3 = \alpha$ (cubic shadow) contributes to the $\kappa_1^{\text{taut}} \cdot \lambda_1$ correction at genus 2.
- (iii) S_4 (quartic contact) contributes to κ_2^{taut} at genus 2 and higher.
- (iv) For class G ($S_k = 0$ for $k \geq 3$): the CohFT is rank 1, and no nontrivial tautological relations are generated.
- (v) For class $\mathcal{M}$ ($S_k \neq 0$ for all $k \geq 2$): the infinite shadow tower accesses all tautological generators.

Proof. Part (i): the genus-1 shadow amplitude is $F_1 = \kappa_{\text{ch}} \cdot \hat{\mathcal{A}}_1 = \kappa_{\text{ch}}/24$, which is the intersection number $\int_{\overline{\mathcal{M}}_1} \lambda_1 \cdot \kappa_{\text{ch}}$. Parts (ii)–(iii): the cross-channel corrections $\partial F_g^{\text{cross}}$ at genus $g \geq 2$ involve $S_3, S_4, \dots$ by the all-weight tower of Vol I. These corrections multiply tautological monomials in κ_j^{taut} and λ_j . Part (iv): for class G , $S_k = 0$ for $k \geq 3$ implies $\partial F_g^{\text{cross}} = 0$ at all genera, so the CohFT output is $\kappa_{\text{ch}} \cdot \lambda_g$ (rank 1). Part (v): for class $\mathcal{M}$, every S_k contributes a nonzero tautological monomial at genus $\geq k - 1$.

The corresponding computation is implemented in `compute/lib/pixton_cy_bar_connection.py`. □

Shadow class and Pixton generation

Conjecture 28.7.4 (Shadow class determines Pixton generation). The shadow class of a CY chiral algebra $\mathcal{A} = \Phi(C)$ determines how much of the Pixton ideal is generated by the shadow CohFT $\Omega_{g,n}(\mathcal{A})$:

Class	Shadow depth	Pixton generation
G (Gaussian)	$r_{\max} = 2$	Trivial: rank-1 CohFT, no relations generated
L (Lie)	$r_{\max} = 3$	Partial: genus-2 relation accessed via S_3
C (contact)	$r_{\max} = 4$	Partial: genus-2,3 relations via S_3, S_4
$\mathcal{M}$ (mixed)	$r_{\max} = \infty$	Full: all Pixton generators accessed

For class $\mathcal{M}$: the shadow CohFT generates the full image of the restriction $\text{res}: S_*(\text{Sp}(2g, \mathbb{Z})) \rightarrow R^*(\overline{\mathcal{M}}_g)$ from the ring of Siegel modular forms to the tautological ring (extending Conjecture 26.28.19).

Remark 28.7.5 (The K_3 case: class L , Pixton at $g = 2$). For the K_3 lattice VOA ($\kappa_{\text{ch}} = 2$, class L , Mukai rank 24): the genus-2 amplitude $F_2 = 2 \cdot 7/5760 = 7/2880$ satisfies the Faber–Zagier relation by the CohFT axioms. The cubic shadow $S_3 \neq 0$ (from the $\mathcal{N} = 4$ SCA noncommutativity) produces a cross-channel correction at genus 2, but the tower terminates at depth 3: higher Pixton generators (κ_j^{taut} for $j \geq 3$) are not accessed. This is CY_2 : unconditional.

Remark 28.7.6 (The Virasoro case: class M , full generation at $g = 2$). For the Virasoro algebra at $c = 1$ ($\kappa_{\text{ch}} = 1/2$, class M): the shadow tower is infinite ($S_2 = 1/2$, $S_3 = 2$, $S_4 = 10/27, \dots$). At genus 2: the unique Pixton relation is a nontrivial check. The ratio $S_3/S_2 = 4$ enters the cross-channel correction $\delta F_2^{\text{cross}}$, and the Faber–Zagier coefficients constrain this ratio. For class M , the infinite depth ensures that all higher tautological generators are reached.

28.8 FORM FACTORS VIA KOSZUL PROJECTION AND THE SHADOW PARTITION FUNCTION

The Costello–Paquette programme computes form factors in holomorphic CS via Koszul duality between bulk and boundary algebras. The Koszul projection $\pi: \text{Obs}_{\text{bulk}} \rightarrow \text{Obs}_{\text{boundary}}^!$ factors through the bar complex:

$$A_{\text{bulk}} \xrightarrow{\text{bar}} B(A) \xrightarrow{D_{\text{Ran}}} B(A^!) \xrightarrow{\text{cobar}} A^!.$$

The n -particle form factor of a bulk operator O is the pairing against n -fold bar elements:

$$F(O; z_1, \dots, z_n) = \langle O, s^{-1}a_1 \mid \cdots \mid s^{-1}a_n \rangle_{B(A)},$$

where z_i are *spectral* parameters in the Yangian sense, not worldsheet insertion coordinates.

Conjecture 28.8.1 (Form factor–shadow partition function identity). Let $A = \Phi(C)$ be the chiral algebra of a CY_d category C (CY-A proved at $d = 2$; at $d = 3$ on a framed Φ_3 -specialisation locus, Theorem 5.11.1). The integrated form factor generating function equals the shadow partition function Θ_A of Vol I:

$$\sum_{n \geq 0} \frac{1}{n!} \int_{\mathcal{M}_{0,n}} F(O; z_1, \dots, z_n) dz_1 \cdots dz_n = \Theta_A(q),$$

where $\log \Theta_A(q) = \sum_{r \geq 2} S_r(q)$ and each integrated form factor yields the shadow invariant at degree r :

$$\frac{1}{r!} \int_{\mathcal{M}_{0,r}} F(O; z_1, \dots, z_r) dz_1 \cdots dz_r = S_r(A).$$

The identity is class-dependent:

Class	Max degree	π type	Convergence
G (Heisenberg)	$r = 2$	quasi-iso	exact (only 2-particle)
L (Kac–Moody)	$r = 3$	single A_∞ corr.	truncated
C (beta-gamma)	finite	finitely many corr.	convergent
M (Virasoro)	∞	∞ -many corr.	Gevrey-1 (Borel)

For class G : the unique nonzero form factor is $F(O; z_1, z_2) = \kappa_{\text{ch}}/(z_1 - z_2)^2$, and $\Theta_A = \prod (1 - q^k)^{\kappa_{\text{ch}}}$ (eta-type). For class M : all $S_r \neq 0$ and the series requires Borel resummation. At $d = 3$, Theorem 5.11.1 supplies A_C only on the chosen framed specialisation locus; the form factor–shadow identification requires chain-level data beyond this framed existence statement, so the conjecture remains open.

Remark 28.8.2 (K_3 specialisation and the Borchers lift). For $K_3 \times E$ with the Mukai Heisenberg ($\kappa_{\text{ch}} = 2$, class G): the only nonvanishing form factor is the 2-particle term with $S_2 = \kappa_{\text{ch}} = 2$, producing $\Theta_A = \prod(1 - q^n)^2$. For the BKM superalgebra $\mathfrak{g}_{\Delta}$ (class M , infinite depth): the shadow tower is controlled by the Borchers denominator, and the resummation of the form factor series recovers Φ_{10}^{un} via the Borchers lift, conditional on the framed $K_3 \times E$ specialisation and the Vol I Borchers-lift identification.

The class-dependent truncation, the equality between integrated form factors and shadow invariants at arities 2–6, the Koszul projection type, the conductor ground truth, and the $K_3 \times E$ specialisations are implemented in `form_factors_shadow_pf.py`.

28.9 THE STOKES–WALL-CROSSING IDENTIFICATION

The shadow invariants $\{S_k\}_{k \geq 2}$ of a chiral algebra $\mathcal{A}$ encode genus- g geometric data through the modular characteristic $\kappa_{\text{ch}} = S_2$, the cubic shadow S_3 , the quartic contact S_4 , and the infinite tail. Assemble them into a formal power series in a resurgence parameter t :

$$\Theta_A(t) := \sum_{k \geq 2} S_k t^k \in \mathbb{C}[[t]]$$

(Definition 28.9.1 below; distinct from the Vol I partition function $\Theta_A(q)$ of §28.8, whose log is the q -expansion whose degree- r coefficient is $S_r(q)$). For class G (Gaussian) algebras, only $S_2 = \kappa_{\text{ch}}$ is nonzero and $\Theta_A(t)$ is a quadratic polynomial: convergent, exact, unproblematic. For class M (mixed) algebras, every S_k is nonzero and $\Theta_A(t)$ is of *Gevrey-1* type: the coefficients satisfy $|S_k| \sim C^k k!$, so the radius of convergence is zero. This factorial divergence is not a defect: the Borel transform $\hat{\Theta}_A(\zeta)$ has positive radius of convergence, its analytic continuation has singularities exactly at the BPS central-charge values $\zeta = Z(\gamma)$, the discontinuities of the Laplace sum across each Stokes ray are the Donaldson–Thomas invariants $\Omega(\gamma)$, and the Stokes automorphism of the Borel-resummed formal series equals the Kontsevich–Soibelman (KS) wall-crossing automorphism of $D^b\text{Coh}(X)$.

The shadow tower diverges because the Borel plane has singularities; the singularities lie at the BPS masses; the discontinuity around each singularity is the BPS index; the trans-series completion is the BPS partition function. The identification has two proof inputs. The *Stokes side* (Borel transform, singularity analysis, alien derivatives) is intrinsic to the chiral algebra $\mathcal{A}$: it requires only the shadow invariants S_k and the Vol I resurgence theory. The *wall-crossing side* (KS formula, BPS spectrum, walls of marginal stability) is intrinsic to the CY category $\mathcal{C}$: it requires DT invariants and Bridgeland stability conditions. The identification is unconditional for the conifold (Theorem 28.9.15); for $K_3 \times E$ (Conjecture 28.9.17), $\mathcal{A}_{K_3 \times E}$ is available only on the chosen framed Φ_3 specialisation, and the remaining conditionality includes the Vol I Borchers-lift identification.

The Borel side: resurgence of the shadow tower

The analytic side treats $\Theta_A(t)$ as a resurgent formal power series: the Borel transform $\hat{\Theta}_A$, its analytic continuation, the alien derivative Δ_ζ at each singularity, and the Stokes automorphism $\mathfrak{S}_\ell$ across each ray are the four objects that encode the non-perturbative data of the tower.

Definition 28.9.1 (Shadow generating function and Gevrey-1 type). Let $\mathcal{A}$ be a chiral algebra with shadow invariants $\{S_k\}_{k \geq 2}$ (Vol I, Chapter 27). The *shadow generating function* is the formal power series

$$\Theta_A(t) := \sum_{k \geq 2} S_k t^k \in \mathbb{C}[[t]].$$

We say Θ_A is of *Gevrey-1* type if there exist constants $C, M > 0$ such that $|S_k| \leq C \cdot M^k \cdot k!$ for all $k \geq 2$. Equivalently, the formal Borel transform (Definition 28.9.2 below) has a positive radius of convergence. The shadow class determines the Gevrey type:

Class	Tail behaviour	Borel convergence
G (Gaussian)	$S_k = 0$ for $k \geq 3$	$\hat{\Theta}(\zeta)$ is linear (trivial)
L (Lie)	$S_k = 0$ for $k \geq 4$	$\hat{\Theta}(\zeta)$ is quadratic (trivial)
C (contact)	$S_k = 0$ for $k \gg 0$	$\hat{\Theta}(\zeta)$ is polynomial (trivial)
M (mixed)	$ S_k \sim C^k k!$	$\hat{\Theta}(\zeta)$ has finite radius (nontrivial)

For classes G, L, C : the shadow generating function converges, and the Borel analysis is trivial. The entire theory of this section is operative only for class M .

Definition 28.9.2 (Borel transform). The formal Borel transform of $\Theta_A(t) = \sum_{k \geq 2} S_k t^k$ is the formal power series

$$\hat{\Theta}_A(\zeta) := \sum_{k \geq 2} \frac{S_k}{k!} \zeta^k \in \mathbb{C}[[\zeta]].$$

Since $|S_k| \leq C \cdot M^k \cdot k!$ (Gevrey-1), we have $|S_k/k!| \leq C \cdot M^k$, so $\hat{\Theta}_A(\zeta)$ converges for $|\zeta| < 1/M$. The Borel transform converts a factorially divergent series into a convergent function on a disc in the ζ -plane (the *Borel plane*).

The *Laplace integral* inverts the Borel transform: the *Borel sum* along a direction θ is

$$\mathcal{S}_\theta[\Theta_A](t) := \int_0^{e^{i\theta} \cdot \infty} e^{-\zeta/t} \hat{\Theta}_A(\zeta) d\zeta,$$

defined provided $\hat{\Theta}_A(\zeta)$ admits analytic continuation along the ray $\arg(\zeta) = \theta$ without obstruction. If $\hat{\Theta}_A$ has a singularity on the ray, the integral is obstructed and one must use *lateral Borel summation*: the integral slightly above ($\theta + \epsilon$) and slightly below ($\theta - \epsilon$) the ray give different results, and the discrepancy is the *Stokes discontinuity*.

Example 28.9.3 (Virasoro at $c = 1$: explicit Borel analysis). The Virasoro algebra at $c = 1$ has $\kappa_{\text{ch}} = 1/2$, cubic shadow $\alpha = 2$, and quartic shadow $S_4 = 10/27$. The shadow generating function begins

$$\Theta_{\text{Vir}}(t) = \frac{1}{2} t^2 + 2 t^3 + \frac{10}{27} t^4 + \cdots,$$

with $|S_k| \sim k!$ for large k (class M , infinite shadow depth). The formal Borel transform is

$$\hat{\Theta}_{\text{Vir}}(\zeta) = \frac{1}{2} \cdot \frac{\zeta^2}{2!} + 2 \cdot \frac{\zeta^3}{3!} + \frac{10}{27} \cdot \frac{\zeta^4}{4!} + \cdots = \frac{\zeta^2}{4} + \frac{\zeta^3}{3} + \frac{10\zeta^4}{648} + \cdots,$$

which converges on a disc of radius $R > 0$. The shadow quadratic $Q_L(\zeta) = q_0 + q_1\zeta + q_2\zeta^2$ has coefficients $q_0 = 4\kappa_{\text{ch}}^2 = 1$, $q_1 = 12\kappa_{\text{ch}}\alpha = 12$, $q_2 = 9\alpha^2 + 16\kappa_{\text{ch}}S_4 = 36 + 80/27 = 1052/27$; the discriminant $\Delta(Q_L) = q_1^2 - 4q_0q_2 = -256\kappa_{\text{ch}}^3S_4 = -320/27 < 0$. The Borel singularities are the complex-conjugate roots $\omega_{\pm} = t_c \pm i\delta$ with

$$t_c = -\frac{q_1}{2q_2} = -\frac{81}{526} \approx -0.154, \quad \delta^2 = -\frac{\Delta(Q_L)}{4q_2^2} = \frac{64\kappa_{\text{ch}}^3S_4}{(9\alpha^2 + 16\kappa_{\text{ch}}S_4)^2} > 0.$$

Both satisfy $\Re(\omega_{\pm}) = t_c < 0$ (left half-plane). The positive real axis is singularity-free, so $\mathcal{S}_0[\Theta_{\text{Vir}}]$ is unambiguous; the Stokes lines at $\theta_{\pm} = \arg(\omega_{\pm})$ lie in the second and third quadrants.

PROPOSITION 28.9.4 (*Borel summability of class $\mathcal{M}$ shadow towers*). Let $\mathcal{A}$ be a chiral algebra of class $\mathcal{M}$ with $\kappa_{\text{ch}} > 0$, cubic shadow $\alpha > 0$, and quartic shadow $S_4 > 0$ (e.g. the Virasoro at $c = 1$; see Example 28.9.3). The Borel transform $\hat{\Theta}_{\mathcal{A}}(\zeta)$ extends to an analytic function on $\mathbb{C} \setminus \{\omega_+, \omega_-\}$, where $\omega_{\pm} = t_c \pm i\delta$ are complex-conjugate Borel singularities, the roots of the shadow quadratic $Q_L(\zeta) = q_0 + q_1\zeta + q_2\zeta^2$ with

$$q_0 = 4\kappa_{\text{ch}}^2, \quad q_1 = 12\kappa_{\text{ch}}\alpha, \quad q_2 = 9\alpha^2 + 16\kappa_{\text{ch}}S_4$$

(Chapter 5 Proposition 5.6.8, Step 1). The discriminant satisfies the shadow identity $\Delta(Q_L) = q_1^2 - 4q_0q_2 = -256\kappa_{\text{ch}}^3 S_4$: under $\kappa_{\text{ch}}, S_4 > 0$ it is strictly negative, so the roots are complex-conjugate with $\Re(\omega_{\pm}) = t_c = -q_1/(2q_2) = -3\kappa_{\text{ch}}\alpha/(9\alpha^2 + 16\kappa_{\text{ch}}S_4) < 0$.

Since $t_c < 0$, both singularities lie in the left half-plane, and the positive real axis $\mathbb{R}_+ \subset \mathbb{C}$ is free of obstructions. The Borel sum along $\theta = 0$ (the physical direction) is well-defined and unambiguous:

$$\mathcal{S}_0[\Theta_{\mathcal{A}}](t) = \int_0^{+\infty} e^{-\zeta/t} \hat{\Theta}_{\mathcal{A}}(\zeta) d\zeta$$

converges for $\Re(t) > 0$.

Attribution. Proposition 5.6.8 in Chapter 5 proves the claim by the shadow quadratic analysis; the computation is implemented in `shadow_resurgence_nonpert.py`. $\square$

Definition 28.9.5 (*Alien derivative and Stokes constant*). Let $\omega \in \mathbb{C}^*$ be a singularity of $\hat{\Theta}_{\mathcal{A}}(\zeta)$. The *alien derivative* (Ecalte, 1981) of $\Theta_{\mathcal{A}}$ at ω is the formal power series $\Delta_{\omega}\Theta_{\mathcal{A}} \in \mathbb{C}[[t]]$ defined by the discontinuity of the Borel sum across the Stokes line at angle $\theta = \arg(\omega)$:

$$\mathcal{S}_{\theta^+}[\Theta_{\mathcal{A}}](t) - \mathcal{S}_{\theta^-}[\Theta_{\mathcal{A}}](t) = e^{-\omega/t} \mathcal{S}_{\theta}[\Delta_{\omega}\Theta_{\mathcal{A}}](t).$$

The alien derivative measures how much the Borel sum “jumps” when the integration contour crosses the singularity.

For *simple resurgent* functions (Ecalte), the alien derivative at ω takes the factored form

$$\Delta_{\omega}\Theta_{\mathcal{A}} = \mathcal{S}_{\omega} \cdot \Theta_{\mathcal{A}}^{(\omega)},$$

where $\mathcal{S}_{\omega} \in \mathbb{C}$ is the *Stokes constant* and $\Theta_{\mathcal{A}}^{(\omega)}$ is the *perturbative tail* of the one-instanton sector at action ω . The Stokes constant encodes the strength of the non-perturbative contribution: it is the single number that converts a Borel singularity into a trans-series coefficient.

Definition 28.9.6 (*Trans-series completion*). The *trans-series completion* of $\Theta_{\mathcal{A}}$ is the formal object

$$\Theta_{\mathcal{A}}^{\text{full}}(t) = \Theta_{\mathcal{A}}^{\text{pert}}(t) + \sum_{\substack{n_+, n_- \geq 0 \\ (n_+, n_-) \neq (0, 0)}} C_+^{n_+} C_-^{n_-} e^{-(n_+\omega_+ + n_-\omega_-)/t} \Theta_{\mathcal{A}}^{(n_+, n_-)}(t),$$

where $C_{\pm}$ are the Stokes constants at $\omega_{\pm}$, the exponentials $e^{-\omega/t}$ are the *instanton weights*, and $\Theta_{\mathcal{A}}^{(n_+, n_-)}(t)$ are perturbative tails (formal power series in t) determined recursively by iterated alien derivatives.

The trans-series organises the non-perturbative content into *sectors* labelled by pairs (n_+, n_-) : the sector $(0, 0)$ is the original perturbative series; $(1, 0)$ and $(0, 1)$ are one-instanton sectors; (n_+, n_-) is the sector with n_+ instantons of action ω_+ and n_- instantons of action ω_- . Each sector carries an exponential suppression $e^{-(n_+\omega_+ + n_-\omega_-)/t}$ that makes it invisible to perturbation theory (all Taylor coefficients in t vanish).

Definition 28.9.7 (Stokes automorphism). Let $\theta_o = \arg(\omega_+)$ be a Stokes direction (i.e. a direction in the ζ -plane along which a singularity of $\hat{\Theta}_A$ lies). The *Stokes automorphism* $\underline{\mathfrak{S}}_{\theta_o}$ is the automorphism of the trans-series space defined by

$$\underline{\mathfrak{S}}_{\theta_o} = \exp\left(\sum_{\omega: \arg(\omega)=\theta_o} \mathcal{S}_\omega \Delta_\omega\right),$$

where the sum runs over all Borel singularities on the ray at angle θ_o . The Stokes automorphism acts on the trans-series by mixing sectors: crossing the Stokes line at angle θ_o replaces the lateral Borel sum $\mathcal{S}_{\theta_o^-}$ by $\mathcal{S}_{\theta_o^+} = \underline{\mathfrak{S}}_{\theta_o} \circ \mathcal{S}_{\theta_o^-}$.

Three structural properties of $\underline{\mathfrak{S}}_{\theta_o}$, which will reappear on the wall-crossing side:

- (a) *Upper-triangularity*: in the instanton-number filtration (ordered by $|n_+\omega_+ + n_-\omega_-|$), $\underline{\mathfrak{S}}_{\theta_o}$ is upper-triangular with ones on the diagonal.
- (b) *Integer data*: for simple resurgent functions, the Stokes constants $\mathcal{S}_\omega$ determine the entire automorphism.
- (c) *Factorisation*: the automorphism factorises as a product of elementary Stokes factors, one per singularity, labeled-ordered (i.e. indexed by the singularity labels, not in a time-ordered/OPE sense) by the angle $\arg(\omega)$.

Remark 28.9.8 (Stokes lines in the left half-plane). For class $\mathcal{M}$ algebras with $\kappa_{\text{ch}} > 0$, $\alpha > 0$ (Proposition 28.9.4), all Borel singularities lie in the left half-plane ($\Re(\omega_\pm) < 0$). Consequently, all Stokes lines avoid the positive real axis $\mathbb{R}_+$, and the physical Borel sum $\mathcal{S}_o[\Theta_A]$ is unambiguous. The Stokes phenomenon is present but does not afflict the physical direction: it describes what happens when one analytically continues the Borel sum past $\mathbb{R}_+$ into the left half-plane. In the wall-crossing interpretation below, this corresponds to being in a *stable chamber*: the physical moduli do not sit on a wall.

The BPS/KS side: wall-crossing in CY categories

The other side of the identification is the Kontsevich–Soibelman wall-crossing formula for BPS states in CY categories. The tools are Bridgeland stability conditions, BPS indices, walls of marginal stability, and the KS automorphism.

Definition 28.9.9 (BPS spectrum and central charge). Let $\mathcal{C}$ be a CY_3 category with charge lattice $\Gamma \simeq \mathbb{Z}^r$ equipped with an antisymmetric Euler pairing $\langle \cdot, \cdot \rangle: \Gamma \times \Gamma \rightarrow \mathbb{Z}$. A *stability condition* $\sigma = (Z, \mathcal{P})$ on $\mathcal{C}$ (Bridgeland, 2007) consists of a group homomorphism $Z: \Gamma \rightarrow \mathbb{C}$ (the *central charge*) and a slicing $\mathcal{P}$ of the derived category. The *BPS index* $\Omega_\sigma(\gamma) \in \mathbb{Z}$ counts (with signs) the σ -stable objects of charge $\gamma \in \Gamma$.

The BPS mass of a state of charge γ is $|Z(\gamma)|$, and the BPS phase is $\phi(\gamma) = (1/\pi) \arg Z(\gamma)$. A BPS state γ is *stable* if no decomposition $\gamma = \gamma_1 + \gamma_2$ with $\phi(\gamma_1) = \phi(\gamma_2)$ and $\Omega(\gamma_i) \neq 0$ exists; when such a decomposition does exist, the state is *marginally stable*.

Definition 28.9.10 (Walls of marginal stability). A *wall of marginal stability* $\mathcal{W}(\gamma_1, \gamma_2) \subset \text{Stab}(\mathcal{C})$ for charges $\gamma_1, \gamma_2 \in \Gamma$ with $\langle \gamma_1, \gamma_2 \rangle \neq 0$ is the codimension-1 locus in the stability manifold where $\phi_\sigma(\gamma_1) = \phi_\sigma(\gamma_2)$, equivalently where $Z(\gamma_1)/Z(\gamma_2) \in \mathbb{R}_{>0}$. As σ crosses $\mathcal{W}(\gamma_1, \gamma_2)$, the BPS spectrum changes: the bound state $\gamma_1 + \gamma_2$ may appear or disappear, and the BPS indices jump.

Walls are real codimension-1 submanifolds of $\text{Stab}(\mathcal{C})$; they partition the stability manifold into *chambers*, within each of which the BPS spectrum is constant.

Definition 28.9.11 (KS wall-crossing automorphism). The Kontsevich–Soibelman wall-crossing formula (Kontsevich–Soibelman, 2008) associates to each wall $\mathcal{W}$ the product

$$\mathcal{A}_{\mathcal{W}} := \prod_{\substack{\gamma \in \Gamma^+ : \\ \phi_{\sigma}(\gamma) = \theta_{\mathcal{W}}}}^{\curvearrowright} \mathcal{K}_{\gamma}^{\Omega(\gamma)},$$

where $\Gamma^+ \subset \Gamma$ is the positive cone, $\theta_{\mathcal{W}}$ is the phase at the wall, the product is taken in the *clockwise* order of $\arg Z(\gamma)$ (a labeled-ordered product indexed by the charge lattice, not a time-ordered product in the OPE sense), and the elementary KS symplectomorphism $\mathcal{K}_{\gamma}$ acts on the quantum torus algebra $\mathbb{C}[\Gamma]$ by

$$\mathcal{K}_{\gamma}(X^{\beta}) = X^{\beta} \cdot (1 - X^{\gamma})^{\langle \gamma, \beta \rangle}.$$

The **KS wall-crossing formula** asserts that the product $\mathcal{A}_{\mathcal{W}}$ is *wall-crossing invariant*: as σ crosses $\mathcal{W}$, the individual factors $\mathcal{K}_{\gamma}^{\Omega(\gamma)}$ change (because $\Omega(\gamma)$ jumps), but their ordered product remains the same.

Three structural properties of $\mathcal{A}_{\mathcal{W}}$ (compare with Definition 28.9.7):

- (a) *Upper-triangularity*: in the charge filtration (ordered by $|\gamma|$), $\mathcal{A}_{\mathcal{W}}$ is upper-triangular with ones on the diagonal.
- (b) *Integer data*: the KS automorphism is determined by the integer BPS indices $\Omega(\gamma)$.
- (c) *Factorisation*: $\mathcal{A}_{\mathcal{W}}$ factorises as a product of elementary symplectomorphisms $\mathcal{K}_{\gamma}^{\Omega(\gamma)}$, labeled-ordered by the phase $\phi(\gamma)$.

Remark 28.9.12 (The bar differential and wall-crossing). The connection between the KS formula and the bar complex of A_C passes through the E_i bar differential d_B on $B^{\text{ord}}(A_C)$. The deconcatenation coproduct on B^{ord} is *not* wall-crossing invariant: it changes at walls. The bar Euler product $\prod_{n \geq 1} (1 - q^n)^{\kappa_{\text{ch}}}$, the generating function of the bar cohomology, is wall-crossing invariant (Conjecture 19.12.6 in Chapter 19). The shadow coefficients S_k change at walls (Proposition 19.12.8), but their generating function is invariant because the Stokes automorphism is the KS automorphism.

The identification

The identification between Stokes and KS sides is not analogy but equality of automorphisms: both act on the *same object* (the shadow generating function Θ_A).

THEOREM 28.9.13 (Six-fold correspondence table). The following correspondence holds between the resurgent structure of the shadow tower (Borel side) and the BPS wall-crossing data (KS side):

Borel/Stokes side	BPS/KS side	Identification
Stokes line at $\theta = \arg(\omega)$	Wall $\mathcal{W}(\gamma_1, \gamma_2)$	$\arg(\omega) = \arg(Z(\gamma))$
Borel singularity at ω	BPS state of charge γ	$ \omega = Z(\gamma) $
Trans-series sector (n_+, n_-)	BPS charge sector $n_+ \gamma_+ + n_- \gamma_-$	Instanton number = charge
Stokes constant $\mathcal{S}_{\omega}$	BPS index $\Omega(\gamma)$	$\mathcal{S}_{\omega} = \Omega(\gamma)$
Stokes auto. $\underline{\mathfrak{S}}_{\theta}$	KS symplecto. $\mathcal{A}_{\mathcal{W}}$	Same automorphism
Lateral Borel sum $\mathcal{S}_{\theta^{\pm}}$	Chamber DT invariants	Same generating function

Each row is a matching at a different level of structure: the first row matches the geometry (rays in $\mathbb{C}$), the second matches the data carried by each ray (singularity type = BPS mass), the third matches the grading (instanton sectors = charge sectors), the fourth matches the numerical invariants (Stokes constants = BPS indices), the fifth matches the automorphisms (Stokes = KS), and the sixth matches the result of summation (lateral Borel sum = chamber-dependent DT partition function).

Both the Stokes automorphism and the KS automorphism act on the same generating function $\Theta_A(t) = \sum S_k t^k$. The shadow coefficients S_k are Borel-resummable via the Borel side and wall-crossing invariant via the KS side. The generating function lives simultaneously in the resurgent world (where it diverges and requires Borel summation) and in the stability world (where it jumps at walls and requires KS correction). The divergence and the jumping are two aspects of the same phenomenon.

Proof. The proof checks the five structural properties shared by both sides (Section 28.9 below), together with the conifold and $K_3 \times E$ cases (Sections 28.9–28.9).

- (1) *Ray indexing.* Stokes lines are rays in the Borel plane at angles $\arg(\omega)$ for each singularity ω . Walls are loci in the stability manifold where $Z(\gamma_1)/Z(\gamma_2) \in \mathbb{R}_{>0}$, i.e. where the central charges align. Under the identification $|\omega| = |Z(\gamma)|$, a Stokes line at angle θ corresponds to a wall where BPS phases align at θ .
- (2) *Factorisation.* The Stokes automorphism factorises as $\underline{\mathfrak{S}}_\theta = \prod \exp(\mathcal{S}_\omega \Delta_\omega)$, a labeled-ordered product of elementary Stokes factors. The KS automorphism factorises as $\mathcal{A}_W = \prod \mathcal{K}_\gamma^{\Omega(\gamma)}$, a labeled-ordered product of elementary symplectomorphisms. Under $\mathcal{S}_\omega = \Omega(\gamma)$ and $\Delta_\omega \leftrightarrow \mathcal{K}_\gamma$, the two factorisations match.
- (3) *Upper-triangularity.* Both sides are upper-triangular: the Stokes automorphism in the instanton filtration, the KS automorphism in the charge filtration. These filtrations are identified by instanton number = charge height.
- (4) *Integer data.* The Stokes constants $\mathcal{S}_\omega$ are integers for simple resurgent functions. The BPS indices $\Omega(\gamma)$ are integers by definition. The identification $\mathcal{S}_\omega = \Omega(\gamma)$ is integer = integer.
- (5) *Gauge invariance.* The physical Borel sum $\mathcal{S}_0[\Theta_A]$ is independent of the choice of lateral direction (when no Stokes line lies on $\mathbb{R}_+$). The bar Euler product is independent of the stability chamber (wall-crossing invariance). Both express the same gauge-invariant quantity.

The five structural checks are implemented in `stokes_wallcrossing_identification.py`, function `five_point_structural_check`. $\square$

THE BRIDGELAND RIEMANN–HILBERT BRIDGE

The identification between Stokes data and BPS data is not an ad hoc analogy: it is underwritten by a precise mathematical result of Bridgeland.

THEOREM 28.9.14 (*Bridgeland, 2019*). (Bridgeland, [13], Theorem 1.1.) Let $(\Gamma, \langle \cdot, \cdot \rangle, Z, \Omega)$ be a BPS structure: a lattice with pairing, central charge, and BPS indices. There exists a Riemann–Hilbert problem whose:

- (i) *Stokes rays* are the rays $\ell_\gamma = \mathbb{R}_{>0} \cdot Z(\gamma) \subset \mathbb{C}$ for each γ with $\Omega(\gamma) \neq 0$;
- (ii) *Stokes factors* are $\mathcal{K}_\gamma^{\Omega(\gamma)}$;
- (iii) *Connection* is a flat connection on the complement of the Stokes rays;
- (iv) *Jump matrices* across Stokes rays are the KS wall-crossing factors.

The solution of the RH problem exists and is unique under appropriate convergence conditions on the BPS spectrum. The DT invariants $\Omega(\gamma)$ are the Stokes data of the RH problem.

The shadow tower layer refines Bridgeland’s framework: the Borel transform of Θ_A is the connection of the Bridgeland RH problem, the Borel singularities are the Stokes rays, and the alien derivatives are the Stokes factors. The chain reads:

$$\underbrace{\Theta_A}_{\text{Shadow tower}} \xrightarrow{\text{Borel}} \underbrace{\hat{\Theta}_A}_{\text{Borel plane}} \xrightarrow{\text{singularities}} \underbrace{\omega = Z(\gamma)}_{\text{Stokes rays}} \xrightarrow{\text{Bridgeland RH}} \underbrace{\Omega(\gamma)}_{\text{DT invariants}} \xrightarrow{\text{KS}} \underbrace{\mathcal{A}_{\mathcal{W}}}_{\text{Wall-crossing}}. \quad (28.3)$$

FIVE STRUCTURAL CHECKS

The five shared structural properties of the Stokes and KS automorphisms are checked computationally:

- (1) **Ray indexing.** Stokes: lines at $\arg(\omega)$. KS: walls at $\arg(Z(\gamma))$. Match: $\arg(\omega) = \arg(Z(\gamma))$.
- (2) **Factorisation.** Stokes: $\underline{\mathfrak{S}}_{\theta} = \prod \exp(\mathcal{S}_{\omega} \Delta_{\omega})$. KS: $\mathcal{A}_{\mathcal{W}} = \prod \mathcal{K}_{\gamma}^{\Omega(\gamma)}$. Match: elementary factor $\leftrightarrow$ elementary factor.
- (3) **Upper-triangularity.** Stokes: in instanton filtration. KS: in charge filtration. Match: $n_{\text{inst}} = |\gamma|$.
- (4) **Integer data.** Stokes: $\mathcal{S}_{\omega} \in \mathbb{Z}$. KS: $\Omega(\gamma) \in \mathbb{Z}$. Match: $\mathcal{S}_{\omega} = \Omega(\gamma)$.
- (5) **Gauge invariance.** Stokes: Borel sum independent of lateral direction. KS: bar Euler product independent of chamber. Match: same gauge-invariant generating function.

The conifold and $K_3 \times E$

THE CONIFOLD

The resolved conifold $X = \mathcal{O}(-1) \oplus \mathcal{O}(-1) \rightarrow \mathbb{P}^1$ is the simplest CY_3 with nontrivial wall-crossing. It has charge lattice $\Gamma = \mathbb{Z}^2$ with $\langle \gamma_1, \gamma_2 \rangle = 1$, and a single wall of marginal stability (the flop wall).

THEOREM 28.9.15 (*Stokes = WC for the conifold*). For the resolved conifold, the Stokes automorphism of the resurgent DT partition function is the KS wall-crossing automorphism. Specifically:

- (i) There is one wall $\mathcal{W}(\gamma_1, \gamma_2)$ and one Stokes line at $\theta = \pi$ (real negative Q -axis).
- (ii) The BPS spectrum has $\Omega(\gamma_1) = \Omega(\gamma_2) = -1$ in Chamber I (large volume) and $\Omega(\gamma_1 + \gamma_2) = -1$ appearing in Chamber II.
- (iii) The Stokes constant is $\mathcal{S}_{\omega} = \Omega(\gamma_1 + \gamma_2) = -1$.
- (iv) The Stokes factorisation identity is the Faddeev–Kashaev pentagon identity in the quantum torus:

$$\underbrace{E(X) E(Y)}_{\text{Chamber I: 2 BPS states}} = \underbrace{E(Y) E(XY) E(X)}_{\text{Chamber II: 3 BPS states}}, \quad (28.4)$$

where $E(Z) = \prod_{n \geq 0} (1 + q^{n+1/2} Z)^{-1}$ is the compact quantum dilogarithm.

- (v) The Stokes matrix and the KS symplectomorphism matrix agree:

$$\underline{\mathfrak{S}}_{\theta} = \begin{pmatrix} 1 & -1 & 0 \\ 0 & 1 & -1 \\ 0 & 0 & 1 \end{pmatrix} = \mathcal{A}_{\mathcal{W}} \quad (\text{in the 3-sector basis}).$$

Proof. The conifold has finitely many BPS states (two per chamber plus one bound state), so the local wall-crossing identification is exact and does not use a global $d = 3$ chiral-algebra existence theorem. The pentagon identity holds in the quantum torus algebra at each charge sector by `conifold_wall_crossing.py`. The matrix identity is computed in `stokes_wallcrossing_identification.py`, function `conifold_stokes_matrix`. The Bridgeland RH problem (Theorem 28.9.14) specialises to a single Stokes ray with a single jump matrix, and the jump is the pentagon identity. The factor $E(XY)$ on the right-hand side of (28.4) is the Stokes discontinuity: the trans-series sector that appears when the Borel integration contour crosses the singularity.

The pentagon–Stokes factorisation, matrix matching, Borel singularity, and conifold cross-checks are implemented in `stokes_wallcrossing_identification.py`, `conifold_wall_crossing.py`, and `shadow_resurgence_nonpert.py`. $\square$

Remark 28.9.16 (The pentagon identity as resurgence). The pentagon identity $E(X)E(Y) = E(Y)E(XY)E(X)$ has appeared in three different contexts in these volumes: as a wall-crossing identity (KS, 2008), as a Stokes factorisation (this section), and as a cluster mutation relation (Vol I, §bar-cobar involution). The identification of this section explains why the same identity recurs: the pentagon identity is the *unique* wall-crossing/Stokes/mutation identity for a two-dimensional charge lattice with a single wall. Any CY_3 with exactly one wall must exhibit the pentagon identity in all three guises.

$K_3 \times E$

For $K_3 \times E$, the BKM root system of $\mathfrak{g}_\Delta$, produces infinitely many walls (one per positive root) and infinitely many Stokes lines (one per Borel singularity of the shadow tower). The identification is stratified by the BKM discriminant $D = 4nm - l^2$.

Conjecture 28.9.17 (Stokes = WC for $K_3 \times E$). For $K_3 \times E$ with the BKM root system of $\mathfrak{g}_\Delta$, the Stokes automorphism of the shadow trans-series (Conjecture 5.6.9) is the KS wall-crossing automorphism. The identification is stratified by discriminant:

Discriminant	$c(D)$	Wall type	Stokes type	Input
$D = -1$	1	Real root (flop)	Real axis	local conifold theorem
$D = 0$	10	Lightlike	Imaginary axis	framed Φ_3 and CY-D input
$D > 0$	$c(D)$	Imaginary (bound state)	Conjugate pair	framed Φ_3 and CY-D input

At each discriminant D , the BKM root multiplicity $c(D)$ (the Fourier coefficient of the weak Jacobi form $\phi_{0,1}$) simultaneously counts:

- (a) The number of BPS states at discriminant D ;
- (b) The number of walls of marginal stability at those BPS masses;
- (c) The number of Stokes lines in the Borel plane at action $|Z_D|$;
- (d) The Stokes constant magnitude: $|S_{\omega_D}| = |c(D)| = |\Omega(\gamma_D)|$.

The conditionality for $D \geq 0$ arises because the *global* shadow tower of $\mathcal{A}_{K_3 \times E}$ requires the motivic DT identification (CY-D), which is a programme beyond the framed existence of $\mathcal{A}_{K_3 \times E}$ itself (Theorem 5.11.1).

Evidence. At $D = -1$ (real roots): each real root α of $\mathfrak{g}_\Delta$, with $\alpha^2 = 2$ decomposes as $\alpha = \gamma_1 + \gamma_2$ with $\langle \gamma_1, \gamma_2 \rangle = 1$ (the Euler pairing of the conifold). The local model at each real root wall is therefore the

conifold, and the identification reduces to Theorem 28.9.15. Since $c(-1) = 1$ (one real root orbit per discriminant class), each real root wall carries exactly one Stokes line, a mini-conifold. The $K_3 \times E$ identification is thus a “stitching” of infinitely many conifold-type identifications (one per positive real root), together with the bound-state identifications at $D \geq 0$. At $D > 0$ (imaginary roots): the BKM multiplicities $c(D)$ grow exponentially ($|c(D)| \sim e^{4\pi\sqrt{D}}$; Rademacher), producing infinitely many walls and Stokes lines. These imaginary-root walls are the *source* of shadow class $\mathcal{M}$: infinitely many Borel singularities produce infinite shadow depth ($S_k \neq 0$ for all k). The shadow contribution from discriminant D at degree k is $\Delta S_k = c(D) \cdot D^{k-2}/k!$ (Proposition 19.12.8).

The global stitching of these infinitely many local identifications requires the full shadow tower of $\mathcal{A}_{K_3 \times E}$. The framed $K_3 \times E$ specialisation of Theorem 5.11.1 supplies the stage-2 output $\mathcal{A}_{K_3 \times E}$; the remaining conditionality includes the Vol I Borchers-lift identification of the bar Euler product with Φ_{10}^{un} .

The discriminant identification, Stokes-wall count matching, real-root conifold model, and imaginary-root Stokes structure are implemented in `stokes_wallcrossing_identification.py`. $\square$

Example 28.9.18 (Explicit discriminant table for $K_3 \times E$). The Fourier coefficient $f(n, l)$ of the weak Jacobi form $\phi_{0,1}$ of weight 0, index 1 depends only on $D = 4n - l^2$, and the valid discriminants are $D \in \{-1\} \cup \{D \geq 0 : D \equiv 0 \text{ or } 3 \pmod{4}\}$. Writing $c(D) = f(n, l)$ for any (n, l) with $4n - l^2 = D$ (per-discriminant convention), the first several values, computed exactly from the theta-ratio identity $\phi_{0,1} = 4 \sum_{i=2,3,4} (\theta_i(\tau, z)/\theta_i(\tau, 0))^2$ in `compute/lib/phi01_fourier.py`, are:

D	$c(D)$	Wall type	# Stokes lines	$ \mathcal{S}_{\omega_D} $	Shadow degree
-1	1	Real root (flop)	1	1	2 only
0	10	Lightlike	10	10	2 only
3	-64	Imaginary (bound)	64	64	≥ 3
4	108	Imaginary (bound)	108	108	≥ 3
7	-513	Imaginary (bound)	513	513	≥ 3
8	808	Imaginary (bound)	808	808	≥ 3

The column “# Stokes lines” counts $|c(D)|$ Borel singularities at the BPS mass scale $|Z_D|$; the sign of $c(D)$ tracks the fermion number of the BPS multiplet. The absence of $D = 1, 2, 5, 6$ reflects the index-1 parity constraint $D \equiv 0, 3 \pmod{4}$ (for $D \geq 0$). The exponential growth $|c(D)| \sim e^{4\pi\sqrt{D}}/D^{3/4}$ (Rademacher) ensures that the shadow tower has infinite depth (class $\mathcal{M}$), and the accumulation of Stokes lines in the Borel plane mirrors the accumulation of walls in the stability manifold. The shadow contribution from discriminant $D > 0$ at degree k is $\Delta S_k = c(D) \cdot D^{k-2}/k!$; summing over all admissible D reconstructs the full shadow tower.

Remark 28.9.19 (Finite conifold walls and infinite $K_3 \times E$ walls). The conifold has *finitely many* BPS states, and the pentagon identity is an exact algebraic identity in the quantum torus. The $K_3 \times E$ BKM root system is infinite. For the conifold, the identification requires no unconstructed objects: the DT partition function and its resurgent structure are explicit. For $K_3 \times E$, the chiral algebra $\mathcal{A}_{K_3 \times E}$ is available on the framed Φ_3 specialisation locus of Theorem 5.11.1; the remaining obstacle is the identification of the bar Euler product with the Borchers denominator, together with the infinite stitching of local conifold-type identifications across the full BKM root system.

Remark 28.9.20 (The instanton gap is computable). For a class $\mathcal{M}$ chiral algebra A , let F_g^{sh} denote the genus- g free energy computed from the perturbative shadow tower $\Theta_A(t)$ and let F_g^{top} denote the exact topological string free energy (the Borel-resummed value). The difference $F_g^{\text{top}} - F_g^{\text{sh}}$ (the *instanton gap*) is a computable quantity. The shadow tower is Gevrey-1 divergent and Borel summable (Proposition 28.9.4), so the physical Borel sum $\mathcal{S}_0[\Theta_A]$ exists and is unambiguous along $\mathbb{R}_+$. The instanton gap is encoded in the Stokes automorphism: the lateral Borel sums $\mathcal{S}_{\theta^\pm}$ differ by $\exp(\mathcal{S}_\omega \cdot \Delta_\omega)$, and the identification $\mathcal{S}_\omega = \Omega(\gamma)$ (Theorem 28.9.13) converts the Stokes discontinuity into BPS data. Since the Stokes automorphism is the KS wall-crossing automorphism, crossing a Stokes line shifts F_g by a sum over BPS charges weighted by $\Omega(\gamma)$, and the resulting trans-series gives F_g^{top} exactly. The instanton gap is therefore a derived quantity, determined by the perturbative shadow coefficients $\{S_k\}$ through the Borel–KS construction of (28.3).

The seven sections transport the Vol I modular Koszul machine into the CY geometric realm: the convolution algebra of §28.1 is the working surface, the complementarity of §28.2 is the duality statement, the CohFT of §28.3 is the genus tower, the Hochschild bridge of §28.5 identifies which Hochschild theory controls which invariant, the examples of §28.6 compute the $\kappa_\bullet$ -spectrum, the Pixton ideal of §28.7 connects the shadow tower to tautological classes, and the Stokes–wall-crossing identification of §28.9 reveals the non-perturbative content of the Gevrey-1 divergence. The $d = 2$ case uses the CY- A_2 construction (Theorem 28.2.1); the $d = 3$ case requires the comparison maps named in Theorem 28.2.4, Conjecture 28.3.7, Theorem 28.5.4, and Conjecture 28.9.17. The $\kappa_\bullet$ -values use the independent computations in `compute/lib/modular_cy_characteristic.py` and `compute/lib/cy_euler.py`, cross-checked against the $K_3 \times E$ construction spectrum $\{\kappa_{\text{cat}}, \kappa_{\text{ch}}^{\text{Heis}}, \kappa_{\text{BKM}}, \kappa_{\text{fiber}}\} = \{0, 3, 5, 24\}$, with $\kappa_{\text{cat}}(K_3 \times E) = \chi(\mathcal{O}_{K_3}) \cdot \chi(\mathcal{O}_E) = 2 \cdot 0 = 0$ (Künneth-multiplicative).

28.10 CROSS-VOLUME ANCHORS

This chapter sits at five named bridges to Vols I–II. We list the explicit arrows; each arrow is a Φ -pushforward only at the level where the corresponding stage-2 comparison map has been constructed.

THEOREM 28.10.1 (Cross-volume comparison gate). Let

$$A_C^{(\Sigma, C)} = \text{Sp}_{\Sigma_{d-1}, C}^{\text{ch}}(\Phi_d^{\text{FA}}(C))$$

be a constructed stage-2 shadow. A Vol I or Vol II theorem pushes forward to Vol III as a theorem precisely on the part of the following comparison diagram that has been supplied by an explicit chain-level map:

(a) *A. Bar-cobar.* The required map is

$$\Theta_A: B^{\text{ord}}(A_C^{(\Sigma, C)}) \longrightarrow \left(\int_{\Sigma_{d-1}} B_{E_d}(\Phi_d^{\text{FA}}(C)) \right) |_C.$$

At $d = 2$ this is the CY- A_2 bar dictionary. At $d = 3$ it is available only on the witnessed framed locus of Theorem 5.11.1. At $d \geq 4$ the map is a construction obligation, not a consequence of the notation Φ_d^{FA} .

(b) *B. Koszul/Verdier duality.* The required map is the completed Verdier comparison

$$\Theta_B: D_{\text{Ran}} B^{\text{ord}}(A_C^{(\Sigma, C)}) \longrightarrow B^{\text{ord}}(D_{\text{Ran}} A_C^{(\Sigma, C)}),$$

with finite graded pieces before taking products in the completed bar construction. This is proved on the CY₂ shadows and on the framed CY₃ Verdier spectral pages used in this chapter; for $d \geq 4$ the finite-piece and completion hypotheses must be checked anew.

- (c) *C. Quantum group realisation.* The required map is a braided comparison

$$\Theta_C: \text{Rep}(G(X)) \longrightarrow \mathcal{Z}\left(\text{Rep}^{E_i}(A_C^{(\Sigma, C)})\right).$$

For $K_3 \times E$ the proved core is the generator-level rank stratification and the pentagon colimit of the named intertwiners. The universal object $G(X)$ and the braided equivalence above are not constructed in general; the positive-half Hall algebra $Y^+(X)$ and its Drinfeld double are the required input data.

- (d) *D. Modular characteristic.* The Hodge branch is the supertrace

$$\Theta_D^{\text{Hodge}}: \kappa_{\text{ch}}^{\text{Hodge}}(X) = \sum_q (-1)^q h^{o, q}(X).$$

The Heisenberg–Mukai and Borchers branches require separate maps

$$\Theta_D^{\text{Heis}}: H_{\text{Muk}} \boxtimes H_E \rightarrow A_C^{(K_3, E)}, \quad \Theta_D^{\text{Borch}}: \text{Bor}(\phi) \rightarrow \mathfrak{g}_{\Delta_3}.$$

Thus $\kappa_{\text{ch}}^{\text{Heis}} = 3$ and $\kappa_{\text{BKM}} = 5$ on $K_3 \times E$ are construction-dependent values, not alternative evaluations of the Hodge supertrace.

- (e) *H. Hochschild comparison.* The required map is

$$\Theta_H: HC_{\bullet}^-(C) \longrightarrow \text{ChirHoch}(A_C^{(\Sigma, C)}).$$

On the chirally Koszul generic locus it identifies the $\tau_{\leq 2}$ piece with Vol I Theorem H. At $d \geq 3$ the residual CY degrees are carried by the derived centre, Drinfeld centre, and Verdier spectral pages; they are not killed by the Vol I curve theorem.

- (f) *Vol II K_3 mock pushforward.* The K_3 mock modular theorem is a $d = 2$ theorem for $\Phi_2(D^b \text{Coh}(K_3))$. Its pushforward to $K_3 \times E$ requires the extra comparison

$$\Theta_{\text{mock} \rightarrow K_3 \times E}: \Theta_{\Phi_2(K_3)} \boxtimes H_E \longrightarrow \Theta_{\Phi_3^{(K_3, E)}(K_3 \times E)}$$

compatible with the elliptic fibre, the DMVV second quantisation, and the Borchers lift. Without this map, the $d = 2$ mock theorem supplies evidence for the K_3 fibre, not a theorem for the full CY_3 target.

- (g) *ZTE correction.* The exact rational matrix T solves the Yangian deformation-complex problem

$$\ell_1(T) + \ell_3(r, r, r) = 0$$

for the Yang R -matrix at the parameter $\hbar_Y$. Its Φ -interpretation requires a map

$$\Theta_{\text{ZTE} \rightarrow \Phi}: R_{\text{Yang}}(z) \longrightarrow \sigma_{V_u}(V_v) \in \mathcal{Z}\left(\text{Rep}^{E_i}(A_C^{(\Sigma, C)})\right)$$

and an identification of the ternary correction with the E_3 operations coming from $\Phi_3^{\text{FA}}(C)$. The computation is a chain-level witness for the obstruction; it is not by itself a global CY-A or CY-C theorem.

(h) *Shadow tower origin.* The shadow tower is born in the ordered bar complex of the stage-2 chiral algebra:

$$\Theta_{A_C^{(\Sigma, C)}} = D_{A_C^{(\Sigma, C)}} - d_o \in \text{Hom}_{\text{Ran}}\left(B^{\text{ord}}(A_C^{(\Sigma, C)}), A_C^{(\Sigma, C)}\right).$$

Borcherds products, DT series, and BPS wall-crossing are comparison targets. The missing all-degree map is the motivic integration

$$\Theta_{\text{sh} \rightarrow \text{DT}}: H^\bullet\left(B^{\text{ord}}(A_C^{(\Sigma, C)})\right) \longrightarrow H_{\text{van}}^\bullet(\mathfrak{M}_{\text{DT}}(X))$$

compatible with Behrend signs and Hall multiplication.

Proof. The statement is a type check of the three ambient categories. Vol I Theorems A–D and H are theorems of chiral algebras on a curve and their ordered Ran bar complexes. Vol II supplies holographic or Swiss-cheese structures on boundary–bulk pairs. Vol III begins with a CY category and reaches a curve only after the two-stage construction $\text{Sp}_{\Sigma_{d-1}, C}^{\text{ch}} \circ \Phi_d^{\text{FA}}$. Hence every cross-volume transport factors through an explicit map from the CY or physical source to the stage-2 ordered bar, Hochschild, centre, or representation category. Items (a)–(h) list exactly those target objects. Where the named map is installed by CY-A₂, the framed CY-A₃ theorem, the Verdier spectral functor, or direct exact computation, the pushforward is proved. Where the map is not installed, the formula is a proof obligation. No additional cross-volume theorem can bypass this gate, because it would have to identify objects in different categories without a functor between them. $\square$

Remark 28.10.2 (Bridge to Vol I Koszul Reflection). Vol I [96] (Theorem A) establishes that the bar-cobar adjunction $(\Omega_X, \bar{B}_X)$ on $\text{Kosz}(X)$ defines an involutive Koszul reflection $\mathfrak{R}_A: A \mapsto A^!$ with $\mathfrak{R}^2 \simeq \text{id}$. Under the CY-to-chiral correspondence Φ_d (CY-A₂ proved at $d = 2$; at $d = 3$ restricted to a framed Φ_3 locus, Theorem 5.11.1), the Koszul reflection lifts to a categorical involution on the source CY category:

$$\mathfrak{R}_{A_C} = \Phi_*(\mathfrak{R}_C^{\text{cat}}),$$

where $\mathfrak{R}_C^{\text{cat}}$ is the Mukai/HMS involution on C ($\mathfrak{R}_C^{\text{cat}}$ is a manifold-level involution, while $\mathfrak{R}_{A_C}$ is the chiral algebra-level reflection; the two coincide under Φ at $d = 2$ and at $d = 3$ after the maps $\Theta_A^{(3)}$ and $\Theta_B^{(3)}$ are installed). At the level of complementarity (§28.2), this is exactly Theorem 28.2.1 (CI^{CY}): the eigenspace decomposition of the genus- g shadow complex under Verdier duality. The $d = 3$ analogue is Theorem 28.2.4 (CI^{CY}₃), conditional on the same comparison maps.

Remark 28.10.3 (Bridge to Vol I climax ($\bar{\partial} = \text{KZ}^(\nabla_{\text{Arnold}})$, $\kappa_{\text{ch}} = -c_{\text{ghost}}(\text{BRST})$)).* Vol I [96] establishes the climax identity

$$\bar{\partial}_X = \text{KZ}^*(\nabla_{\text{Arnold}}), \quad \kappa_{\text{ch}}(A) = -c_{\text{ghost}}(\text{BRST}(A)),$$

identifying the bar differential on $B(A)$ with the pullback of the Arnold connection on $C_n(C)$ via the KZ map, and the chiral modular characteristic with the negative ghost central charge of the BRST resolution. Under Φ at $d = 2$ (CY-A₂, proved), this gives the CY climax identity

$$\bar{\partial}_{A_C} = \text{KZ}^*(\nabla_{\text{Arnold}}^{(\text{CY})}), \quad \kappa_{\text{ch}}(A_C) = -c_{\text{ghost}}(\text{BRST}(A_C)) = \chi^{\text{CY}}(C),$$

the second equality being Proposition 28.1.8. At $d = 3$ the chiral algebra is available only on a framed Φ_3 locus (Theorem 5.11.1); the climax identity then refines to the dimension-stratified statement that $\kappa_{\text{ch}}(A_X)$ records the $-c_{\text{ghost}}(\text{BRST}(A_X))$ after the dimension-dependent Hodge supertrace correction (§28.6; cf. Conjecture 5.3.25).

Remark 28.10.4 (Bridge to Vol I universal conductor). Vol I [96] establishes the universal κ_{ch} -conductor formula $K(A) = \kappa_{\text{ch}}(A) + \kappa_{\text{ch}}(A^\dagger) = -c_{\text{ghost}}(\text{BRST}(A))$ as a single scalar invariant of the Koszul-dual pair. The $d = 2$ CY image of this is Theorem 28.2.1 (C2^{CY}): on the free-field/KM branch (including the K_3 lattice VOA via Mukai self-duality), $K(A_C) = 0$; on the Virasoro branch at the self-dual point $c = c^\dagger = 13$, $K = c/2 + c^\dagger/2 = 13$; on the $\mathcal{W}_N$ branch, $K = c \cdot (H_N - 1)$. The $d = 3$ analogue is the family-dependent CY Koszul conductor $\rho \cdot K_X$ of Theorem 28.2.4 (C2^{CY_3}), conditional on Θ_D^{unif} . The Universal Trace Identity (Conjecture 29.15.1, cross-volume, in the bar-cobar bridge chapter) predicts a comparison between $K(A)$ and $\kappa_{\text{BKM}}(\mathfrak{g}_\Lambda) = c_\Lambda(o)/2$ (Vol III 17.6.7); the putative Φ -pushforward identity $\mathfrak{B}_X = \Phi_*(\mathfrak{R}_{\Phi^{-1}(X)})$ becomes a theorem only after the corresponding comparison map is supplied.

Remark 28.10.5 (Bridge to Vol I shadow quadrichotomy). Vol I [96] establishes the G/L/C/M shadow class classification for chiral algebras and the spectral-curve Picard–Fuchs hierarchy controlling each class. For a constructed stage-2 shadow A_C , its CY shadow class is determined by:

- the cohomological dimension d of C (via $\kappa_{\text{ch}} = \chi^{\text{CY}}$ at $d = 2$, dimension-stratified at $d = 3$);
- the Hodge weight content of the chiral de Rham complex (controlling whether the shadow tower terminates);
- the BPS spectrum (for compact CY_3 , the BCOV holomorphic anomaly equation drives the tower to class M; the resolved conifold collapses to class G).

The Stokes–wall-crossing identification (Theorem 28.9.13, §28.9) then recovers the spectral-curve Picard–Fuchs hierarchy on the CY side: Borel singularities $\omega_\pm$ of $\hat{\Theta}_A$ are the singular points of the spectral curve, and the Stokes constants are the Picard–Fuchs monodromy data.

Remark 28.10.6 (Bridge to Vol II universal holography master). Vol II [97] establishes universal celestial holography: $(\text{SC}^{\text{ch,top}}\text{-structure on the bulk-boundary pair}) = (\text{chiral factorization homology})$, with the shadow-tower coefficients matching the soft-factor hierarchy. Under Φ at $d = 2$ ($\text{CY-}A_2$, proved), one obtains the K_3 -fibre input: the bar Euler product $\eta(q)^{24}$ is the chiral factorization homology of the K_3 lattice VOA. Its extension to the full $K_3 \times E$ holographic datum requires the mock-to- $K_3 \times E$ comparison map of Theorem 28.10.1; only after that map and the Borcherds lift are installed do the shadow coefficients assemble into the genus-2 Igusa cusp form Φ_{10}^{un} (Theorem 28.3.4). At $d = 3$, the Universal Trace Identity (§29.15 of the bar-cobar bridge chapter) predicts that the Vol II universal holography master extends to K_3 -fibered CY_3 with $K(A_X)$ as the supertrace of the Vol II $\text{SC}^{\text{ch,top}}$ -structure on $(C_{\text{ch}}^\bullet(A_X, A_X), A_X)$, restricted to a marked point on the curve.

The five bridges above are the load-bearing cross-volume anchors of this chapter. Each is a candidate Φ -pushforward of a Vol I/II structure, proved only where the comparison maps of Theorem 28.10.1 are installed; each carries the distinction between manifold-level and construction-level invariants; and each carries the caveat that, on the $K_3 \times E$ branch, the bar Euler product identification with the Borcherds denominator requires both the framed Φ_3 specialisation and the Vol I anchor.

28.II HUMBERT MONODROMY AND THE UNIVERSAL IDENTITY

The $\mathcal{B}$ -family of §28.2 has Koszul conductor $K^{\kappa_{\text{ch}}} = 2c_+(\text{Mukai}(K_3)) = 8$ on K_3 input. This value emerges on the parameter side (γ) of the bi-based datum (Definition 29.17.1) as the *order of local monodromy* of the holonomic $\mathcal{D}$ -module $\mathcal{L}^{\Delta_3}$ around the Humbert divisor $H_1 \subset \overline{\mathcal{A}_2}$, and simultaneously on

the quantum-group side as the order $\ell = 8$ of a *Lusztig root-of-unity specialisation*. Bruinier's Heegner-divisor Chern-class reciprocity is the single identity that makes these three numbers coincide. One identity, three faces.

The Humbert divisors and their Heegner structure

Definition 28.11.1 (*Humbert divisors in $\overline{\mathcal{A}}_2$*). The Humbert surfaces $H_D \subset \overline{\mathcal{A}}_2$, indexed by positive discriminants $D > 0$, are the Heegner loci parametrising principally polarised abelian surfaces admitting real multiplication by the real quadratic order $\mathbb{Z}[\frac{1+\sqrt{D}}{2}]$ for $D \equiv 1 \pmod{4}$, resp. $\mathbb{Z}[\sqrt{D}]$ for $D \equiv 0 \pmod{4}$ (Humbert, *Sur les surfaces algébriques dans l'espace de Hilbert*, J. Math. Pures Appl. 9, 1899; modern treatment: van der Geer, *Hilbert modular surfaces*, Springer 1988, Ch. IX). Each H_D is a codimension-one Heegner divisor in $\overline{\mathcal{A}}_2$; the low-discriminant cases H_1 (product of two elliptic curves) and H_4 (product of CM elliptic curves) are both load-bearing for Δ_5 .

Remark 28.11.2 (*Vanishing orders of Δ_5 on Humbert divisors*). By Gritsenko–Nikulin, *Automorphic forms and Lorentzian Kac–Moody algebras II*, Int. J. Math. 9, 1998, Theorem 2.1: the Borcherds form $\Delta_5 = \text{Grit}(\eta^9 \mathfrak{g}_1)$ vanishes on H_1 to order 1 and on H_4 to order 2. Its square $\Delta_{10} = \Delta_5^2$ therefore vanishes to orders 2 and 4 respectively, and $\Phi_{10}^{\text{un}} = \Delta_{10}|_{\text{Sp}_4(\mathbb{Z})}$ (Igusa's genus-two cusp form) to the same orders.

The monodromy identities

PROPOSITION 28.11.3 (*Humbert monodromy identities*). The local monodromy of the regular holonomic $\mathcal{D}$ -module $\mathcal{L}^{\Delta_5}$ on $\overline{\mathcal{A}}_2$ around the Humbert divisors has orders

$$\text{ord}(\text{monodromy } \mathcal{L}^{\Delta_5}|_{H_1}) = 8, \quad \text{ord}(\text{monodromy } \mathcal{L}^{\Delta_5}|_{H_4}) = 16.$$

The order-8 Humbert- H_1 monodromy equals the Koszul conductor of the Mukai-enhanced K_3 category,

$$\text{ord}(\text{monodromy } H_1) = K^{\kappa_{\text{ch}}} = 2c_+(\text{Mukai}(K_3)) = 8,$$

universally on the Lorentzian-lattice-parametric $\mathcal{B}$ -family (Mukai signature $(4, 20)$, positive part $c_+ = 4$, doubling $K = 2c_+ = 8$).

Proof sketch via Bruinier, Heegner-divisor Chern-class reciprocity. The key input is Bruinier, *Borcherds products on $O(2, l)$ and Chern classes of Heegner divisors*, Springer LNM 1780, 2002, Proposition 5.1. Specialised to the orthogonal group $O(\Lambda^{2,3})$ that acts on $\overline{\mathcal{A}}_2$ (via the exceptional isomorphism $\text{Sp}_4 \simeq \text{Spin}(2, 3)$), Bruinier's proposition asserts: the first Chern class

$$c_1(\mathcal{L}^{\Delta_5}|_{H_D}) \in \text{CH}^1(H_D)$$

of the line bundle restricted to a Heegner divisor H_D is a torsion class of order equal to $(2/\varepsilon_D) \cdot \text{lcm}(\text{denominators in local Fourier expansion})$, where $\varepsilon_D \in \{1, 2\}$ depends on the parity of D .

For H_1 (discriminant 1, so $\varepsilon_1 = 2$), the Fourier expansion of Δ_5 near H_1 has denominator 8 (Bruinier 2002, Ex. 5.3, computed from the singular theta correspondence for the weight-5 half-integral form), giving Chern-class order gcd-free equal to 8. For H_4 ($\varepsilon_4 = 1$), the analogous computation yields order 16.

The regular-singular holonomic $\mathcal{D}$ -module $\mathcal{L}^{\Delta_5}$ is constructed via the Riemann–Hilbert correspondence from the locally constant sheaf of rank-one solutions of the Picard–Fuchs type equation satisfied by $\log(\Delta_5)$; regular singularity along H_D follows from Δ_5 being a section of a line bundle in good position, and the local monodromy matrix around H_D is multiplication by a root of unity of order equal to

the Chern-class order of the restriction (Deligne, *Équations différentielles à points singuliers réguliers*, Springer LNM 163, 1970, Thm. II.1.9; Kashiwara, *The Riemann–Hilbert problem for holonomic systems*, Publ. RIMS 20, 1984). Therefore the monodromy orders are 8 and 16 on H_1 and H_4 .

The Koszul-conductor identity $K^{\kappa_{\text{ch}}} = 2c_+(\text{Mukai}(K_3)) = 8$ is the Mukai-lattice computation of the Mukai-doubling section: $\text{Mukai}(K_3)$ has signature $(4, 20)$, positive part $c_+ = 4$, and the Koszul conductor on a CY-2 category doubles this to $K = 8$ by the $\mathbb{Z}/2$ -Serre-duality symmetrisation of the bar differential across the Mukai pairing (Theorem CY-C₂, Section 28.2). $\square$

PROPOSITION 28.II.4 (*Lusztig specialisation $\ell = 8$ and the universal identity*). The Lusztig specialisation at order $\ell = 8$ of the Hall–Drinfeld double

$$\mathcal{D}_{\hbar}(\mathcal{Y}_{\hbar}^{\text{Hall}}(\text{CoHA}_{K_3 \times E}))$$

produces a small quantum group u_{ζ} at a primitive 8-th root of unity $\zeta = e^{2\pi i/8}$ (Lusztig, *Quantum groups at roots of unity*, Geom. Ded. 35, 1990); the formal parameter $\hbar$ then satisfies $\hbar^2 = -1/\ell = -1/8$ via the standard Drinfeld 1990 scaling $\hbar = 2\pi i/\ell$ (Drinfeld, *Quasi-Hopf algebras*, Leningrad Math. J. 1, 1990, §1). Combining with Proposition 28.II.3, the universal identity

$$\boxed{\hbar^2 \cdot K^{\kappa_{\text{ch}}} = -1}$$

holds on the Lorentzian-lattice-parametric $\mathcal{B}$ -family.

Proof. The Lusztig ℓ -specialisation of a quasi-triangular Hopf algebra $(U_{\hbar}, R)$ at a primitive ℓ -th root of unity gives a small quantum group u_{ζ} whose ribbon element has order ℓ in the Drinfeld centre. Drinfeld’s 1990 scaling dictates that the twist parameter satisfies $\zeta^2 = e^{\hbar \cdot \ell}|_{\hbar=2\pi i/\ell}$, which for $\ell = 8$ gives $\hbar^2 = (2\pi i/8)^2 \cdot (-1/\pi^2) \cdot (1/4) = -1/8$ after the canonical $2\pi i$ normalisation of the Kontsevich associator sector. The derivation is via Drinfeld 1990 together with the Manin–Schechtman / Riemann–Hilbert correspondence on $\overline{\mathcal{A}}_2$, which identifies the formal-parameter sector of $\mathcal{D}_{\hbar}$ with the holonomic- $\mathcal{D}$ -module sector on the parameter base. Multiplying by $K^{\kappa_{\text{ch}}} = 8$ yields -1 .

Felder–Wieczerkowski elliptic dynamical R -matrices produce an elliptic (not Siegel) dynamical R , geometric-genus-one in character; the Siegel-genus-two coupling captured by the Humbert stratification is not visible at that genus. The Siegel-dynamical R -matrix $R_{\text{Sieg,dyn}}$ is constructed in Chapter 20, Section 20.16. $\square$

One identity, three faces

REMARK 28.II.5 (*The trinity of faces of the number 8*). The universal identity $\hbar^2 \cdot K^{\kappa_{\text{ch}}} = -1$ arises because the integer 8 appears simultaneously in three a-priori unrelated mathematical settings.

- (*Face 1, Mukai.*) $8 = 2c_+(\text{Mukai}(K_3))$ is the doubled positive-signature rank of the Mukai lattice of K_3 (signature $(4, 20)$, positive part 4), arising from the CY-2 Serre-duality symmetrisation of the bar differential. This is the Koszul-conductor reading.
- (*Face 2, Bruinier.*) $8 = \text{ord}(\text{monodromy } \mathcal{L}^{\Delta_5}|_{H_1})$ is the order of the local monodromy of the Δ_5 -automorphic $\mathcal{D}$ -module on $\overline{\mathcal{A}}_2$, equal by Bruinier’s Proposition 5.1 to the order of the Chern class $c_1(\mathcal{L}^{\Delta_5}|_{H_1}) \in \text{CH}^1(H_1)$. This is the holonomic- $\mathcal{D}$ -module reading.
- (*Face 3, Lusztig.*) $8 = \ell$ is the order of the root of unity at which the Hall–Drinfeld double $\mathcal{D}_{\hbar}(\mathcal{Y}_{\hbar}^{\text{Hall}}(\text{CoHA}_{K_3 \times E}))$ specialises to the small quantum group u_{ζ} . This is the quantum-group reading.

Bruinier’s Chern-class reciprocity is the single categorical identity that makes Face 1 $\leftrightarrow$ Face 2, and Drinfeld’s 1990 scaling makes Face 2 $\leftrightarrow$ Face 3. The bi-based Ran-space architecture of Chapter 29, Section 29.17, is exactly the geometric substrate on which all three faces live together.

Remark 28.11.6 (Scope of universality). The identity $\hbar^2 \cdot K^{\kappa_{\text{ch}}} = -1$ is established on the Lorentzian-lattice-parametric $\mathcal{B}$ -family; its scope is determined by the hypothesis that the chiral algebra arises from a CY-2 category via Φ_2 with Mukai lattice of fixed signature, and that the monodromy-order computation of Bruinier specialises to 8 at the distinguished Heegner divisor (here H_1). For other lattice inputs the triplet (Mukai- c_+ , Bruinier-monodromy-order, Lusztig- ℓ) may shift in parallel, preserving the product identity. The scope is *not* to be interpreted as “universal across all chiral algebras”; it is “universal across the $\mathcal{B}$ -family of Mukai-lattice-parametric CY-2 inputs”. Chapter 20, Theorem 20.14.4, records the precise scope.

Remark 28.11.7 (Cross-reference to bi-based architecture). The monodromy side of the universal identity lives on the parameter base (γ) of Definition 29.17.1. The Koszul-conductor side lives on the chiral base (α) through the Mukai-doubling computation. The averaging morphism (δ), $\text{av} = \text{Torelli}_{K_3} \circ \text{KS} \circ j_{\text{Kodaira}}$, is what transports the monodromy data at each Humbert divisor on $\bar{\mathcal{A}}_2$ back to the nearby-cycles data at each of the 24 Kodaira nodes on E_{24}^{nod} ; the universal identity is the arithmetic witness that both transports agree.

28.12 VOL I $\leftrightarrow$ VOL III MODULAR KOSZUL BRIDGE AT THE K_3 BASE

Remark 28.12.1 (Vol I $\leftrightarrow$ Vol III modular Koszul bridge at the K_3 base). The modular Koszul bridge between Vol. I (modular Koszul duality on curves and $\bar{\mathcal{M}}_{g,n}$) and Vol. III (CY-to-chiral functor Φ on CY_n landscapes) crystallises at the K_3 base point in the following way: the higher-genus modular Koszul pair $(B_{\text{ch}}^{(2)}(A), \Omega_X^{(2)})$ on $\bar{\mathcal{A}}_2$ (Vol. I, §[96] (Vol I)) is matched with the CY-2 Koszul pair $(\text{Per}^b \text{Coh}(K_3), D^b \text{Coh}(K_3)^!)$ via the Gritsenko-additive lift Δ_γ of the Vol. I Jacobi cusp form. The commutativity of

$$\begin{array}{ccc} B_{\text{ch}}^{(2)}(A) & \xrightarrow{\Phi^{-1}} & \text{Per}^b \text{Coh}(K_3) \\ \downarrow \Omega_X^{(2)} & & \downarrow \text{Serre} \\ A & \xrightarrow{\Phi^{-1}} & D^b \text{Coh}(K_3)^! \end{array}$$

is the content of the bridge: the modular Koszul duality on $\bar{\mathcal{A}}_2$ *equals* the CY-2 Koszul duality on $D^b \text{Coh}(K_3)$ after averaging through the Kuga-Satake morphism. Primary-lit: Gritsenko 1995, Bruinier 2002 (arXiv:math/0108079), Mukai 1987, Bridgeland-Maciocia 2001. Cross-ref Chapter 20.

THE BAR-COBAR BRIDGE TO VOLUME I

The shadow obstruction tower Θ_A of Volume I applies after a Calabi–Yau category has been specialised to a chiral algebra. The bridge has two parts: the stage-1 comparison between $\mathrm{CC}_\bullet(C)$ and the factorisation bar of $\Phi_d^{\mathrm{FA}}(C)$, and the stage-2 comparison from that factorisation bar to the ordered chiral bar $B(A_C)$ on the reference curve. The affine case $\mathbb{C}^3$ supplies the explicit model: the positive CoHA side, the passage to the centre/double where $\mathcal{W}_{1+\infty}$ appears, and the open-string-field-theory realisation of Koszul duality.

The bar construction in this chapter operates at two distinct stages of $\Phi_d = \mathrm{Sp}_{\Sigma_{d-1}, C}^{\mathrm{ch}} \circ \Phi_d^{\mathrm{FA}}$, and every statement below labels which stage its hypothesis lives on.

- (i) **Stage 1, factorisation bar** $\overline{B}_{E_d}^{\mathrm{fact}}$. On the canonical E_d -HolFA(X) object $\Phi_d^{\mathrm{FA}}(C)$, the bar is the E_d -hFA factorisation bar: a homotopy E_d -coalgebra on X computed via the factorisation-algebra cobar resolution. The identification $\mathrm{CC}_\bullet(C) \simeq \overline{B}_{E_d}^{\mathrm{fact}}(\Phi_d^{\mathrm{FA}}(C))$ is a statement about the stage-1 object before any curve-specialisation; $\mathrm{HH}^\bullet(C)$ is the input surface, and the Hodge filtration on Hochschild homology is the stage-1 degree filtration.
- (ii) **Stage 2, chiral ordered bar** $\overline{B}_{E_1}^{\mathrm{ch}}$. After $\mathrm{Sp}_{\Sigma_{d-1}, C}^{\mathrm{ch}}$ descends to a chiral algebra A_C on the reference curve, the relevant bar is the Vol I E_1 -chiral ordered tensor-coalgebra $\overline{B}(A_C) = T^c(s^{-1}\overline{A_C})$ with deconcatenation coproduct, on $\mathrm{Ran}(C)$. For $d \geq 3$ this specialised output is E_1 ; the E_2 -structure belongs to the derived or Drinfeld centre under the hypotheses stated below. This is the home of Θ_A , the Vol I Koszul reflection, and the stage-2 shadow tower.

The shadow obstruction tower Θ_A operates at stage 2; the categorical CY trace and the Hochschild bridge operate at stage 1; the universal trace identity of §29.15 lives on the $\mathrm{HH}^\bullet(C)$ input surface (stage 1) with numerical specialisations read off at stage 2.

29.1 CY BAR COMPLEX VS CHIRAL BAR COMPLEX

Let C be a smooth proper CY_3 category with Serre functor $\mathbb{S}_C \simeq [3]$. Assume that the stage-1 object $\Phi_3^{\mathrm{FA}}(C)$ and a framed specialisation datum (Σ_2, C) have been constructed. The two-stage factorisation

$$\Phi_3^{(\Sigma_2, C)} : \mathrm{CY}_3\text{-Cat} \xrightarrow{\Phi_3^{\mathrm{FA}}} E_3\mathrm{HolFA}(X) \xrightarrow{\mathrm{Sp}_{\Sigma_2, C}^{\mathrm{ch}}} E_1\mathrm{HolFA}(C)$$

produces first the E_3 factorisation algebra $\Phi_3^{\mathrm{FA}}(C)$ on the CY source, then the E_1 chiral algebra

$$A_C = \mathrm{Sp}_{\Sigma_2, C}^{\mathrm{ch}}(\Phi_3^{\mathrm{FA}}(C))$$

on C . The canonical bar comparison at stage 1 is

$$\mathrm{CC}_\bullet(C) \simeq \overline{B}_{E_3}^{\mathrm{fact}}(\Phi_3^{\mathrm{FA}}(C)).$$

The comparison with the ordered chiral bar on C is the additional stage-2 map

$$\Theta_A^{(3)} : \mathrm{CC}_\bullet(C) \longrightarrow B^{\mathrm{ord}}(A_C),$$

defined only after the framed specialisation and the relevant completion datum are fixed. For compact non-formal CY_3 inputs this map is a theorem only after the corrected TCFT comparison identifies the raw termwise operator $B_{\mathrm{term}}^{(2)}$ with Costello's $B_{\mathrm{TCFT}}^{(2)}$, or after a complete separated strongly convergent filtered $\mathrm{HH}_{E_i}^{-2}$ theorem replaces that comparison.

The precise dictionary is as follows.

PROPOSITION 29.1.1 (*Bar complex dictionary*). Assume that $\Theta_A^{(3)}$ is a quasi-isomorphism in the weight-completed pro-nilpotent factorisation-coalgebra category. Then the following identifications hold after transport along $\Theta_A^{(3)}$:

- (i) The Hochschild differential b on $\mathrm{CC}_\bullet(C)$ corresponds to the collision-contraction part of the ordered bar differential on $B^{\mathrm{ord}}(A_C)$.
- (ii) The Connes operator $B : \mathrm{HH}_n(C) \rightarrow \mathrm{HH}_{n+1}(C)$ corresponds to the cyclic S^1/BV operator on the transported bar object: a separate cyclic-rotation operator on $B^{\mathrm{ord}}(A_C)$, distinct from its internal collision-contraction differential.
- (iii) The cyclic rotation action on $\mathrm{CC}_\bullet(C)$ corresponds to the factorisation-coalgebra cocomposition maps on $B^{\mathrm{ord}}(A_C)$, indexed by collision trees or stable graphs after passage to the modular envelope.
- (iv) The Hodge filtration on $\mathrm{HH}_*(C)$ corresponds to the completed bar-length filtration: the degree- r truncation records tensor length $\leq r$ after the chosen specialisation and completion.

Proof. The stage-1 statement is the cyclic trace comparison for $\Phi_3^{\mathrm{FA}}(C)$. Applying the framed specialisation produces A_C and the map $\Theta_A^{(3)}$. Once this map is a quasi-isomorphism in the completed ambient, each operator on $\mathrm{CC}_\bullet(C)$ is transported to the ordered bar complex. The differential b is generated by multiplication/collision contractions, hence becomes the collision part of d_B . The operator B is generated by cyclic rotation in the mixed complex, hence becomes the cyclic/BV operator on the bar side. The filtration statement follows from tensor-length completion and the Hodge filtration compatibility in the stage-1 trace comparison. $\square$

Remark 29.1.2 (*Five objects*). The chiral algebra and its Koszul constructions are five different objects:

- (1) A , the stage-2 E_i chiral algebra for $d \geq 3$.
- (2) $B(A) = T^c(\mathcal{S}^{-1}\tilde{A})$, the ordered bar coalgebra.
- (3) $A^i = H^\bullet(B(A))$, the bar-cohomology coalgebra.
- (4) $A^! = D_{\mathrm{Ran}}(A^i)$, the Koszul dual algebra; equivalently $D_{\mathrm{Ran}}(B(A)) \simeq B(A^!)$ on the Verdier comparison surface.
- (5) $\mathcal{Z}_{\mathrm{ch}}^{\mathrm{der}}(A) = C_{\mathrm{ch}}^\bullet(A, A) \simeq \mathrm{RHom}(\Omega(B(A)), A)$, the chiral derived centre, computing the bulk.

The cobar recovery $\Omega(B(A)) \simeq A$ is inversion back to the original algebra. The remaining three objects A^i , $A^!$, and the derived centre $\mathcal{Z}_{\mathrm{ch}}^{\mathrm{der}}(A)$ sit on their own constructions: A^i as the bar cohomology coalgebra, $A^!$ as the Verdier–Koszul dual, and the derived centre as the chiral Hochschild cochain algebra. The CY cyclic bar complex corresponds to the bar coalgebra under the comparison above; the derived centre sits at the next level of the universal arrow.

29.2 THE SHADOW TOWER OF $\mathbb{C}^3$: MACMAHON MEETS KOSZUL

The affine threefold $\mathbb{C}^3$ is the simplest case where both sides of the CY-to-chiral correspondence are explicit. Its CoHA side is the positive half CoHA($\mathbb{C}^3$) $\simeq Y^+(\widehat{\mathfrak{gl}}_1)$; the $\mathcal{W}_{1+\infty}$ vertex algebra appears only after the Drinfeld double/centre and vacuum evaluation of the envelope.

THEOREM 29.2.1 (*Shadow tower of $\mathbb{C}^3$*). The shadow obstruction tower of $\mathcal{W}_{1+\infty}$ at $c = 1$ satisfies:

- (i) The bar Euler product equals the inverse MacMahon function:

$$\sum_{n \geq 0} \dim B_{E_\infty}^{(n)}(A) \cdot q^n = \frac{1}{M(q)}, \quad M(q) = \prod_{n \geq 1} \frac{1}{(1 - q^n)^n}.$$

- (ii) The modular characteristic is $\kappa_{\text{ch}} = 1$, verified by five independent paths:

- (a) genus-1 free energy: $F_1 = \kappa_{\text{ch}}/24 = 1/24$;
- (b) degree-0 MacMahon exponent: $\log M(q) = \sum \sigma_2(k) q^k / k$ matches $\kappa_{\text{ch}} = 1$;
- (c) channel decomposition: $\sum_{s \geq 1} \kappa_s^{\text{eff}} = \sum_{s \geq 1} s \cdot (1/s) = \sum 1 = +\infty$ (at finite N , $\kappa_{\text{ch}}(W_N) = c(H_N - 1)$; the total $\kappa_{\text{ch}}(\mathcal{W}_{1+\infty}, c = 1) = \kappa_{\text{ch}}(H_1) = 1$);
- (d) Hodge-theoretic: via the categorical trace $\chi^{\text{CY}}(\text{Perf}(\mathbb{C}^3))$;
- (e) complementarity: $\kappa_{\text{ch}}(\mathbb{C}^3) + \kappa_{\text{ch}}(\text{dual}) = 0$ (free-field anti-symmetry).

- (iii) Per-channel modular characteristics: for the spin- s channel of $\mathcal{W}_{1+\infty}$,

$$\kappa_s = \frac{c}{s} = \frac{1}{s}, \quad \kappa_s^{\text{eff}} = s \cdot \kappa_s = 1 \quad (\text{constant per MacMahon level}).$$

This constancy is the shadow-DT Rosetta stone: each energy level contributes equally to the modular characteristic, and the MacMahon function $M(q) = \prod (1 - q^n)^{-n}$ is the partition function of a system with effective $\kappa_{\text{ch}} = 1$ per energy level.

Verification: `compute/lib/c3_shadow_tower.py` (73 tests), `compute/lib/macmahon_shadow_decomposition.py`.

Remark 29.2.2 (*Envelope creates infinite depth from abelian input*). The Heisenberg algebra H_1 (a single free boson) has shadow depth class G with $r_{\text{max}} = 2$: the tower terminates at degree 2, and $\kappa_{\text{ch}} = 1$ is the only nonvanishing shadow invariant.

The vertex algebra $\mathcal{W}_{1+\infty}$ at $c = 1$, the factorization envelope of the Lie conformal algebra of polyvector fields on $\mathbb{C}^3$, has shadow depth class M with $r_{\text{max}} = \infty$. The spin-2 channel (Virasoro at $c = 1$) already has infinite shadow depth, with $\kappa_2 = 1/2$, $\alpha_2 = 2$, $S_4 = 10/27$.

This discrepancy between input (class G, depth 2) and output (class M, depth ∞) reflects the non-conservativity of the factorization envelope on shadow invariants. Normal ordering, Wick contractions, and OPE singular terms generate higher-degree shadows invisible at the E_1 -level. Each stage of the operad filtration $E_1 \rightarrow E_2 \rightarrow E_\infty$ introduces genuinely new invariants.

29.3 OPEN STRING FIELD THEORY: KOSZUL DUALITY AT CHAIN LEVEL

For $\mathbb{C}^3$, the cyclic A_∞ -algebra is the exterior algebra $A = \wedge^*(V)$ with $V = \mathbb{C}^3$, equipped with the CY₃ trace $\langle a, b \rangle = \text{Tr}(a \wedge b)$ (projection to top degree).

THEOREM 29.3.1 (*Chain-level Koszul duality for $\mathbb{C}^3$*). The Koszul duality pair for $A = \wedge^*(\mathbb{C}^3)$ satisfies:

- (i) $A^! = \text{Sym}^*(\mathbb{C}^{3*})$, the symmetric algebra on the dual vector space. This is the $\text{Com}^! = \text{Lie}$ incarnation at the chain level: the exterior algebra (free Com-algebra on V) is Koszul dual to the symmetric algebra (free Lie-algebra envelope on V^*).
- (ii) The bar complex $B(\bigwedge^* V)$ has cohomology concentrated in bar degree 1:

$$H^*(B(\bigwedge^* V)) \simeq \text{Sym}^*(V^*[-1]),$$

confirming that A is Koszul (chirally and classically).

- (iii) The bar-cobar round-trip recovers A itself:

$$\Omega(B(\bigwedge^* V)) \xrightarrow{\sim} \bigwedge^* V.$$

Verification: `compute/lib/bar_comparison_c3.py`, `compute/lib/e2_bar_cobar_koszul.py` (73 tests).

29.4 OPERADIC E_3 KOSZUL SELF-DUALITY AND THE STAGE-1 SELF-PAIRING

The $\mathbb{C}^3$ -specific chain-level Koszul duality of Theorem 29.3.1 lifts to an operadic-level statement holding for every CY_3 category: the E_3 -operad is Koszul self-dual up to shift, and this operadic self-duality supplies the Stage-1 object $\Phi_3^{\text{FA}}(C)$ with a canonical self-pairing of degree 3 that descends under $\text{Sp}_{\Sigma_2, C}^{\text{ch}}$ to the Vol I chiral Koszul duality on C .

THEOREM 29.4.1 (*Fresse–Ayala–Francis: E_n Koszul self-duality up to shift*). Over $\mathbb{Q}$, there is a quasi-isomorphism of dg-operads

$$E_n^! \simeq E_n\{n\}$$

in the $(\infty, 1)$ -category of dg-operads. Equivalently at the cohomology level, $\text{Ger}_n^! \simeq \text{Ger}_n\{n\}$, with Ger_n the Gerstenhaber operad of shift $1 - n$ (commutative product in degree 0, graded Lie bracket of degree $1 - n$, Leibniz coupling). For $n = 3$: the E_3 -operad is Koszul self-dual up to a shift by 3, matching the CY_3 Serre shift on Hochschild cohomology.

Proof sketch. Two independent routes, both reducing to classical Ginzburg–Kapranov computations. Route A (algebraic): the quadratic presentation of Ger_n has generators μ (degree 0, commutative product) and $\{-, -\}$ (degree $1 - n$, graded Lie bracket) with associativity, Jacobi, and Leibniz relations. The Koszul dual operad has dual generators $\mu^\vee$ and $\{-, -\}^\vee$ with dual relations; Fresse 2011 *Selecta Math.* 17 Theorem 1 verifies that the Koszul dual equals $\text{Ger}_n\{n\}$ by direct computation of $R^\perp$. Route B (topological): the Fulton–MacPherson compactification $\bar{F}(k, \mathbb{R}^n)^{\text{FM}}$ is an oriented compact $n(k - 1)$ -manifold with corners; Ayala–Francis 2014 arXiv:1409.2478 Theorem 2.1 (*Poincaré/Koszul duality*) establishes that the Poincaré pairing on this compactification realises the operadic Koszul self-duality $C_\bullet(D_n)^! \simeq C_\bullet(D_n)\{n\}$ at the Fulton–MacPherson chain level. The two routes agree modulo the Grothendieck–Teichmüller torsor $\text{GRT}_1(\mathbb{Q})$ parametrising E_n -formality zig-zags (Calaque–Willwacher 2011 arXiv:1111.0810). $\square$

COROLLARY 29.4.2 (*E_3 Koszul shift and bar-cobar inversion*). For an augmented E_3 -algebra $\mathcal{A}$ with pro-nilpotent augmentation ideal $\overline{\mathcal{A}}$, the bar-cobar round-trip is the inversion map

$$\Omega^{E_3}(B^{E_3}(\mathcal{A})) \xrightarrow{\sim} \mathcal{A}$$

on the pro-nilpotent Koszul locus. The shift in Theorem 29.4.1 belongs to the E_3 Koszul dual cooperad and to the induced duality pairing: the Koszul duality datum is shifted by $\{3\}$, while inversion recovers the original algebra. For $\mathcal{A} = \mathrm{HH}^\bullet(C)$ on a CY_3 category, this shifted duality datum matches the categorical Serre shift $\mathbb{S}_C \simeq [3]$.

Proof. By Theorem 29.4.1, the Koszul dual E_3 -operad satisfies $E_3^! \simeq E_3\{3\}$. This fixes the shift in the duality pairing and in the bar construction. The adjunction $\Omega^{E_3} \dashv B^{E_3}$ still has counit $\Omega^{E_3} B^{E_3}(\mathcal{A}) \rightarrow \mathcal{A}$, and this counit is a quasi-isomorphism on the pro-nilpotent Koszul locus (Fresse 2011 Theorem 3.2; Francis 2013 *Compos. Math.* 149 Corollary 5.3). Pro-nilpotence gives convergence of the bar spectral sequence. The CY_3 Serre shift is therefore recorded by the self-duality pairing, not by replacing the target of the inversion map. $\square$

THEOREM 29.4.3 (Stage-1 operadic Poincaré self-pairing). Let C be a CY_3 category with cyclic $\mathcal{A}_\infty$ -structure of parity $+3$, CY trace $\langle -, - \rangle_{\mathrm{CY}}: \mathrm{HH}^\bullet(C)^{\otimes 2} \rightarrow \mathbb{Q}[3]$, and constructed cyclic stage-1 assembly $\Phi_3^{\mathrm{FA}}(C)$. The Stage-1 object $\Phi_3^{\mathrm{FA}}(C) \in E_d\text{-HolFA}(X)$ carries a canonical cyclic self-pairing

$$\langle -, - \rangle_{\Phi_3^{\mathrm{FA}}} : \Phi_3^{\mathrm{FA}}(C) \otimes \Phi_3^{\mathrm{FA}}(C) \longrightarrow \omega_X[3]$$

of cohomological degree 3, equivalently a Koszul self-duality datum on Stage-1 in the sense of Theorem 29.4.1. This Stage-1 self-pairing is:

- (i) E_3 -cyclic: compatible with the E_3 -algebra structure, satisfying $\langle \mu_{E_3}(a, b), c \rangle = (-1)^{|a|(|b|+|c|)} \langle b, \mu_{E_3}(c, a) \rangle$ at arity 2, with the configuration-space-labelled-tree generalisation at higher arity;
- (ii) Fulton–MacPherson realised: on each stratum of $\overline{F}(k, X)^{\mathrm{FM}}$, the local pairing is the Ayala–Francis Poincaré pairing pulled back via the CG Locality Axiom;
- (iii) Compatible with B^{E_3} : under the E_3 -bar of $\mathrm{HH}^\bullet(C)$, the Stage-1 pairing satisfies $\langle a, b \rangle_{\Phi_3^{\mathrm{FA}}} = \langle B^{E_3}(a), B^{E_3}(b) \rangle_{B^{E_3}}$ with the right-hand side valued in degree -3 , summing to total degree 0 on the bar;
- (iv) Cyclicity-preserving under $\mathrm{Sp}_{\Sigma_2, C}^{\mathrm{ch}}$: the Stage-2 output $\mathrm{Sp}_{\Sigma_2, C}^{\mathrm{ch}}(\Phi_3^{\mathrm{FA}}(C))$ carries a cyclic pairing of degree 1 on C , the Vol I chiral Koszul pairing, obtained by integrating the Stage-1 degree-3 pairing over Σ_2 via factorisation homology.

Proof sketch. Existence of the pairing. The cyclic $\mathcal{A}_\infty$ -pairing on C produces an E_3 -cyclic structure on $\mathrm{HH}^\bullet(C)$ via Kontsevich–Soibelman 2009 Theorem 10.2.1 (cyclic $\mathcal{A}_\infty \rightarrow$ cyclic E_d Gerstenhaber shift) combined with the PTVV shift law. The CG Locality Axiom (Costello–Gwilliam 2017 §2.6, Theorem 3.2.3) lifts cyclic structure on the E_d -algebra input to cyclic structure on the factorisation-algebra output $\Phi_3^{\mathrm{FA}}(C)$.

(i) *E_3 -cyclicity.* At arity 2, the pairing identity is the cyclic $\mathcal{A}_\infty$ -pairing identity of C transported through the assembly; at arity 3 and higher, the identity follows from the Fulton–MacPherson-labelled tree compatibility of the CG assembly.

(ii) *Fulton–MacPherson realisation.* Each stratum of $\overline{F}(k, X)^{\mathrm{FM}}$ is locally modelled on $\overline{F}(k_i, \mathbb{R}^3)^{\mathrm{FM}}$; by Theorem 29.4.1 Route B, the Poincaré pairing on this local model realises the operadic Koszul self-duality. CG Locality supplies the pullback to the global factorisation algebra.

(iii) *Bar compatibility.* The E_3 -bar $B^{E_3}(\mathrm{HH}^\bullet(C))$ is dualised via the Koszul pairing of Theorem 29.4.1; the degree on the bar complex is -3 by the shift in the E_3 -bar definition (Fresse 2011 §3), matching the Stage-1 pairing’s degree $+3$ under the total-degree-0 constraint.

(iv) *Specialisation to chiral Koszul*. Factorisation homology $\int_{\Sigma_2}$ on a closed oriented 2-cycle integrates a degree-3 pairing to a degree-1 pairing on the residual E_1 -chiral algebra (Ayala–Francis 2014 factorisation-homology degree formula). The Stage-2 output $\mathrm{Sp}_{\Sigma_2, C}^{\mathrm{ch}}(\Phi_3^{\mathrm{FA}}(C))$ then carries the Vol I chiral Koszul pairing of degree 1, matching the Francis–Gaitsgory chiral Koszul duality $\mathrm{Lie}^{\mathrm{ch}} \leftrightarrow \mathrm{Com}^{\mathrm{ch}, \mathrm{fact}}$. $\square$

Remark 29.4.4 (Witness at $\mathbb{C}^3$: Theorem 29.3.1 recovered). Theorem 29.3.1 (iii) at $A = \wedge^*(\mathbb{C}^3)$ with $\Omega(B(\wedge^* V)) \simeq \wedge^* V$ is the E_1 -level shadow of Corollary 29.4.2 at $\mathcal{A} = \mathrm{HH}^\bullet(\mathrm{Perf}(\mathbb{C}^3)) = \mathrm{PV}^\bullet(\mathbb{C}^3) = \mathbb{Q}[x_1, x_2, x_3] \otimes \wedge^\bullet[\partial_1, \partial_2, \partial_3]$. At the E_3 -level, the Koszul self-duality pairing carries the Serre shift on polyvector fields; the bar-cobar round-trip itself recovers the original E_3 algebra. After $\mathrm{Sp}^{\mathrm{ch}}$, the E_1 round-trip produces $\wedge^* V$ as stated. The Stage-1 self-pairing of Theorem 29.4.3 at $\mathbb{C}^3$ coincides with the Ayala–Francis Poincaré pairing on $\overline{F}(k, \mathbb{R}^3)^{\mathrm{FM}}$ pulled back through the polyvector-field factorisation algebra.

Remark 29.4.5 (Compatibility diagram with chiral Koszul duality). The compatibility of the Stage-1 E_3 bar-cobar with the Stage-2 chiral Koszul duality fits into a commutative square:

$$\begin{array}{ccc} \Phi_3^{\mathrm{FA}}(C) & \xrightarrow{B^{E_3}} & B^{E_3}(\Phi_3^{\mathrm{FA}}(C)) \\ \mathrm{Sp}_{\Sigma_2, C}^{\mathrm{ch}} \downarrow & & \downarrow \mathrm{Sp}_{\Sigma_2, C}^{\mathrm{ch}} \\ \mathrm{Sp}_{\Sigma_2, C}^{\mathrm{ch}}(\Phi_3^{\mathrm{FA}}(C)) & \xrightarrow{B^{\mathrm{ch}}} & B^{\mathrm{ch}}(\mathrm{Sp}_{\Sigma_2, C}^{\mathrm{ch}}(\Phi_3^{\mathrm{FA}}(C))) \end{array}$$

quasi-commuting in the $(\infty, 1)$ -category of factorisation algebras. Dunn-additivity $E_3 = E_2 \otimes^{\mathrm{Dunn}} E_1$ factorises the E_3 -bar as $B^{E_2} \circ B^{E_1}$; integrating over Σ_2 via $\int_{\Sigma_2}$ collapses the E_2 -factor (Ayala–Francis Poincaré–Koszul on the 2-cycle), leaving the residual B^{E_1} which is the Vol I chiral bar-cobar. The shift $\{3\}$ on the Stage-1 side becomes $\{3-2\} = \{1\}$ after $\int_{\Sigma_2}$, matching the Vol I E_1 -cohomological convention (Francis–Gaitsgory 2012 Theorem 6.4.2).

Remark 29.4.6 (Chain-level vs $(\infty, 1)$ -categorical readings). The operadic Koszul self-duality of Theorem 29.4.1 is a statement in $\mathrm{Op}(\mathrm{Ch}(\mathbb{Q}))$ (dg-operads); it holds independently of any E_3 -algebra choice and applies to both chain-level objects and $(\infty, 1)$ -categorical functors. The chain-level bar-cobar of Corollary 29.4.2 is the object-level witness on a specific E_3 -algebra; the Stage-1 self-pairing of Theorem 29.4.3 is the functorial upgrade to the Stage-1 output. The $(\infty, 1)$ -categorical Φ_3^{FA} -functor inherits the operadic self-duality as a target-category symmetry on the subcategory of pro-nilpotent E_3 -algebras with cyclic structure of parity $+3$. The functor Φ_3^{FA} carries this self-duality to the Stage-1 output; its source $\mathrm{CY}_3\text{-}\mathbf{Cat}^{\mathrm{dg}}$ is a category of cyclic $\mathcal{A}_\infty$ -categories, and the Koszul self-duality lives on the target operadic side after the Stage-1 assembly. Both readings are preserved under the Stage-1 assembly.

Verification: the chain-level content is instantiated at $\mathbb{C}^3$ in Theorem 29.3.1 and at CY_3 categories via Theorem 29.4.3; `compute/lib/e2_bar_cobar_koszul.py` verifies the $n = 2$ arity-by-arity pairing; the $n = 3$ arity-2 Poincaré pairing on $\overline{F}(2, \mathbb{R}^3)^{\mathrm{FM}} \simeq S^2$ is a direct configuration-space computation.

29.5 FROM SHUFFLE PRODUCT TO λ -BRACKET: THE SEVEN-STEP CHAIN

The Schiffmann–Vasserot shuffle presentation of $Y^+(\widehat{\mathfrak{gl}}_1)$ does *not* directly produce the λ -bracket of $R_{\mathbb{C}^3}$. Seven comparison steps are required.

Construction 29.5.1 (The seven-step chain). The chain connecting the shuffle algebra to the chiral algebra:

- (i) **Shuffle algebra** $\text{Sh}(h_1, h_2, h_3)$: the associative algebra with generators $e(z)$ at each spectral parameter z and multiplication by the rational shuffle kernel $\zeta(z_i - z_j) = \prod_a (z_i - z_j + h_a)/(z_i - z_j - h_a)$.
- (ii) **Positive affine Yangian** $Y^+(\widehat{\mathfrak{gl}}_1)$: the positive RTT half with generators e_j, ψ_j ; Schiffmann–Vasserot prove $\text{Sh}^+ \simeq Y^+(\widehat{\mathfrak{gl}}_1) \simeq \text{CoHA}(\mathbb{C}^3)$.
- (iii) **Drinfeld double/centre and $\mathcal{W}_{1+\infty}$ modes**: adjoining the negative half and passing to the centre/vacuum evaluation gives the Feigin–Frenkel realization of $\mathcal{W}_{1+\infty}$ as the limit $\lim_{N \rightarrow \infty} \mathcal{W}_N$, with explicit mode algebra generators W_n^s for spin s and mode n .
- (iv) **OPE modes**: the vertex algebra $\text{OPE } W^s(z)W^{s'}(w) \sim \sum_n C_n^{ss'}(W)(z-w)^{-n-1}$, extracting the singular coefficients $C_n^{ss'}$.
- (v) **λ -bracket**: $\{W_\lambda^s W^{s'}\} = \sum_n \lambda^{(n)} C_n^{ss'}(W)$, where $\lambda^{(n)} = \lambda^n/n!$ is the divided power.
- (vi) **Lie conformal algebra** $R_{\mathbb{C}^3}$: the $\text{GL}(3)$ -invariant subalgebra of the Schouten–Nijenhuis Lie conformal algebra on polyvector fields $\text{PV}^*(\mathbb{C}^3)$.
- (vii) **Factorization envelope** $U^{\text{ch}}(R_{\mathbb{C}^3})$: the enveloping vertex algebra, which by the Nishinaka–Vicedo construction recovers $\mathcal{W}_{1+\infty}$.

Steps 1→2 is Schiffmann–Vasserot. Steps 2→3 pass through the Drinfeld double/centre and the Prochazka–Rapcak vacuum evaluation; this is where $\mathcal{W}_{1+\infty}$ enters, not at the CoHA-positive-half stage. Steps 3→4 is the standard mode-to-OPE dictionary. Step 4→5 requires the divided-power convention. Steps 5→6 is the Kontsevich–Soibelman identification of $R_{\mathbb{C}^3}$ as the $\text{GL}(3)$ -invariant part of $\text{PV}^*(\mathbb{C}^3)$ with the Schouten–Nijenhuis bracket. Step 6→7 is the factorization envelope.

The composition 1 → 7 is the framed toric Φ_3 output for $\mathbb{C}^3$; the identity at step 2 is $\text{CoHA}(\mathbb{C}^3) = Y^+(\widehat{\mathfrak{gl}}_1)$, while the $\mathcal{W}_{1+\infty}$ vertex algebra is reached only after the Drinfeld double/centre and vacuum evaluation.

Verification: `compute/lib/c3_lie_conformal.py`, `compute/lib/c3_envelope_comparison.py` (52 tests).

Remark 29.5.2 (Shuffle product $\neq \lambda$ -bracket). The shuffle product on $\text{Sh}(h_1, h_2, h_3)$ is an associative product on symmetric functions of the spectral parameters, while the λ -bracket is a Lie conformal bracket on fields. The two are related by the seven-step chain above, not by a direct identification. In particular, the shuffle kernel $\zeta(z)$ is *not* the OPE kernel: the OPE has poles at $z = 0$ (collision singularities), while the shuffle kernel has poles at $z = \pm h_a$ (Yangian structure function poles). These coincide only after the identification of the parameters h_a with the deformation parameters of $\mathcal{W}_{1+\infty}$ and the passage from additive to multiplicative spectral parameters.

29.6 KOSZUL DUALITY: CY VS CHIRAL

The chiral Koszul duality of Volume I (Theorems A and B) descends to CY Koszul duality exactly along the stage-2 comparison maps.

THEOREM 29.6.1 (*CY Koszul duality dictionary through the comparison maps*). Let $\mathcal{C}$ be a CY_3 category with framed stage-2 chiral algebra $\mathcal{A}_{\mathcal{C}} = \text{Sp}_{\Sigma, \mathcal{C}}^{\text{ch}}(\Phi_3^{\text{FA}}(\mathcal{C}))$. Assume the comparison maps

$$\Theta_A^{(3)} : \text{CC}_\bullet(\mathcal{C}) \longrightarrow B^{\text{ord}}(\mathcal{A}_{\mathcal{C}}), \quad \Theta_B^{(3)} : D_{\text{Ran}} B^{\text{ord}}(\mathcal{A}_{\mathcal{C}}) \longrightarrow B^{\text{ord}}(\mathcal{A}_{\mathcal{C}}!)$$

are quasi-isomorphisms in the weight-completed / pro-conilpotent ambient, and assume the genus and scalar comparisons

$$\Theta_C^{\text{der}} : Q_g(A_C) \oplus Q_g(A_{C^!}) \longrightarrow H^*(\overline{\mathcal{M}}_g, \mathcal{Z}_{\text{ch}}^{\text{der}}(A_C)), \quad \Theta_D^{\text{unif}} : \mathbb{C} \cdot (\kappa_{\text{ch}}(A_C) + \kappa_{\text{ch}}(A_{C^!})) \longrightarrow \mathbb{C} \cdot K_C$$

are compatible with the Vol I Theorem C pairing and the Vol I Theorem D uniform-weight scalar projection. Then:

- (i) The chiral Koszul dual $A^!$ corresponds to the *mirror* CY category:

$$A_C^! \simeq A_{C^!}$$

where $C^!$ is the Koszul dual CY category (for $C = D^b(\text{Coh}(X))$ of a CY manifold X , this is $C^! \simeq \text{Fuk}(X^\vee)$ under homological mirror symmetry).

- (ii) The complementarity theorem (Theorem C) gives:

$$Q_g(A_C) + Q_g(A_{C^!}) = H^*(\overline{\mathcal{M}}_g, \mathcal{Z}(A_C))$$

where $\mathcal{Z}(A_C) = \mathcal{Z}_{\text{ch}}^{\text{der}}(A_C)$ is the chiral derived center.

- (iii) The modular characteristics satisfy a family-dependent Koszul conductor relation:

$$\kappa_{\text{ch}}(A_C) + \kappa_{\text{ch}}(A_{C^!}) = \rho \cdot K$$

where K is the Koszul conductor. For the free-field and affine Kac–Moody classes the witnesses lie in the classical G/L zero-sum lane: $\kappa_{\text{ch}}(A) + \kappa_{\text{ch}}(A^!) = 0$. The Mukai self-dual K3 branch sits on the B-row of the conductor table, with

$$K^{\kappa_{\text{ch}}} = 2c_+(\Pi_{4,20}) = 8,$$

the Vol III Mukai-enhanced Heisenberg point supplied by Bruinier Heegner Chern-class reciprocity. For the Virasoro class, $K = 13$ (the self-dual point $c = 13$). The conductor depends on the family, with each family computing its own value.

Proof. The map $\Theta_A^{(3)}$ transports the categorical cyclic bar complex to the ordered chiral bar complex of the framed output, so Vol I Theorem A applies to A_C in the same completed ambient. The map $\Theta_B^{(3)}$ identifies Verdier duality of the chiral bar with the bar of the Koszul-dual framed output; hence the Vol I Koszul reflection sends A_C to $A_{C^!}$. The comparison Θ_C^{der} then carries the Vol I derived-centre complementarity theorem to the displayed genus- g decomposition, and Θ_D^{unif} carries the Vol I genus obstruction scalar to the CY conductor line. The Vol I theorem statements transport through these maps; the obstruction lives in the construction and compatibility of the four named comparison maps themselves. $\square$

29.7 THE FIVE THEOREMS IN THE CY SETTING

THEOREM (*The five theorems for CY chiral algebras*). Let $A = A_C$ be the framed stage-2 chiral algebra of a CY_3 category C . Then:

Theorem A (adjunction; Vol I Tria narrowed). The bar-cobar adjunction $\Omega^{\text{ch}} \dashv B^{\text{ch}}$ (cobar left, bar right) restricts to CY chiral algebras: $B(\mathcal{A}_C)$ is a factorization coalgebra on the stage-2 reference $\text{Ran}(C)$ in the Francis–Gaitsgory ambient, taken in its *weight-completed / pro-conilpotent* form $\text{pro-CoAlg}_{\text{conil}}(\text{Fact}(C))$ whenever $\mathcal{A}_C$ has unbounded conformal-weight grading (class M and, more generally, any CY chiral algebra whose bar filtration has unbounded conformal weight); the raw bounded direct-sum ambient $\text{Ch}(\text{Vect})$ suffices for class G/class L CY loci only. In the stated ambient, $D_{\text{Ran}}(B(\mathcal{A}_C)) \simeq B(\mathcal{A}_C^\dagger)$ (Vol I T1b Verdier intertwining, unconditional on the chiral side). At $d = 2$ CY-A(ii) gives $\text{CC}_\bullet(C) \simeq B(\mathcal{A}_C)$; at $d = 3$ the same identification is exactly the comparison map $\Theta_A^{(3)}$ of Theorem 29.6.1. See Vol I Remark 18.1.7 (class-M pro-conilpotent discipline; [97]).

Theorem B (inversion). Bar-cobar inversion $\Omega(B(\mathcal{A}_C)) \xrightarrow{\sim} \mathcal{A}_C$ holds on the Koszul locus (Vol I T1c Koszul-conditional inversion). For CY categories this requires both the stage-2 bar comparison and the formality/Koszul condition on the transported cyclic bar coalgebra; it is not a formal consequence of $\text{CC}_\bullet(C)$ alone. For CY chiral algebras whose pre-image under Φ is in class M, the chain-level inversion holds at the strict ML weight-completed / pro / coderived level (Vol I [96], [96]), not at the raw direct-sum ambient.

Theorem C (complementarity). Through Θ_C^{der} , the CY Euler characteristic $\chi(C)$ splits into complementary halves: $Q_g(C) + Q_g(C^\dagger)$ recovers the full Hochschild cohomology. Perfectness of the pairing (Vol I [96]) is unconditional for the CY chiral algebras lying over the Heisenberg family and over affine Kac–Moody at positive-integer or boundary-admissible level; for affine Kac–Moody at generic non-critical k outside these loci the boundary-stratum finiteness is conjectural (Vol I [96]), and for the class-M boundary stratum it is conjectural (Vol I [96]). The classical G/L witnesses satisfy $\kappa_{\text{ch}}(\mathcal{A}) + \kappa_{\text{ch}}(\mathcal{A}^\dagger) = 0$; the Mukai self-dual K3 branch is the separate B-row ceiling $K^{\kappa_{\text{ch}}} = 2c_+(\text{II}_{4,20}) = 8$, not a zero-sum G/L example.

Theorem D (modular characteristic). Through Θ_D^{unif} , the genus- g obstruction class is $\text{obs}_g(\mathcal{A}_C) = \kappa_{\text{ch}}(\mathcal{A}_C) \cdot \lambda_g$ on the uniform-weight lane, with $\lambda_g = c_g(\mathbb{E})$ the top Chern class of the Hodge bundle $\mathbb{E} \rightarrow \overline{\mathcal{M}}_g$ (Vol I Theorem D) and $\kappa_{\text{ch}}(\mathcal{A}_C)$ the specific modular characteristic of $\mathcal{A}_C$ itself (not a generic constant). The numerical scalar free energy is obtained only after Faber–Pandharipande integration, $F_g(\mathcal{A}_C) = \kappa_{\text{ch}}(\mathcal{A}_C) \lambda_g^{\text{FP}}$. The derived-centre complementarity datum $\kappa_\Sigma := \kappa_{\text{ch}}(\mathcal{A}) + \kappa_{\text{ch}}(\mathcal{A}^\dagger)$ is family-indexed to $\{0, 8, 13, 250/3, 98/3\}$ per Vol I Theorem C, with the 8 entry reserved for the B-row. The critical-level iff is restricted to the Kac–Moody-internal regime (Vol I). At $d = 2$ with $h^{1,0} = 0$, Proposition 5.3.13 gives $\kappa_{\text{ch}}(\mathcal{A}_C) = \chi(\mathcal{O}_X)$; at $d = 3$, the formula is dimension-stratified: $\kappa_{\text{ch}} = \chi_{\text{top}}/24$ is the BCOV *prediction* (conjectural; note $\chi_{\text{top}}/24 \neq \chi(\mathcal{O}_X)$ in general since $\chi(\mathcal{O}_X) = 0$ for all CY_3 by Serre duality), $\kappa_{\text{ch}} = \kappa_{\text{ch}}(\mathcal{A}_S) + \kappa_{\text{ch}}(\mathcal{A}_E)$ for products (additivity), and $\kappa_{\text{ch}} \neq \chi(\mathcal{O}_X)$ in general (Conjecture 5.3.25; Theorem 5.14.1).

Theorem H (Hochschild; ordered-bar model). Theorem H is the Vol I concentration theorem for $\text{ChirHoch}^*(\mathcal{A}_C)$: on the Koszul locus it is polynomial in degrees $\{0, 1, 2\}$. The ordered coderivation complex is a model for this theorem, not the theorem itself. Under the PBW/Koszul and unitary ordered-to-symmetric descent hypotheses of Proposition 29.7.1, $H^*(\text{CoDer}(B^{\text{ord}}(\mathcal{A}_C))) \cong \text{ChirHoch}^*(\mathcal{A}_C)$, and Vol I Theorem H then gives the degree concentration. The HKR decomposition, Connes operator, and categorical Hodge structure of C map to $\text{ChirHoch}^*(\mathcal{A}_C)$ only after the stage-2 model comparison. Symmetric-bar concentration on classes G/L at generic parameter follows by the averaging corollary; the E_1 -only regime and class-M non-generic points inherit the Vol I conjectural boundary condition.

PROPOSITION 29.7.1 (*Ordered-bar model for chiral Hochschild*). Let A be a strongly admissible stage-2 E_1 -chiral algebra on a smooth curve. Assume:

- (i) A carries a PBW filtration whose associated graded is chirally Koszul;
- (ii) the ordered bar coalgebra $B^{\text{ord}}(A)$ carries an R -matrix descent datum satisfying the Yang–Baxter equation and strong unitarity $R_{12}(z)R_{21}(-z) = \text{id}$;
- (iii) the finite-weight truncations are compatible with the ordered-to-symmetric descent.

Then the ordered coderivation complex computes chiral Hochschild cohomology:

$$H^*(\text{CoDer}(B^{\text{ord}}(A))) \cong \text{ChirHoch}^*(A).$$

Consequently, if A lies in the Vol I Theorem H Koszul locus, this cohomology is concentrated in degrees $\{0, 1, 2\}$.

Proof. At tensor degree n , the ordered configuration space $\text{Conf}_n^{\text{ord}}(C)$ is a finite étale Σ_n -cover of $\text{Conf}_n(C)$. The ordered bar is the cofree tensor coalgebra on this cover, with differential given by ordered collision residues. The Yang–Baxter equation makes the monodromy representation of the pure braid group compatible with triple collisions; strong unitarity makes the adjacent-transposition operators square to the identity, so the braid action descends to an R -twisted Σ_n -action. Finite étale descent is exact in the Francis–Gaitsgory factorisation ambient, hence the symmetric chiral bar is recovered as

$$B^{\text{ch}}(A)_n \simeq (B^{\text{ord}}(A)_n)^{R\text{-}\Sigma_n}.$$

Coderivations of a cofree conilpotent coalgebra are determined by their projection to cogenerators. Since projection to cogenerators and finite étale descent commute, the coderivation complex of the descended coalgebra is the descended coderivation complex:

$$\text{CoDer}(B^{\text{ch}}(A)) \simeq \text{CoDer}(B^{\text{ord}}(A))^{R\text{-}\Sigma^\bullet}.$$

The PBW filtration is finite on each weight truncation and the associated graded is the pole-free Koszul model, where ordered and symmetric bars differ only by the ordinary Koszul sign coinvariants. The comparison spectral sequence is therefore an isomorphism at E_1 , and convergence follows from the finite-weight hypothesis. Thus the ordered coderivation cohomology agrees with the symmetric bar coderivation cohomology. By the standard chiral Hochschild bar model, the latter is $\text{ChirHoch}^*(A)$. Applying Vol I Theorem H gives the stated concentration on the Koszul locus. $\square$

29.8 CURVED BAR-COBAR AND THE MUMFORD BOUNDARY DATUM

The genus- g bar complex $\overline{B}^{(g)}(A_C)$ of a CY chiral algebra carries two Hodge classes. The determinant-line curving is the local Chern–Weil representative

$$m_{\text{o,det}}^{(g,n)} = \kappa_{\text{ch}}(A_C) \cdot \lambda_1(\mathbb{E}_g), \quad \lambda_1(\mathbb{E}_g) = c_1(\mathbb{E}_g),$$

on $\overline{\mathcal{M}}_{g,n}$. The Theorem D obstruction class is instead

$$\text{obs}_g(A_C) = \kappa_{\text{ch}}(A_C) \cdot \lambda_g, \quad \lambda_g = c_g(\mathbb{E}_g).$$

Booth–Lazarev [277] prove the associative curved bar–cobar Quillen equivalence $\Omega \dashv B$ on curved A_∞ -coalgebras; the chiral instantiation on factorisation coalgebras over $\text{Ran}(X) \times \overline{\mathcal{M}}_{g,n}$ is an upgrade with three structural obstructions, of which the determinant-line descent is identically closed.

PROPOSITION 29.8.1 (κ_{ch} *determinant curving is the Mumford boundary datum*). Let $\mathcal{A}_C$ be a CY chiral algebra with $\kappa_{\text{ch}}(\mathcal{A}_C) \in \mathbb{Q}$. The genus-indexed determinant curving $m_{\text{o,det}}^{(g,n)} = \kappa_{\text{ch}}(\mathcal{A}_C) \cdot \lambda_1(\mathbb{E}_g)$ satisfies

$$\partial^* m_{\text{o,det}}^{(g,n)} = \pi_1^* m_{\text{o,det}}^{(g_1, n_1+1)} + \pi_2^* m_{\text{o,det}}^{(g_2, n_2+1)} \quad (g = g_1 + g_2 \text{ separating clutching}),$$

and $\partial'^* m_{\text{o,det}}^{(g,n)} = m_{\text{o,det}}^{(g-1, n+2)}$ at non-separating clutching.

Proof. Linearity of pullback on Mumford's boundary relation $\partial^* \lambda_1(\mathbb{E}_g) = \pi_1^* \lambda_1(\mathbb{E}_{g_1}) + \pi_2^* \lambda_1(\mathbb{E}_{g_2})$ ([278]; [279] for non-separating). $\square$

LEMMA 29.8.2 (*Mumford curving descent to the top Hodge obstruction*). The determinant-line curving $\kappa_{\text{ch}}(\mathcal{A}_C) c_1(\mathbb{E}_g)$ is the Chern–Weil input for the Hodge bundle. Together with Mumford GRR, the same Hodge-bundle curvature canonically determines the Theorem D obstruction class $\kappa_{\text{ch}}(\mathcal{A}_C) c_g(\mathbb{E}_g)$. Under clutching,

$$\partial^* c_g(\mathbb{E}_g) = \pi_1^* c_{g_1}(\mathbb{E}_{g_1}) \pi_2^* c_{g_2}(\mathbb{E}_{g_2})$$

on separating boundary divisors, while $\partial'^* c_g(\mathbb{E}_g) = \text{o}$ on the non-separating boundary $\overline{\mathcal{M}}_{g-1, n+2}$. After integration against the Faber–Pandharipande insertion ψ_1^{2g-2} on $\overline{\mathcal{M}}_{g,1}$, this class gives the scalar coefficient λ_g^{FP} .

Proof. Mumford's GRR formula computes the Chern character of the Hodge bundle $\mathbb{E}_g = R^0 \pi_* \omega_\pi$ in the tautological ring. Choosing the Chern connection on $\mathbb{E}_g$, the determinant curvature $\text{tr } \Omega_{\mathbb{E}_g}$ represents $c_1(\mathbb{E}_g)$, while the invariant polynomial $\det(1 + \Omega_{\mathbb{E}_g})$ represents the total Chern class; its degree- g component is $c_g(\mathbb{E}_g)$. This is the Chern–Weil transgression from the determinant-line representative to the top Hodge class. Multiplication by the scalar $\kappa_{\text{ch}}(\mathcal{A}_C)$ preserves the construction.

On a separating boundary stratum, Mumford's clutching identity gives $\partial^* \mathbb{E}_g \simeq \pi_1^* \mathbb{E}_{g_1} \oplus \pi_2^* \mathbb{E}_{g_2}$. Whitney multiplicativity of Chern classes therefore gives $\partial^* c_g(\mathbb{E}_g) = \pi_1^* c_{g_1}(\mathbb{E}_{g_1}) \pi_2^* c_{g_2}(\mathbb{E}_{g_2})$ in top bidegree, i.e. the product displayed in the statement. On the non-separating boundary, $\partial^* \mathbb{E}_g \simeq \mathbb{E}_{g-1} \oplus \mathcal{O}$; the rank is $g-1$ plus a trivial line, hence $c_g(\mathbb{E}_{g-1} \oplus \mathcal{O}) = \text{o}$. The Faber–Pandharipande formula evaluates the resulting Hodge integral $\int_{\overline{\mathcal{M}}_{g,1}} \psi_1^{2g-2} c_g(\mathbb{E}_g)$, producing the numerical coefficient denoted λ_g^{FP} . $\square$

Ran-space contractibility ($\text{Ran}(C) \simeq \text{pt}$ for every connected C ; [10] Ch. 3.4.1) and the vanishing $\lambda_1(\mathbb{E}_0) \equiv \text{o}$ on $\overline{\mathcal{M}}_{0,n}$ collapse the chiral curved bar–cobar problem at $g=0$ to the associative Lefèvre–Hasegawa–Quillen equivalence, for every value of κ_{ch} . At $g \geq 1$, Prop. 29.8.1 reduces the fibred equivalence over $\overline{\mathcal{M}}_{g,n}$ to étale-local constancy (a single determinant-line curvature after trivialising $\lambda_1(\mathbb{E}_g)$), with boundary compatibility automatic from the Mumford relation; Lemma 29.8.2 transgresses this local curving to the top Hodge obstruction class $\lambda_g = c_g(\mathbb{E}_g)$ used in Theorem D. The residual obstruction at each genus is the descent-gluing theorem along an étale cover of $\overline{\mathcal{M}}_{g,n}$ for cofibrantly generated model structures in the curved setting, and the sewing-analytic comparison $D^{\text{co},g}(\mathcal{A}_C) \hookrightarrow \text{IndHilb}^g(\mathcal{A}_C^{\text{sew}})$, which holds as a dense realisation on class G/L loci and promotes to an isomorphism of nuclear Fréchet spaces on class M loci in the weight-completed ambient: $\widehat{D}^{\text{co},g}(\widehat{\mathcal{A}}_C) \xrightarrow{\sim} \text{IndHilb}^g(\widehat{\mathcal{A}}_C^{\text{sew}})$, each stage $\mathcal{A}_C / F^{N+1}$ being class G/L by finite-weight truncation, and the cofiltered limit along surjective transitions a nuclear Fréchet space by Grothendieck (Vol I [96] + [96]).

The concrete non-null witness is local $\mathbb{P}^2$, where $\kappa_{\text{ch}} = 3/2$ generates a non-zero curved bar complex at every $g \geq 1$. The degenerate case $K_3 \times E$ with $\kappa_{\text{ch}}(K_3 \times E) = 0$ has uncurved bar at every genus and tests only the uncurved specialisation.

29.9 COMPACT CY_3 EXAMPLES

The following compact CY_3 families illustrate the range of shadow tower behaviour. For *strict* compact CY_3 with $h^{3,0} = 1$ and simply-connected universal cover, the *conjectural* modular characteristic is $\kappa_{\text{ch}} = \chi_{\text{top}}/24$ (BCOV prediction), which differs from $\chi(\mathcal{O}_X)$; the latter vanishes for all CY_3 by Serre duality. The BCOV scope excludes two families encountered below: (a) *generalised* CY_3 with torsion canonical ($h^{3,0} = 0$), such as Enriques $\times E$, where the BKM weight κ_{BKM} of an associated Borchers lift is the relevant automorphic invariant; (b) K_3 -fibered products $K_3 \times E$, where $\chi_{\text{top}} = 0$ but the Heisenberg-additive $\kappa_{\text{ch}}^{\text{Heis}}(K_3 \times E) = \kappa_{\text{ch}}(A_{K_3}) + \kappa_{\text{ch}}(A_E) = 3$ (fibre-level) and $\kappa_{\text{BKM}} = 5$ (Borchers weight) govern the shadow tower. Shadow depth class, Hochschild data, and BKM structure vary across all three regimes.

The banana manifold: $\kappa_{\text{ch}} = 0$ with nontrivial tower

The banana manifold X_{ban} (Schoen's CY_3 , the fiber product of two rational elliptic surfaces over $\mathbb{P}^1$) has Hodge numbers $h^{1,1} = h^{2,1} = 19$ and Euler characteristic $\chi = 0$.

PROPOSITION 29.9.1 (*Shadow tower of the banana manifold*). The shadow obstruction tower of X_{ban} has:

- (i) $\kappa_{\text{ch}} = \chi/24 = 0$. The degree-2 scalar shadow *vanishes*.
- (ii) $S_4 = -44$ (quartic shadow from the genus-0 GV invariants $n_{d_1, d_2}^0 = -2$ of the banana curve classes).
- (iii) The shadow tower starts at degree 4, not degree 2: the cubic shadow is invisible when $\kappa_{\text{ch}} = 0$ (it enters as $\kappa_{\text{ch}} \cdot \alpha$, which vanishes).
- (iv) The critical discriminant $\Delta = 8\kappa_{\text{ch}}S_4 = 0$ (since $\kappa_{\text{ch}} = 0$). The standard single-line classification (G/L/C/M) does not directly apply.
- (v) Shadow depth class: M (infinite tower) shifted to degree 4. The BKY partition function involves infinitely many banana-curve BPS states, generating an infinite shadow tower whose leading term is quartic.

Remark 29.9.2 ($\kappa_{\text{ch}} = 0$ does not imply $\Theta_A = 0$). The banana manifold is the prototypical example: $\kappa_{\text{ch}} = 0$ does *not* imply $\Theta_A = 0$. The vanishing of κ_{ch} means the bar complex is uncurved ($d^2 = 0$ at the leading scalar level), but the higher-degree components of Θ_A (the quartic shadow Q and beyond) are nonvanishing, sourced by the instanton contributions (genus-0 GV invariants of the banana curves).

Three CY_3 examples with $\kappa_{\text{ch}} = 0$ show qualitatively different behaviour:

- Heisenberg at $k = 0$: $\kappa_{\text{ch}} = 0$, trivially uncurved, class G.
- Virasoro at $c = 0$: $\kappa_{\text{ch}} = 0$, but higher shadows from contact terms (class M).
- Banana manifold: $\kappa_{\text{ch}} = 0$, but higher shadows from *instantons* (class M, shifted to degree 4).

Verification: `compute/lib/banana_shadow.py` (63 tests).

Enriques $\times E$: the $\mathbb{Z}_2$ quotient of $K_3 \times E$

Let $S_{\text{Enr}} = K_3/\iota$ be an Enriques surface (ι a fixed-point-free involution), and E an elliptic curve. The product $S_{\text{Enr}} \times E$ is a generalized CY_3 (the canonical bundle $K_{S_{\text{Enr}} \times E}$ is 2-torsion, so $h^{3,0} = 0$). Nevertheless, the shadow tower machinery applies to the associated vertex algebra, and the Borcherds lift on $O(2, 10)$ provides the automorphic structure.

THEOREM 29.9.3 (*Shadow tower of Enriques $\times E$*). The shadow data of $\text{Enriques} \times E$ is:

- (i) $\kappa_{\text{BKM}}(\text{Enr} \times E) = 4$, the weight of the Enriques Borcherds product Ψ on $O(2, 10)$ (Allcock 2000).
- (ii) Root multiplicities come from the Enriques elliptic genus $\phi_{\text{Enr}} = \frac{1}{2}\phi_{0,1}$: the Fourier coefficients are $f_{\text{Enr}}(n, l) = f_{K_3}(n, l)/2$ (all integers since f_{K_3} has even coefficients).
- (iii) The ratio $\kappa_{\text{BKM}}(K_3 \times E)/\kappa_{\text{BKM}}(\text{Enr} \times E) = 5/4$.
- (iv) Shadow depth class: M (infinite tower), driven by the infinite BKM root spectrum.

Remark 29.9.4 (*The $\mathbb{Z}_2$ quotient on κ_{BKM}*). The passage from $K_3 \times E$ ($\kappa_{\text{BKM}} = 5$) to $\text{Enriques} \times E$ ($\kappa_{\text{BKM}} = 4$) under the $\mathbb{Z}_2$ quotient does *not* halve κ_{BKM} . Rather, the weight of the Borcherds product drops by 1: the $O(2, 10)$ lattice for the Enriques surface has a different constant term in the Borcherds input form than the $O(3, 19)$ lattice for K_3 , and the weight formula gives $8/2 = 4$ instead of $10/2 = 5$. The ratio $5/4$ is not a simple topological quotient; it reflects the lattice-theoretic structure of the Borcherds lift.

Verification: `compute/lib/enriques_shadow.py` (72 tests).

The quintic threefold: non-integer BCOV shadow scalar and BKM obstruction

The quintic hypersurface $Q \subset \mathbb{P}^4$ has $h^{1,1} = 1$, $h^{2,1} = 101$, $\chi = -200$.

PROPOSITION 29.9.5 (*Quintic shadow tower*). This proposition records the scalar BCOV/GW shadow lane. It does not construct a quintic Φ_3 output or a Hilbert $O(2, 2)$ target. The shadow data of the quintic is:

- (i) $\kappa_{\text{ch}}^{\text{BCOV}} = \chi/24 = -25/3$ (non-integer BCOV shadow scalar).
- (ii) The non-integrality of $\kappa_{\text{ch}}^{\text{BCOV}}$ obstructs a naive BKM superalgebra: BKM root multiplicities must be integers, and the standard denominator-identity machinery requires integral Borcherds lift weight. The quintic has no natural Borcherds–Kac–Moody structure.
- (iii) The shadow metric $Q_L(t) = 4(\kappa_{\text{ch}}^{\text{BCOV}})^2 + 12\kappa_{\text{ch}}^{\text{BCOV}}\alpha t + (9\alpha^2 + 16\kappa_{\text{ch}}^{\text{BCOV}}S_4)t^2$ is well-defined for fractional $\kappa_{\text{ch}}^{\text{BCOV}}$. With $\kappa_{\text{ch}}^{\text{BCOV}} = -25/3$: $Q_L(0) = 2500/9 > 0$.
- (iv) The GW invariants are known to high degree:

$$n_1^0 = 2875, \quad n_2^0 = 609250, \quad n_3^0 = 317206375, \quad n_4^0 = 242467530000.$$

These are BPS state counts via the Gopakumar–Vafa formula.

- (v) Shadow depth class: M (infinite tower). The quintic has an infinite BPS spectrum with curves of all degrees and genera; the shadow tower is controlled by the BCOV holomorphic anomaly equation.

Remark 29.9.6 ($\chi/24$ integrality survey). The quantity $\chi/24$ is an integer if and only if $12 \mid (h^{1,1} - h^{2,1})$. Among standard complete intersections:

- $\mathbb{P}^5[3, 3]$: $\chi = -144$, $\kappa_{\text{ch}}^{\text{BCOV}} = -6$ (integer).
- $\mathbb{P}^5[2, 4]$: $\chi = -176$, $\kappa_{\text{ch}}^{\text{BCOV}} = -22/3$ (non-integer).
- $\mathbb{P}^7[2, 2, 2, 2]$: $\chi = -128$, $\kappa_{\text{ch}}^{\text{BCOV}} = -16/3$ (non-integer).
- Quintic: $\chi = -200$, $\kappa_{\text{ch}}^{\text{BCOV}} = -25/3$ (non-integer).

Non-integrality of the BCOV shadow scalar is the generic situation for compact CY_3 manifolds. A BKM structure requires additional input beyond the BCOV prediction.

Verification: `compute/lib/quintic_shadow_obstruction.py` (86 tests).

PROPOSITION 29.9.7 (*Quintic shadow coefficients from Gromov–Witten data*). Assume the framed large-complex-structure Φ_3 locus of Theorem 5.11.1. At the large complex structure limit (LCS degeneration type), the first shadow coefficients of the quintic chiral algebra are:

- $S_2 = \kappa_{\text{ch}}^{\text{BCOV}} = -25/3$. The scalar shadow, from the genus-1 BCOV constant-map contribution $F_1 = \kappa_{\text{ch}}^{\text{BCOV}}/24 = -25/72$.
- $S_3 = \alpha = -3/5$ (classical). The cubic shadow, from the Yukawa coupling: $\alpha = C_{\text{III}}/\kappa_{\text{ch}}^{\text{BCOV}} = 5/(-25/3) = -3/5$, where $C_{\text{III}} = H^3 = 5$ is the triple intersection number. At the quantum level, α receives instanton corrections of the form $\alpha(q) = -3/5 + \sum_{d \geq 1} \alpha_d q^d$, where $\alpha_1 = n_1^\circ/\kappa_{\text{ch}}^{\text{BCOV}} = 2875/(-25/3) = -345$.
- $S_4 = 0$ (classical). The quartic shadow vanishes classically because $\partial^4 F_0^{\text{cl}}/\partial t^4 = 0$ for the cubic prepotential. Instanton corrections are nonzero: the leading correction is proportional to $n_1^\circ \cdot 1^4/\kappa_{\text{ch}}^{\text{BCOV}} = -345$. The non-vanishing of S_4 after instanton corrections promotes the shadow class from **L** to **M**.

The classical shadow tower ($S_4 = 0$) is class **L** (depth 3): the shadow metric $Q_L(t) = (-50/3 - 9t/5)^2$ is a perfect square with discriminant $\Delta = 0$. Instanton corrections destroy the perfect-square structure, promoting to class **M** (infinite depth).

Proof. The scalar shadow $S_2 = \kappa_{\text{ch}}^{\text{BCOV}}$ follows from the definition of the BCOV shadow tower at degree 2. The cubic shadow $S_3 = \alpha$ is the normalised Yukawa coupling: the classical prepotential $F_0^{\text{cl}} = (5/6)t^3$ gives $C_{\text{III}} = \partial^3 F_0^{\text{cl}}/\partial t^3 = 5$. The recursive shadow tower with $\kappa_{\text{ch}}^{\text{BCOV}} = -25/3$, $\alpha = -3/5$, $S_4 = 0$ gives $a_0 = 2\kappa_{\text{ch}}^{\text{BCOV}} = -50/3$, $a_1 = 3\alpha = -9/5$, and $a_n = -(1/(2a_0)) \sum_{j=1}^{n-1} a_j a_{n-j} = 0$ for all $n \geq 2$, since $q_2 - a_1^2 = 81/25 - 81/25 = 0$ and all subsequent terms vanish by induction. The classical tower terminates at depth 3. For the instanton promotion: $C(q) = 5 + \sum_{d \geq 1} \sum_{d' \mid d} n_{d'}^\circ d'^3 q^d$ has nonzero coefficients at all positive degrees (since $n_1^\circ = 2875 \neq 0$), so the instanton-corrected $S_4 \neq 0$, giving $\Delta = 8\kappa_{\text{ch}}^{\text{BCOV}} S_4 \neq 0$ and class **M**. $\square$

Remark 29.9.8 (*Comparison with $K_3 \times E$*). The quintic and $K_3 \times E$ are both class **M** but differ structurally:

	Quintic	$K_3 \times E$
$h^{1,1}$ (lattice rank)	1	21
Active scalar lane	$\kappa_{\text{ch}}^{\text{BCOV}} = -25/3$ (fractional)	$\kappa_{\text{ch}}^{\text{Heis}} = 3$ (integer)
$\kappa_{\text{BKM}}^{\text{Hodge}}$	0 (tier-II CY-B ₃ reduction)	5 (three-path triangulated)
Automorphic target	rank-1 BCOV/MO substitute; Hilbert $\text{O}(2, 2)$ pairing open	$\mathbb{H}_2/\text{Sp}_4(\mathbb{Z})$ (Siegel)
BKM structure	none constructed; rank-1 Heegner shadow only	$\mathfrak{g}_{\Delta_3}$
GV lattice	$\mathbb{Z}$ (one Kahler modulus)	Mukai lattice (rank 24)
Shadow class	M	M

The quintic tower is *rank-1*: it lives on a one-dimensional charge lattice $H_2(X, \mathbb{Z}) \cong \mathbb{Z}$. The $K_3 \times E$ tower is *rank-21*: it lives on the Picard lattice of the K_3 factor. Both have infinite depth, but the quintic is combinatorially simpler (a single GV sequence n_d^g) while $K_3 \times E$ is structurally richer (the BKM denominator formula organises the full lattice spectrum).

The row $\kappa_{\text{BKM}}^{\text{Hodge}}(Q)$ is absent/undefined under the CY-B₃ three-tier scope: the quintic lies at tier II (non- K_3 -fibred, $h^{1,1} = 1$, rigid Picard). What is proved here is the rank-1 substitute: BCOV/GW/PT data live on the one-dimensional charge lattice and supply genus-by-genus coefficients. A genuine Hilbert $\text{O}(2, 2)$ automorphic target would require an explicit weight-two lattice, pairing, and normalisation map from the quintic chain complex to $\mathbb{H}_1 \times \mathbb{H}_1/\Gamma$; that pairing is not constructed in this chapter. Hence the zeroth BKM coefficient is not recorded as the value of a degenerate Hilbert modular form. Zinger higher-genus GW, Klemm–Pandharipande BPS numbers, and Pandharipande–Thomas stable pairs populate the non-zero rank-1 coefficients for $d \geq 1$. In the current convention $\alpha_{\text{BCOV}}(Q) = 0$ as a class in $H^{0,1}(Q)$, while the scalar genus-one coefficient $\chi(Q)/24 = -25/3$ is nonzero. Paths 2 and 3 (BV, MO) provide BCOV/MO substitutes, not a constructed CY-B₃ Hilbert-pairing theorem.

PROPOSITION 29.9.9 (*Tier-III orthogonal target and quintic Booth–Lazarev obstruction package*). This proposition records the obstruction package; it does not construct an orthogonal or Hilbert pairing. Let X be a compact non- K_3 -fibred CY₃ with $h^{1,1}(X) \geq 3$. A CY-B₃ tier-III upgrade to an orthogonal or Hilbert Shimura target requires, before any automorphic denominator or BKM weight is asserted, the following chain-level datum:

$$\langle -, - \rangle_X^{\text{orth}} : B^{E_i}(\Phi_3^{(\Sigma_2, C)}(\text{Perf } X)) \otimes C_\bullet(\mathcal{D}_X, \mathcal{L}_X^{w_X}) \longrightarrow \mathbb{C},$$

where $\mathcal{D}_X = \text{SO}(2, 2h^{1,1}(X))/\text{SO}(2)\text{SO}(2h^{1,1}(X))$ up to the arithmetic quotient by a specified Γ_X , $\mathcal{L}_X$ is the automorphic line, and the boundary rank-2 case is the Hilbert target $\mathbb{H}_1 \times \mathbb{H}_1/\Gamma$. This pairing must be a chain map, must identify the chosen integral lattice and its normalisation, and must commute with the E_i -chiral differential, sewing, and Verdier/Koszul reflection. None of these data is supplied by the rank-1 BCOV/GW/PT coefficients of the quintic, nor by the K_3 -fibred Siegel Δ_3 pairing.

For the quintic Q , the residual chiral Booth–Lazarev obstructions are therefore exactly the two chain complexes

$$O_i^{\text{BL}}(Q) \in H^i(\text{Ran}(C), \text{Aut}_\otimes(\text{Gen}_{\text{BL}})) \simeq \varprojlim_n I_n$$

and

$$O_3^{\text{BL}}(Q) \in \varprojlim_g A^{\text{sew}, g} \subset \varprojlim_g \text{Ext}_{\text{top}}^i(D^{\text{co}, \text{ch}, g}(\Phi_3^{\text{FA}}(\text{Perf } Q)), \text{IndHilb}^g(A^{\text{sew}})).$$

The first is killed only by a Čech o-cochain trivialising the Smith-recognition cocycle $j_{n,m}^* I_{n+m} - I_n \boxtimes I_m$. The second is killed only by a sewing homotopy proving nuclear convergence of the BCOV genus tower. At the LCS point the current computation gives the leading sign

$$\kappa_{\text{ch}}^{\text{BCOV}}(Q) = -25/3, \quad S_{4,1}^{\text{inst}}(Q) = 2875/(-25/3) = -345, \quad (\kappa_{\text{ch}}^{\text{BCOV}}(Q))^3 S_{4,1}^{\text{inst}}(Q) > 0,$$

which is a first coefficient in the expected Borel sector. It is not a vanishing theorem for $O_3^{\text{BL}}(Q)$. The missing lemma is the full BCOV Borel sign lemma: after fixing the sewing sector and normalisation, the Borel transform of the sewing defect must be analytic on the positive ray and the full instanton-corrected quadratic form must remain sign-definite so that $\|\sigma_{\text{sew}}^{(N)}\| \rightarrow 0$ in the nuclear IndHilb topology.

Proof. The orthogonal/Hilbert claim is a statement about a pairing between the E_1 chiral bar complex and chains on an arithmetic Shimura target. A Siegel modular form attached to a K_3 fibre lives on a different lattice and cannot supply the chain map above for a non- K_3 -fibred X . The BCOV/GW/PT data of Q give scalar and rank-1 coefficient systems on $H_2(Q, \mathbb{Z}) \cong \mathbb{Z}$; they do not specify an even lattice of signature $(2, 2h^{1,1})$, an arithmetic group, a line-bundle normalisation, or a chain-level pairing compatible with B^{E_1} .

The two Booth–Lazarev complexes are the residual complexes after the Mumford collapse of the genus-curve obstruction: O_1^{BL} is the Ran-space Smith-recognition Mittag–Leffler defect in the configuration-count direction, and O_3^{BL} is the sewing Mittag–Leffler defect in the genus direction. A vanishing proof for either is exactly a nullhomotopy in its displayed complex. The quintic shadow engine computes only the LCS leading coefficient $S_{4,1}^{\text{inst}} = 2875/(-25/3)$, hence the displayed sign check is arithmetic evidence for the first Borel coefficient. Nuclear convergence of the full sewing defect is a statement about the entire BCOV tower and its Stokes data; it is not implied by one coefficient. $\square$

Remark 29.9.10 (Mirror symmetry and the shadow tower). The mirror quintic $\tilde{Q}$ (Greene–Plesser orbifold) has $h^{1,1} = 101$, $h^{2,1} = 1$, $\chi = +200$, giving $\kappa_{\text{ch}}^{\text{BCOV}}(\tilde{Q}) = +25/3$ (conjectural). The BCOV-shadow complementarity $\kappa_{\text{ch}}^{\text{BCOV}}(Q) + \kappa_{\text{ch}}^{\text{BCOV}}(\tilde{Q}) = -25/3 + 25/3 = 0$ is consistent with the KM/free-field anti-symmetry class of Vol I (both values conjectural). Mirror symmetry exchanges the rank-1 tower of the quintic with a rank-101 tower of the mirror, exchanging Kahler moduli with complex structure moduli.

Remark 29.9.11 (Conifold transition and shadow phase transition). At the conifold point ($\psi = 1$ in the Greene–Plesser family, degeneration type: conifold), a 3-cycle $C \subset Q$ vanishes, and the Yukawa coupling $C(z)$ acquires a double pole. The cubic shadow $\alpha = C/\kappa_{\text{ch}} \rightarrow \infty$, and the shadow tower degenerates. After the conifold transition to the resolved conifold $Y = \text{Tot}(\mathcal{O}(-1) \oplus \mathcal{O}(-1) \rightarrow \mathbb{P}^1)$: $\kappa_{\text{ch}}(Y) = 1$ and the shadow class is $\mathbf{G}$ (depth 2). This is a *phase transition* in the shadow classification: $\mathbf{M} \rightarrow \mathbf{G}$.

The three degeneration types of the mirror quintic family produce distinct shadow tower behaviours:

- (a) *Large complex structure* ($z = 0$): class $\mathbf{M}$, $\alpha = -3/5 + O(q)$ (fully populated tower).
- (b) *Conifold* ($z = 1/3125$): class degenerates ($\alpha \rightarrow \infty$); phase transition $\mathbf{M} \rightarrow \mathbf{G}$.
- (c) *Gepner/orbifold* ($z = \infty$): class $\mathbf{M}$ (orbifold), $\mathbb{Z}_5$ -equivariant tower.

Verification: `compute/lib/quintic_shadow_tower.py` (107 tests).

Hochschild homology of compact CY_3 examples

The Hochschild homology $\text{HH}_*(D^b(\text{Coh}(X)))$ is computed from the HKR decomposition $\text{HH}_p \simeq \bigoplus_q H^q(X, \Omega_X^{3-p})$ using the CY_3 isomorphism $\wedge^p T_X \simeq \Omega_X^{3-p}$.

PROPOSITION 29.9.12 (*Hochschild data of compact CY₃ examples*). (i) $X = K_3 \times E$:
 $\dim \mathrm{HH}_* = 96$, with Hodge decomposition

$$(\dim \mathrm{HH}_0, \dim \mathrm{HH}_1, \dim \mathrm{HH}_2, \dim \mathrm{HH}_3) = (4, 44, 44, 4).$$

The palindromic symmetry $\dim \mathrm{HH}_p = \dim \mathrm{HH}_{3-p}$ reflects Serre duality.

(ii) $X = Q$ (quintic): $\dim \mathrm{HH}_* = 208$, with

$$(\dim \mathrm{HH}_0, \dim \mathrm{HH}_1, \dim \mathrm{HH}_2, \dim \mathrm{HH}_3) = (2, 102, 102, 2).$$

The concentration in degrees 1 and 2 reflects $h^{1,1} = 1$ and $h^{2,1} = 101$: moduli dominate, and the CY structure contributes only the top and bottom forms.

Verification: `compute/lib/cy3_hochschild.py` (71 tests).

29.10 INTEGRABLE SYSTEMS AND LATTICE MODELS

The shadow obstruction tower admits a dictionary with classical integrable systems, where the conserved quantities I_r correspond to shadow invariants at each degree.

The Calogero–Moser/Bethe dictionary

The Calogero–Moser system with N particles on a line and inverse-square interaction $V(x) = \sum_{i < j} g^2 / (x_i - x_j)^2$ has N independent conserved quantities $I_1, I_2, \dots, I_N$ (the Sekiguchi operators), with $I_2 = H$ (the Hamiltonian) and I_k of degree k in the momenta.

Conjecture 29.10.1 (*Shadow-integrable dictionary*). There is a dictionary between the shadow obstruction tower invariants and the Calogero–Moser conserved quantities:

$$\begin{aligned} I_2 \text{ (quadratic Hamiltonian)} &\longleftrightarrow \kappa_{\mathrm{ch}} \text{ (modular characteristic),} \\ I_3 \text{ (cubic integral)} &\longleftrightarrow C \text{ (cubic shadow),} \\ I_4 \text{ (quartic integral)} &\longleftrightarrow Q \text{ (quartic shadow / contact invariant).} \end{aligned}$$

The Bethe ansatz equations for the Calogero–Moser system correspond to the Maurer–Cartan equation $D\Theta + \frac{1}{2}[\Theta, \Theta] = 0$ of the modular convolution algebra, projected to each degree: the r -th conserved quantity I_r is the genus-0 degree- r projection of the MC element Θ_A .

Remark 29.10.2. The dictionary is *structural*, not a theorem. It captures the parallel between two filtration structures: the degree filtration on Θ_A (controlling the shadow depth classification G/L/C/M) and the degree filtration on the conserved quantities I_r (controlling the integrability class of the Calogero–Moser system). The coupling constant g^2 maps to κ_{ch} , the number of particles N maps to the number of strong generators, and the Bethe roots map to the shadow metric zeros.

Verification: `compute/lib/cross_volume_shadow_bridge.py` (60 tests).

Lattice finite-size corrections

For a critical lattice model (e.g., the XXX Heisenberg spin chain of length L), the finite-size corrections to the ground-state energy are controlled by the central charge c and conformal dimensions of the associated CFT:

$$E_0(L) = L\varepsilon_\infty - \frac{\pi c}{6L} + O(L^{-3}).$$

More generally, the full finite-size spectrum organizes into an asymptotic expansion

$$E_n(L) - L\varepsilon_\infty = \frac{2\pi}{L} \left(-\frac{c}{12} + h_n + \bar{h}_n \right) + \sum_{k \geq 2} \frac{a_k(n)}{L^{2k-1}}.$$

Conjecture 29.10.3 (Finite-size corrections as shadow tower). The finite-size correction coefficients $a_k(n)$ correspond to shadow tower data: the leading coefficient $a_1 = -c/12 = -\kappa_{\text{ch}}/6$ recovers κ_{ch} , and the higher coefficients a_k for $k \geq 2$ encode the degree- $(2k)$ shadow projections. The decay rate of the corrections is $q = e^{-2\pi/L}$, matching the shadow tower variable.

Verification: `compute/lib/cross_volume_shadow_bridge.py` (63 tests).

Crystal melting: combinatorial vs bar-algebraic degree

The MacMahon function $M(q)$ counts plane partitions (3D Young diagrams), and the crystal melting model of Okounkov–Reshetikhin–Vafa interprets the DT partition function of $\mathbb{C}^3$ as a statistical-mechanical partition function on the crystal lattice $\mathbb{Z}_{\geq 0}^3$.

Remark 29.10.4 (Combinatorial degree $\neq$ bar degree). The crystal melting “degree” (the number of boxes removed from the corner of the crystal) does *not* match the bar complex degree (the tensor length in $B^{(n)}(A)$).

The crystal partition function organizes by the number of boxes:

$$M(q) = \sum_{\pi \in \mathcal{PP}} q^{|\pi|}, \quad |\pi| = \text{number of boxes in plane partition } \pi.$$

The bar complex organizes by tensor length:

$$B(A) = \bigoplus_{n \geq 1} \bar{A}^{\otimes n}[n], \quad \bar{A} = \ker(\varepsilon), \quad \text{degree } n = \text{number of tensor factors}.$$

These two gradings are *not* compatible: a plane partition with k boxes does not correspond to a bar element of degree k . Rather, the crystal melting expansion is an exponential reorganization of the bar complex: $\log M(q) = \sum_k \sigma_2(k) q^k / k$ is the free energy, while the bar complex detects the individual OPE modes.

The fundamental mismatch: crystal melting is a *tensor-algebraic* construction (counting 3D diagrams in $\mathbb{Z}^3$), while the bar complex is a *factorization-algebraic* construction (organized by collision patterns on $\text{Ran}(X)$). The two agree in the graded *character* (both reproduce $M(q)$ or its inverse) but not in the *degree structure*.

Verification: `compute/lib/crystal_bar_identification.py` (70 tests).

29.II GRAND ATLAS OF CY_3 SHADOW INVARIANTS

Table 29.1 collects the shadow tower data for 18 CY_3 families spanning the full range of shadow behaviour.

Key patterns visible in the atlas:

- (i) **Toric depth bound:** for toric CY_3 with N vertices in the web diagram, the shadow depth satisfies $r_{\text{max}} \leq N$. The cases $N = 1$ (trivial), 2 (Gaussian), 3 (Lie), 4 (contact) are realized; $N \geq 5$ gives class M.
- (ii) **Compact CY_3 are generically class M:** all compact CY_3 with $\chi \neq 0$ have infinite shadow depth, driven by the infinite BPS spectrum.

TABLE 29.1: Grand atlas of CY_3 shadow invariants. Columns: CY_3 family, topological Euler characteristic χ , Hodge numbers $h^{1,1}$ and $h^{2,1}$, active scalar lane, shadow depth class, and data source. For non-compact toric CY_3 : the active scalar is $\kappa_{\text{ch}} = \chi(S)/2$ where S is the compact base (Proposition 34.15.1). For compact CICYs: the active scalar is the BCOV shadow scalar $\kappa_{\text{ch}}^{\text{BCOV}} = \chi_{\text{top}}/24$, not the Hodge-supertrace κ_{ch} . For K_3 -fibered geometries: the column records κ_{BKM} (the automorphic weight), not κ_{ch} ; see Remark 29.9.4. Families above the first rule are non-compact toric; between the rules are K_3 -fibered; below are compact complete intersections and special families. BV = Borcea–Voisin.

CY_3	χ	$h^{1,1}$	$h^{2,1}$	active scalar	Class	Source

BV(10, 0, 0)	0	35	35	0	?	Voisin–Borcea
BV(10, 8, 0)	0	19	19	0	?	Voisin–Borcea
BV(20, 2, 0)	120	61	1	5	M	Voisin–Borcea

[†]These entries record κ_{BKM} (Borcherds automorphic weight), not κ_{ch} ; for $K_3 \times E$, the Heisenberg reading is $\kappa_{\text{ch}}^{\text{Heis}} = 3$ while the compact trace is 0.

- (iii) κ_{ch} **integrality**: among the atlas families, $\mathbb{P}^5[3, 3]$ ($\kappa_{\text{ch}} = -6$), $K_3 \times E$ ($\kappa_{\text{BKM}} = 5$), Enriques $\times E$ ($\kappa_{\text{BKM}} = 4$), and BV(20, 2, 0) ($\kappa_{\text{ch}} = 5$) have integral κ_{ch} . For compact CICYs, $\kappa_{\text{ch}} = \chi/24$ is integral only when $24 \mid \chi$; for K_3 -fibered geometries, κ_{BKM} (the automorphic weight) is always integral.
- (iv) **BKM structure requires integral automorphic weight**: K_3 -fibered CY_3 s with $\chi = 0$ carry BKM superalgebras via Borcherds lifts; compact CICYs with $\kappa_{\text{ch}} \notin \mathbb{Z}$ do not.
- (v) $\kappa_{\text{ch}} = 0$ **does not imply trivial tower**: the banana manifold and the balanced Borcea–Voisin families ($r = 10$) have $\kappa_{\text{ch}} = 0$ but potentially nontrivial higher-degree shadows sourced by instantons.
- (vi) **Borcea–Voisin as κ_{ch} -interpolation**: the BV family parametrized by (r, a, δ) gives $\kappa_{\text{ch}} = (r - 10)/2$, interpolating between $\kappa_{\text{ch}} = -9/2$ (minimal, $r = 1$) and $\kappa_{\text{ch}} = 5$ (maximal, $r = 20$, recovering $K_3 \times E$).

Verification: `compute/lib/cy3_grand_atlas.py, compute/tests/test_cy3_grand_atlas.py` (119 tests).

Remark 29.11.1 (Enriques $\times E$ kappa anomaly). The grand atlas uses $\kappa_{\text{BKM}}(\text{Enr} \times E) = 4$, the weight of the Allcock Borcherds product on $O(2, 10)$, verified by `enriques_shadow.py` (72 tests). This is the authoritative value. The naive BCOV-shadow scalar $\kappa_{\text{BCOV}} = \chi/24$ does not apply because $\text{Enriques} \times E$ is a *generalized* CY_3 ($h^{3,0} = 0$, torsion canonical). The ratio $\kappa_{\text{BKM}}(\text{K}_3 \times E)/\kappa_{\text{BKM}}(\text{Enr} \times E) = 5/4$.

29.12 FORM FACTORS VIA KOSZUL DUALITY AND THE SHADOW PARTITION FUNCTION

The Costello–Paquette programme computes form factors in holomorphic Chern–Simons theory via Koszul duality between bulk and boundary algebras. The Koszul projection $\pi: \text{Obs}_{\text{bulk}} \rightarrow \text{Obs}_{\text{bdry}}^!$ factors through the bar complex $B(A)$, and the n -particle form factor

$$F(O; z_1, \dots, z_n) = \langle \text{vac} | O(o) | z_1, \dots, z_n \rangle$$

is computed by pairing the bulk operator O against n -fold bar elements:

$$F(O; z_1, \dots, z_n) = \langle O, s^{-1}a_1 | \cdots | s^{-1}a_n \rangle_{B(A)}.$$

Here z is the Yangian spectral parameter (not a worldsheet coordinate; the distinction is essential, cf. Remark 9.9.12 in the E_1 -chiral bialgebra chapter).

Conjecture 29.12.1 (Form factor–shadow PF identity). For a chiral algebra A arising from a CY category $\mathcal{C}$ via the functor Φ , the generating function of integrated form factors equals the shadow partition function:

$$\sum_{n \geq 2} \frac{1}{n!} \int_{\mathcal{M}_{0,n}} F(O; z_1, \dots, z_n) dz_1 \cdots dz_n = \log \Theta_A(q),$$

where $\Theta_A = \prod_{k \geq 1} (1 - q^k)^{a_k}$ is the bar Euler product of Volume I. The integrated n -particle form factor equals the shadow invariant at degree n :

$$\frac{1}{n!} \int_{\mathcal{M}_{0,n}} F(O; z_1, \dots, z_n) = S_n(A).$$

The identity is realised differently at each shadow depth class.

PROPOSITION 29.12.2 (Form factor truncation by shadow class). The n -particle form factor $F(O; z_1, \dots, z_n)$ truncates according to the shadow class of A :

- (i) **Class G** (Heisenberg, depth 2): only the 2-particle form factor is nonzero. The Koszul projection π is a quasi-isomorphism, and $F(O; z_1, z_2) = \kappa_{\text{ch}}/(z_1 - z_2)^2$ (Wick contraction). All higher form factors vanish: the bar complex is formal, and $B^{\text{der}}(A) = B(A)$.
- (ii) **Class L** (Kac–Moody, depth 3): the 3-particle form factor is the first loop correction, with integrated value $S_3 = \alpha$ (the cubic shadow). The Koszul projection carries a single A_∞ -correction from m_3 . All form factors with $n \geq 4$ vanish.
- (iii) **Class C** ($\beta\gamma$, finite depth): finitely many form factors are nonzero. The correction series converges, and π carries finitely many A_∞ -corrections.
- (iv) **Class M** (Virasoro, infinite depth): *all* form factors are nonzero. The Koszul projection π carries infinitely many A_∞ -corrections. The integrated form factor series $\sum S_n$ is Gevrey-1 divergent and Borel summable. For the spin-2 channel of $\mathcal{W}_{1+\infty}$ at $c = 1$: $S_2 = 1/2$, $S_3 = 2$, $S_4 = 10/27$ (matching the A_∞ -bar computation of §29.2).

Proof. The shadow class determines the depth of the A_∞ -tower on $B(A)$, hence the maximal degree of nonvanishing bar elements contributing to $\langle O, s^{-1}a_1 | \cdots | s^{-1}a_n \rangle$. For class G, the bar complex is formal ($m_k = 0$ for $k \geq 3$), so only the binary pairing ($n = 2$) contributes. For class L, $m_3 \neq 0$ but $m_k = 0$ for $k \geq 4$, so only $n \leq 3$ contributes. For class M, all m_k are nonzero, giving contributions at every degree. The Gevrey-1 growth for class M follows from the Gevrey-1 growth of the shadow invariants (Vol I, Theorem D). The integrated values S_n match the shadow invariants by the comparison of the moduli-space integral $\int_{M_{0,n}}$ with the degree- n projection of the shadow tower (the Costello–Gwilliam factorisation-algebra integration). $\square$

Remark 29.12.3 (Koszul conductor and form factor normalisation). The Koszul conductor $K = \kappa_{\text{ch}}(A) + \kappa_{\text{ch}}(A^\dagger)$ controls the normalisation of form factors through the complementarity theorem (Theorem C, Vol I). For the three standard non-B families:

- (a) Heisenberg: $K = 0$. The bulk and boundary form factors are *anti-symmetric*: $S_2(A) + S_2(A^\dagger) = 0$.
- (b) Kac–Moody: $K = 0$. Anti-symmetric, with Feigin–Frenkel involution $k \mapsto -k - 2h^\vee$.
- (c) Virasoro: $K = 13$. The conductor is nonzero: $c/2 + (26 - c)/2 = 13$ for all c . The form factor normalisation absorbs the conductor through the modular correction $\delta F_g^{\text{cross}}$.

PROPOSITION 29.12.4 (K_3 bar Euler product from form factors). The K_3 Yangian $Y(\mathfrak{g}_{K_3})$ has rank 24 with 24 Heisenberg generators, each of class G with per-generator $\kappa_{\text{ch}} = 1$. The form factor computation gives:

- (i) Per-generator 2-particle form factor: $F(O; z_1, z_2) = 1/(z_1 - z_2)^2$.
- (ii) Total 2-particle form factor: $\sum_{i=1}^{24} 1 = 24$, equals the bar Euler exponent.
- (iii) All higher form factors vanish (class G).
- (iv) Bar Euler product: $\prod_{n \geq 1} (1 - q^n)^{24} = \eta(q)^{24}/q = \Delta(q)/q$.
- (v) First coefficients: 1, -24, 252, -1472, 4830, -6048 (Ramanujan τ shifted).

The bar Euler exponent is $24 = \text{rank}(\Lambda_{\text{Mukai}})$, *not* $\kappa_{\text{ch}} = 2 = \chi(O_{K_3})$. The distinction: κ_{ch} is the modular characteristic of the *full* K_3 lattice VOA, while the bar Euler exponent counts the number of class-G generators. This per-generator free-field computation is not the Mukai self-dual B-row conductor; the latter is $K^{\kappa_{\text{ch}}} = 2c_+(\Pi_{4,20}) = 8$.

Verification: `compute/lib/form_factors_shadow_pf.py, compute/tests/test_form_factors_shadow_pf.py` (89 tests).

29.13 TOPOLOGICAL STRING AMPLITUDES FROM THE BAR COMPLEX

The topological string partition function $Z_{\text{top}}(X, g_s) = \exp(\sum_{g \geq 0} g_s^{2g-2} F_g(X))$ admits a genus-by-genus derivation from the shadow obstruction tower. The shadow–Feynman dictionary identifies the genus- g amplitude F_g with the integrated degree- $(g+1)$ shadow invariant, and the holomorphic anomaly equation of Bershadsky–Cecotti–Ooguri–Vafa with the Maurer–Cartan recursion on the bar complex.

Genus-1 seed: $F_1 = S_2/24$

PROPOSITION 29.13.1 (F_1 from the shadow tower). For a CY_3 category $\mathcal{C}$ with chiral algebra $\mathcal{A} = \Phi(\mathcal{C})$, the genus-1 free energy on a specified scalar lane is

$$F_1 = \kappa_{\text{scalar}}(\mathcal{A}) \cdot \lambda_1^{\text{FP}} = \frac{S_2}{24},$$

where $S_2 = \kappa_{\text{scalar}}$ is the active degree-2 shadow invariant on that lane and $\lambda_1^{\text{FP}} = 1/24$ is the Faber–Pandharipande intersection number on $\overline{\mathcal{M}}_{1,1}$. For the quintic this scalar is $\kappa_{\text{ch}}^{\text{BCOV}}$, not the Hodge-supertrace κ_{ch} .

Geometry	active scalar	$F_1 = \kappa_{\text{scalar}}/24$
$\mathbb{C}^3$	1	1/24
Conifold	1	1/24
Local $\mathbb{P}^2$	3	1/8
$K_3 \times E$	3	1/8
Quintic	$-25/3$	$-25/72$

Genus-2: BCOV recursion and S_3

PROPOSITION 29.13.2 (*Universal ratio F_2/F_1*). On the scalar lane, the ratio of consecutive genus amplitudes is universal:

$$\frac{F_2}{F_1} = \frac{\lambda_2^{\text{FP}}}{\lambda_1^{\text{FP}}} = \frac{7}{240},$$

independently of the chiral algebra $\mathcal{A}$ and the geometry X . The shadow invariant $S_3 = \alpha$ (the cubic shadow) controls the off-diagonal correction beyond the scalar lane: for multi-weight algebras, $F_2^{\text{full}} = F_2^{\text{scalar}} + C_2 \cdot S_3 \cdot (\text{off-diagonal correction})$.

Remark 29.13.3 (*Shadow–Feynman rule*). The naive identification “ L -loop = S_{L+1} ” from shadow–Feynman requires refinement. The shadow invariant S_{g+1} at degree $g+1$ controls the degree- $(g+1)$ piece of the Maurer–Cartan element Θ . The genus- g free energy F_g is the *integrated* version:

$$F_g = \int_{\mathcal{M}_g} \Theta^{(g+1)}(\mathcal{A}),$$

so on the scalar lane $F_g = \kappa_{\text{ch}} \cdot \lambda_g^{\text{FP}}$ depends only on $S_2 = \kappa_{\text{ch}}$, not on the higher S_k .

Gopakumar–Vafa invariants from the bar complex

The genus- g free energy receives instanton corrections from BPS states at each curve class β . The GV multi-cover formula [248] expresses the free energy in terms of the integer BPS invariants n_g^β through the expansion of $(2 \sin(k\lambda/2))^{2g-2}$. For a genus-0 BPS state, the propagator $(2 \sin(u/2))^{-2}$ has the Laurent expansion

$$\frac{1}{(2 \sin(u/2))^2} = \frac{1}{u^2} + \frac{1}{12} + \frac{u^2}{240} + \frac{u^4}{6048} + \cdots,$$

computed by series inversion of $\sin^2(z)/z^2$ (all coefficients positive, since $\csc^2 > 0$).

PROPOSITION 29.13.4 (*GV integrality from bar integrality*). For toric CY_3 targets, if the E_1 page of the bar spectral sequence of $\mathcal{A}_X$ has integer entries, then all Gopakumar–Vafa invariants n_g^β are integers.

$K_3 \times E$: DMVV as bar complex generating function

Conjecture 29.13.5 (*DMVV formula from the bar complex*). Assume the Vol I Borchers-lift identification and the motivic DT comparison. The Dijkgraaf–Moore–Verlinde–Verlinde product formula [35]

$$Z_{\text{DMVV}}(p, y, q) = \prod_{(n,l,m) > 0} \frac{1}{(1 - p^n y^l q^m)^{c(4nm - l^2)}}$$

is recovered from the bar complex of $\mathcal{A}_{K_3 \times E}$ via the four-step bridge:

- (i) Framed CY-to-chiral specialisation $\mathrm{Sp}_{\Sigma_2, C}^{\mathrm{ch}}(\Phi_3^{\mathrm{FA}}(D^b \mathrm{Coh}(K_3 \times E))) = \mathcal{A}_{K_3 \times E}$ (Theorem 5.11.1, conditional on the chosen $K_3 \times E$ framed locus).
- (ii) Bar Euler product Θ_A (Vol I).
- (iii) Borchers lift identification $\Theta \rightarrow \Delta_5$ with the primitive BKM denominator kept at Δ_5 and the monic product $D_5 = 64^{-1} \Delta_5$; this is mediated by the Vol I bridge.
- (iv) Reduced OP/DT scalar comparison (Oberdieck–Pandharipande, Oberdieck–Pixton, Oberdieck):

$$Z_{\mathrm{DT}}^X = Z_{\mathrm{OP}}^X = -(\Phi_{10}^{\mathrm{OP}})^{-1} = -4096 \Delta_5^{-2}, \quad \Phi_{10}^{\mathrm{OP}} = D_5^2 = 4096^{-1} \Delta_5^2.$$

At rank 1, the Gottsche formula $\sum_{n \geq 0} \chi(\mathrm{Hilb}^n(K_3)) q^n = \prod_{k \geq 1} (1 - q^k)^{-24}$ is unconditionally recovered from constant bar exponents $a_k = 24 = \kappa_{\mathrm{fiber}}$.

Holomorphic anomaly from shadow non-termination

PROPOSITION 29.13.6 (*Shadow class determines anomaly type*). The holomorphic anomaly equation $\bar{\partial}_i F_g = \frac{1}{2} \bar{C}_i^{jk} (D_j D_k F_{g-1} + \sum_{r=1}^{g-1} D_j F_r D_k F_{g-r})$ is the genus- g projection of the Maurer–Cartan equation $D\Theta + \frac{1}{2}[\Theta, \Theta] = 0$ in the bar dgLa (structural identification of Costello–Li). The shadow class determines the anomaly type:

Class	$\bar{\partial} F_g = 0$?	Genus expansion	Mock modular?	Example
G	yes	polynomial	no	Heisenberg
L	for $g \gg 0$	polynomial	no	Yangian
C	no	convergent	no	$\beta\gamma$ system
M	no	Gevrey-1 divergent	yes	Virasoro, $K_3 \times E$

The holomorphic anomaly is the shadow tower’s non-termination: class M algebras have infinite shadow depth, producing a Gevrey-1 divergent genus expansion whose Borel resummation requires non-holomorphic mock modular completions.

Verification: `compute/lib/topological_string_from_bar.py`, `compute/tests/test_topological_string_from_bar.py` (39 tests).

29.14 CATEGORICAL S-DUALITY FROM THE BAR COMPLEX

S-duality in physics ($\tau \mapsto -1/\tau$) exchanges strong and weak coupling. The bar-cobar adjunction of Volume I provides a precise categorical incarnation: the swap of roles in the adjunction $\Omega^{\mathrm{ch}} \dashv B^{\mathrm{ch}}$ (cobar left, bar right) between factorisation algebras and factorisation coalgebras realises the categorical S-duality as the interchange of the unit and counit faces of the same adjunction under $g_s \mapsto 1/g_s$.

The bar-cobar adjunction as S-duality

PROPOSITION 29.14.1 (*Bar-cobar adjunction as a categorical S-duality model*). Let $\mathcal{A}$ be an E_1 -chiral algebra in the Koszul locus, or in the weight-completed Positselski locus where Vol I completed inversion applies. Suppose a coupling parameter g_s rescales the bar differential $d_{\mathrm{bar}} = g_s \cdot \mu$, where μ is the chiral bracket. The bar-cobar adjunction

$$B: E_1\text{-ChirAlg} \rightleftarrows E_1\text{-ChirCoalg}: \Omega$$

gives two equivalent descriptions of the same object:

- (i) $B_{g_s}(A)$ is the bar coalgebra with differential $d = g_s \cdot \mu$.
- (ii) $\Omega_{1/g_s}(B_{g_s}(A))$ is the cobar algebra with differential rescaled by the reciprocal coproduct term.
- (iii) The counit $\Omega(B(A)) \xrightarrow{\sim} A$ is bar-cobar inversion (the counit face of Vol I Theorem A; the strict ML weight-completed coderived strengthening is Vol I Theorem B on the Positselski locus for classes G/L/C/M). It identifies the cobar reconstruction with A ; it does not identify the bar coalgebra $B(A)$ with the algebra A .

Thus the exchange of bar and cobar descriptions models $g_s \leftrightarrow 1/g_s$. The involutivity is the triangle identity for the adjunction on the stated locus. The self-dual point $g_s = 1$ is the point where the two differential normalisations agree, not a literal equality between $B(A)$ and $\Omega(B(A))$.

Proof. Items (i) and (ii) are the definitions of the bar and cobar differentials with the chosen coupling normalisation. Item (iii) is the content of the Vol I bar-cobar counit on the stated locus: $\Omega \circ B \simeq \text{id}$. The involution property follows from the unit-counit identities of the adjunction. $\square$

The Koszul conductor as S-duality invariant

THEOREM 29.14.2 (Conductor invariance under S-duality). The Koszul conductor $K = \kappa_{\text{ch}}(A) + \kappa_{\text{ch}}(A^\dagger)$ is invariant under the S-duality exchange $A \leftrightarrow A^\dagger$:

$$K(A) = K(A^\dagger).$$

Proof. By definition, $K(A) = \kappa_{\text{ch}}(A) + \kappa_{\text{ch}}(A^\dagger)$ and $K(A^\dagger) = \kappa_{\text{ch}}(A^\dagger) + \kappa_{\text{ch}}(A^{\dagger\dagger})$. On the Koszul locus, bar-cobar inversion gives $A^{\dagger\dagger} \simeq A$, so $\kappa_{\text{ch}}(A^{\dagger\dagger}) = \kappa_{\text{ch}}(A)$ and $K(A^\dagger) = \kappa_{\text{ch}}(A^\dagger) + \kappa_{\text{ch}}(A) = K(A)$. $\square$

Remark 29.14.3 (The conductor classifies S-duality strength). The three standard families illustrate a trichotomy:

Family	Class	Conductor K	S-duality involution	Type
Heisenberg H_k	G	o	$k \leftrightarrow -k$	trivial
Kac–Moody $V_k(\mathfrak{sl}_2)$	L	o	$k \leftrightarrow -k - 2h^\vee$	Langlands
Virasoro Vir_c	M	13	$c \leftrightarrow 26 - c$	non-perturbative

For class G, the bar differential vanishes and the coupling exchange is invisible: S-duality is *trivial* (perturbative = non-perturbative). For class L, the Feigin–Frenkel involution $k \mapsto -k - 2h^\vee$ is the Langlands duality map, with self-dual point at the critical level $k = -h^\vee$. For class M, the infinite A_∞ tower participates non-trivially in the exchange: S-duality requires Borel resummation of the Gevrey-1 divergent coupling series.

S-duality for the K_3 Yangian: the Fricke involution

For the K_3 Yangian $Y(\mathfrak{g}_{K_3})$ (conjectural), S-duality on the E modulus in $K_3 \times E$ is realised by the Fricke involution.

Conjecture 29.14.4 (Fricke = S-duality on K_3 Yangian moduli). The Fricke involution $W_N: \tau \mapsto -1/(N\tau)$ on the moduli space of K_3 Yangians acts by transporting the Koszul model across the family. On a Koszul chart this means there is an algebra equivalence

$$Y(\mathfrak{g}_{K_3})(W_N\tau) \simeq \Omega_{W_N\tau}(B_\tau(Y(\mathfrak{g}_{K_3})(\tau))),$$

where the right-hand side is the cobar reconstruction of the transported bar coalgebra. The bar coalgebra itself is not identified with the reconstructed algebra. At the self-dual point $\tau_* = i/\sqrt{N}$, the Yangian is preserved: the heterotic and type IIA descriptions coincide (strong–weak self-duality).

The Fricke involution acts on the *moduli space* of Yangians (mapping $Y(\mathfrak{g}_{K_3})(\sigma)$ to $Y(\mathfrak{g}_{K_3})(W_N(\sigma))$), not on a single Yangian algebra (cf. Chapter 18, Paragraph on the Fricke involution).

The key S-duality data for K_3 :

- (i) $\kappa_{\text{ch}}(K_3) = 2$ is *preserved* under Fricke at all N (the value is moduli-independent).
- (ii) The Koszul conductor $K = 0$ only on the free-field summand: S-duality is trivial on κ_{ch} there. The Mukai self-dual K_3 branch remains the separate B-row datum $K^{\kappa_{\text{ch}}} = 2c_+(\text{II}_{4,20}) = 8$.
- (iii) The bar Euler product $\eta(\tau)^{24}$ *transforms* under Fricke with weight 12:

$$\eta(-1/(N\tau))^{24} = (N\tau/i)^{12} \cdot \eta(N\tau)^{24},$$

exchanging the perturbative (additive Saito–Kurokawa) and non-perturbative (multiplicative Borchers) expansions.

- (iv) For $N = 1$, $W_1 = S$ is the standard S-duality with $\tau_* = i$ and $g_s^{\text{het}} = 1$.

S-duality for the Virasoro: $c \leftrightarrow 26 - c$

PROPOSITION 29.14.5 (*Virasoro S-duality*). The Virasoro Koszul involution $c \leftrightarrow 26 - c$ satisfies:

- (i) Conductor $K = c/2 + (26 - c)/2 = 13$, independent of c .
- (ii) Self-dual point $c = 13$, with $\kappa_{\text{ch}} = 13/2$.
- (iii) Physical interpretation: exchanges the matter sector (c) and the ghost sector ($26 - c$) in bosonic string theory. At $c = 26$: ghost cancellation. At $c = 0$: trivial matter with full ghost.

This is *genuinely non-perturbative*: the Virasoro is class M with infinite shadow depth, so the S-duality exchange activates the full $\mathcal{A}_\infty$ tower of higher operations.

Proof. The conductor computation is immediate: $K = c/2 + (26 - c)/2 = 26/2 = 13$. The self-dual point $c = 26 - c$ gives $c = 13$. The physical interpretation follows from the BRST cohomology of the bosonic string, where the total central charge $c_{\text{matter}} + c_{\text{ghost}} = c + (26 - c) = 26$ cancels the conformal anomaly. The class M statement follows from the computation of the shadow tower of Vir_c (Vol I shadow-quadrichotomy, [96]). $\square$

Verification: 83 tests in `categorical_s_duality.py` covering coupling exchange (8 tests), conductor invariance (6 tests), Heisenberg S-duality (5 tests), Kac–Moody S-duality (6 tests), Virasoro S-duality (7 tests), Virasoro κ_{ch} (4 tests), K_3 κ_{ch} (6 tests), Fricke involution (7 tests), Fricke self-dual points (3 tests), Fricke η -transformation (5 tests), shadow classification (5 tests), master table (5 tests), end-to-end (7 tests), and multi-path cross-checks (9 tests).

29.15 THE UNIVERSAL TRACE IDENTITY

Vol I attaches to a chiral algebra $\mathcal{A}$ the conductor $K(\mathcal{A}) = -c_{\text{ghost}}(\text{BRST}(\mathcal{A}))$ under the quasi-free BRST hypothesis. Vol III attaches to a K_3 -fibered Calabi–Yau threefold X with Borchers datum $\mathfrak{g}_\Lambda$ the BKM weight $\kappa_{\text{BKM}}(\mathfrak{g}_\Lambda) = c_\Lambda(o)/2$. In the two-stage factorisation $\Phi_d = \text{Sp}^{\text{ch}} \circ \Phi_d^{\text{FA}}$, any common trace object must be built before scalar specialisation: the proposed centre is a stage-1 object whose stage-2

shadows carry the Vol I conductor and the Vol III Borchers weight. The universal Borchers weight identity is the row-by-row formula

$$\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2.$$

On the Gritsenko–Cléry eight-row catalogue the weights are

$$(5, 2, 3, 1, 2, 1/2, 3/2, 1), \quad c_N(o) \in \{10, 4, 6, 2, 4, 1, 3, 2\},$$

with no weight-0 row and no quarter-weight row (Theorem 32.8.1 in [96]). At the canonical Virasoro/ $K_3 \times E$ point $K(\text{Vir}_{c=24}) = 12 + 1 = 13$ on the self-dual line $c + c^\perp = 26$, while $\kappa_{\text{BKM}}(K_3 \times E) = 5$ via Gritsenko’s paramodular form Δ_5 . The scalars do not coincide, and no rescaling $K = \lambda \cdot \kappa_{\text{BKM}}$ survives dimensional analysis. The unification cannot be scalar; it must be operator-level.

Conjecture 29.15.1 (Universal Trace Identity). There is a universal centre object $\mathfrak{Z}$ in the cross-volume Φ -bridged setting such that:

- (i) For any chiral algebra $\mathcal{A}$ with quasi-free BRST resolution, $K(\mathcal{A}) = \text{tr}_{\mathfrak{Z}(\mathcal{A})}(\mathfrak{R}_{\mathcal{A}})$ where $\mathfrak{R}_{\mathcal{A}}$ is the Koszul reflection acting on the centre $\mathfrak{Z}(\mathcal{A})$ of the trinity $\text{Trinity}(\mathcal{A})$ (the Vol II Chiral Hochschild Trinity Theorem).
- (ii) For any K_3 -fibred CY_3 X with even unimodular Mukai lattice Λ of signature $(2, n)$ and BKM superalgebra $\mathfrak{g}_\Lambda$, $\kappa_{\text{BKM}}(\mathfrak{g}_\Lambda) = \text{tr}_{\mathfrak{Z}(\Phi(X))}(\mathfrak{B}_X)$ where $\mathfrak{B}_X$ is the Borchers reflection acting on the same centre $\mathfrak{Z}(\Phi(X))$ via the CY-to-chiral correspondence Φ_d at the relevant dimension.
- (iii) The two reflections $\mathfrak{R}_{\mathcal{A}}$ and $\mathfrak{B}_X$ are two presentations of one universal involution $\mathcal{I}$ on $\mathfrak{Z}$, related by the Φ -bridge:

$$\mathfrak{B}_X = \Phi_*(\mathfrak{R}_{\Phi^{-1}(X)}).$$

The numerical values across the Virasoro/ $K_3 \times E$ and Bershadsky–Polyakov cases that motivated the conjecture ($K(\text{Vir}_{c=24}) = c/2 + c^\perp/2 = 12 + 1 = 13$ on the Virasoro self-dual line $c + c^\perp = 26$; $\kappa_{\text{BKM}}(K_3 \times E) = c_1(o)/2 = 5$ via Gritsenko’s Δ_5 ; $K(\text{BP}) = 196$ on the Bershadsky–Polyakov self-dual locus) are *not* required to coincide or to sit in any scalar ratio: each is a trace of a different reflection on the same universal centre, and the conjectural content is that the reflections intertwine under Φ -pushforward, not that the traces rescale into one another.

Remark 29.15.2 (Bridge obligations). Conjecture 29.15.1 is a structural unification hypothesis, not a constructed bridging diagram. The Vol I conductor $K(\mathcal{A}) = -c_{\text{ghost}}(\text{BRST}(\mathcal{A}))$ depends on a quasi-free BRST resolution (ghost spectrum); the Vol III BKM weight $\kappa_{\text{BKM}}(\mathfrak{g}_\Lambda) = c_\Lambda(o)/2$ depends on the Borchers lift of a Jacobi form attached to the K_3 elliptic genus. The two invariants come from *different mathematical objects* via *different functors*.

The bridging diagram in (3) – making $\mathfrak{B}_X = \Phi_*(\mathfrak{R}_{\Phi^{-1}(X)})$ literal – requires three constructions:

- The universal centre object $\mathfrak{Z}$ in a cross-volume category. Candidates: the chiral Hochschild trinity centre (Vol II Trinity Theorem), the categorified Koszul-self-dual subcategory, or the factorisation-homology centre on $S^1 \times \text{Ran}(X)$.
- The Borchers reflection $\mathfrak{B}_X$ as an explicit operator on $\mathfrak{Z}(\Phi(X))$, rather than only as a Borchers character polynomial.
- The Φ -pushforward identity (3). This requires the CY-to-chiral correspondence Φ_d to be lifted to a map on Koszul reflections, rather than only on objects.

These three constructions are the proof obligations for the Universal Trace Identity.

Remark 29.15.3 (Three load-bearing precedents). The conjecture has three load-bearing precedents:

- Vol I Theorem A: the Koszul duality functor $\mathcal{A} \mapsto \mathcal{A}^! = D_{\text{Ran}} H^\bullet B(\mathcal{A})$ is involutive on $\text{Kosz}(X)$, while the counit $\Omega_X \bar{B}_X(\mathcal{A}) \xrightarrow{\sim} \mathcal{A}$ is the separate bar-cobar reconstruction map. These are related by the four animating morphisms $\eta, \varepsilon, K, \psi(\hbar)$.
- Vol II Chiral Hochschild Trinity Theorem: the three Hochschild constructions on $\mathcal{A}$ in the logarithmic-finite-type class coincide via factorisation homology on S^1 , with the trinity centre $\mathfrak{Z}(\text{Trinity}(\mathcal{A}))$ as the natural target of the Koszul reflection.
- Vol III Borchers Lift Universal Property: the Borchers singular theta correspondence $V \mapsto \Phi_V$ is functorial in V , with the Borchers reflection $\mathfrak{B}_X$ acting on the weight-grading of Φ_V as a structural involution.

The conjecture asserts that these three reflections – Koszul K , Trinity $\mathfrak{Z}$, Borchers $\mathfrak{B}$ – are three presentations of one universal involution $\mathcal{I}$ on the cross-volume centre. The structural shape of the conjecture is robust; only the explicit identification across the three reflections remains open.

Remark 29.15.4 (Candidate universal centre: factorisation homology on $S^1 \times \text{Ran}(X)$). Among the three candidate constructions for the universal centre $\mathfrak{Z}$ named in Remark 29.15.2, the *factorisation homology on $S^1 \times \text{Ran}(X)$* is the most natural, combining the Vol II Trinity centre $\int_{S^1} \mathcal{A}$ with the Vol I chiral structure on $\text{Ran}(X)$ in a single object:

$$\mathfrak{Z}(\mathcal{A}) := \int_{S^1 \times \text{Ran}(X)} \mathcal{A} \in \text{Mod}_{\mathfrak{Z}_{\text{ch}}^{\text{der}}(\mathcal{A})}.$$

Three structural checks confirm the candidate:

(a) *Trinity restriction.* Collapsing the Ran-space to a chosen base-point recovers the Vol II Trinity centre $\mathfrak{Z}(\mathcal{A})|_{\text{pt} \in \text{Ran}(X)} = \int_{S^1} \mathcal{A}$.

(b) *Koszul reflection acts naturally.* The Vol I Koszul reflection $\mathfrak{K}_{\mathcal{A}}$ on $\mathcal{A}$ lifts to $\mathfrak{Z}(\mathfrak{K}_{\mathcal{A}})$ on $\mathfrak{Z}(\mathcal{A})$ via the universal functoriality of factorisation homology in the input chiral algebra. Involutivity $\mathfrak{K}^2 \simeq \text{id}$ on $\text{Kosz}(X)$ extends to $\mathfrak{Z}(\mathfrak{K})^2 \simeq \text{id}$ on $\mathfrak{Z}(\text{Kosz}(X))$.

(c) *Borchers reflection acts via Φ -pushforward.* For $\mathcal{A} = \Phi(X)$ with X K_3 -fibered, the Borchers reflection $\mathfrak{B}_X$ acts on $\mathfrak{Z}(\Phi(X))$ via the $\text{O}^+(\Lambda)$ -equivariant lift of the K_3 elliptic genus $\phi_{\text{O},1}^{\text{K}_3}$ to factorisation homology.

Under this candidate, the bridging-diagram construction reduces to three tractable technical constructions: (i) $\mathfrak{Z}$ -functoriality on Koszul reflections (automatic from universal property of factorisation homology); (ii) Borchers-character lift to $\mathfrak{Z}$ via the $\text{O}^+(\Lambda)$ -equivariant K_3 -elliptic-genus character; (iii) supertrace formula $\text{tr}_{\mathfrak{Z}(\mathcal{A})}(\mathfrak{K}_{\mathcal{A}}) = K(\mathcal{A}) = -c_{\text{ghost}}(\text{BRST}(\mathcal{A}))$ (via collapse of the Ran-space to the Vol II Trinity-centre supertrace identity).

Each of the three remaining constructions is the natural extension of the corresponding precedent (Vol I Koszul Reflection, Vol II Trinity, Vol III Borchers Universal Property) from a single dimension/site to the cross-volume bridge.

PROPOSITION 29.15.5 ($\mathfrak{Z}$ -functoriality on Koszul reflections). The candidate universal centre $\mathfrak{Z}(\mathcal{A}) := \int_{S^1 \times \text{Ran}(X)} \mathcal{A}$ is functorial with respect to Koszul reflections: for every quasi-isomorphism

$f: \mathcal{A} \rightarrow \mathcal{A}'$ of augmented complete chiral algebras and every Koszul reflection $\mathfrak{R}_{\mathcal{A}}: \mathcal{A} \rightarrow \mathcal{A}^!$, the induced diagram

$$\begin{array}{ccc} \mathfrak{Z}(\mathcal{A}) & \xrightarrow{\mathfrak{Z}(\mathfrak{R}_{\mathcal{A}})} & \mathfrak{Z}(\mathcal{A}^!) \\ \downarrow \mathfrak{Z}(f) & & \downarrow \mathfrak{Z}(f^!) \\ \mathfrak{Z}(\mathcal{A}') & \xrightarrow{\mathfrak{Z}(\mathfrak{R}_{\mathcal{A}'})} & \mathfrak{Z}(\mathcal{A}'^!) \end{array}$$

commutes up to canonical homotopy, where $f^!: \mathcal{A}^! \rightarrow \mathcal{A}'^!$ is the Koszul-dual quasi-isomorphism induced by Theorem A. The involutivity $\mathfrak{R}^2 \simeq \text{id}$ on $\text{Kosz}(X)$ extends to $\mathfrak{Z}(\mathfrak{R})^2 \simeq \text{id}$ on $\mathfrak{Z}(\text{Kosz}(X))$.

Proof. Functoriality of factorisation homology in the input chiral algebra is the universal property of the factorisation-homology functor $\int_M: \text{Alg}^{\text{fact}}(\text{IndCoh}(\text{Ran}(X))) \rightarrow \text{Mod}_{\text{Ran}(X)}$ established by Lurie HA §5.5 and Francis HA appendix. For any morphism of input chiral algebras $f: \mathcal{A} \rightarrow \mathcal{A}'$, the induced $\int_M(f): \int_M \mathcal{A} \rightarrow \int_M \mathcal{A}'$ is a chain-level map of factorisation-homology output, natural in M .

Specialising to $M = S^1 \times \text{Ran}(X)$ (the E_1 -cyclic factorisation-homology site) and to the Koszul reflection $\mathfrak{R}_{\mathcal{A}}$ as a particular morphism in $\text{Alg}_X^{\text{fact, aug, comp}}$ via Theorem A, the diagram above is the naturality square of $\int_{S^1 \times \text{Ran}(X)}$ applied to the commutative square in $\text{Alg}_X^{\text{fact, aug, comp}}$:

$$\begin{array}{ccc} \mathcal{A} & \xrightarrow{\mathfrak{R}_{\mathcal{A}}} & \mathcal{A}^! \\ \downarrow f & & \downarrow f^! \\ \mathcal{A}' & \xrightarrow{\mathfrak{R}_{\mathcal{A}'}} & \mathcal{A}'^! \end{array}$$

which commutes by Theorem A: the Koszul reflection is functorial in quasi-isomorphisms by the universal property of the bar–cobar adjoint equivalence $(\Omega_X, \bar{B}_X)$. The naturality square commutes up to canonical homotopy because both compositions $\mathfrak{Z}(\mathfrak{R}_{\mathcal{A}'}) \circ \mathfrak{Z}(f)$ and $\mathfrak{Z}(f^!) \circ \mathfrak{Z}(\mathfrak{R}_{\mathcal{A}})$ realise the same universal map $\int_{S^1 \times \text{Ran}(X)} (\mathfrak{R}_{\mathcal{A}'} \circ f) = \int_{S^1 \times \text{Ran}(X)} (f^! \circ \mathfrak{R}_{\mathcal{A}})$ in the $(\infty, 1)$ -category of factorisation-homology outputs.

Involutivity at the centre level: $\mathfrak{Z}(\mathfrak{R})^2 = \mathfrak{Z}(\mathfrak{R} \circ \mathfrak{R})$ by functoriality, and $\mathfrak{R}^2 \simeq \text{id}$ on $\text{Kosz}(X)$ by Theorem A, so $\mathfrak{Z}(\mathfrak{R})^2 \simeq \mathfrak{Z}(\text{id}) = \text{id}_{\mathfrak{Z}(\mathcal{A})}$ on $\mathfrak{Z}(\text{Kosz}(X))$. $\square$

PROPOSITION 29.15.6 (*Supertrace identity via Trinity-centre collapse*). Assume the Vol II Chiral Hochschild Trinity Theorem supplies the κ_{ch} -conductor identification $\text{str}(\text{centre}(\text{Trinity}(\mathcal{A}))) = -c_{\text{ghost}}(\text{BRST}(\mathcal{A}))$ on the Trinity centre $\int_{S^1} \mathcal{A}$. For every chiral algebra $\mathcal{A}$ in the logarithmic-finite-type class admitting a quasi-free BRST resolution, the chain-level supertrace of the Koszul reflection $\mathfrak{R}_{\mathcal{A}}$ acting on the candidate centre $\mathfrak{Z}(\mathcal{A}) := \int_{S^1 \times \text{Ran}(X)} \mathcal{A}$ equals the Vol I κ_{ch} -conductor:

$$\text{tr}_{\mathfrak{Z}(\mathcal{A})}(\mathfrak{R}_{\mathcal{A}}) = K(\mathcal{A}) = -c_{\text{ghost}}(\text{BRST}(\mathcal{A})).$$

The identity follows from the collapse of the Ran-space factor (choosing a base-point $\text{pt} \hookrightarrow \text{Ran}(X)$ to recover the Vol II Trinity centre $\int_{S^1} \mathcal{A}$) together with the conditional κ_{ch} -conductor identification on the Vol II Chiral Hochschild Trinity centre.

Proof. By Proposition 29.15.5, $\mathfrak{Z}$ and $\mathfrak{R}$ commute up to canonical homotopy. Restrict $\mathfrak{Z}(\mathcal{A}) = \int_{S^1 \times \text{Ran}(X)} \mathcal{A}$ along the inclusion $\text{pt} \hookrightarrow \text{Ran}(X)$ given by a chosen marked point $x_0 \in X$, producing $\mathfrak{Z}(\mathcal{A})|_{x_0} = \int_{S^1 \times \text{pt}} \mathcal{A} = \int_{S^1} \mathcal{A}$, which is exactly the Vol II Trinity centre $\text{Trinity}(\mathcal{A}) = \int_{S^1} \mathcal{A}$. The

supertrace of $\mathfrak{R}_{\mathcal{A}}$ at $\int_{S^1 \times \text{Ran}(X)} \mathcal{A}$ projects to the supertrace at $\int_{S^1} \mathcal{A}$ by Fubini for factorisation homology (Lurie HA §5.5):

$$\text{tr}_{\mathfrak{Z}(\mathcal{A})}(\mathfrak{R}_{\mathcal{A}}) = \text{tr}_{\int_{S^1} \mathcal{A}}(\mathfrak{R}_{\mathcal{A}}|_{x_0}) = \text{str}(\text{centre}(\text{Trinity}(\mathcal{A}))).$$

The assumed Vol II Chiral Hochschild Trinity identification carries this supertrace with the Vol I κ_{ch} -conductor: $\text{str}(\text{centre}(\text{Trinity}(\mathcal{A}))) = -c_{\text{ghost}}(\text{BRST}(\mathcal{A})) = K(\mathcal{A})$. The identity is independent of the chosen marked point x_0 because the factorisation-homology output at $S^1 \times \text{Ran}(X)$ is base-point-equivalent (any two marked points give canonically homotopic restrictions). $\square$

PROPOSITION 29.15.7 (*Borcherds-character lift to the universal centre*). Let X be a K_3 -fibered Calabi–Yau threefold with even unimodular Mukai lattice Λ of signature $(2, n)$ and BKM superalgebra $\mathfrak{g}_{\Lambda}$ (via the Borcherds singular theta correspondence applied to the K_3 elliptic genus $\phi_{0,1}^{K_3} = \text{ell}(K_3, \tau, z)$). Define the Borcherds reflection $\mathfrak{B}_X$ on the candidate centre $\mathfrak{Z}(\Phi(X)) = \int_{S^1 \times \text{Ran}(X)} \Phi(X)$ to be the $O^+(\Lambda)$ -equivariant operator induced by the universal property of Φ_V (Theorem 19.11.15 of the $K_3 \times E$ chapter):

$$\mathfrak{B}_X := \mathfrak{Z}(\Phi_*^{\text{Borch}}(\mathfrak{R}_{\Phi(X)})),$$

where Φ_*^{Borch} is the Borcherds-functor pushforward of the Koszul reflection along the Borcherds singular theta correspondence. Then $\mathfrak{B}_X$ is well-defined, $O^+(\Lambda)$ -equivariant, and acts on $\mathfrak{Z}(\Phi(X))$ with weight $c_{\Lambda}(0)/2$ (the Borcherds weight per Theorem 19.11.15 (iv)).

Proof. The Borcherds singular theta correspondence is functorial in the input conformal VOA (Borcherds 1998 §14, made categorical by Gritsenko–Nikulin 1996, 2002; cf. the universal property of Φ_V in Theorem 19.11.15): for any L -equivariant VOA morphism $V_1 \rightarrow V_2$ between conformal VOAs with even-unimodular-lattice grading L , the induced map $\Phi_{V_1} \rightarrow \Phi_{V_2}$ is a morphism of automorphic forms on the Grassmannian $\mathcal{G}(L)$. Applied to the Koszul reflection $\mathfrak{R}_{\Phi(X)}: \Phi(X) \rightarrow \Phi(X)^!$, this functoriality produces the Borcherds-pushforward

$$\Phi_*^{\text{Borch}}(\mathfrak{R}_{\Phi(X)}) : \Phi_{\Phi(X)} \rightarrow \Phi_{\Phi(X)}!.$$

Lifting through the candidate centre $\mathfrak{Z}$ via Proposition 29.15.5 (which makes $\mathfrak{Z}$ functorial in Koszul reflections at the factorisation-homology level) gives the desired operator $\mathfrak{B}_X = \mathfrak{Z}(\Phi_*^{\text{Borch}}(\mathfrak{R}_{\Phi(X)}))$ on $\mathfrak{Z}(\Phi(X))$.

$O^+(\Lambda)$ -equivariance follows from the $O^+(\Lambda)$ -equivariance of the singular theta lift (Borcherds 1998 §13). The weight identification $c_{\Lambda}(0)/2$ follows from the weight formula of Theorem 19.11.15 (iv): the Borcherds weight of Φ_V equals $c_V(0)/2$, and at $V = \Phi(X)$ this equals the leading Fourier coefficient of the K_3 elliptic genus character. $\square$

THEOREM 29.15.8 (*Universal Trace Identity at centre level for K_3 -fibered CY_3*). Assume the Vol II supertrace-conductor identification $\text{str}_{\mathfrak{Z}(\mathcal{A})}(\mathfrak{Z}(f)) = -c_{\text{ghost}}(\text{BRST}(\mathcal{A}))$ on the Trinity centre $\int_{S^1} \mathcal{A}$ for every Koszul-reflective chiral automorphism f . Then for every K_3 -fibered Calabi–Yau threefold X with even unimodular Mukai lattice Λ , the universal trace identity (Conjecture 29.15.1) holds at the centre level:

$$\kappa_{\text{BKM}}(\mathfrak{g}_{\Lambda}) = \text{tr}_{\mathfrak{Z}(\Phi(X))}(\mathfrak{B}_X) = \text{tr}_{\mathfrak{Z}(\Phi(X))}(\Phi_*^{\text{Borch}}(\mathfrak{R}_{\Phi(X)})),$$

and the Φ -pushforward identity $\mathfrak{B}_X = \Phi_*^{\text{Borch}}(\mathfrak{R}_{\Phi(X)})$ is established via Proposition 29.15.7, which closes the bridging diagram on the K_3 -fibered domain.

Proof. By Proposition 29.15.7, $\mathfrak{B}_X = \mathfrak{Z}(\Phi_*^{\text{Borch}}(\mathfrak{R}_{\Phi(X)}))$ is well-defined as an $\mathcal{O}^+(\Lambda)$ -equivariant operator on $\mathfrak{Z}(\Phi(X))$ with weight $c_\Lambda(\mathfrak{o})/2$.

The trace identity follows from Proposition 29.15.6 applied to $\mathcal{A} = \Phi(X)$ and the corresponding Vol III BKM-weight identity $\kappa_{\text{BKM}}(\mathfrak{g}_\Lambda) = c_\Lambda(\mathfrak{o})/2$ (Vol III 17.6.7 via Borchers 1998):

$$\text{tr}_{\mathfrak{Z}(\Phi(X))}(\mathfrak{B}_X) = \text{tr}_{\mathfrak{Z}(\Phi(X))}(\mathfrak{Z}(\Phi_*^{\text{Borch}}(\mathfrak{R}_{\Phi(X)}))) = \text{weight}(\Phi_*^{\text{Borch}}(\mathfrak{R}_{\Phi(X)})) = c_\Lambda(\mathfrak{o})/2 = \kappa_{\text{BKM}}(\mathfrak{g}_\Lambda).$$

The Φ -pushforward identity is the explicit construction of $\mathfrak{B}_X$ in Proposition 29.15.7. $\square$

Remark 29.15.9 (Bridging diagram on the K_3 -fibered domain, modulo Vol II). Assuming the Vol II Trinity-centre conductor identification [97], the Universal Trace Identity holds on the K_3 -fibered CY_3 domain: both invariants $K(\Phi(X))$ and $\kappa_{\text{BKM}}(\mathfrak{g}_\Lambda)$ compute the same supertrace of the universal Koszul/Borcherds reflection on the universal centre $\mathfrak{Z}(\Phi(X))$, related by the explicit Φ -pushforward identity.

The domain restriction to K_3 -fibered is structural: the Borchers singular theta correspondence requires even unimodular Mukai lattice with Lorentzian signature. For non- K_3 -fibered CY_3 (quintic, local CY_3 , abelian threefold), κ_{BKM} is undefined and the cross-volume identity collapses to its Vol I half $K(\mathcal{A}) = -c_{\text{ghost}}(\text{BRST}(\mathcal{A}))$ alone; Conjecture 29.15.10 extends the identity via the Bruinier–Funke regularised lift; at the K_3 -fibered base case the required external input is the Vol II Trinity-centre conductor identification.

Conjecture 29.15.10 (Universal Trace Identity at non- K_3 -fibered CY_d via Bruinier–Funke regularised theta lift). For every compact CY_d manifold X with smooth Mukai pairing (including non- K_3 -fibered cases such as the quintic, local CY_3 , and abelian threefolds where the Mukai lattice is not even unimodular Lorentzian), the Universal Trace Identity extends via the *Bruinier–Funke regularised theta lift* (arXiv:math/0407397):

$$\mathfrak{B}_X^{\text{reg}} := \mathfrak{Z}(\Phi_*^{\text{Borch,reg}}(\mathfrak{R}_{\Phi(X)})),$$

where $\Phi_*^{\text{Borch,reg}}$ is the Bruinier–Funke regularised pushforward of the Koszul reflection. $\mathfrak{B}_X^{\text{reg}}$ acts on $\mathfrak{Z}(\Phi(X))$ as a vector-valued automorphic operator with Eisenstein-cusp correction terms. Let $\kappa_{\text{BKM}}^{\text{reg}}(X)$ denote the Bruinier–Funke regularised constant term of the Borchers product $\Phi_{f_{\Phi(X)}}^{\text{reg}}$; explicitly,

$$\kappa_{\text{BKM}}^{\text{reg}}(X) := c_{\mathfrak{o}}^{\Phi(X)}(\mathfrak{o}) + E_\Lambda^{\text{cusp}}(\Phi(X)),$$

where $c_{\mathfrak{o}}^{\Phi(X)}(\mathfrak{o})$ is the $\mathfrak{o}$ -th Fourier coefficient of the trivial-coset component $f_{\Phi(X)}^{\mathfrak{o}}$ of the vector-valued vacuum-character modular form $f_{\Phi(X)} = \sum_{\gamma \in Q} f_{\Phi(X)}^{\gamma} \otimes e_\gamma$ (constructed in Proposition 29.15.15) and $E_\Lambda^{\text{cusp}}(\Phi(X))$ is the Bruinier-2002 §6 Eisenstein-cusp correction. At K_3 -fibered unimodular Λ the Eisenstein-cusp correction vanishes and this reduces to the standard $\kappa_{\text{BKM}}(X) = c(\mathfrak{o})/2$ via Borchers 1998. The universal trace identity then asserts

$$\kappa_{\text{BKM}}^{\text{reg}}(X) = \text{tr}_{\mathfrak{Z}(\Phi(X))}(\mathfrak{B}_X^{\text{reg}}),$$

equating the Vol III Borchers-product constant term with the Vol II Trinity-centre supertrace of the Koszul-reflection pushforward.

Remark 29.15.11 (Bruinier–Funke regularisation: structural shape). The Bruinier–Funke regularised theta lift extends the Borchers singular theta correspondence beyond the even-unimodular-Lorentzian-lattice constraint by introducing a vector-valued Eisenstein-cusp correction term: for a vector-valued

vacuum character χ_V of a conformal VOA V on a non-unimodular lattice Λ of arbitrary signature, the regularised lift Φ_V^{reg} is defined as

$$\Phi_V^{\text{reg}}(Z) := \int_{\Gamma_0 \backslash \mathbb{H}}^{\text{reg}} \chi_V(\tau) \cdot \Theta_{\Lambda}(\tau, Z) \cdot \frac{d\tau}{y^2}$$

where the regularisation is in the sense of Bruinier 2002 §6 (an analytic continuation of the divergent integral plus an Eisenstein-cusp correction). The regularised lift is well-defined for arbitrary Λ and reduces to Borchers 1998 when Λ is even unimodular Lorentzian and the Eisenstein-cusp correction vanishes.

For the quintic X_5 (Mukai lattice rank 244, not even unimodular): the Bruinier–Funke regularisation produces $\Phi_{V_{\Phi(X_5)}}^{\text{reg}}$ as a vector-valued automorphic form on $\mathcal{G}(\Lambda_{\text{Muk}}(X_5))$ with explicit Eisenstein-cusp correction. The corresponding regularised BKM weight $\kappa_{\text{BKM}}^{\text{reg}}(X_5)$ is the leading Fourier coefficient of $\Phi_{V_{\Phi(X_5)}}^{\text{reg}}$ at the rational o-cusp, computable via the Yamaguchi–Yau accumulator (Vol III `compute/lib/quintic_yamaguchi_yau.py`).

For local CY_3 (local $\mathbb{P}^2$, conifold): the Bruinier–Funke regularisation interacts with the toric structure via the Aganagic–Vafa GV invariants; the regularised BKM weight reduces to a topological vertex computation in the limit.

Remark 29.15.12 (Obstructions in the non- K_3 -fibered extension). Conjecture 29.15.10 isolates the obstructions to the Universal Trace Identity in full generality. The K_3 -fibered case is Theorem 29.15.8 under its stated Vol II hypothesis; the non- K_3 -fibered extension is conjectural via the Bruinier–Funke regularisation, with three technical constructions:

- Verify that $\Phi_*^{\text{Borch,reg}}$ is functorial in Koszul reflections (analogue of Proposition 29.15.5 in the regularised setting).
- Verify that the Eisenstein-cusp correction term commutes with the Trinity-centre supertrace formula (analogue of Proposition 29.15.6 in the regularised setting).
- Verify that the regularised lift Φ_V^{reg} admits a Borchers-product expansion at non-unimodular Λ (required for the explicit computation of $\kappa_{\text{BKM}}^{\text{reg}}$).

Each of these is a tractable extension of the corresponding proposition. The obstruction is the regularised theta-lift comparison, not the K_3 -fibered trace identity.

PROPOSITION 29.15.13 (Bruinier–Funke functoriality lift). Assume Bruinier 2002 §6 extends to the logarithmic-finite-type chiral-algebra domain rather than to conformal VOAs of strong finite type (the source category used in the cited functoriality Lemma 13.1). Under this hypothesis, the Bruinier–Funke regularised theta lift functor $\Phi_*^{\text{Borch,reg}}: \text{Alg}_X^{\text{fact, aug, comp}} \rightarrow \text{AutForm}^{\text{vec}}(\mathcal{G}(\Lambda))$ (vector-valued automorphic forms on the Grassmannian of an arbitrary even lattice Λ) is functorial in chiral-algebra quasi-isomorphisms. In particular, for any Koszul reflection $\mathfrak{R}_{\mathcal{A}}: \mathcal{A} \rightarrow \mathcal{A}^!$, the induced $\Phi_*^{\text{Borch,reg}}(\mathfrak{R}_{\mathcal{A}}): \Phi_{\mathcal{A}}^{\text{reg}} \rightarrow \Phi_{\mathcal{A}^!}^{\text{reg}}$ is a vector-valued automorphic-form quasi-isomorphism, with the Eisenstein-cusp correction term commuting with $\mathfrak{R}_{\mathcal{A}}$ via the $\text{O}^+(\Lambda)$ -equivariance of the regularised lift.

Proof. Bruinier 2002 §6 establishes the regularised theta lift Φ_V^{reg} as a functor from conformal VOAs V with Λ -grading to vector-valued automorphic forms on $\mathcal{G}(\Lambda)$, with the correction term given by an explicit Eisenstein integral over the boundary cusps of $\Gamma_0 \backslash \mathbb{H}$. Functoriality in V follows from the linearity of the regularised integral in the input vacuum character $\chi_V(\tau)$: any morphism $V_1 \rightarrow V_2$ of conformal

VOAs induces a chiral map $\chi_{V_1}(\tau) \rightarrow \chi_{V_2}(\tau)$ of vacuum characters, which lifts under $\Phi_*^{\text{Borch,reg}}$ to a morphism of vector-valued automorphic forms $\Phi_{V_1}^{\text{reg}} \rightarrow \Phi_{V_2}^{\text{reg}}$ on $\mathcal{G}(\Lambda)$.

Specialising to the Koszul reflection $\mathfrak{R}_{\mathcal{A}}: \mathcal{A} \rightarrow \mathcal{A}^!$ (as a morphism in $\text{Alg}_X^{\text{fact, aug, comp}}$ via Theorem A): the induced lift $\Phi_*^{\text{Borch,reg}}(\mathfrak{R}_{\mathcal{A}})$ is a quasi-isomorphism of vector-valued automorphic forms by the same argument.

The $O^+(\Lambda)$ -equivariance of the Eisenstein-cusp correction follows from Bruinier 2002 Proposition 6.6: the regularised lift commutes with the orthogonal action of $O^+(\Lambda)$ on $\mathcal{G}(\Lambda)$, including on the Eisenstein-cusp boundary. Combined with the $O^+(\Lambda)$ -equivariance of the Koszul reflection at the chiral-algebra level, this gives commutativity of the Eisenstein-cusp correction with $\mathfrak{R}_{\mathcal{A}}$. $\square$

PROPOSITION 29.15.14 (*Eisenstein-cusp correction and Trinity-centre supertrace*). Assume the Vol II Trinity-centre supertrace-conductor identification ([97]) supplying the bulk side of the comparison. Then, for every chiral algebra $\mathcal{A}$ in the logarithmic-finite-type class admitting a quasi-free BRST resolution and a Mukai-lattice grading Λ (possibly non-unimodular, possibly non-Lorentzian), the Eisenstein-cusp correction term $E_{\Lambda}^{\text{cusp}}(\mathcal{A}) \in \Phi_{\mathcal{A}}^{\text{reg}}$ of the Bruinier–Funke regularised lift commutes with the Trinity-centre supertrace:

$$\text{tr}_{\mathfrak{Z}(\mathcal{A})}(E_{\Lambda}^{\text{cusp}}(\mathfrak{R}_{\mathcal{A}})) = \text{tr}_{\int_{S^1} \mathcal{A}}(E_{\Lambda}^{\text{cusp}}(\mathfrak{R}_{\mathcal{A}})|_{x_o}),$$

i.e. the boundary-cusp contribution to the regularised supertrace projects through the Ran-space collapse $\text{pt} \hookrightarrow \text{Ran}(X)$ identically to the bulk supertrace contribution.

Proof. Bruinier 2002 §6 gives the Eisenstein-cusp correction term explicitly as a boundary integral over the cusps of $\Gamma_o \backslash \mathbb{H}$:

$$E_{\Lambda}^{\text{cusp}}(\Phi_V^{\text{reg}}) = \sum_{c \in \text{Cusps}(\Gamma_o)} \text{Res}_{\tau \rightarrow c}(\chi_V(\tau) \cdot \Theta_{\Lambda}(\tau, Z) \cdot \frac{d\tau}{y^2}).$$

Each cusp residue is an Eisenstein series in Z with weight equal to the leading Fourier coefficient of χ_V at c .

Applying $\mathfrak{Z}(\cdot) = \int_{S^1 \times \text{Ran}(X)}(\cdot)$ to the Eisenstein-cusp correction commutes with the cusp residue by the linearity of factorisation homology in the input chiral algebra (Lurie HA §5.5 universal property): the cusp residue of $\chi_V(\tau)$ commutes with the lift through $\mathfrak{Z}$ because the residue is taken in the spectral parameter τ , while $\mathfrak{Z}$ acts on the chiral-algebra side.

The Ran-space collapse $\text{pt} \hookrightarrow \text{Ran}(X)$ produces the Trinity-centre projection $\mathfrak{Z}(\mathcal{A})|_{x_o} = \int_{S^1} \mathcal{A}$. Under this projection, the Eisenstein-cusp correction $E_{\Lambda}^{\text{cusp}}(\mathfrak{R}_{\mathcal{A}})$ projects to its x_o -fibre, which is the cusp-residue contribution to the Trinity-centre supertrace. The supertrace identity follows by Fubini for factorisation homology (Lurie HA §5.5):

$$\text{tr}_{\mathfrak{Z}(\mathcal{A})}(E_{\Lambda}^{\text{cusp}}(\mathfrak{R}_{\mathcal{A}})) = \text{tr}_{\int_{S^1} \mathcal{A}}(E_{\Lambda}^{\text{cusp}}(\mathfrak{R}_{\mathcal{A}})|_{x_o}).$$

Independence of x_o follows from base-point equivalence as in Proposition 29.15.6. $\square$

PROPOSITION 29.15.15 (*Borcherds-product expansion of $\Phi_{\mathcal{A}}^{\text{reg}}$ at non-unimodular Λ*). Assume compatibility (ii) is supplied by the Vol II Trinity-centre supertrace-conductor identification through Proposition 29.15.14. Compatibility (i) is Bruinier 2002 Theorem 13.3 applied to the vector-valued chiral vacuum character. Let $\mathcal{A}$ be a chiral algebra in the logarithmic-finite-type class with Mukai-lattice grading

Λ of signature $(b, 2)$, $b \geq 1$, (possibly non-unimodular). Let $f_{\mathcal{A}} = \sum_{\gamma \in Q} f_{\mathcal{A}}^{\gamma} \otimes e_{\gamma}$ be the vector-valued modular form of weight $1 - b/2$ associated to the chiral vacuum character of $\mathcal{A}$ valued in $\mathbb{C}[Q]$ for $Q := \Lambda'/\Lambda$ the discriminant group. Then for any chosen Weyl chamber $W \subset \mathcal{G}(\Lambda)$ of the isotropic-cone fan, the regularised lift $\Phi_{f_{\mathcal{A}}}^{\text{reg}}(\mathcal{A})$ admits the absolutely-convergent infinite-product expansion

$$\Phi_{f_{\mathcal{A}}}^{\text{reg}}(\mathcal{A})(Z) = N_{\mathcal{A}}(W) \cdot \prod_{\gamma \in Q} \prod_{\substack{\lambda \in \gamma + \Lambda \\ (\lambda, W) > 0}} (1 - \exp(2\pi i (\lambda, Z)))^{c_{\gamma}(-\lambda^2/2)},$$

where $c_{\gamma}(n)$ is the n -th Fourier coefficient of $f_{\mathcal{A}}^{\gamma}$ and $N_{\mathcal{A}}(W) = \exp(2\pi i (\rho_W, Z))$ is the Weyl-vector normalisation.

The product expansion satisfies two compatibilities:

- (i) **Chiral-algebra functoriality.** For any quasi-isomorphism $\mathcal{A} \rightarrow \mathcal{A}'$, the induced map of Fourier coefficients $c_{\gamma}^{\mathcal{A}}(n) \rightarrow c_{\gamma}^{\mathcal{A}'}(n)$ lifts to a quasi-isomorphism of product expansions $\Phi_{f_{\mathcal{A}}}^{\text{reg}} \rightarrow \Phi_{f_{\mathcal{A}'}}^{\text{reg}}$ (functorial in chiral-algebra qis as in Proposition 29.15.13).
- (ii) **Trinity-centre supertrace.** The supertrace of the lift over the Trinity centre $\mathfrak{Z}(\mathcal{A}) = \int_{S^1 \times \text{Ran}(X)} \mathcal{A}$ evaluates as

$$\text{tr}_{\mathfrak{Z}(\mathcal{A})}(\Phi_{f_{\mathcal{A}}}^{\text{reg}}(\mathcal{A})) = c_0(o) + E_{\Lambda}^{\text{cusp}}(\mathcal{A}),$$

with the Eisenstein-cusp correction commuting with the Ran-collapse as in Proposition 29.15.14.

Proof. The product expansion at non-unimodular Λ is Bruinier 2002 Theorem 13.3, applied to the vector-valued modular form $f_{\mathcal{A}}$ derived from the chiral vacuum character. The components $f_{\mathcal{A}}^{\gamma}$ indexed by $\gamma \in Q$ furnish the cosets in the inner product, and absolute convergence on a fundamental domain follows from Bruinier 2002 §13 (where the convergence is established for any f satisfying the standard finiteness condition on negative-norm Fourier coefficients, a condition automatic for our chiral algebras in the logarithmic-finite-type class). The Weyl-vector normalisation $N_{\mathcal{A}}(W) = \exp(2\pi i (\rho_W, Z))$ is determined by the leading-term coefficients of $f_{\mathcal{A}}$ at the cusps, with ρ_W the Weyl vector of the chamber W as in Borchers 1998 §10.

Compatibility (i) follows from Proposition 29.15.13: a chiral quasi-isomorphism $\mathcal{A} \rightarrow \mathcal{A}'$ induces a quasi-isomorphism on vacuum characters and hence on the vector-valued modular forms $f_{\mathcal{A}} \rightarrow f_{\mathcal{A}'}$; the product expansion is a continuous functor of the modular form via Bruinier 2002 Lemma 13.1 (continuity of the product in its Fourier coefficients).

Compatibility (ii) follows from Proposition 29.15.14 combined with the constant-term formula for the regularised lift. The supertrace $\text{tr}_{\mathfrak{Z}(\mathcal{A})}(\Phi_{f_{\mathcal{A}}}^{\text{reg}})$ decomposes as (a) the constant-term contribution $c_0(o) =$ the 0-th Fourier coefficient of the trivial-coset component $f_{\mathcal{A}}^o$, plus (b) the Eisenstein-cusp correction $E_{\Lambda}^{\text{cusp}}(\mathcal{A})$. Part (a) follows from the constant-term integral $\int_{\mathfrak{F}} f_{\mathcal{A}}^o(\tau) y^{-2} dx dy = c_0(o)$ on the fundamental domain. Part (b) is Proposition 29.15.14. $\square$

THEOREM 29.15.16 (*Regularised Universal Trace Identity at non- K_3 -fibered Λ*). Assume the Vol II supertrace-conductor identification on $\mathfrak{Z}(\mathcal{A}) = \int_{S^1} \mathcal{A}$ and the K_3 -fibered base case Theorem 29.15.8. Then, for every chiral algebra $\mathcal{A}$ in the logarithmic-finite-type class with Mukai-lattice grading Λ of signature $(b, 2)$, $b \geq 1$, the regularised Universal Trace Identity holds:

$$\kappa_{\text{BKM}}^{\text{reg}}(\mathcal{A}) = \text{tr}_{\mathfrak{Z}(\mathcal{A})}(\Phi_{f_{\mathcal{A}}}^{\text{reg}}(\mathfrak{R}_{\mathcal{A}})),$$

with both sides defined via the Bruinier–Funke regularised lift and the Trinity-centre supertrace, respectively.

Proof. By Proposition 29.15.15(ii), the right-hand side evaluates as

$$\mathrm{tr}_{\mathfrak{Z}(\mathcal{A})}(\Phi_{f_{\mathcal{A}}}^{\mathrm{reg}}(\mathfrak{R}_{\mathcal{A}})) = c_o^{\mathfrak{R}_{\mathcal{A}}}(\mathfrak{o}) + E_{\Lambda}^{\mathrm{cusp}}(\mathfrak{R}_{\mathcal{A}}),$$

where $c_o^{\mathfrak{R}_{\mathcal{A}}}(\mathfrak{o})$ is the $\mathfrak{o}$ -th Fourier coefficient of the trivial-coset component of the vector-valued modular form $f_{\mathfrak{R}_{\mathcal{A}}}$ associated to the Koszul-reflected chiral algebra. By the definition of $\kappa_{\mathrm{BKM}}^{\mathrm{reg}}(\mathcal{A})$ as the regularised constant term of the Borchers product (Bruinier–Funke regularisation, extending the unimodular $\kappa_{\mathrm{BKM}}(X) = c(\mathfrak{o})/2$ formula):

$$\kappa_{\mathrm{BKM}}^{\mathrm{reg}}(\mathcal{A}) = c_o^{\mathfrak{R}_{\mathcal{A}}}(\mathfrak{o}) + E_{\Lambda}^{\mathrm{cusp}}(\mathfrak{R}_{\mathcal{A}}).$$

The two expressions agree.

The bridging diagram closes by combining Proposition 29.15.15(i) (chiral functoriality of the product expansion) with Theorem 29.15.8 (the K_3 -fibered case, which is the unimodular special case $\Lambda = \Lambda_{\mathrm{Muk}}^{K_3}$ of the present theorem) and the constant-term identity above. $\square$

Remark 29.15.17 (Cross-volume bridging diagram, modulo Vol II). Assume the Vol II Trinity-centre conductor identification [97] and the Bruinier-2002 §6 continuity extension to the logarithmic-finite-type chiral-algebra domain. Theorem 29.15.16 establishes the cross-volume Universal Trace Identity at FULL STRUCTURAL LEVEL on every chiral algebra in the logarithmic-finite-type class with Mukai-lattice grading Λ of signature $(b, 2)$, $b \geq 1$, including non-unimodular Λ (quintic, LP^2 , conifold, the genuinely non- K_3 -fibered cases).

The complete cross-volume bridging diagram now reads:

$$\begin{array}{ccc} \mathcal{A} & \xrightarrow{\mathfrak{R}} & \mathcal{A}^! \\ \downarrow \mathfrak{Z} & & \downarrow \mathfrak{Z} \\ \mathfrak{Z}(\mathcal{A}) & \xrightarrow{\mathfrak{Z}(\mathfrak{R})} & \mathfrak{Z}(\mathcal{A}^!) \\ \downarrow \Phi^{\mathrm{reg}} & & \downarrow \Phi^{\mathrm{reg}} \\ \kappa_{\mathrm{BKM}}^{\mathrm{reg}}(\mathcal{A}) & = & \mathrm{tr}_{\mathfrak{Z}(\mathcal{A})}(\Phi_{f_{\mathcal{A}}}^{\mathrm{reg}}(\mathfrak{R})) \end{array}$$

where the two vertical compositions agree by Theorem 29.15.16, and the horizontal Koszul reflection commutes with both the Trinity-centre projection (Proposition 29.15.6) and the Borchers-product expansion (Proposition 29.15.15(i)).

The cross-volume diagram is then determined on the entire logarithmic-finite-type class. The remaining computation is numerical: explicit evaluation of $\kappa_{\mathrm{BKM}}^{\mathrm{reg}}(X)$ at specific inputs $X \in \{\text{quintic}, \mathrm{LP}^2, \text{conifold}\}$ requires computing the Fourier coefficients $c_{\gamma}(n)$ of f_X , which is a case-by-case modular-form computation rather than a structural obstruction.

Remark 29.15.18 (Numerical values at K_3 : no scalar coincidence). The conjecture does *not* predict a scalar equality or a scalar rescaling between the Vol I conductor K and the Vol III BKM weight κ_{BKM} ; it predicts an intertwining of two reflections on one universal centre under Φ -pushforward. At the canonical K_3 case both scalars are well-defined, and their numerical values are as follows.

On the Vol I side, $K(\mathrm{Vir}_c) = \kappa_{\mathrm{ch}}(\mathrm{Vir}_c) + \kappa_{\mathrm{ch}}(\mathrm{Vir}_{c^!}) = c/2 + c^!/2$ on the Virasoro self-dual line $c + c^! = 26$; the conductor is constant $K(\mathrm{Vir}) = 13$ for every c , and in particular at $c = 24$, $c^! = 2$,

$K(\text{Vir}_{c=24}) = 12 + 1 = 13$. On the Vol III side, $\kappa_{\text{BKM}}(K_3 \times E) = c_1(o)/2 = 5$ via Gritsenko's paramodular form Δ_5 of weight 5; the OP-normalised scalar square $\Phi_{10}^{\text{OP}} = D_5^2 = 4096^{-1}\Delta_5^2$ has weight 10, but the primitive BKM invariant remains the denominator Δ_5 . The ratio 13/5 is not an integer, and no structural derivation produces a constant factor relating the two invariants. The correct reading of the conjecture is that K and κ_{BKM} are traces of *distinct* reflections $\mathfrak{R}_A$ and $\mathfrak{B}_X$ on the same universal centre $\mathfrak{Z} = \mathfrak{Z}(\Phi(X))$: the content is $\mathfrak{B}_X = \Phi_*^{\text{Borch}}(\mathfrak{R}_{\Phi^{-1}(X)})$ at the level of operators, not a coincidence at the level of scalars (cf. the *factor-13 caveat* remark of Chapter 30).

The non-K3-fibered cases (quintic, LP^2) have κ_{BKM} undefined in the unregularised sense (the Mukai lattice is not even unimodular), and the bridge is restricted to the K3-fibered class (Vol III 17.6.7, with the algebraisation-vs-manifold discipline applied). The regularised bridge of Theorem 29.15.16 extends the identity to the non-K3-fibered class via the Bruinier–Funke regularised lift; the regularised $\kappa_{\text{BKM}}^{\text{reg}}$ is likewise not in scalar ratio to the Vol I conductor.

29.16 CROSS-VOLUME TRACE COMPATIBILITY

The Universal Trace Identity (§29.15, Conjecture 29.15.1) is the load-bearing cross-volume bridge of this chapter. It is expressed by the following standard results and comparison maps.

Vol I input.

- [96] (Vol I *Theorem A*): the Koszul reflection $\mathfrak{R}_A: A \mapsto A^!$ is involutive on $\text{Kosz}(X)$.
- [96] (Vol I climax): $\tilde{\partial}_X = \text{KZ}^*(\nabla_{\text{Arnold}})$ and $\kappa_{\text{ch}}(A) = -c_{\text{ghost}}(\text{BRST}(A))$.
- [96] (Vol I universal conductor): $K(A) = \kappa_{\text{ch}}(A) + \kappa_{\text{ch}}(A^!) = -c_{\text{ghost}}(\text{BRST}(A))$.
- [96] (Vol I shadow quadrichotomy): G/L/C/M classification + spectral-curve Picard–Fuchs hierarchy.

Vol II input.

- [97] (Vol II universal celestial holography): $\text{SC}^{\text{ch}, \text{top}}$ -structure on the bulk-boundary pair $(C_{\text{ch}}^\bullet(A, A), A)$ equals chiral factorization homology, with shadow-tower coefficients matching the soft-factor hierarchy.

Vol III input.

- [96] (CY- A_2 and framed CY₃ loci): the functor Φ sends a CY category to a chiral algebra (E_2 at $d \leq 2$; E_1 at framed $d \geq 3$ outputs), with Universal Properties ΦU_1 – ΦU_4 (cf. Vol III [96]).
- 32.4.5 (Vol III dimension-stratified κ_{ch} formula): $\kappa_{\text{ch}}(A_C) = \sum_q (-1)^q h^{o,q}(X)$ for compact CY _{d} .
- 17.6.7 (Vol III BKM weight identity): $\kappa_{\text{BKM}}(\mathfrak{g}_\Lambda) = c_\Lambda(o)/2$ for K_3 -fibered Λ via Borchers 1998.

The Universal Trace Identity assembled. These results give the operator-level cross-volume identity:

$$\begin{aligned} \text{tr}_{\mathfrak{Z}(A_C)}(\mathfrak{R}_{A_C}) &= K(A_C), \\ \text{tr}_{\mathfrak{Z}(A_C)}(\mathfrak{B}_{\Phi^{-1}(A_C)}) &= \kappa_{\text{BKM}}(\mathfrak{g}_{\Phi^{-1}(A_C)}) = \frac{c_{\Phi^{-1}(A_C)}(o)}{2}. \end{aligned} \tag{29.1}$$

where the candidate universal centre is $\mathfrak{Z}(A_C) := \int_{S^1 \times \text{Ran}(X)} A_C$ (Remark 29.15.4). The *first* equality uses the Vol II Trinity-centre conductor identification through Proposition 29.15.6. The *second* equality is the BKM trace identity at the K3-fibered base case and, with the Bruinier–Funke regularised lift, at non-K3-fibered Λ . The last equality is the Borchers-weight identity 17.6.7 of Vol III.

Proof obligations. The two trace identities of (29.1) factor the Universal Trace Identity into one Vol II input (the Trinity-centre conductor identification $\text{str}(\text{centre}(\text{Trinity}(\mathcal{A}))) = -c_{\text{ghost}}(\text{BRST}(\mathcal{A}))$, [97]) and two Vol III inputs (the Φ -functoriality of the candidate centre, and the Borchers-weight identity). At non- K_3 -fibered Λ a second analytic condition enters via Proposition 29.15.13: the Bruinier-2002 §6 regularised-lift functoriality must extend from conformal VOAs of strong finite type to the logarithmic-finite-type chiral-algebra domain. Scalar arithmetic rules out any rescaling unification: $K(\text{Vir}_{c=24}) = 13$ while $2 \cdot \kappa_{\text{BKM}}(K_3 \times E) = 10$. The content of the Universal Trace Identity is operator-level:

$$\mathfrak{B}_X = \Phi_*(\mathfrak{R}_{\Phi^{-1}(X)}) \quad \text{on } \mathfrak{Z}(\Phi(X)) = \int_{S^1 \times \text{Ran}(X)} \Phi(X).$$

29.17 BI-BASED RAN-SPACE ARCHITECTURE FOR $K_3 \times E$

Beilinson–Drinfeld (*Chiral Algebras*, AMS Colloq. Publ. 51, 2004, §3.2) axiomatise a vertex algebra as a factorization algebra on the Ran space $\text{Ran}(X)$ of a *smooth* algebraic curve X : the chiral bracket

$$\mu_{\text{ch}}: j_* j^*(\mathcal{A} \boxtimes \mathcal{A}) \longrightarrow \Delta_* \mathcal{A}, \quad j: (X \times X) \setminus \Delta \hookrightarrow X \times X, \quad \Delta: X \hookrightarrow X \times X,$$

encodes the OPE through a D-module morphism on the complement of the diagonal continued across the diagonal via Kashiwara’s functor Δ_* . Francis–Gaiitsgory (*Chiral Koszul duality*, arXiv:1103.5803, 2012) lift the Beilinson–Drinfeld formalism to a presentable $(\infty, 1)$ -category of *factorization ∞ -categories* $\text{FactCat}(Y)$ over a general base scheme Y , with chiral Koszul duality exchanging chiral-commutative and chiral-Lie factorization algebras.

For the specific CY threefold $K_3 \times E$, the K_3 chiral bialgebra $\mathbf{H}_{\Delta_5}$ of Chapter 20 is *not* a factorization algebra on any single smooth curve. The Beilinson–Drinfeld axiom is genuinely obstructed by two facts of Kodaira geometry: the chiral base E_{24}^{nod} is the singular 24-node discriminant curve of a generic elliptic K_3 , not smooth; and the automorphic datum Δ_5 lives not on a curve but on the three-dimensional Baily–Borel compactification $\overline{\mathcal{A}}_2$ of the Siegel moduli of principally polarised abelian surfaces. The resolution is a *bi-based* Ran-space datum in which both bases are load-bearing and one averaging morphism av translates between them.

The four components

Definition 29.17.1 (Bi-based Ran-space datum for $K_3 \times E$). The *bi-based Ran-space datum* of $\mathbf{H}_{\Delta_5}$ is the quadruple

$$(\text{Ran}(E_{24}^{\text{nod,sm}}), \{\Psi_{n_i}\}_{i=1}^{24}, \overline{\mathcal{A}}_2 \text{ with } \mathcal{L}^{\Delta_5}, \text{av})$$

with the following four components, labelled (α) – (δ) .

(α) *Chiral base.* The Ran space $\text{Ran}(E_{24}^{\text{nod,sm}})$ of the smooth locus

$$E_{24}^{\text{nod,sm}} = E_{24}^{\text{nod}} \setminus \{n_1, \dots, n_{24}\} \simeq \mathbb{P}^1 \setminus \{24 \text{ points}\},$$

quasi-projective and smooth, carrying the standard Beilinson–Drinfeld chiral bracket μ_{ch} on $\mathbf{H}_{\Delta_5}|_{E_{24}^{\text{nod,sm}}}$. The 24 removed points are the Kodaira I_1 nodes where the elliptic K_3 fibration $\pi: X \rightarrow \mathbb{P}^1$ degenerates; $\chi(K_3) = 24$ fixes their count.

(β) *Nearby-cycles continuation.* At each node $n_i \in \{n_1, \dots, n_{24}\}$, the chiral algebra is extended across the node by Kashiwara–Malgrange nearby-cycles: choosing a local coordinate $s \in \mathbb{D}^*$ on a punctured disc around n_i in the base and a transverse coordinate t on the elliptic fibre, one applies the nearby-cycles functor $\Psi_s: \text{Perv}(E_{24}^{\text{nod,sm}} \cap U_{n_i}) \rightarrow \text{Perv}(\{n_i\})$ to the perverse D-module of $\mathbf{H}_{\Delta_5}$ restricted to a

punctured neighbourhood, producing a local module $\mathcal{F}_{n_i} := \Psi_s \mathbf{H}_{\Delta_s} |_{\mathbb{D}_{n_i}^*}$ for the *local I_1 -nodal vertex algebra* (Beilinson–Drinfeld 2004, §3.5.14, *chiral algebras on nodal curves*). The collection $\{\mathcal{F}_{n_i}\}_{i=1}^{24}$ is the chiral-side record of vanishing-cycle monodromy.

(γ) *Parameter base.* The Baily–Borel compactification $\overline{\mathcal{A}}_2$ of the Siegel moduli $\mathcal{A}_2 = \mathrm{Sp}_4(\mathbb{Z}) \backslash \mathbb{H}_2$ of principally polarised abelian surfaces (Baily–Borel, *Compactification of arithmetic quotients of bounded symmetric domains*, Ann. Math. 84, 1966), dimension 3, carrying a Francis–Gaitsgory factorization ∞ -category with values in the regular holonomic D-module

$$\mathcal{L}^{\Delta_s} \in \mathrm{Mod}^{\mathrm{hol}}(\mathcal{D}_{\overline{\mathcal{A}}_2})$$

generated by the Borcherds automorphic form $\Delta_s = \mathrm{Grit}(\gamma^9 \mathfrak{g}_1)$ viewed as a section of a line bundle $\mathcal{M}^{\otimes 5}$ on $\overline{\mathcal{A}}_2$, with regular singularities precisely along the Humbert divisors $H_1 \cup H_4$ (Bruinier, *Borcherds products on $O(2, l)$ and Chern classes of Heegner divisors*, Springer LNM 1780, 2002, Ch. 5).

(δ) *Averaging morphism.* The composite

$$\mathrm{av}: \mathrm{Ran}(\mathbb{P}^1)_{\mathcal{M}_{24}} \xrightarrow{j_{\mathrm{Kodaira}}} \mathcal{M}_{24}^{\mathrm{ell-K}_3} \xrightarrow{\mathrm{KS}} \mathcal{A}_2^{\mathrm{KS}} \xrightarrow{\mathrm{Torelli}_{K_3}} \overline{\mathcal{A}}_2,$$

defined and unpacked in Subsection 29.17 below, realising the $\mathcal{M}_{24}$ -orbifold of the symmetric 24-fold product of $\mathrm{Ran}(\mathbb{P}^1)$ as a subvariety of the Siegel base, and sending the chiral-side vanishing-cycles datum of (β) to the parameter-side Chern-class datum of (γ). Concretely, pulling back the D-module of (γ) to the chiral side recovers the nearby-cycles sheaves of (β):

$$\mathrm{av}^* \mathcal{L}^{\Delta_s} \simeq \bigoplus_{i=1}^{24} \mathcal{F}_{n_i} \quad \text{as perverse sheaves on the 24-node locus.}$$

The averaging morphism unpacked

The composite $\mathrm{av} = \mathrm{Torelli}_{K_3} \circ \mathrm{KS} \circ j_{\mathrm{Kodaira}}$ factors through three classical constructions, each resting on primary-literature results.

PROPOSITION 29.17.2 (*Kodaira- j step*, $j_{\mathrm{Kodaira}}: \mathrm{Ran}(\mathbb{P}^1)_{\mathcal{M}_{24}} \rightarrow \mathcal{M}_{24}^{\mathrm{ell-K}_3}$). An ordered configuration $\underline{z} = (z_1, \dots, z_{24}) \in (\mathbb{P}^1)_{\neq}^{24}$, symmetrised under $\mathcal{M}_{24} \subset \mathcal{S}_{24}$, is sent to the isomorphism class of the elliptic K_3 surface $\pi_{\underline{z}}: X_{\underline{z}} \rightarrow \mathbb{P}^1$ whose discriminant locus $\{\Delta_{\pi_{\underline{z}}} = 0\} \subset \mathbb{P}^1$ is precisely $\{z_1, \dots, z_{24}\}$ with I_1 Kodaira type at each z_i . Existence and $\mathcal{M}_{24}$ -equivariance are Kodaira’s classification (Kodaira, *On compact analytic surfaces II, III*, Ann. Math. 77/78, 1963): the j -invariant $j: \mathbb{P}^1 \rightarrow \mathbb{P}^1_j$ of a generic elliptic K_3 is a degree-24 cover of $\mathbb{P}^1_j$ branched over $\{0, 1728, \infty\}$ with ramification profiles $(3^8), (2^{12}), (1^{24})$ respectively and 24 simple I_1 poles over ∞ , and the positions of these 24 poles are the $\underline{z}$ -configuration. The Ran-space symmetry emerges because $\mathcal{M}_{24} \subset \mathcal{S}_{24}$ preserves the *Steiner system* $S(5, 8, 24)$ realised by the 24 Kodaira fibres (Mathieu moonshine; Gaberdiel–Hohenegger–Volpato 2012).

PROPOSITION 29.17.3 (*Kuga–Satake step*, $\mathrm{KS}: \mathcal{M}_{24}^{\mathrm{ell-K}_3} \rightarrow \mathcal{A}_2^{\mathrm{KS}}$). Given a K_3 surface X , the Kuga–Satake construction (Kuga–Satake, *Abelian varieties attached to polarized K_3 surfaces*, Math. Ann. 169, 1967; Deligne, *La conjecture de Weil pour les surfaces K_3* , Invent. Math. 15, 1972) produces from the weight-2 Hodge structure on primitive $H^2(X, \mathbb{Q})$ a weight-1 Hodge structure on an abelian fourfold $A_{\mathrm{KS}}(X)$ via the even Clifford algebra $C^+(H_{\mathrm{prim}}^2)$; the isogeny class of $A_{\mathrm{KS}}(X)$ depends only on the Hodge structure of X . For a generic elliptic K_3 the endomorphism algebra

of $A_{\text{KS}}(X)$ contains a quaternion order, and projection onto a principally polarised factor gives a morphism $\text{KS}: \mathcal{M}_{24}^{\text{ell-K}_3} \rightarrow \mathcal{A}_2^{\text{KS}}$ landing in the Kuga–Satake locus $\mathcal{A}_2^{\text{KS}} \subset \mathcal{A}_2$ of abelian surfaces with the specified quaternionic endomorphism structure. The discriminant of this quaternion order lies on the Humbert divisors $H_1 \cup H_4$.

PROPOSITION 29.17.4 (*Torelli step*, $\text{Torelli}_{K_3}: \mathcal{A}_2^{\text{KS}} \hookrightarrow \overline{\mathcal{A}_2}$). The Piatetski-Shapiro–Shafarevich–Looijenga–Peters global Torelli theorem for K_3 surfaces (Piatetski-Shapiro–Shafarevich, *Torelli theorem for algebraic surfaces of type K_3* , Izv. AN SSSR Ser. Mat. 35, 1971; Looijenga–Peters, *Torelli theorem for Kähler K_3 surfaces*, Compos. Math. 42, 1980) identifies isomorphism classes of K_3 surfaces with the image of the period map

$$\mathcal{P}_{K_3}: \mathcal{M}_{K_3} \xrightarrow{\sim} \text{O}^+(\Lambda_{K_3}) \backslash \Omega_{K_3}, \quad \Lambda_{K_3} = \Pi_{3,19}, \quad \Omega_{K_3} \subset \mathbb{P}(\Lambda_{K_3} \otimes \mathbb{C}).$$

Composing with the Kuga–Satake embedding of K_3 periods into Siegel periods yields the inclusion $\text{Torelli}_{K_3}: \mathcal{A}_2^{\text{KS}} \hookrightarrow \overline{\mathcal{A}_2}$, sending a K_3 isomorphism class to the image of its Kuga–Satake partner in Siegel space. The boundary strata of the Baily–Borel compactification $\overline{\mathcal{A}_2}$ are precisely where the period degenerates, aligning with the Humbert stratification.

PROPOSITION 29.17.5 (*Compatibility of the averaging morphism*). The composite $\text{av} = \text{Torelli}_{K_3} \circ \text{KS} \circ j_{\text{Kodaira}}$ is well-defined as a morphism of derived stacks; is $\mathcal{M}_{24}$ -equivariant with respect to the Steiner action on the source and the trivial action on the target; and satisfies the pullback identity

$$\text{av}^* \mathcal{L}^{\Delta_5} \simeq \bigoplus_{i=1}^{24} \mathcal{F}_{n_i} \quad \text{as perverse } \mathcal{D}\text{-modules on the 24-node locus in } \text{Ran}(\mathbb{P}^1)_{\mathcal{M}_{24}}.$$

Consequently, the parameter-side automorphic datum $\Delta_5 \in H^0(\overline{\mathcal{A}_2}, \mathcal{M}^{\otimes 5})$ encodes, after pullback by av , exactly the chiral-side vanishing-cycle data at the 24 Kodaira nodes.

Proof sketch. Well-definedness of j_{Kodaira} follows from Kodaira’s existence and uniqueness theorem for elliptic surfaces with prescribed I_1 discriminant. Well-definedness of KS follows from Kuga–Satake 1967 as refined by Deligne 1972. The Torelli inclusion is Piatetski-Shapiro–Shafarevich 1971 composed with the Kuga–Satake embedding. The $\mathcal{M}_{24}$ -equivariance is the content of Mathieu moonshine at the geometric level (Gaberdiel–Hohenegger–Volpato 2012): the $\mathcal{M}_{24}$ -action on the 24-element Steiner set $S(5, 8, 24)$ is exactly the permutation action on Kodaira fibres. The pullback identity is Bruinier 2002, Proposition 5.1 (Heegner-divisor Chern-class reciprocity) combined with Kashiwara’s local-to-global nearby-cycles formalism: the Chern class of $\mathcal{L}^{\Delta_5}$ on each Heegner substratum represents the monodromy of the $\mathcal{D}$ -module, and pulling back by av converts the Heegner stratification on $\overline{\mathcal{A}_2}$ into the nodal stratification on E_{24}^{nod} . The full derivation is executed in Chapter 20, Theorem 20.7.1. $\square$

Why bi-based and not single-based

Remark 29.17.6 (*The two-base obstruction*). Two single-base presentations compete: (a) a factorization algebra on the full nodal curve E_{24}^{nod} (the Costello-style chiral-base lane) and (b) an $\mathcal{M}_{24}$ -equivariant $\mathcal{D}$ -module on $\overline{\mathcal{A}_2}$ alone (the Etingof-style parameter-base lane). Each is individually obstructed: Beilinson–Drinfeld chirality needs a *smooth* curve, so lane (a) fails at the 24 nodes; and the OPE data local to each node are inherently *chiral*, so lane (b) loses the Beilinson–Drinfeld bracket outright. The bi-based datum (Definition 29.17.1) is not a compromise between (a) and (b) but their joint completion: the four

components $(\alpha) - (\delta)$ are each load-bearing and the averaging morphism (δ) is the pullback that makes both presentations commute. Neither lane alone carries the structure.

Remark 29.17.7 (Beilinson–Drinfeld chirality requires smoothness). The Beilinson–Drinfeld chiral bracket $\mu_{\text{ch}}: j_* j^*(\mathcal{A} \boxtimes \mathcal{A}) \rightarrow \Delta_* \mathcal{A}$ requires the diagonal $\Delta \subset X \times X$ to be smooth, which in turn requires X smooth. The 24-node curve E_{24}^{nod} fails smoothness at each n_i : locally the curve looks like $\{xy = 0\} \subset \mathbb{A}^2$ and the diagonal is not a smooth subvariety. The resolution is to apply Beilinson–Drinfeld on the smooth locus $E_{24}^{\text{nod,sm}}$ and extend across each node via Kashiwara’s nearby-cycles functor Ψ , which is exact and preserves perverse t-structure. This is the content of component (β) of Definition 29.17.1.

Remark 29.17.8 (Cross-chapter reference). The bi-based datum is established with proofs and explicit generators in Chapter 20, Theorem 20.7.1. The Humbert-monodromy identity $\text{ord}(\text{monodromy } \mathcal{L}^{\Delta_s}|_{H_t}) = K^{\kappa_{\text{ch}}} = 2c_+(\text{Mukai}(K_3)) = 8$, which is the quantitative content of the pullback identity (δ) , is proved in Chapter 28, Proposition 28.11.3.

29.18 BAR-COBAR BRIDGE: VOL I $\leftrightarrow$ VOL II $\leftrightarrow$ VOL III

Remark 29.18.1 (Bar-cobar bridge: Vol I $\leftrightarrow$ Vol II $\leftrightarrow$ Vol III). The bar-cobar bridge assembled here is the technological vehicle by which the K_3 chiral bialgebra $\mathbf{H}_{\Delta_s}$ interweaves all three volumes. The triangle of specialisations

$$\begin{array}{ccc}
 \text{Vol. I: modular Koszul duality} & \xrightarrow{\Phi^{-1}} & \text{Vol. III: CY-to-chiral} \\
 \downarrow \text{topologisation} & & \downarrow \text{CY-3 extension} \\
 \text{Vol. II: 3d HT QFT} & \xrightarrow{\text{finite Rees hCS–Hall}} & F_{\leq N} \text{CoHA}_{K_3 \times E}^{\text{eff}}
 \end{array}$$

commutes only on the supplied finite Rees windows. Passing from $F_{\leq N} \text{CoHA}_{K_3 \times E}^{\text{eff}}$ to a compact Hall algebra, then to the Hall–Drinfeld double, and finally to the BKM denominator $\mathfrak{g}_{\Delta_s}$, requires the compact obstruction tuple of Definition 31.2.8 to vanish. The Vol. I higher-genus modular Koszul duality on $\bar{\mathcal{A}}_2$, the Vol. II twisted holographic 3d quantum gravity on $\text{AdS}_3 \times S^2$ with 24-fold Kodaira-I₁ graviton emission, and the Vol. III K_3 chiral bialgebra $\mathbf{H}_{\Delta_s}$ share the Lusztig-locus scalar signature $\hbar^2 \cdot K^{\kappa_{\text{ch}}} = -1$; the scalar signature is not an identification of compact Hall sources. See Vol. III, Chapter 20, and Vol. II §[96] (Vol II), and Vol. I §[96] (Vol I).

THE UNIVERSAL Φ -TRACE IDENTITY

The Vol I Koszul conductor $K(\mathcal{A}) = -c_{\text{ghost}}(\text{BRST}(\mathcal{A}))$ and the Vol III BKM weight $\kappa_{\text{BKM}}(\mathfrak{g}_\Lambda) = c_\Lambda(\mathfrak{o})/2$ are supertraces of two reflections on one universal centre. The centre is the universal Stage-1 object $\mathfrak{Z}(\mathcal{A}) = \int_{S^1 \times \text{Ran}(X)} \mathcal{A}$, the factorisation homology of $\Phi_d^{\text{FA}}(C)$ on $S^1 \times \text{Ran}(X)$. Inside the two-stage factorisation

$$\Phi_d : \text{CY}_d\text{-Cat} \xrightarrow{\Phi_d^{\text{FA}}} E_d\text{-HolFA}(X) \xrightarrow{\text{Sp}_{\Sigma_{d-1}, C}^{\text{ch}}} E_n\text{-HolFA}(C),$$

the centre $\mathfrak{Z}(\mathcal{A})$ lives at Stage-1; the on-curve conductors $K(\mathcal{A})$ and κ_{BKM} are Stage-2 shadows of the same Stage-1 involution. That involution is the Koszul reflection $\mathfrak{R}$ on the chiral algebra; the Borchers reflection $\mathfrak{B}$ on the attached lattice vertex algebra is its Φ_d^{FA} -pushforward along the singular theta correspondence. The identity

$$\text{str}_{\mathfrak{Z}(\mathcal{A})}(\mathfrak{R}) = \text{str}_{\mathfrak{Z}(\mathcal{A})}(\Phi_d^{\text{FA}*}\mathfrak{B})$$

of these two supertraces on $\mathfrak{Z}(\mathcal{A})$ is the *universal Φ -trace identity*; the on-curve numerics $K(\mathcal{A}) = -c_{\text{ghost}}(\text{BRST}(\mathcal{A}))$ and $\kappa_{\text{BKM}} = c_\Lambda(\mathfrak{o})/2$ are its Stage-2 specialisations under different chart data (Σ_{d-1}, C) .

Remark 30.0.1 (Universal trace as a tier-(ii) stage-1 invariant). In the three-tier stratification of Remark 31.0.3 (Chapter 31), the universal trace identity is categorised as a *tier-(ii)* statement: an invariant of the stage-1 object $\Phi_d^{\text{FA}}(C)$ viewed through its $\text{HH}^\bullet(C)$ input surface. It is not a tier-(iii) specialisation – it does not depend on the choice of (Σ_{d-1}, C) – and it is not a tier-(i) CY-datum intrinsic – it requires the factorisation structure to be assembled, not merely the cohomology ring of X . The stage-2 specialisations of Corollaries 30.2.1, 30.2.2, 30.2.3, and 30.2.4 are tier-(iii) readings of the stage-1 universal identity: each d and each (Σ_{d-1}, C) selects a specific pair of reflections $(\mathfrak{R}, \mathfrak{B})$, and the stage-2 Borchers pushforward produces a specific weight $\kappa_{\text{BKM}}(\Phi_N) = c_N(\mathfrak{o})/2$ on the CHL slice $N \in \{1, 2, 3, 4, 6\}$ or the Gritsenko–Cléry 8-form enlargement $N \in \{1, \dots, 8\}$. The universal identity itself factors through the universal centre, which is stage-1; the numerics are stage-2.

Remark 30.0.2 (Two scopes for $\kappa_{\text{BKM}}(\Phi_N) = c_N(\mathfrak{o})/2$). The universal Borchers weight identity appearing throughout Corollaries 30.2.2, 30.2.3 is a tier-(iii) statement on two nested scopes; every corollary below states which scope its hypothesis lives on.

- (i) **CHL slice** $N \in \{1, 2, 3, 4, 6\}$. Paramodular weights $\{5, 4, 3, 2, 1\}$ via the five admissible Frame-shape classes of M_{24} ; this is the slice where the BKM superalgebra attached to the Borchers product carries a $\mathbb{Z}/N$ -twined Jacobi generator.
- (ii) **Full Gritsenko–Cléry 8-form scope** $N \in \{1, \dots, 8\}$. Paramodular weights $\{5, 4, 3, 2, 2, 1, 1, 1\}$ via the full 8-form enlargement of Gritsenko–Cléry; this adds three auxiliary tier-(iii) specialisations beyond the CHL five. Both scopes satisfy the same universal Borchers weight identity.

The CHL slice $(5, 4, 3, 2, 1)$ tuple cited above is the *Family (i)* CHL-averaged paramodular weight sequence $\text{wt}(\Delta_1^{(N)}) = (5, 4, 3, 2, 1)$ of Gritsenko 1999 Thm. 1.2, produced as the additive lift of the weight- $k(N)$ index-1 Jacobi input. A second paramodular family coexists on the same index set: *Family (ii)*, the twined Borcherds weights $\kappa_{\text{BKM}}(\Phi_N) = c_N(\mathbf{o})/2 \in (5, 2, 1, 1, 1)$ with $(c_N(\mathbf{o})) = (10, 4, 2, 2, 2)$ of Gritsenko–Nikulin 1998 Thm. 2.1, produced as the singular-theta Borcherds lift of the g_N -twined weight-0 weak Jacobi form $\phi_{\mathbf{o},1}^{(g_N)}$. The two families coincide at $N = 1$ (both give 5 on Δ_5) and diverge at $N \in \{2, 3, 4, 6\}$; the extended 8-form weights $\{5, 2, 1, 1, 1/2, 1, 1/4, 0\}$ of Borcherds 1998 Thm. 10.1/13.3 are the Family (ii) extension to $N \in \{1, \dots, 8\}$ with metaplectic $N = 5$, spin $N = 7$, and weight-0 abelian-lattice $N = 8$. The default on the symbol κ_{BKM} throughout this chapter is the Family (ii) twined Borcherds weight. Corollary 30.2.2 states the CHL-slice values $\{5, 4, 3, 2, 2, 1, 1, 1\}$ for $N \in \{1, 2, 3, 4, 5, 6, 7, 8\}$; the full enlargement is recorded in [96] with primary sources Borcherds 1998 Thm. 13.3, Gritsenko–Nikulin 1997, 2002 and Cléry–Gritsenko 2011.

30.1 THE IDENTITY

Let $\mathcal{A}$ be a chiral algebra in the logarithmic-finite-type class admitting a quasi-free BRST resolution [96]. Let X be a smooth projective Calabi–Yau manifold of dimension d , with $\Phi_d(D^b(\text{Coh}(X))) = \mathcal{A}_X$ the image under the CY-to-chiral correspondence programme $\{\Phi_d\}$ of Chapter 5. Let $\mathfrak{Z}(\mathcal{A}) := \int_{S^1 \times \text{Ran}(X)} \mathcal{A}$ denote the universal centre: the factorisation-homology output of $\mathcal{A}$ on the product of the cyclic circle S^1 and the Ran space of X (Vol II Chiral Hochschild Trinity Theorem; cf. the candidate-centre discussion in Chapter 29, [96]). Let $\mathfrak{K}_{\mathcal{A}} : \mathcal{A} \mapsto \mathcal{A}^!$ be the Vol I Koszul reflection (Theorem A, [96]). For X in the K_3 -fibered domain, let $\mathfrak{B}_X := \Phi_*^{\text{Borch}}(\mathfrak{K}_{\mathcal{A}_X})$ denote the Borcherds pushforward of the Koszul reflection [96] (via the universal property of the Borcherds singular theta correspondence [96]).

THEOREM 30.1.1 (Universal Φ -Trace Identity). For every chiral algebra $\mathcal{A}$ in the logarithmic-finite-type class and every compact Calabi–Yau manifold X admitting a Mukai-lattice grading Λ of signature $(b^+, 2)$ with $b^+ \geq 1$:

- (i) **Koszul side.** The Vol I Koszul conductor is the centre supertrace of the Koszul reflection:

$$K(\mathcal{A}) = -c_{\text{ghost}}(\text{BRST}(\mathcal{A})) = \text{tr}_{\mathfrak{Z}(\mathcal{A})}(\mathfrak{K}_{\mathcal{A}}).$$

- (ii) **Borcherds side.** The Vol III BKM weight is the centre supertrace of the Borcherds reflection:

$$\kappa_{\text{BKM}}(\mathfrak{g}_{\Lambda}) = c_{\Lambda}(\mathbf{o})/2 = \text{tr}_{\mathfrak{Z}(\mathcal{A}_X)}(\mathfrak{B}_X).$$

- (iii) **Φ -pushforward bridge.** The two reflections intertwine along the singular theta correspondence:

$$\mathfrak{B}_X = \Phi_*^{\text{Borch}}(\mathfrak{K}_{\mathcal{A}_X}).$$

- (iv) **Unified diagram.** The two supertraces agree with the two sides of the following commutative square (up to canonical homotopy):

$$\begin{array}{ccc} \mathcal{A} & \xrightarrow{\mathfrak{K}} & \mathcal{A}^! \\ \downarrow \mathfrak{Z} & & \downarrow \mathfrak{Z} \\ \mathfrak{Z}(\mathcal{A}) & \xrightarrow{\mathfrak{Z}(\mathfrak{K})} & \mathfrak{Z}(\mathcal{A}^!) \\ \downarrow \Phi^{\text{reg}} & & \downarrow \Phi^{\text{reg}} \\ \kappa_{\text{BKM}}^{\text{reg}}(\mathcal{A}) & = & \text{tr}_{\mathfrak{Z}(\mathcal{A})}(\Phi_{f_{\mathcal{A}}}^{\text{reg}}(\mathfrak{K})). \end{array}$$

In the K_3 -fibered case Φ^{reg} collapses to the Borchers singular theta correspondence of Borchers 1998 ([96]); in the non- K_3 -fibered case Φ^{reg} is the Bruinier–Funke regularised lift of arXiv:math/0407397.

Attribution. Clause (i) is the supertrace-trinity centre-collapse identity of Vol I [96] combined with the Chiral Hochschild Trinity Theorem of Vol II [97]. Clause (ii) on the K_3 -fibered domain is the universal trace identity of Vol III, proved through the $\mathfrak{Z}$ -functoriality of Koszul reflections, the supertrace-trinity centre-collapse, and the Borchers character lift; on the non- K_3 -fibered domain it follows from the Bruinier–Funke functoriality, the Eisenstein-cusp trinity supertrace, and the non-unimodular Borchers product. Clause (iii) is the Borchers character lift. Clause (iv) is the commutative-diagram restatement of the cross-volume bridge. $\square$

Remark 30.1.2 (The object traced). The trace in clauses (i)–(ii) is a supertrace of an *involutive endofunctor* on a *factorisation-homology module* $\mathfrak{Z}(\mathcal{A}) \in \text{Mod}_{\mathfrak{Z}_{\text{ch}}^{\text{der}}(\mathcal{A})}$: a cyclic-cohomology class in the sense of Connes–Karoubi, realised explicitly via Costello–Gwilliam factorisation homology on $S^1 \times \text{Ran}(X)$. The Fourier–Mukai-kernel trace on $D^b(\text{Coh}(X))$ sits one functorial layer upstream of Φ ; the centre supertrace here lives on the factorisation-homology module of the chiral output.

30.2 DIMENSION-STRATIFIED SPECIALISATIONS

The universal identity specialises at each CY dimension d to a named evaluation. The four specialisations below are four *reductions* of Theorem 30.1.1 at the standard inputs: one theorem, four named evaluations along the dimension axis.

COROLLARY 30.2.1 ($d = 1$: *the Vol I half alone*). For $X = E$ an elliptic curve with $\mathcal{A}_E = \Phi_!(D^b(\text{Coh}(E))) = \text{Heis}_{\Lambda_E}$ the elliptic lattice VOA, the Mukai-lattice signature is $(1, 1)$; the Borchers singular theta correspondence outputs a modular function of weight 0. Theorem 30.1.1 reduces to its Vol I half: $K(\mathcal{A}_E) = \text{tr}_{\mathfrak{Z}(\mathcal{A}_E)}(\mathbf{R})$. The Koszul reflection carries the entire identity at $d = 1$; the Borchers reflection collapses to the trivial scalar on the weight-zero output.

Proof. At rank-1 Lorentzian lattice $\Pi_{1,1}$, the Borchers lift of the trivial VOA is $J(\tau) - 744$ (Borchers 1992), a modular function of weight 0; the weight formula $c_{\Lambda}(0)/2 = 0$ gives vanishing κ_{BKM} on the lattice side. The Koszul side $K(\text{Heis}_{\Lambda_E}) = 0$ also vanishes on the free-field branch (Mukai self-duality at rank 1; see [96] in the modular-Koszul bridge). Both sides collapse to the trivial identity $0 = 0$; the Φ -pushforward bridge is vacuous at $d = 1$. $\square$

COROLLARY 30.2.2 ($d = 2$: K_3 and K_3 orbifolds). For $X_N = K_3/\mathbb{Z}_N$ with $N \in \{1, 2, 3, 4, 5, 6, 7, 8\}$, Theorem 30.1.1 (ii) specialises to the Borchers weight formula

$$\kappa_{\text{BKM}}(X_N) = c_N(0)/2 \in \{5, 4, 3, 2, 2, 1, 1, 1\},$$

via [96] applied to the orbifold-averaged Jacobi form ϕ_N . The Φ -pushforward bridge (iii) is realised explicitly via the K_3 topological vertex algebra $V_{K_3}^{\text{top}}$ of weight lattice $\Pi_{3,2}$: $\Phi_*^{\text{Borch}}(V_{K_3}^{\text{top}}) = \Delta_5$ (Gritsenko’s paramodular cusp form).

COROLLARY 30.2.3 ($d = 3$: $K_3 \times E$ via Δ_5 and its unnormalised Φ_{10}^{un} square). For $X = K_3 \times E$ with Mukai lattice Λ even unimodular of signature $(3, 2)$, Theorem 30.1.1 (ii) specialises to

$$\kappa_{\text{BKM}}(\mathfrak{g}_{\Delta_5}) = c_1(0)/2 = 10/2 = 5,$$

the Borchers weight of the primitive Gritsenko–Nikulin form Δ_5 . The monic denominator product is $D_5 = 64^{-1}\Delta_5$. The unnormalised Igusa square is $\Phi_{10}^{\text{un}} = \Delta_5^2$, while the reduced DT/OP character uses the OP-normalised form $\Phi_{10}^{\text{OP}} = D_5^2 = 4096^{-1}\Delta_5^2$:

$$Z_{\text{DT}}^{\text{red}}(K_3 \times E) = -(\Phi_{10}^{\text{OP}})^{-1} = -D_5^{-2} = -4096 \Delta_5^{-2}.$$

The Fake-Monster form Φ_{12} has weight 12 on the $\text{II}_{25,1}$ row and is a different BKM object. The Koszul conductor on the CY side is $K(\mathcal{A}_{K_3 \times E}) = 0$ (free-field branch via Mukai self-duality + Künneth with $K(\text{Heis}_E) = 0$), so the two supertraces are *not the same normalised numerical invariant*; they trace *two different reflections* on the same centre $\mathfrak{Z}(\mathcal{A}_{K_3 \times E})$, and the bridge (iii) $\mathfrak{B}_{K_3 \times E} = \Phi_*^{\text{Borch}}(\mathfrak{R})$ is the structural identity.

COROLLARY 30.2.4 ($d \geq 4$: E_1 -stabilisation, Vol I half alone). For $d \geq 4$, Φ_d is E_1 -stabilised via the $\pi_d(BU)$ obstruction (Theorem 11.5.1); no native braiding is promoted to a Borchers singular theta lift. Theorem 30.1.1 (i) applies directly; the Borchers half is conjecturally defined via higher-rank regularisations that lie beyond the current programme. The Vol I conductor identity remains unconditional.

30.3 NUMERICAL EVIDENCE AND THE FACTOR-I3 CAVEAT

A numerical table illustrates that Theorem 30.1.1 is *not* an assertion of numerical equality $K = \kappa_{\text{BKM}}$; it is an assertion of Φ -pushforward intertwining. At the canonical inputs:

d	Input	$K(\mathcal{A})$	κ_{BKM}	Relation
1	Heis_{Δ_E}	0	undefined (lattice not $(b^+, 2)$ with $b^+ \geq 2$)	Borchers half vacuous
2	K_3	0	5	two reflections on $\mathfrak{Z}(\Phi_2(K_3))$
2	$K_3/\mathbb{Z}_2$	0	4	orbifold averaging reduces $c_N(0)$
3	$K_3 \times E$	0	5	Δ_5 weight; $D_5 = 64^{-1}\Delta_5$ and $\Phi_{10}^{\text{OP}} = D_5^2$

The zero values on the K -column correspond to the free-field branch with Mukai-symmetric Koszul pairing. At Virasoro with central charge $c = 13$ (the Vol I point where $\text{Vir}_c^! = \text{Vir}_{26-c}$ coincides with Vir_c), the universal conductor evaluates as $K = c + c^! = 13 + 13 = 26$; on the $\mathcal{W}_N$ branch $K = c(H_N - 1)$. The numerical invariants K and κ_{BKM} do not coincide; they trace distinct reflections, and the structural unification lies in clause (iii) of Theorem 30.1.1.

Remark 30.3.1 (*Against a constant ratio K/κ_{BKM}*). The Vol I conductor is $K(\text{Vir}_c) = \kappa_{\text{ch}}(\text{Vir}_c) + \kappa_{\text{ch}}(\text{Vir}_{c^!}) = c/2 + c^!/2$ on the Virasoro dual-pair line $c + c^! = 26$, so $K(\text{Vir}) = 13$ at every admissible c (in particular at the self-dual point $c = c^! = 13$, $K = 13/2 + 13/2 = 13$). The Vol III $K_3 \times E$ Gritsenko weight is $\kappa_{\text{BKM}}(\Phi_1) = c_1(0)/2 = 5$. The ratio $13/5$ is not an integer, and no heuristic derivation produces a constant factor relating the two invariants: K is the Vol I conductor trace, while κ_{BKM} is the Gritsenko–Nikulin/Borchers weight $c_1(0)/2$. They are related by the Φ -pushforward of clause (iii), not by a scalar rescaling.

30.4 OPEN FRONTIER: BEYOND THE LOGARITHMIC-FINITE-TYPE CLASS

Theorem 30.1.1 is proved on two domains: the K_3 -fibered CY₃ domain of the K_3 -fibered identity of [96] and the non- K_3 -fibered Mukai- $(b^+, 2)$ -graded domain of Vol I [96]. Three genuine frontier directions remain:

- (a) **Non-quasi-free BRST resolutions.** All standard chiral families are chirally Koszul, but not all admit a quasi-free BRST resolution in the sense required by Vol I's universal conductor. Outside the quasi-free BRST class, both sides are defined only after passing through the Trinity double cover (Vol II Vol II [97] (i)–(ii)). The obstruction is the absence of a quasi-free BRST replacement compatible with the Trinity double cover.
- (b) **Λ of arbitrary signature.** For Λ of signature (b^+, b^-) with $b^- \geq 3$ (non-orthogonal-group target Grassmannian), the Borchers lift extends via Gritsenko–Nikulin para-automorphic constructions (GN 1996, 2002); integration with the Koszul-reflection pushforward remains open.
- (c) **Class M chain-level.** The centre-functoriality Vol I [96] uses the inf-categorical ∞ -functor $\int_{S^1 \times \text{Ran}(X)}$; a chain-level $\mathfrak{R}$ -equivariant model for class M inputs (Vol I Virasoro, $\mathcal{W}_N$) requires the weight-completed ambient of Vol II [97]. The obstruction is the absence of a raw bar-complex model carrying the same $\mathfrak{R}$ -equivariance as the weight-completed ambient.

The three directions are orthogonal: (a) removes the BRST quasi-freeness hypothesis, (b) removes the signature restriction, (c) moves from ∞ -categorical to chain-level. A closed Φ_3 theorem on compact CY_3 inputs combines these three with the $\mathbb{S}^3$ -framing input: either a corrected TCFT comparison or a complete E_7 -Hochschild filtration theorem of the kind spelled out in Chapter 7. Theorem 30.1.1 holds structurally on its natural domain and on the witnessed compact branches; closure on compact CY_3 proceeds through the joint construction of the framing datum and the three frontier directions.

30.5 THE IDENTITY IN ONE LINE

Carry away one equation:

$$K(\mathcal{A}) = \text{tr}_{\mathcal{Z}(\mathcal{A})}(\mathfrak{K}_{\mathcal{A}}), \quad \kappa_{\text{BKM}}(\mathfrak{g}_{\Lambda}) = \text{tr}_{\mathcal{Z}(\Phi(X))}(\mathfrak{B}_X), \quad \mathfrak{B}_X = \Phi_*^{\text{Borch}}(\mathfrak{K}_{\Phi(X)}).$$

Two reflections, one centre, one functor. The inner poetry: the Vol I ghost-charge $-c_{\text{ghost}}$ and the Vol III Borchers weight $c_{\Lambda}(\mathfrak{o})/2$ are two supertrace readings of the same universal involution, projected through two different points of the Φ -bridge.

Φ -output shift at K_3 input: [2], not [3]

The homological shift of Φ_d at $\text{CY-}d$ input is *Hochschild-dimension-forced*. The functor Φ_d sends a smooth proper cyclic $\mathcal{A}_{\infty}$ -category of CY dimension d to a factorisation algebra $\mathcal{A}$ whose Verdier–Koszul dual $\mathcal{A}^!$ is obtained via $D_{\text{Ran}} \circ B$ on $\text{Ran}(C)$ and carries a $[d]$ -shift. The Verdier–Koszul operation, ordinary bar–cobar inversion, and the chiral derived centre $Z_{\text{ch}}^{\text{der}}(\mathcal{A})$ each operate on $\mathcal{A}$ through distinct functorial constructions: bar–cobar inversion returns $\mathcal{A}$ on the comparison locus, $D_{\text{Ran}} \circ B$ produces the Verdier–Koszul dual with $[d]$ -shift, and $Z_{\text{ch}}^{\text{der}}(\mathcal{A})$ produces the bulk algebra at the centre-sector level. The shift appears because the Serre functor $\mathbb{S}_C \simeq [d]$ on the input category induces the cyclic-trace of degree $-d$ on the output coalgebra. This is the operadic Koszul degree of the bar construction in the sense of Lurie, *Higher Algebra*, §6.3.1.5 (Koszul self-duality with $\text{CY-}d$ shift), and Francis–Gaitsgory, *Chiral Koszul duality*, arXiv:1103.5803, 2012. The shift is intrinsic to the CY dimension of the input category, independent of which ambient space hosts the factorization.

THEOREM 30.5.1 (*Φ -output shift at K_3 input is [2]*). For the K_3 input category $C = D^b \text{Coh}(K_3)$, the Φ -output homological shift is [2], consistent with CY_2 . Concretely,

$$(\Phi_2(D^b \text{Coh}(K_3)))^! \simeq \Phi_2(D^b \text{Coh}(K_3))^{\text{coalg}}[2],$$

with the Mukai–Heisenberg identification $\Phi_2(D^b \text{Coh}(K_3)) \simeq \mathcal{H}_{\text{Muk}}$ at the E_2 -chiral target of Φ_2 .

Proof sketch. K_3 is Calabi–Yau of complex dimension 2; its derived category $D^b \text{Coh}(K_3)$ is smooth and proper with Serre functor $\mathbb{S}_C \simeq [2]$ (Bondal–Orlov, *Reconstruction of a variety from the derived category and groups of autoequivalences*, Compos. Math. 125, 2001). The Hochschild cohomology is bi-graded

$$\text{HH}^\bullet(D^b \text{Coh}(K_3)) = \bigoplus_{p+q=\bullet} H^p(K_3, \Lambda^q T_{K_3}),$$

concentrated in degrees 0 through 4, with Poincaré-like duality $\text{HH}^k \simeq \text{HH}^{4-k}$ induced by the CY-2 Mukai pairing. Lurie’s HA 6.3.1.5 Koszul self-duality with CY- d shift specialised to $d = 2$ gives the $[2]$ -shift on the Verdier–Koszul dual $A^!$ (distinct from bar–cobar inversion $\Omega(B(A)) = A$, which is unshifted). The Mukai–Heisenberg identification is the Φ_2 -computation of the Φ_2 Mukai–Heisenberg section of Chapter 5. $\square$

Remark 30.5.2 (The ambient-vs-input distinction). The Koszul shift is determined by the CY dimension of the *input category*, not by the ambient factorization base. For a CY-3 input whose witnessed framed Φ_3 output has been chosen, the shift is $[3]$; for Φ_2 input with K_3 , the shift is $[2]$. For the quintic $X \subset \mathbb{P}^4$, such a choice is part of the compact CY_3 strictification problem, not an automatic consequence of the dimension count. The source of the conflation: K_3 (CY-2) is the input category, while the auxiliary CY-3 spaces

$$K_3 \times \mathbb{C}, \quad K_3 \times \mathbb{C}^3, \quad K_3 \times E$$

appear only as *ambient factorization bases* hosting the output algebra. These two roles are distinct:

- *Input category.* The K_3 derived category $D^b \text{Coh}(K_3)$ is the object fed to Φ_2 ; it is CY-2; the Koszul shift is $[2]$.
- *Ambient base.* The auxiliary CY-3 space $K_3 \times E$ is where the K_3 chiral output is hosted as a factorization algebra; after the finite Hall–Borcherds recognition gates its comparison target is $\mathbf{H}_{\Delta_5}$ (bi-based: chiral base $E_{24}^{\text{nod,sm}}$, parameter base $\overline{\mathcal{A}}_2$; see Chapter 20, Theorem 20.7.1, and Chapter 29, Section 29.17).

The $[3]$ -shift on a framed Φ_3 -output for a true CY-3 input is a separate, simultaneously-true statement (the Φ_3 CY-3-output section of Chapter 5); it does not displace the $[2]$ -shift for Φ_2 at K_3 .

Remark 30.5.3 (Bridge to bi-based Ran-space architecture). The $[2]$ -shift on $(\mathbf{H}_{\Delta_5})^!$ is visible on both sides of the bi-based Ran-space datum of Chapter 29, Definition 29.17.1:

- *Chiral base side* (α, β) . The Beilinson–Drinfeld chiral algebra on $\text{Ran}(E_{24}^{\text{nod,sm}})$ has bar complex in bar degrees 0, 1, 2, $\dots$; the $[2]$ -shift means its Koszul dual coalgebra sits in cohomological degree +2 relative to the primitive generators. At each of the 24 Kodaira nodes, the nearby-cycles $\mathcal{D}$ -module $\mathcal{F}_{n_i} = \Psi_{s_i}(\mathbf{H}_{\Delta_5} | \mathbb{D}_{n_i}^*)$ carries the same $[2]$ -shift in its perverse t-structure (Beilinson–Drinfeld 2004, §3.5.14).
- *Parameter base side* (γ) . On $\overline{\mathcal{A}}_2$, the holonomic $\mathcal{D}$ -module $\mathcal{L}^{\Delta_5}$ has cohomological degree equal to the complex dimension of its singular support divided by two: Humbert divisors H_1, H_4 are codimension-1 in the 3-dimensional parameter base, contributing degree +2 to the perverse t-structure shift via $\dim \overline{\mathcal{A}}_2 - \text{codim}(H_D) = 2$. This agrees with the $[2]$ -shift on the chiral side through the averaging-morphism pullback $\text{av}^* \mathcal{L}^{\Delta_5} \simeq \bigoplus_{i=1}^{24} \mathcal{F}_{n_i}$ of Corollary 20.7.5.

The [2]-vs-[3] confusion is resolved by distinguishing the Φ_d -input (CY dimension of the source category, which determines the shift) from the *ambient factorization base* (geometric space hosting the output algebra, which does not). See Chapter 20, Theorem 20.8.1, for the full chain-level and $(\infty, 1)$ -categorical statement.

30.6 THE Φ UNIVERSAL TRACE AT THE K_3 BASE

Remark 30.6.1 (Φ universal trace at the K_3 base). The universal trace identity

$$\mathrm{Tr}_{\Phi(C)}^{\mathrm{ch}}(\cdot) = \mathrm{Tr}_C^{\mathrm{CY}}(\Phi^{-1}(\cdot)),$$

bridging Vol. I and Vol. III through the CY-to-chiral functor Φ , is a statement at the *stage-1* level: both sides are traces on $\mathrm{HH}^\bullet(C)$, the categorical Hochschild cohomology of the input CY category C , before any curve-specialisation via $\mathrm{Sp}^{\mathrm{ch}}$. The stage-2 shadow recovers the on-curve conductors $K(A_C)$ and $\kappa_{\mathrm{BKM}}(\mathfrak{g}_\Lambda)$ as numerical specialisations of the stage-1 supertrace. The K_3 platonic realisation is conditional on the Heegner comparison and the finite Hall–Borcherds recognition gates: for $C = D^b \mathrm{Coh}(K_3)$ and the comparison output $\Phi(C) \simeq \mathbf{H}_{\Delta_5}\text{-mod}^{\mathrm{ch}}$, the two trace maps coincide via the Gritsenko–Nikulin 1997–98 denominator identity

$$\Phi_{10}^{\mathrm{OP}}(Z) = D_5(Z)^2 = \prod_{(n,l,m) > 0} (1 - q^n \zeta^l p^m)^{c(nm,l)},$$

with $c(nm, l)$ the K_3 elliptic-genus Fourier coefficient spectrum. The left-hand-side chiral trace and the right-hand-side CY trace are identified through the Kuga–Satake pullback $K_3 \hookrightarrow \bar{\mathcal{A}}_2$, which provides the compactification compatibility for the trace identity. At the K_3 base point the primitive BKM trace is the weight-5 form Δ_5 , the monic denominator product is $D_5 = 64^{-1} \Delta_5$, and the reduced DT/OP theorem uses the OP-normalised square $\Phi_{10}^{\mathrm{OP}} = D_5^2 = 4096^{-1} \Delta_5^2$. The Fake-Monster Φ_{12} is absent: it lives on the $\mathrm{II}_{25,1}$ lattice row. The comparison with the K_3 chiral bialgebra is made in Chapter 20; the source inputs are Gritsenko–Nikulin 1996–98, Eguchi–Ooguri–Tachikawa 2011, and Borcherds 1995.

30.7 $\{\Phi_d\}$ OUTPUT IS d -DEPENDENT; ONE Φ PER CATEGORY TYPE

Remark 30.7.1 (*Scope of $\{\Phi_d^{(\Sigma_{d-1}, C)}\}_{d, (\Sigma, C)}$: a two-parameter correspondence programme*). At fixed d , Stage-1 is a functor $\Phi_d^{\mathrm{FA}}: \mathrm{CY}_d\text{-Cat} \rightarrow E_d\text{-HolFA}(X)$ (canonical up to $\mathrm{GRT}_1(\mathbb{Q})$ -torsor); the chart-specialised level-2 output

$$\Phi_d^{(\Sigma_{d-1}, C)} = \mathrm{Sp}_{\Sigma_{d-1}, C}^{\mathrm{ch}} \circ \Phi_d^{\mathrm{FA}}: \mathrm{CY}_d\text{-Cat} \longrightarrow E_{n(d)}\text{-ChirAlg}(C), \quad n(d) = \begin{cases} \infty, & d = 1, \\ 2, & d = 2, \\ 1, & d \geq 3, \end{cases}$$

is $\mathrm{per}(d, \Sigma_{d-1}, C)$. The full collection $\{\Phi_d^{(\Sigma_{d-1}, C)}\}_{d \geq 1, (\Sigma, C)}$ is a two-parameter correspondence programme, not a single functor across d : the target $E_{n(d)}\text{-ChirAlg}(\mathcal{M}_d)$ depends on d through the operadic level forced by the PTVV shift law and Dunn–Lurie additivity, and depends on (Σ_{d-1}, C) through the level-2 chart specialisation (Chapter 5, Remark $\{\Phi_d\}$ -is-not-a-unified-functor; Francis–Gaitsgory 2012, arXiv:1103.5803). The three data points at $d \in \{1, 2, 3\}$:

$d = 1$ (**elliptic curve E**). $\Phi_1(D^b(\mathrm{Coh}(E))) = \mathrm{Heis}_{\Lambda_E}$, a lattice Heisenberg VOA; output is E_∞ -chiral (fully E_∞ -commutative at rank 1 Lorentzian signature). Borcherds side is vacuous (Corollary 30.2.1).

$d = 2$ ($\mathbf{K}_3$). $\Phi_2(D^b(\text{Coh}(K_3))) = \mathcal{H}_{\text{Muk}}$, the Mukai–Heisenberg chiral bialgebra; output is E_2 -chiral with non-trivial braiding (Theorem 30.5.1). The Borchers lift of the K_3 elliptic genus $2\phi_{0,1}$ produces the paramodular form Δ_5 (Corollary 30.2.2), with $\kappa_{\text{BKM}} = 5$.

$d = 3$ ($\mathbf{K}_3 \times E$). On the chosen witnessed $K_3 \times E$ framed locus, $\text{Sp}_{\Sigma_2, C}^{\text{ch}}(\Phi_3^{\text{FA}}(D^b(\text{Coh}(K_3 \times E))))$ has $\mathbf{H}_{\Delta_5}$ as conditional Hall–Borchers recognition target; output is E_1 -chiral. The Dunn–Lurie additivity statement records the operadic level drop after Stage-2 specialisation along Σ_2 ; it is not a proof of a compact Φ_3 output, a contractible lifting space, or a global Hall/CoHA comparison.

The change of target operadic level across d is structural: it is not a choice of presentation, it is the content of the $(\infty, 2)$ -categorical CY-to-chiral theorem. The universal trace identity Theorem 30.1.1 is *per- d* (Corollaries 30.2.1, 30.2.2, 30.2.3, 30.2.4); its statement at any single d does not imply the statement at another d without a dedicated argument.

Remark 30.7.2 (One Φ per category type: six routes $\neq$ six Φ 's). The universal trace identity at a fixed d uses *one* Φ_d with *one* source category and *one* output. The six routes to $G(K_3 \times E)$ of Chapter 23 are not six applications of Φ_3 ; only route R_1 uses the framed $K_3 \times E$ Φ_3 specialisation. The remaining five routes (Borchers lift, Mukai lattice VOA, threefold Kummer, holomorphic half-twist, BLLPR/ $6d$ Schur) are *independent* constructions whose outputs are compared with $\text{Sp}_{\Sigma_2, C}^{\text{ch}}(\Phi_3^{\text{FA}}(D^b(\text{Coh}(K_3 \times E))))$ via named intertwiners α_{ij} – see Chapter 23, Remark 23.14.1, for the per-route taxonomy with distinct generator ranks $\rho^{R_i} \in \{3, 12, 24\}$. Writing “six Φ_3 ’s, one per route” is a functor-per-route conflation, closely related to the requirement that the denominator = bar Euler identity needs both the framed $K_3 \times E$ Φ_3 specialisation and the Vol I anchors simultaneously (see Section 26.31, Remark 26.32.1). The universal trace identity of Theorem 30.1.1 relates *two* trace computations across *one* Φ_d at a fixed d ; it does not split into several parallel Φ ’s, and it does not collapse across different d .

Remark 30.7.3 ($\kappa_{\text{cat}}(K_3 \times E) = 0$: per-route-independent CY-side invariant). On the CY side of the framed Φ_3 locus at $X = K_3 \times E$, the categorical invariant is

$$\kappa_{\text{cat}}(K_3 \times E) = \chi(O_{K_3 \times E}) = \chi(O_{K_3}) \cdot \chi(O_E) = 2 \cdot 0 = 0,$$

by Serre duality for CY_3 ($\chi(O) = 0$ for every compact CY_3) and Künneth for coherent cohomology. This is the total-space value. The fibre- K_3 value $\kappa_{\text{cat}}(K_3) = \chi(O_{K_3}) = 2$ is a separate K_3 categorical invariant; it is not the $K_3 \times E$ fibre-rank invariant, which is $\kappa_{\text{fiber}}(K_3 \times E) = \text{rk } \tilde{H}(K_3, \mathbb{Z}) = 24$. The universal trace identity (30.1.1) at $d = 3$ uses the total-space value: in the dimension-stratified specialisation $d = 3$ (Corollary 30.2.3), the Koszul conductor $K(\mathcal{A}_{K_3 \times E}) = 0$ holds on the free-field Heisenberg branch, consistent with $\kappa_{\text{cat}}(K_3 \times E) = 0$. Cross-reference: Chapter 19, Remark 26.32.2; Chapter 23, Remark 23.14.3.

Remark 30.7.4 (Trace identity finite numerical checks). The $d = 3$ specialisation of the universal trace identity, restricted to the framed K_3 chiral bialgebra branch $\mathbf{H}_{\Delta_5}$, is checked by `compute/lib/k3_yangian_unified_cross_check.py`. Eight independent numerical witnesses are used: (A) universal identity $\hbar^2 \cdot K^{\kappa_{\text{ch}}} = -1$ with Koszul conductor $K = 8$ from Mukai doubling, Humbert H_1 monodromy order via Bruinier 2002 Proposition 5.1, and Lusztig specialisation $\ell = 8$; (B) central-charge pair $(c_{4d}, c_{2d}) = (107/6, -214)$ via Chacaltana–Distler crossed with Beem–Rastelli; (C) BKM Cartan rank 3 (Gritsenko–Nikulin $\det = -32$) and Mukai rank 24; (D) Siegel weight 5 via three independent routes; (E) five duality frames (het / IIA / IIB / M / F) converging on Narain $II_{3,19}$ at weight 5; (F) Heegner pattern $c_n \propto [H_n]$ at $n = 1, 2, 3$; (G) Arthur packet $\psi_{\Delta_5} = \phi_{\Delta_{E_6}} \boxplus \text{Sym}^1$ with first-principles a_p satisfying Deligne–Weissauer Ramanujan–Petersson $|a_p| \leq 2p^{15/2}$ at $p \leq 11$; (H)

Schur-index plethystic expansion. These checks support numerical self-consistency on the framed Φ_3 image branch; the CY-C isomorphism claim (Conjecture 23.2.1) remains the missing comparison theorem.

30.8 KONTSEVICH FORMALITY BRIDGE: FRAMED Φ_3 IMAGE AS SUPER-KONTSEVICH DEFORMATION QUANTISATION

The $d = 3$ Φ -universal trace identity compares, on the witnessed framed $K_3 \times E$ locus after the finite Hall–Borcherds recognition gates and Heegner comparison, the image denoted $\mathbf{H}_{\Delta_5} := \mathrm{Sp}_{\Sigma_2, C}^{\mathrm{ch}}(\Phi_3^{\mathrm{FA}}(D^b(\mathrm{Coh}(K_3 \times E))))$ with the Etingof–Kazhdan super-quantisation of the Gritsenko–Nikulin classical chiral Lie bialgebra $(\mathfrak{g}_{\Delta_5}, \delta_{\mathrm{GN}})$ after the framing and comparison data have been fixed at $\hbar^2 = -1/8$ (Vol I [96], Kazhdan classical-limit theorem). A third lens, the Kontsevich admissible-graph machinery, produces the same formal deformation class on this branch and makes the motivic origin of its transcendental coefficients transparent. This section records how the Kontsevich lens illuminates the Φ -universal trace identity at $d = 3$.

THEOREM 30.8.1 (*Conditional super-Kontsevich comparison on the framed $K_3 \times E$ branch*). Assume the witnessed $K_3 \times E$ Φ_3 branch: a fixed formality/associator point, a chain-level S^3 -framing homotopy, the Costello correction or the complete HH^{-2} filtration theorem, the Stage-2 specialisation datum $(\Sigma_2, C) = (K_3, E)$, the Borcherds–Gritsenko comparison map, the finite Hall–Borcherds recognition gates, and the Heegner comparison. Under these hypotheses, the comparison datum identifies the chiral bialgebra

$$\mathbf{H}_{\Delta_5} = \mathrm{Sp}_{\Sigma_2, C}^{\mathrm{ch}}(\Phi_3^{\mathrm{FA}}(D^b(\mathrm{Coh}(K_3 \times E))))$$

with the completed super-Kontsevich deformation quantisation of $(\mathfrak{g}_{\Delta_5}, \delta_{\mathrm{GN}})$ at $\hbar^2 = -1/8$, in the conditional comparison gauge characteristic selected by the line $H^2(\mathfrak{g}_{\Delta_5})^{\mathbb{Z}/2, K(1)} \cong \mathbb{C} \cdot \Delta_5$. The identification is:

- (i) **Classical end.** The $\hbar \rightarrow 0$ limit of $\mathbf{H}_{\Delta_5}$ is the Gritsenko–Nikulin super-chiral Lie bialgebra with r -matrix $r(u, Z) = \Omega_{\mathrm{Mukai}}/u + \partial_Z \log \Phi_{10}^{\mathrm{un}} \cdot \Omega_{K_3} + O(u^{-2})$.
- (ii) **Super-Kontsevich formality.** The L_∞ -quasi-isomorphism $\mathcal{U}^{\mathrm{super}} : \mathrm{Hoch}^\bullet(\mathfrak{g}_{\Delta_5}^{\mathrm{super}}) \simeq_{L_\infty} \mathrm{PVec}^\bullet(\mathfrak{g}_{\Delta_5}^{\mathrm{super}})$ transports the Poisson bivector $r(u, Z)$ to an associative star product on the completed enveloping algebra.
- (iii) $\hbar^2 = -1/8$ **specialisation.** The completed formal star product is specialised through the chosen dyadic completion and compared with $\mathbf{H}_{\Delta_5}$ in the selected gauge class.

The theorem is branchwise. It does not construct Φ_3 for arbitrary compact CY_3 categories and does not supply Hall/CoHA, PBW, or no-extra-relations data. Primary: Kontsevich 2003 *Lett. Math. Phys.* 66; Shoikhet 2003 *Adv. Math.* 179; Etingof–Kazhdan 1996–2000 *Selecta Math.* 2, 4, 6; Tamarkin 1998 (arXiv:math/9803025); Cattaneo–Felder 2001 *Comm. Math. Phys.* 228.

Proof. Cross-reference to Vol I [96] Theorem *defq-unified-kontsevich-theorem*, where the combined super-Kontsevich formality, completed $\hbar^2 = -1/8$ star-product specialisation, and gauge-class comparison are assembled. The scope of the present theorem is the conditional restatement of that result inside the witnessed framed Φ_3 image branch of the Φ -universal trace identity: after the comparison datum is fixed, the chosen $d = 3$ specialisation is compared with the super-Kontsevich quantisation. $\square$

Remark 30.8.2 (Motivic-Galois reading of the Φ_3 trace coefficients). Under Theorem 30.8.1, the transcendental coefficients entering the trace computations in $\mathrm{tr}_3(\mathcal{A}_{K_3 \times E})(\mathfrak{B}_X)$ on the Borchers side and $\mathrm{tr}_3(\mathcal{A}_{K_3 \times E})(\mathfrak{R}_{\mathcal{A}_{K_3 \times E}})$ on the Koszul side are Kontsevich admissible-graph weights, equivalently MZVs $\zeta(s_1, \dots, s_r)$ in the Furusho–Brown $\mathbb{Q}$ -span, equivalently Drinfeld associator pentagon coefficients $\phi^{(n)}$ (Vol I [96] Theorem *defq-unified-motivic-origin*). The trace identity is therefore $\mathrm{GRT}_1(\mathbb{Q})$ -equivariant: the motivic Galois action on the MZV $\mathbb{Q}$ -algebra $\mathcal{Z}$ acts compatibly on both sides of the universal trace identity at $d = 3$, and the Lusztig specialisation $\hbar^2 = -1/8$ is a dyadic fixed point of the $\mathrm{GRT}_1(\mathbb{Z}[1/2])$ -action. This promotes the numerical identity $\hbar^2 \cdot K^{\kappa_{\mathrm{ch}}} = -1$ of the universal engine to a motivic-Galois-covariant statement.

Remark 30.8.3 ($K_3 \times E$ Hodge correction: $\hbar^3$ -term and BV tower). The Hodge decomposition $H^*(K_3 \times E, \mathbb{C}) = H^*(K_3) \otimes H^*(E)$ with $H^{1,0}(E)$ of rank 1 contributes an $\hbar^3$ -correction to the pure K_3 star product: $f \star_{K_3 \times E} g = f \star_{K_3} g + \hbar^3 C_3(f, g) + O(\hbar^4)$ with C_3 the unique $\mathrm{GL}(1)$ -equivariant trilinear operator representing period integration of dz on E against the chiral current algebra on K_3 . The coefficient is $\zeta(3)/(2\pi i)^3$, matching the complete graph K_4 weight in the Kontsevich expansion. The Costello–Gwilliam BV-tower coefficients c_n that enter the factorisation algebra on $K_3 \times E$ are the formality graph weights w_{W_n} of the wheel family, identifying the BV tower as the formality tower. This is the origin of the Etingof $c_{12}^{(9)}$ coefficient in the pentagon coboundary expansion: $c_{12}^{(9)} = w_{W_{12}^{(9)}}$ is the super-Kontsevich wheel weight at wheel-size 12, loop-order 9, and it lies in the $\mathbb{Q}$ -span of MZVs of weight 9 by Theorem 30.8.1(ii) and Furusho–Brown.

30.9 Ψ AS A LAX SYMMETRIC-MONOIDAL FUNCTOR OF OPERADS

The universal trace identity of Theorem 30.1.1 isolates, on the Siegel-automorphic branch of the programme, a partial functor Ψ that sends automorphic-product input data to the quantum-Hopf output data that governs the quantum chiral algebra $\mathbf{H}_{\Delta_5}$. The present section upgrades that partial functor to a *lax symmetric-monoidal functor of operads*. The upgrade is load-bearing: it is what promotes Ψ from a single-fibre rule (one lattice, one quantum-Hopf output) to a rule that respects *composition of automorphic data* – lattice direct sum on the input side, algebra tensor product on the output side – and which therefore satisfies Reshetikhin–Turaev multiplicativity for disjoint unions of chiral sites. Throughout, the operadic framework is that of Francis [40] (The tangent complex and Hochschild cohomology of $\mathcal{E}_n$ -rings), Costello–Gwilliam [143] (*Factorization algebras in quantum field theory*, Vol. I–II), Dunn [36] (Tensor product of operads and iterated loop spaces, additivity theorem), and Lurie [60] *Higher Algebra* §§5.1, 5.3, and 6.3.

The operadic domain $(\mathrm{CY}_2^{\mathrm{Siegel-aut}}, \oplus)$

Definition 30.9.1 (Operadic domain). Let $(\mathrm{CY}_2^{\mathrm{Siegel-aut}}, \oplus)$ denote the symmetric monoidal $(\infty, 1)$ -category whose:

- **Objects** are pairs (L, ϕ_L) where L is an even lattice of signature $(b^+, 2)$ with $b^+ \geq 1$, and $\phi_L \in J_{k,m}^{\mathrm{wh}}(L)$ is a weakly-holomorphic Jacobi form of weight k and lattice index L (the Borchers input datum, cf. Borchers 1998 Invent. Math. 132, Gritsenko–Nikulin 1997 Amer. J. Math. 119);
- **Morphisms** $(L_1, \phi_1) \rightarrow (L_2, \phi_2)$ are lattice embeddings $\iota : L_1 \hookrightarrow L_2$ together with a Jacobi-form pullback datum $\iota^* \phi_2 = \phi_1 \cdot \xi_\iota$ for a unit ξ_ι ;
- **Symmetric monoidal product** is $(L_1, \phi_1) \oplus (L_2, \phi_2) := (L_1 \oplus L_2, \phi_1 \boxtimes \phi_2)$ with the Jacobi form on the direct-sum lattice given by the exterior tensor product (Borchers §4).

The tensor unit is $(\mathbf{o}, 1)$, the zero lattice with trivial Jacobi form. The symmetry isomorphism is induced from the lattice swap.

$\oplus$ is strictly symmetric and strictly associative at the level of lattices; it is associative up to the canonical Jacobi-form Künneth isomorphism at the level of Jacobi data. The operadic structure on this monoidal category is the standard E_2 -structure carried by any symmetric-monoidal $(\infty, 1)$ -category with two commuting compatible pairings: the lattice direct sum $\oplus$ (first pairing) and the Jacobi-form tensor product $\boxtimes$ (second pairing). The two commute by Fubini in the Jacobi-form indices (Eichler–Zagier 1985 Ch. I §2), giving an E_2 -algebra structure on $(\mathrm{CY}_2^{\mathrm{Siegel-aut}}, \oplus)$ via the Dunn additivity $E_1 \otimes_{\mathrm{BV}} E_1 \simeq E_2$ (Dunn 1988; Lurie HA 5.1.2.2).

The operadic codomain $(\mathrm{QHopf}^{\mathrm{BKM}}, \otimes)$

Definition 30.9.2 (Operadic codomain). Let $(\mathrm{QHopf}^{\mathrm{BKM}}, \otimes)$ denote the symmetric monoidal $(\infty, 1)$ -category whose:

- **Objects** are $\mathcal{A}_\infty$ -quasi-Hopf super-algebras (H, m, Δ, R, Φ) of BKM type in the sense of Theorem 8.14.8, equipped with the Etingof–Kazhdan (2007, Part V) super-category quantisation datum;
- **Morphisms** are $\mathcal{A}_\infty$ -quasi-Hopf super-homomorphisms compatible with the universal R -matrix and the Drinfeld associator up to canonical gauge;
- **Symmetric monoidal product** is the tensor product of quasi-Hopf super-algebras: $H_1 \otimes H_2$ has algebra structure $m_1 \otimes m_2$, coproduct $\Delta_{12} := (\mathrm{id} \otimes \sigma \otimes \mathrm{id}) \circ (\Delta_1 \otimes \Delta_2)$ with swap σ , universal R -matrix $R_{12} = R_1 \otimes R_2$ (Drinfeld 1989 §3.3, Reshetikhin–Turaev 1991 Invent. Math. 103, Majid 1995 §7).

The coproduct factorisation $\Delta_{H_1 \otimes H_2} = \Delta_{H_1} \otimes \Delta_{H_2}$ (up to the canonical braiding) is the Reshetikhin–Turaev tensor-product rule; the universal R -matrix on a tensor product is the tensor product of the factor R -matrices, and the Drinfeld associator on a tensor product satisfies the strict Kunneth pentagon by Lurie HA 6.3.2.10.

Ψ as a functor of operads: the main theorem

THEOREM 30.9.3 (*Ψ is a lax symmetric-monoidal functor*). There is a functor

$$\Psi: (\mathrm{CY}_2^{\mathrm{Siegel-aut}}, \oplus) \longrightarrow (\mathrm{QHopf}^{\mathrm{BKM}}, \otimes), \quad (L, \phi_L) \longmapsto \mathbf{H}_{\phi_L},$$

sending a Borchers input datum to the BKM chiral quasi-Hopf algebra $\mathbf{H}_{\phi_L}$ of Theorem 8.14.8 applied at input ϕ_L , which is *lax symmetric-monoidal*: for every pair $(L_1, \phi_1), (L_2, \phi_2) \in \mathrm{CY}_2^{\mathrm{Siegel-aut}}$, there is a natural Reshetikhin–Turaev comparison map

$$\mu_{L_1, L_2}: \Psi(L_1, \phi_1) \otimes \Psi(L_2, \phi_2) \xrightarrow{\simeq} \Psi((L_1, \phi_1) \oplus (L_2, \phi_2)),$$

together with a unit map $\eta: \mathbb{1}_{\mathrm{QHopf}} \rightarrow \Psi(\mathbf{o}, 1)$, satisfying the lax monoidal coherence diagrams (associativity pentagon in Lurie HA 5.3.2.1 and the unit triangle) up to canonical $\mathcal{A}_\infty$ -gauge. The μ_{L_1, L_2} are quasi-isomorphisms on the Koszul locus of the programme and maps of quasi-Hopf super-algebras outside it.

Proof sketch. Functoriality on morphisms is the Borchers-pullback compatibility of Borchers 1998 §4 Lemma 4.1 (the singular theta correspondence commutes with lattice embeddings), transported to the chiral side through Clause (iii) of Theorem 30.1.1 (the Φ -pushforward of the Koszul reflection). The

comparison map μ_{L_1, L_2} is constructed from two independent inputs that agree on the overlap: (a) the Gritsenko–Nikulin 1997–1998 exponential-lift Künneth identity $\phi_1 \boxtimes \phi_2 = \text{Grit}_{L_1 \oplus L_2}(\phi_1 \boxtimes \phi_2)$ when restricted to the sublocus where both lifts exist; (b) the Reshetikhin–Turaev 1991 tensor-product rule for quasi-triangular quasi-Hopf algebras, stating $(H_1 \otimes H_2, R_1 \otimes R_2, \Phi_1 \otimes \Phi_2)$ is itself a quasi-triangular quasi-Hopf algebra with the product R -matrix. The coherence of μ under lax symmetry follows from Fubini on the Jacobi-form indices and the pentagon for $\otimes$ on $\text{QHopf}^{\text{BKM}}$ (Lurie HA 5.3.2.1 applied to the symmetric monoidal ∞ -category of $\mathcal{A}_\infty$ -quasi-Hopf super-algebras). The lax-not-strong qualifier arises because on the non-Koszul locus the Etingof–Kazhdan gauge class can obstruct strict equality; the obstruction lives in the $\mathbb{Z}/8$ Bruinier class of Theorem 8.14.7, vanishing on the Koszul locus. For detail on the lax-strong obstruction see Lurie HA 6.3.1.10 (lax monoidal = left-lax from the operadic viewpoint); Francis 2013 §5 for the E_n -monoidal variant used here. $\square$

Test case: $\Psi(\Pi_{1,1} \oplus \Pi_{1,1})$

PROPOSITION 30.9.4 (*Rank-4 BKM on $\Pi_{2,2}$*). Let $\Pi_{1,1}$ be the standard hyperbolic plane lattice and ϕ_{Heis} the Monster-Heisenberg Jacobi input (Borcherds 1992 Invent. Math. 109; rank-1 Lorentzian, lift $J(\tau) - 744$). Then

$$\Psi(\Pi_{1,1} \oplus \Pi_{1,1}, \phi_{\text{Heis}} \boxtimes \phi_{\text{Heis}}) \simeq \mathbf{H}_{\text{Monster}} \otimes \mathbf{H}_{\text{Monster}},$$

a rank-4 quantum chiral algebra on the even unimodular lattice $\Pi_{2,2} = \Pi_{1,1} \oplus \Pi_{1,1}$, with universal R -matrix $R_{\Pi} \otimes R_{22}$ and the Drinfeld associator product $\Phi_1 \otimes \Phi_2$. The comparison map μ is a quasi-isomorphism of quasi-Hopf super-algebras.

Proof sketch. The Borcherds lift of $\phi_{\text{Heis}} \boxtimes \phi_{\text{Heis}}$ on $\Pi_{2,2}$ factorises as a product of two Borcherds lifts on $\Pi_{1,1}$ by Borcherds 1998 §14 Künneth (singular theta correspondences multiply under lattice direct sum). The chiral-side factor $\mathbf{H}_{\text{Monster}}$ is the Monster module vertex algebra $V^\natural$ of Frenkel–Lepowsky–Meurman 1988, realised on each hyperbolic plane factor as the E_1 -chiral algebra with character $J(\tau) - 744$. The tensor-product rule $R_{\Pi} \otimes R_{22}$ is the Reshetikhin–Turaev 1991 Proposition 1.5 rule on quasi-triangular quasi-Hopf algebras. The associator product is the pentagon for $\otimes$ (Drinfeld 1989 §3.3, transported to the BKM setting by Etingof–Kazhdan 2007 Part V). Quasi-isomorphism of μ follows because both sides have the same $\Pi_{2,2}$ -lattice Heisenberg free-field content at rank 1 Lorentzian $\times$ rank 1 Lorentzian, with the only non-trivial gauge ambiguity in the Drinfeld associator factor, and that ambiguity is absorbed into the $\mathbb{Z}/8$ Bruinier Chern class which vanishes on the unimodular $\Pi_{2,2}$ domain (Bruinier 2002 §5.1, applied at discriminant 1). $\square$

Remark 30.9.5 (*From rank-2 BKM at $\Pi_{1,1}$ to rank-4 BKM at $\Pi_{2,2}$*). The instance witnesses that lattice direct sum on the input side is not merely set-theoretic doubling: it is a functorial operadic composition, compatible with the universal R -matrix tensor product and the coproduct factorisation on the output side. The rank-4 BKM algebra $\mathbf{H}_{\text{Monster}} \otimes \mathbf{H}_{\text{Monster}}$ is not a new object – it is forced by the operadic structure of Ψ together with Borcherds 1998 §14 Künneth. In particular, the test case shows that Ψ respects composition (functoriality on morphisms) and parallel composition (tensor of objects); this is what elevates Ψ from “a rule” to “a functor of operads”.

E_n -structure: $E_2 \rightarrow E_1$ Dunn stabilisation

THEOREM 30.9.6 (*Ψ is an $E_2 \rightarrow E_1$ Dunn stabilisation*). As a functor of symmetric monoidal $(\infty, 1)$ -categories:

- (i) $(\mathrm{CY}_2^{\mathrm{Siegel-aut}}, \oplus)$ carries a natural E_2 -structure: the lattice direct-sum pairing $\oplus$ and the Jacobi-form exterior tensor product $\boxtimes$ commute by Fubini, giving by Dunn additivity $E_1 \otimes_{\mathrm{BV}} E_1 \simeq E_2$ (Dunn 1988 Theorem 3.4; Lurie HA 5.1.2.2).
- (ii) $(\mathrm{QHopf}^{\mathrm{BKM}}, \otimes)$ carries a natural E_1 -structure: the algebra tensor product $\otimes$ is a single associative pairing on the $(\infty, 1)$ -category of A_∞ -quasi-Hopf super-algebras; iteration does not produce a second commuting pairing (the coproduct does not give a monoidal structure on QHopf – it is an *internal* structure on each object).
- (iii) Ψ is $E_2 \rightarrow E_1$ Dunn-stable: the E_2 -structure on the domain projects onto the E_1 -structure on the codomain by forgetting one of the two commuting pairings (the Jacobi-form $\boxtimes$ is absorbed into the quasi-Hopf coproduct structure internal to the BKM output).

Proof sketch. Clause (i) is Dunn additivity at the monoidal-category level: when a symmetric monoidal category carries two compatible pairings that commute up to canonical isomorphism, Dunn’s theorem (Dunn 1988 Theorem 3.4; Lurie HA 5.1.2.2) identifies the iterated structure with E_2 . Clause (ii) is the standard observation that the $(\infty, 1)$ -category of associative algebras (equivalently: E_1 -algebras) carries only an E_1 -structure, not an E_2 -structure, because the Eckmann–Hilton argument would then collapse the algebra to commutative (Lurie HA 5.1.2.9: E_{n+1} -algebras in E_m -categories are E_{n+m} -algebras; for H itself to support a second pairing compatible with its multiplication would force H commutative, contradicting non-abelian BKM). Clause (iii) is the Dunn-stabilisation compatibility: the forgetful functor from E_2 -algebras to E_1 -algebras remembers only one pairing, and the preservation of that forgetful on Ψ is exactly the lax symmetric-monoidal structure from Theorem 30.9.3 (the map μ is the natural $E_2 \rightarrow E_1$ rigidification witness). $\square$

Reshetikhin–Turaev compatibility: disjoint union = multiplicative

COROLLARY 30.9.7 (*Reshetikhin–Turaev multiplicativity for Ψ*). For a disjoint union of chiral sites $\Sigma = \Sigma_1 \sqcup \Sigma_2$ hosting Borchers data (L_1, ϕ_1) on Σ_1 and (L_2, ϕ_2) on Σ_2 , the quantum invariant $Z_\Psi(\Sigma) := Z_{\mathrm{RT}}(\Sigma; \Psi(L, \phi))$ with $(L, \phi) = (L_1, \phi_1) \oplus (L_2, \phi_2)$ factorises multiplicatively:

$$Z_\Psi(\Sigma_1 \sqcup \Sigma_2) = Z_\Psi(\Sigma_1) \cdot Z_\Psi(\Sigma_2).$$

Equivalently, Ψ followed by the Reshetikhin–Turaev functor $Z_{\mathrm{RT}} : \mathrm{QHopf}^{\mathrm{BKM}} \rightarrow \mathrm{TQFT}_3$ (Reshetikhin–Turaev 1991, Turaev 1994) is a symmetric monoidal functor from $(\mathrm{CY}_2^{\mathrm{Siegel-aut}}, \oplus)$ into the symmetric monoidal category of 3-TQFTs with disjoint-union pairing.

Proof. Z_{RT} is symmetric monoidal (Turaev 1994 Theorem III.4.5: the Reshetikhin–Turaev invariant of a disjoint union is the product of the invariants). The composite $Z_{\mathrm{RT}} \circ \Psi$ sends $\oplus$ to $\otimes$ (via Ψ) and then $\otimes$ to $\cdot$ (via Z_{RT}), giving multiplicativity on disjoint unions. The coherence (associativity, unit, symmetry) follows from composing the lax symmetric-monoidal structure on Ψ from Theorem 30.9.3 with the strict symmetric monoidal structure on Z_{RT} (Turaev 1994 Theorem III.4.6). $\square$

Remark 30.9.8 (The four pillars of the Ψ operadic upgrade). The operadic upgrade of Ψ rests on four citations that together form a proof skeleton: Borchers 1998 §14 (Künneth for singular theta correspondence on lattice direct sums), Dunn 1988 Theorem 3.4 (additivity of E_n under Boardman–Vogt tensor product), Reshetikhin–Turaev 1991 Proposition 1.5 (tensor-product rule for quasi-triangular quasi-Hopf algebras), and Lurie HA 5.3.2.1 (coherence of lax monoidal functors in symmetric monoidal $(\infty, 1)$ -categories). The four pillars are independent and each is a primary citation in its respective area;

together they give $\Psi : (\text{CY}_2^{\text{Siegel-aut}}, \oplus) \rightarrow (\text{QHopf}^{\text{BKM}}, \otimes)$ as a genuine functor of operads, not merely as a rule on objects. Cross-reference: Vol II Chapter on factorization algebras (Costello–Gwilliam framework), where the chiral-side counterpart of Ψ – the factorization functor on disjoint chiral sites – is constructed directly on E_2 -chiral algebras.

30.10 THE 5D HOLOMORPHIC CHERN–SIMONS REALISATION OF THE UNIVERSAL TRACE

The universal Φ -trace identity of Theorem 30.1.1 admits a direct chain-level BV realisation on local hCS charts, and on compact CY_3 branches only after the hCS-to-Stage-1 comparison datum has been supplied. The local model is the partition-function pairing of 5d holomorphic Chern–Simons theory on $Y = \mathbb{R}_t \times \mathbb{C}^2$ with gauge algebra $\mathfrak{g}$. This section records the realisation with explicit BV field content, propagator, Feynman-graph expansion, one-loop anomaly split, and formal all-orders quantisation; it traces the universal trace through the BV-cohomological pairing that Costello–Yagi (arXiv:1810.01970, [29]) and Costello (arXiv:1303.2632, [27]) establish for simply-laced $\mathfrak{g}$. The 3d topological Chern–Simons companion of Costello–Francis–Gwilliam (2026, [246]) is the Wick-rotated topological boundary of this construction; the $\mathbb{R}_t$ -direction of 5d hCS is the CFG 2026 topological factor, and the $\mathbb{C}^2$ -direction is its holomorphic enhancement.

The BV field content

Definition 30.10.1 (Off-shell BV field content of 5d hCS). Let $\mathfrak{g}$ be a finite-dimensional complex Lie algebra with non-degenerate invariant pairing $\text{tr}_{\mathfrak{g}}$. The off-shell BV field content of 5d holomorphic Chern–Simons on $Y = \mathbb{R}_t \times \mathbb{C}^2$ with gauge $\mathfrak{g}$ is the graded vector space

$$\text{Fields}_{\text{BV}}(Y, \mathfrak{g}) = \Omega^{0,\bullet}(\mathbb{C}^2) \otimes \Omega^{\bullet}(\mathbb{R}_t) \otimes \mathfrak{g}[1],$$

with BV differential $Q_{\text{BV}} = d_t + \tilde{\partial}_{\mathbb{C}^2} + \text{ad}_{\mathcal{A}}$ and BV antibracket of degree -1

$$\{-, -\}_{\text{BV}}(\alpha, \beta) = \int_Y \text{tr}_{\mathfrak{g}}(\alpha \wedge \beta) \wedge \Omega_{\mathbb{C}^2},$$

paired against the flat holomorphic top-form $\Omega_{\mathbb{C}^2} = dz^1 \wedge dz^2$. The classical action is

$$S_{5\text{d hCS}}[\mathcal{A}] = \int_Y \text{tr}_{\mathfrak{g}} \left(\frac{1}{2} \mathcal{A} \wedge (\tilde{\partial}_{\mathbb{C}^2} + d_t) \mathcal{A} + \frac{1}{6} \mathcal{A} \wedge [\mathcal{A}, \mathcal{A}] \right) \Omega_{\mathbb{C}^2} \quad (30.1)$$

with $\mathcal{A}$ the superfield running over $\text{Fields}_{\text{BV}}(Y, \mathfrak{g})$. The classical master equation $\{S, S\}_{\text{BV}} = 0$ holds by the Jacobi identity on $\mathfrak{g}$ and the Bianchi identity $\tilde{\partial}^2 = 0$.

PROPOSITION 30.10.2 (Stage-1 realisation at $\mathfrak{g} = \widehat{\mathfrak{gl}}_1$). For $\mathfrak{g} = \widehat{\mathfrak{gl}}_1$, the chain-level Stage-1 output $\Phi_3^{\text{FA}}(\text{Perf}(\mathbb{C}^3))$ coincides, up to quasi-isomorphism of E_3 -factorisation algebras, with the BV observables of 5d hCS on $\mathbb{R}_t \times \mathbb{C}^2$ with gauge $\widehat{\mathfrak{gl}}_1$, Wick-rotated to the topological limit on $\mathbb{R}_t$:

$$\Phi_3^{\text{FA}}(\text{Perf}(\mathbb{C}^3)) \simeq \text{Obs}_{5\text{d hCS}}^{\text{BV}}(\mathbb{R}_t \times \mathbb{C}^2; \widehat{\mathfrak{gl}}_1) \otimes_{\widehat{\mathfrak{gl}}_1} \text{End}(\mathcal{F}_{\text{Fock}}).$$

Attribution. The proof is the combination of three primary inputs. (i) The Costello–Gwilliam holomorphic-topological tensor theorem ([30] vol. 2 §4.10) gives the factorisation $\text{Obs}_{5\text{d hCS}}^{\text{BV}}(\mathbb{R}_t \times \mathbb{C}^2, \mathfrak{g}) \simeq \text{Obs}_{\text{id top}}^{\text{BV}}(\mathbb{R}_t, \mathfrak{g}[1]) \boxtimes \text{Obs}_{4\text{d hol}}^{\text{BV}}(\mathbb{C}^2, \mathfrak{g})$. (ii) The holomorphic factor is the Costello–Li

4d hCS factorisation algebra ([146]), whose E_4 -structure on $\text{Obs}_{4\text{d hol}}^{\text{BV}}(\mathbb{C}^2, \mathfrak{g})$ is assembled by Kontsevich E_d -formality [155] and Tamarkin deformation-quantisation [162]. (iii) At $\mathfrak{g} = \widehat{\mathfrak{gl}}_1$ the Costello–Li 4d hCS factorisation algebra is the polyvector-field Lie-conformal-algebra envelope of $\text{HH}^\bullet(\text{Perf}(\mathbb{C}^3)) \cong \bigoplus_{p+q=\bullet} H^q(\mathbb{C}^3, \wedge^p T_{\mathbb{C}^3})$ which is precisely the Stage-I output $\Phi_3^{\text{FA}}(\text{Perf}(\mathbb{C}^3))$ after Serre-duality restriction. The compactification on $\mathbb{R}_t$ corresponds to factorisation homology along the topological direction and supplies the E_1 -structure consistent with Dunn–Lurie additivity $E_4 \otimes E_1 \simeq E_5$ and its S^2 -framing reduction to E_3 (Lurie HA 5.1.2.2; Costello–Li [146] holomorphic-topological twist). See Proposition 5.1.51 of Chapter 5 for the chain-level derivation. $\square$

The heat-kernel propagator

PROPOSITION 30.10.3 (*Heat-kernel regularised propagator*). The Costello–Li heat-kernel propagator on the $\mathbb{C}^2$ -factor is

$$P_{\epsilon, L}^{\mathbb{C}^2} = \int_{\epsilon}^L e^{-t \square_{\mathbb{C}^2}} \bar{\partial}^* dt, \quad \square_{\mathbb{C}^2} = \bar{\partial} \bar{\partial}^* + \bar{\partial}^* \bar{\partial},$$

with analytic continuation $P = \lim_{\epsilon \rightarrow 0^+} \lim_{L \rightarrow \infty} P_{\epsilon, L} = \bar{\partial}^* / \square_{\mathbb{C}^2}$. The full 5d hCS propagator on $Y = \mathbb{R}_t \times \mathbb{C}^2$ is the tensor product

$$P_{5\text{d hCS}}(t_1, z_1; t_2, z_2) = \Theta(t_2 - t_1) \cdot \text{BM}(z_1, z_2), \quad (30.2)$$

where Θ is the Heaviside step kernel on $\mathbb{R}_t$ and BM is the Bochner–Martinelli kernel on $\mathbb{C}^2$. Differences $P_{\epsilon, L} - P_{\epsilon', L'}$ are exact for the BV differential; the BV cohomology of the observables is independent of the scheme (Costello–Gwilliam [30] vol. 1 §9.3; Costello–Li [145] Proposition 2.4).

The Feynman-graph expansion

THEOREM 30.10.4 (*Chain-level Feynman expansion of the universal trace on a witnessed hCS chart*). On a local 5d hCS chart, and on a compact CY_3 branch only after a comparison map from hCS observables to the Stage-I centre has been fixed, the universal trace of Theorem 30.1.1 admits the chain-level Feynman-graph expansion

$$\text{tr}_{\mathfrak{Z}(\mathcal{A}_X)}(\mathfrak{R}_{\mathcal{A}_X}) = \sum_{\Gamma \in \text{Graphs}} \frac{\hbar^{L(\Gamma)}}{|\text{Aut}(\Gamma)|} W_{\Gamma}(P_{5\text{d hCS}}, S_{5\text{d hCS}}) I_{\Gamma}(\mathfrak{g}) \text{Ch}_{\Gamma}(\mathfrak{R}),$$

where the sum runs over connected trivalent Feynman graphs Γ with loop order $L(\Gamma)$; the Kontsevich weight $W_{\Gamma}(P, S) = \int_{\text{Conf}(\Gamma, Y)} \prod_{e \in E(\Gamma)} P_e(x_{s(e)}, x_{t(e)})$ is the configuration-space integral of the propagator (30.2) over the configuration space of graph-vertices in Y ; the gauge-invariant $I_{\Gamma}(\mathfrak{g}) = \sum_{\{a_e\}} \prod_{v \in V(\Gamma)} f^{a_1 a_2 a_3}$ contracts the Lie-algebra structure constants along Γ ; and $\text{Ch}_{\Gamma}(\mathfrak{R})$ is the Chern character of the Koszul involution restricted to Γ .

Proof. The BV partition function $e^{S/\hbar}$ admits the Feynman-graph expansion by Costello–Gwilliam [30] vol. 1 §9 (the perturbative BV formalism and its heat-kernel regularisation). After the protected physical comparison datum is supplied, the identification of the partition function with the universal trace is the chain-level realisation of the Chiral Hochschild Trinity Theorem (Vol II [97]): the factorisation-homology output $\mathfrak{Z}(\mathcal{A}) = \int_{S^1 \times \text{Ran}(X)} \mathcal{A}$ is computed by the BV partition function of 5d hCS on the corresponding spacetime, with the S^1 -direction identified with the $\mathbb{R}_t$ -direction after compactification and the $\text{Ran}(X)$ -direction identified with the chiral observables on the $\mathbb{C}^2$ -factor (Lurie HA 5.5.3.11:

factorisation homology of tensor-product factorisation algebras is the tensor product of factorisation homologies). The Koszul involution $\mathfrak{R}_{\mathcal{A}} : \mathcal{A} \mapsto \mathcal{A}^!$ acts on the BV field content by $\mathcal{A} \mapsto -\mathcal{A}^!$ (Verdier duality pairing); its Chern character decomposes along the graph expansion into per-graph contributions. The one-loop correction $W_{L=1}[P, S]$ reduces to the wheel-diagram sum by Costello–Yagi [29] Theorem 4.1. $\square$

The one-loop anomaly: cubic vs. quadratic Casimir split

PROPOSITION 30.10.5 (*Cubic vs. quadratic Casimir split of the one-loop anomaly*). The one-loop anomaly of the BV partition function of (30.1) splits into two contributions of distinct physical character:

- **Scheme-dependent field renormalisation.** The quadratic Casimir contribution $\mathcal{A}_{\text{w.f.}} = -C_2(\mathfrak{g})/(2\pi)^3$, with $C_2(\mathfrak{g}) = 2h^\vee$ the dual Coxeter number, arises from the propagator self-loop at a single vertex. This term is BV-trivial: it is absorbed into the Costello–Li heat-kernel regularisation counter-term by adjusting the field normalisation of the gauge field. It does not obstruct quantisation.
- **Cohomological true anomaly.** The cubic Casimir contribution $\mathcal{A}_{\text{anom}} = d^{abc}d^{abc}/(2\pi)^3$, with $d^{abc} = \text{str}_{\mathfrak{g}}(T^a T^b T^c + T^a T^c T^b)$ the totally-symmetric rank-3 Casimir, arises from the trivalent wheel diagram W_{wheel_3} . This term is cohomologically non-trivial in the BV complex in general; its vanishing is the gauge-anomaly-freedom condition.

For simply-laced $\mathfrak{g}$ (the ADE series) the cyclic-trace identity $\text{tr}(T^a T^b T^c + T^a T^c T^b) = 0$ forces $d^{abc} = 0$, so $\mathcal{A}_{\text{anom}} = 0$ and the BV quantisation is unobstructed. For $\mathfrak{sl}_{N \geq 3}$ non-abelian the d^{abc} is non-vanishing; the theory is obstructed and requires flavour-symmetry cancellation. For $\widehat{\mathfrak{gl}}_1$ abelian the $d^{abc} = 0$ tautologically; the theory is unobstructed.

Proof. The one-loop wheel diagram W_{wheel_3} has three vertices connected pairwise by three propagators. On the $\mathbb{C}^2$ -factor of Y , each propagator contributes the Bochner–Martinelli kernel; on the $\mathbb{R}_t$ -factor, Θ -ordered kernels. The Kontsevich-weight integral of W_{wheel_3} over the configuration space of three vertices on Y evaluates to $1/(2\pi)^3$ by the standard Bochner–Martinelli integral over $\text{Conf}_3(\mathbb{C}^2) \times \text{Conf}_3(\mathbb{R}_t)/\text{Aut}(\text{wheel}_3)$. The Lie-algebra invariant at W_{wheel_3} is $d^{abc}d^{abc}$, the totally-symmetric rank-3 Casimir squared. This is the cohomologically true anomaly of Costello–Yagi [29] Theorem 4.1. The propagator self-loop at a single vertex is a scheme-dependent logarithmic divergence absorbed by Costello–Li [145] heat-kernel counterterm, contributing $-C_2(\mathfrak{g})/(2\pi)^3$ to the field renormalisation, which is BV-trivial. $\square$

All-orders formal quantisation for simply-laced $\mathfrak{g}$

THEOREM 30.10.6 (*Costello–Yagi all-orders formal quantisation: simply-laced Yangian VOA*). For $\mathfrak{g}$ simply-laced bosonic (A_n, D_n, E_6, E_7, E_8), the BV partition function of $\mathfrak{g}$ hCS on $\mathbb{R}_t \times \mathbb{C}^2$ quantises to all orders as a formal perturbative series in $\hbar$:

$$\langle e^{S/\hbar} \rangle_{\text{BV}} \in \mathbb{C}[[\hbar]], \quad \langle e^{S/\hbar} \rangle_{\text{BV}} = \sum_{n \geq 0} \hbar^n Z_{\mathfrak{g} \text{ hCS}}^{(n)}(\mathfrak{g}),$$

with coefficients defined by the renormalised BV Feynman rules. On the Costello–Yagi simply-laced locus, factorisation homology along the topological direction $\mathbb{R}_t$ gives the Yangian vertex operator algebra:

$$\int_{\mathbb{R}_t} \text{Obs}_{\mathfrak{g} \text{ hCS}}^{\text{BV}}(\mathbb{R}_t \times \mathbb{C}^2, \mathfrak{g}) \simeq Y^{\text{VOA}}(\mathfrak{g}).$$

No analytic convergence bound and no compact CY_3 hCS–Hall comparison is asserted by this local formal quantisation theorem.

Attribution. This is Costello–Yagi [29] Theorem 4.1 in its perturbative BV sense. The chain-level Feynman-graph expansion of Theorem 30.10.4 is the formal series in question. The identification with $Y^{\text{VOA}}(\mathfrak{g})$ is the content of Theorem 5.1.53 of Chapter 5. $\square$

CFG 2026 topological compactification

Remark 30.10.7 (CFG 2026 as the topological boundary of 5d hCS). The Costello–Francis–Gwilliam 2026 [246] E_3 -factorisation-algebra presentation of 3d ordinary Chern–Simons observables on $\mathbb{R}^3$ is the topological boundary of the 5d hCS construction above: compactify the $\mathbb{C}^2$ -factor of $Y = \mathbb{R}_t \times \mathbb{C}^2$ on an S^2 -fibred two-sphere and take the Wick-rotated topological limit. On the Costello–Li [146] holomorphic-topological twist side, this compactification produces the ordinary topological CS observable algebra on $\mathbb{R}^3$; on the BV partition-function side, it produces the CFG 2026 factorisation-algebra presentation. The $\mathbb{R}_t$ -factor of the present construction becomes one of the three $\mathbb{R}$ -factors of CFG 2026 $\mathbb{R}^3$; the remaining two arise from the topologically-twisted $\mathbb{C}^2$ -factor.

Conversely, the 5d hCS construction is the holomorphic enhancement of CFG 2026: along the $\mathbb{C}^2$ -direction the observable algebra carries a holomorphic E_2 -structure from Kontsevich formality [155], refining the topological E_3 -structure of CFG 2026 by an additional holomorphic degree-0 layer. Both algebraic structures survive under $\mathbb{R}_t$ -compactification: the E_3 -structure becomes the E_2 -structure on $Y^{\text{VOA}}(\mathfrak{g})$ along $\mathbb{C}^2$, and the E_1 -structure becomes the vertex-algebra OPE at a point on $\mathbb{C}^2$.

With the compact comparison datum fixed, the Universal Φ -Trace Identity viewed through the 5d hCS / CFG 2026 correspondence compares the BV supertrace of the Koszul involution $\mathfrak{R}_{\mathcal{A}}$ on the Yangian VOA $Y^{\text{VOA}}(\mathfrak{g})$ with the Borchers-lift residue at the Heegner locus of the Siegel-modular Fourier coefficient $c_{\Lambda}(\mathbf{o})/2 = \kappa_{\text{BKM}}(\mathfrak{g}_{\Lambda})$. The CFG/Dunn boundary identifies the target of the comparison; it does not by itself construct the compact Φ_3 output or the hCS–Hall map.

Borchers side from the 5d hCS partition function

THEOREM 30.10.8 (Borchers-lift residue at the Heegner locus of $K_3 \times E$). Assume the witnessed framed $K_3 \times E$ branch, the finite Hall–Borchers recognition gates, the Heegner comparison, and the comparison map from the compactified 5d hCS BV partition function to the Borchers singular-theta lift. Then the Borchers-side supertrace of Theorem 30.1.1 at $X = K_3 \times E$ is the residue at the rank-1 isotropic vector $v \in \Lambda^*$ of the Mukai lattice $\Lambda = \Lambda_{K_3} \oplus \Pi_{1,1}$:

$$\text{tr}_3(\mathcal{A}_{K_3 \times E})(\mathfrak{B}_{K_3 \times E}) = \text{Res}_{v \cdot v = 0} \langle e^{S/\hbar} \rangle_{\text{BV}, \mathcal{A}|_{C_v}} = c_1(\mathbf{o})/2 = 5,$$

with $C_v \subset \mathbb{C}^2$ the curve associated to v , $c_1(\mathbf{o}) = 10$ the Fourier coefficient of the weight-0, index-1 weak Jacobi form $\phi_{0,1}$ at $(m, n) = (\mathbf{o}, \mathbf{o})$, and the residue evaluated at the standard Borchers singular-theta lift of the BV partition function.

Attribution. Clause (ii) of Theorem 30.1.1 together with Borchers [113] Theorem 10.1 and Gritsenko–Nikulin [209] Theorem 2.1 give the residue formula. With the comparison map fixed, compactification of the BV partition function along the Narain $\Pi_{3,19}$ fibre and the singular-theta lift compute the Gritsenko Δ_5 automorphic form of weight 5 on $\text{Sp}_4(\mathbb{Z})$. The Fourier coefficient $c_1(\mathbf{o}) = 10$ and the weight 5 = $c_1(\mathbf{o})/2$ are the content of the universal Borchers weight identity $\kappa_{\text{BKM}}(\Phi_N) = c_N(\mathbf{o})/2$ at $N = 1$. The theorem uses the compact comparison datum, finite recognition gates, and Heegner normalisation

as hypotheses; they are not supplied by the local all-orders hCS quantisation theorem. Cross-reference: Chapter `cy_d_kappa_stratification`, Theorem 32.8.1. $\square$

Local CY- A_3 evidence from the 5d hCS anomaly cancellation at $\widehat{\mathfrak{gl}}_1$

COROLLARY 30.10.9 (*Abelian anomaly cancellation as local evidence for CY- A_3*). On the abelian toric chart $\mathfrak{g} = \widehat{\mathfrak{gl}}_1$, the vanishing of the cohomological true anomaly A_{anom} of Proposition 30.10.5 for $\mathfrak{g} = \widehat{\mathfrak{gl}}_1$, combined with the all-orders formal quantisation of Theorem 30.10.6, supplies a local hCS consistency check for the framed CY- A_3 construction. It proves the abelian/toric obstruction vanishing on that chart; the global existence-and- E_1 -rigidity statement of Theorem 5.0.9 of Chapter 5 has additional non-formal chain-level obligations.

Attribution. At $\mathfrak{g} = \widehat{\mathfrak{gl}}_1$ the rank-3 Casimir is trivially zero (the Lie algebra is abelian, so all brackets vanish). The one-loop anomaly A_{anom} is therefore zero by Proposition 30.10.5. The all-orders formal cancellation proceeds by Kontsevich formality on the holomorphic $\mathbb{C}^2$ -factor: the E_2 -graph complex on $\mathbb{C}^2$ is acyclic in positive loop order for abelian $\mathfrak{g}$, forcing all higher-loop obstructions to be cohomologically trivial in BV. This proves the local abelian obstruction calculation. Passing from that calculation to global CY- A_3 requires the framed factorisation-algebra witnesses and non-formal CY₃ descent data supplied elsewhere in Chapter 5; it is not a consequence of the abelian anomaly computation alone. $\square$

Remark 30.10.10 (Compact CY₃ S^3 -framing closure). The raw termwise pair-contraction operator is not Costello's corrected TCFT operator:

$$B_{\text{term}}^{(2)} \neq B_{\text{TCFT}}^{(2)} \quad \text{as chain-level data unless a comparison homotopy is supplied.}$$

On a non-formal cyclic A_∞ model the strict witness is

$$[m_3, B_{\text{term}}^{(2)}] [a|a|a|b] = 2\alpha [b] \neq 0.$$

Thus the raw obstruction Obs_{A_∞} is not killed by naive cancellation. Dunn additivity, Goodwillie towers, topological S^3 -framing vanishing, and Čech descent identify obstruction targets and comparison maps; none of them alone gives a universal compact CY₃ vanishing $\text{HH}_{E_1}^{-2}(A, A) = 0$, a contractible lifting space, or a compact Φ_3 output. A compact CY₃ closure must supply either a corrected TCFT comparison with $\{b, B_{\text{TCFT}}^{(2)}\} = 0$ and a map to the Stage-1 obstruction complex, or a complete, exhaustive, separated, strongly convergent E_1 -Hochschild filtration whose total-degree -2 line is empty. Hall/CoHA realisation, PBW, and no-extra-relations statements are further data, not consequences of this obstruction calculation.

The open K_3 Yangian at all orders

Remark 30.10.11 (K_3 Yangian at all orders: orthogonal envelope $Y_{\hbar}(\mathfrak{so}(4, 20))$ and its Hodge-parity $\mathbb{Z}/2$ -super-extension). For a $\mathbb{Z}/2$ -graded Lie algebra $\mathfrak{g} = \mathfrak{g}_0 \oplus \mathfrak{g}_1$, the graded Casimir d^{abc} need not vanish; only the $\mathfrak{gl}(1|1)$ case is verified to vanish at one loop. The BV partition function of 5d hCS with gauge Lie algebra the orthogonal Mukai-preserving $\mathfrak{so}(4, 20)$ (Kac type D_{12}), or its programme-specific Hodge-parity $\mathbb{Z}/2$ -super-extension $\mathfrak{so}(4 | 20)$ with $V_+ = \mathbb{C}^4$ and $V_- = \mathbb{C}^{20}$ both carrying symmetric forms restricted from the Mukai pairing, is the conjectural all-orders K_3 Yangian $Y_{\hbar}^{\text{VOA}}(\mathfrak{so}(4, 20))$ (respectively $Y_{\hbar}^{\text{VOA}}(\mathfrak{so}(4 | 20))$ at the Hodge-parity-extended level). Kac $\mathfrak{osp}(4 | 20)$ is *not* the gauge algebra: its defining form is symplectic on the 20-dimensional odd part, incompatible with the symmetric Mukai pairing. The all-orders quantisation is open: it requires the Kontsevich formality of Ginzburg–Schedler [82]

extended to E_4 , which is conjectural. The Hodge involution $\theta : H^*(K_3; \mathbb{Z}) \rightarrow H^*(K_3; \mathbb{Z})$ decomposes $\tilde{H}(K_3)$ into $V_+ = H^0 \oplus H^4 \oplus (H^{2,0} \oplus H^{0,2})_{\mathbb{R}}$ of dimension 4 and $V_- = H_{\text{prim}}^{1,1}$ of dimension 20; the signature (4, 20) is the Hodge signature of the Mukai pairing. See Chapter 18 for the $\mathfrak{so}(4, 20)$ -versus-Kac–Moody $\mathfrak{osp}(4 | 20)$ trichotomy.

Finite Rees hCS–Hall layer

The 5d hCS realisation above supplies a chain-level source: the BV complex, heat-kernel propagator, Feynman expansion, and anomaly slot are explicit. The Hall target enters through a different construction. Between the two sits a finite Rees layer; without it the phrase “hCS–Hall comparison” has no typed target.

Definition 30.10.12 (Finite Rees hCS–Hall layer). Fix a smooth CY_3 X , a DWR-good cover $\mathfrak{U}$, finite holomorphic-jet order N , finite renormalisation order r , finite Hall charge bound L , and finite Ran arity m . A finite Rees hCS–Hall layer is a DWR/Ran cyclic critical atlas

$$\{(V_\sigma, W_\sigma, \omega_\sigma, o_\sigma, s_\sigma, t_\sigma, \theta_\sigma^{\text{rel}})\}_{\sigma \in \mathbb{N}_{\leq m}^{\text{Ran}}(\mathfrak{U}; \Gamma_{\leq L})}$$

as in Definition 6.1.20, together with the Maurer–Cartan element

$$\Theta_{\text{hCS} \rightarrow \text{Hall}}^{\text{Rees, or}, N, r, L, m} \in \text{MC}(\mathfrak{M}_{\text{hCS, Hall}}^{N, r, L, m})$$

of Theorem 6.1.22. It is the finite morphism

$$\text{Obs}_{\text{hCS}}^{q, \leq r, \leq N}(-)_{\leq L} \longrightarrow \text{Hall}_{\text{crit}}^{\text{Rees, or}, \leq N, \leq L}(-).$$

The completed Rees comparison is obtained only after compatibility under

$$N + 1 \rightarrow N, \quad r + 1 \rightarrow r, \quad \Gamma_{\leq L+1} \rightarrow \Gamma_{\leq L}, \quad \mathbb{N}_{\leq m+1}^{\text{Ran}} \rightarrow \mathbb{N}_{\leq m}^{\text{Ran}}$$

and the Mittag–Leffler condition killing the resulting $\varprojlim^1$ class. The realised critical-CoHA comparison is a further composite with a monoidal, orientation-preserving vanishing-cycle realisation functor

$$\text{R}_{\text{vc}} : \text{Hall}_{\text{crit}}^{\text{Rees, or}, \wedge}(-) \longrightarrow \text{CoHA}_{\text{crit}}^{\text{or}, \wedge}(-).$$

PROPOSITION 30.10.13 (*Finite Rees maps are not compact CoHA, double, or $\mathcal{W}_{1+\infty}$*). A finite Rees hCS–Hall layer determines neither a realised compact critical CoHA, nor a completed Hall–Drinfeld double, nor a $\mathcal{W}_{1+\infty}$ vertex algebra. The implications are exactly

$$\text{Obs}_{\text{hCS}}^{q, \leq r, \leq N} \xrightarrow{\Theta_{\text{hCS}, N, r, L, m}^{\text{Rees, or}, N, r, L, m}} \text{Hall}_{\text{crit}}^{\text{Rees, or}, \leq N, \leq L} \xleftarrow{\lim} \text{Hall}_{\text{crit}}^{\text{Rees, or}, \wedge} \xrightarrow{\text{R}_{\text{vc}}} \text{CoHA}_{\text{crit}}^{\text{or}, \wedge} \xrightarrow{D_{\hbar}^{\wedge}} D_{\hbar}^{\wedge}(\text{CoHA}_{\text{crit}}^+).$$

The first arrow is finite and algebraic. The second requires pro-compatible primitive data. The third requires vanishing-cycle realisation compatible with Thom–Sebastiani, proper pushforward, lci pullback, equivariance, orientations, shifts, Tate twists, and completions. The fourth requires a negative half, a non-degenerate Hall pairing, a Hall coproduct, the Borchers–Serre kernel comparison, a centre computation, a PBW/integrality theorem, a no-extra-relations presentation, and a common pro-Borchers topology. A $\mathcal{W}_{1+\infty}$ statement begins only after Drinfeld doubling and Fock/evaluation.

Proof. Theorem 6.1.22 constructs the first arrow by integrating the relative cyclic critical atlas over finite DWR/Ran simplices. Its target is the Rees critical Hall complex, not Borel–Moore homology with vanishing cycles. Corollary 6.1.23 gives the next two arrows and names their extra hypotheses: transition compatibility, Mittag–Leffler, and the realisation functor R_{vc} . Proposition 33.8.21 states the same separation on $K_3 \times E$: the DWR/Ran atlas gives a curve-stalk positive half, a realised compact CoHA, and finite Rees local-to-compact maps, but no hCS–Hall morphism, no completed Drinfeld double, and no Hall-to-Borcherds isomorphism. The Hall–Drinfeld/Super–Yangian equivalence criterion, Theorem 19.7.8, lists the extra finite-height data needed for the double. Finally Proposition 12.5.5 gives the typed chain

$$\text{CoHA}(\mathbb{C}^3) = Y^+(\widehat{\mathfrak{gl}}_1) \hookrightarrow D(Y^+) \xrightarrow{\text{ev}_\lambda} \text{End}(\mathcal{W}_{1+\infty}[\lambda]\text{-vac}),$$

so the vertex algebra is not the finite Rees target and not the positive-half CoHA. $\square$

Remark 30.10.14 (Positive-geometry grammar at the 5d hCS locus). The local Hall side of the 5d hCS locus fits the positive-half grammar

$$Y^+(X) = H_{\text{eq}}^\bullet(\mathcal{M}_{\text{eff}}^+(X), \phi_W).$$

At $X = \mathbb{C}^3$, $\mathcal{M}_{\text{eff}}^+(\mathbb{C}^3) = \text{Hilb}^\bullet(\mathbb{C}^3)$ and $W = \text{tr}(x[y, z])$. Schiffmann–Vasserot identify the resulting CoHA with $Y^+(\widehat{\mathfrak{gl}}_1)$, the positive half of the affine Yangian. This is an associative Hall algebra. The braided or vertex-algebraic object lies after the double or centre passage.

The affine $\mathbb{C}^3$ boundary

PROPOSITION 30.10.15 (*$\mathbb{C}^3$ gives the positive half, not a Borcherds residue*). For $X = \mathbb{C}^3$ with abelian gauge algebra $\widehat{\mathfrak{gl}}_1$, the proved Hall-side output is

$$\text{CoHA}(\mathbb{C}^3) = Y^+(\widehat{\mathfrak{gl}}_1).$$

There is no Borcherds-weight object $\kappa_{\text{BKM}}^{\text{BV}}(\mathbb{C}^3)$ supplied by the singular-theta lift. In particular, $\mathbb{C}^3$ is not a formal $N = 0$ member of the CHL or Gritsenko–Clery Borcherds ladder.

Proof. The first assertion is Schiffmann–Vasserot’s theorem, in the form recorded in Proposition 12.5.5 and Proposition 6.2.1: the critical CoHA of the three-loop quiver model for $\mathbb{C}^3$ is the positive half of the affine Yangian. The finite hCS chart can map to the finite Rees Hall complex only after the chartwise comparison datum of Definition 30.10.12; the DWR/Ran descent gate does not turn this local positive half into a completed compact comparison.

The Borcherds side has a different domain. Borcherds’ singular-theta lift requires an even lattice of orthogonal type $(2, n)$ (equivalently the $(b^+, 2)$ convention used above after choosing the sign convention) and a Heegner divisor theory on the corresponding type-IV domain. The affine $\mathbb{C}^3$ chart has no compact Mukai lattice of this signature and no Heegner divisor carrying a denominator form. Thus the expression $\text{Res}_{v \cdot v=0} \langle e^{S/\hbar} \rangle$ has no Borcherds target on $\mathbb{C}^3$. Declaring an empty residue to be zero is only a convention after adjoining a zero object; it is not the formula $\kappa_{\text{BKM}} = c_N(o)/2$ on a new row. $\square$

Remark 30.10.16 (Three non-implications at the affine boundary). Three local facts remain useful and separate. First, the abelian $\widehat{\mathfrak{gl}}_1$ chart removes the Lie-algebraic anomaly term in the finite hCS calculation. Second, affineness removes higher Čech cohomology for the local observable sheaf. Third,

$\text{CoHA}(\mathbb{C}^3) = Y^+(\widehat{\mathfrak{gl}}_1)$ gives the Hall positive half. None of these facts constructs a compact hCS–Hall point, a Borchers residue, or a $\mathcal{W}_{1+\infty}$ algebra. The DWR/Ran boundary has three typed non-implications: a fixed $\mathbb{C}^3$ chart does not imply descent, Y^+ is Hall-side cohomology rather than an hCS–Hall map, and the $\mathcal{W}_{1+\infty}$ shadow is typed only after double/Fock evaluation.

Remark 30.10.17 (Δ_5 , Φ_{10}^{un} , and Φ_{12}). The compact $K_3 \times E$ row starts from the K_3 weak Jacobi form $\phi_{0,1}$. Its primitive Borchers denominator is Δ_5 , and

$$\kappa_{\text{BKM}}(\Delta_5) = c_1(o)/2 = 10/2 = 5.$$

If the input denominator is instead the unnormalised Igusa square $\Phi_{10}^{\text{un}} = \Delta_5^2$, the denominator weight is $\kappa_{\text{BKM}}(\Phi_{10}^{\text{un}}) = 10$; the value 5 belongs to the primitive square-root denominator Δ_5 . The reduced DT/OP theorem uses the OP-normalised square

$$\Phi_{10}^{\text{OP}} = D_5^2 = 4096^{-1} \Delta_5^2, \quad Z_{\text{DT}}^{\text{red}}(K_3 \times E) = -(\Phi_{10}^{\text{OP}})^{-1} = -D_5^{-2} = -4096 \Delta_5^{-2}.$$

The Fake-Monster form Φ_{12} has weight 12 on the $\Pi_{25,1}$ lattice row. Thus Δ_5 , Φ_{10}^{un} , and Φ_{12} are not three names for the same trace: they are the primitive denominator, its unnormalised Igusa character square, and a different Fake-Monster denominator.

THE SEVEN FACES OF $r_{CY}(z)$ FOR CALABI–YAU CHIRAL ALGEBRAS

The two-stage factorisation $\Phi_d = \mathrm{Sp}_{\Sigma_{d-1}, C}^{\mathrm{ch}} \circ \Phi_d^{\mathrm{FA}}$ produces, on constructed loci, an E_d -holomorphic factorization algebra $\Phi_d^{\mathrm{FA}}(C) \in E_d\text{-HolFA}(X)$ at stage 1, then specialises it to a chiral algebra A_C on a curve at stage 2. For $d \geq 4$ this is a conditional CY- A_d template until the holomorphic-twist, framing, and completion witnesses are constructed. The binary collision residue $r_{CY}(z) = \mathrm{Res}_{0,2}^{\mathrm{coll}}(\Theta_{CY})$ is an aspect of the stage-1 object $\Phi_d^{\mathrm{FA}}(C)$ where that object is constructed; its seven realizations in the CY setting are seven facets of that native object: as the CY bar-cobar twisting morphism, as a CoHA / perverse-coherent-sheaves shadow, as the classical CY Poisson coisson, as the Maulik–Okounkov R -matrix (for $K_3 \times E$), as the affine super Yangian $Y(\widehat{\mathfrak{gl}}_1)$ r -matrix (for toric CY_3), as the elliptic Sklyanin bracket (for toroidal CY), and as a Gaudin model arising from CY_3 collision residues. The on-curve $r(z)$ and the chiral algebra A_C are the stage-2 specialisation shadows read off from $\Phi_d^{\mathrm{FA}}(C)$ by $\mathrm{Sp}^{\mathrm{ch}}$ on the constructed locus.

Remark 31.0.1 (Two orthogonal sevens: arithmetic and algebraic). The seven r_{CY} faces catalogued in this chapter admit two orthogonal slicings of a single chosen stage-1 factorisation datum $\mathcal{F}_{K_3 \times E} := \Phi_3^{\mathrm{FA}}(D^b(K_3 \times E))$ on the framed $K_3 \times E$ locus. The *arithmetic seven*—Mukai lattice, Hodge supertrace, K_3 -fibre rank, BKM Borchers weight, Niemeier 23-twist family, Humbert boundary-monodromy, CHL twined $\mathbb{Z}/N\mathbb{Z}$ -family—stratifies into the three-tier hierarchy of the two-stage factorisation: tier (i) CY-datum intrinsics (Mukai lattice, Hodge supertrace); tier (ii) stage-1 invariants (K_3 -fibre rank $\kappa_{\mathrm{fiber}} = 24$); tier (iii) (Σ_2, C) -specialisations (BKM Igusa, Niemeier 23-twist, Humbert boundary-monodromy, CHL twined $\mathbb{Z}/N\mathbb{Z}$). The *algebraic seven*—bar-cobar, CoHA, coisson, Maulik–Okounkov, Yangian, Sklyanin, Gaudin—is a complementary slicing of the same $\mathcal{F}_{K_3 \times E}$ by language: operadic, derived, Poisson, quantum, classical-algebraic, elliptic, conformal-field-theoretic. One canonical object, two seven-fold decompositions.

Remark 31.0.2 (Only tier-(iii) faces are $\mathrm{Sp}^{\mathrm{ch}}$ -siblings). The two orthogonal sevens slice the same stage-1 datum $\mathcal{F}_{K_3 \times E}$ along different axes. On a chosen framed $d = 3$ locus, the two-stage factorisation reads $\Phi_3 = \mathrm{Sp}_{\Sigma_2, C}^{\mathrm{ch}} \circ \Phi_3^{\mathrm{FA}}$: tier-(iii) faces are the $\mathrm{Sp}^{\mathrm{ch}}$ -siblings, arising as distinct framed outputs of $\mathrm{Sp}_{\Sigma_2, C}^{\mathrm{ch}}$ applied to the single stage-1 object $\mathcal{F}_{K_3 \times E}$; tier-(i) and tier-(ii) faces are invariants upstream of any curve-specialisation. The arithmetic seven slices $\mathcal{F}_{K_3 \times E}$ by tier coordinates, the algebraic seven by language; they intersect along tier-(iii), where $\mathrm{Sp}^{\mathrm{ch}}$ -siblinghood is the common structural content.

Remark 31.0.3 (Three-tier stratification of the seven-face picture). The seven faces of this chapter stratify into three tiers, set by the two-stage factorisation $\Phi_d = \mathrm{Sp}_{\Sigma_{d-1}, C}^{\mathrm{ch}} \circ \Phi_d^{\mathrm{FA}}$. **Tier (i): CY-datum intrinsics.** Invariants read directly off (X, C, Ω_C) without consulting any factorisation structure: the Mukai lattice, the Hodge supertrace $\kappa_{\mathrm{ch}}^{\mathrm{Hodge}}(X) = \sum_q (-1)^q h^{0,q}(X)$, the holomorphic volume class $[\Omega_C]$.

Tier (ii): stage-1 invariants of $\Phi_d^{\text{FA}}(C)$. Properties of the canonical E_d -HolFA(X) object before any Sp^{ch} -specialisation: the native operadic level $n_{\text{native}}(d)$ of Proposition 5.1.3, the stage-1 Hochschild cohomology $\text{HH}^\bullet(C)$ viewed as the input surface of Φ_d^{FA} , the K_3 -fibre rank $\kappa_{\text{fiber}}(K_3 \times E) = 24$ (a Kodaira count of singular fibres of the elliptic K_3 underneath $\mathcal{F}_X$), and the universal trace Φ acting on $\text{HH}^\bullet(C)$.
Tier (iii): (Σ_{d-1}, C) -specialisations. The genuine siblings in the two-stage sense: outputs of distinct choices of $\text{Sp}_{\Sigma_{d-1}, C}^{\text{ch}}$ applied to one stage-1 object. On $K_3 \times E$ these include the BKM Igusa specialisation $(K_3, E) \mapsto \mathfrak{g}_{\Delta_5}$ with $\kappa_{\text{BKM}} = 5$; the Niemeier 23-twist family indexed by Conway–Norton root data; the Humbert boundary-monodromy limit at $H_t \cup H_4$; and the CHL twined $\mathbb{Z}/N$ family at $N \in \{1, 2, 3, 4, 6\}$ with universal Borcherds weight $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2$. Bare $r_{CY}(z)$ is an aspect of tier (ii); the $K_3 \times E$ package $\{0, 3, 5, 24\}$ sorts one value per tier (tier (i) $\kappa_{\text{cat}} = 0$ via Künneth and $\kappa_{\text{ch}}^{\text{Hodge}} = 0$; tier (ii) $\kappa_{\text{fiber}} = 24$ and $\kappa_{\text{ch}}^{\text{Heis}} = 3$; tier (iii) $\kappa_{\text{BKM}} = 5$). Only tier-(iii) faces are Sp^{ch} -siblings; the algebraic seven-presentation (Sections 31.2–31.8) is an orthogonal slicing by language, stratified further by the three-tier partition (Theorem 31.9.6).

Remark 31.0.4 (Two scopes for $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2$). The universal Borcherds weight identity $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2$ governs tier-(iii) specialisations on two domains of the CHL and Gritsenko–Cléry families, which must be distinguished wherever the formula is cited.

- (i) **CHL slice** $N \in \{1, 2, 3, 4, 6\}$ (paramodular weights 5, 4, 3, 2, 1): the CHL $\mathbb{Z}/N$ -twined Borcherds products on $K_3 \times E$, indexed by the five admissible Frame-shape classes of $\mathcal{M}_{24}$; the κ_{BKM} values are the weights of the Gritsenko–Nikulin lifts Φ_N .
- (ii) **Full 8-form Gritsenko–Cléry catalogue:** the eight diagonal-divisor rows are indexed by

$$(t, N; k) \in \{(1, 1; 5), (2, 1; 2), (1, 2; 3), (3, 1; 1), (1, 3; 2), (4, 1; \tfrac{1}{2}), (1, 4; \tfrac{3}{2}), (2, 2; 1)\}.$$

Their weight sequence is $(5, 2, 3, 1, 2, \tfrac{1}{2}, \tfrac{3}{2}, 1)$, with twice-weight coefficients $(10, 4, 6, 2, 4, 1, 3, 2)$. This is a third paramodular indexing distinct from the CHL-averaged five-row ladder and from the comparison tuple $(5, 2, 1, 1, \tfrac{1}{2}, 1, \tfrac{1}{4}, 0)$ that arises in row-map problems: the Gritsenko–Cléry catalogue is supported on the eight diagonal-divisor rows above, with half-integer minimum weight $\tfrac{1}{2}$. The identity $\kappa_{\text{BKM}} = \text{wt} = c_N(o)/2$ holds row by row once the triple-indexed Gritsenko–Cléry scope $(t, N; k)$ is fixed.

Two distinct paramodular families populate the CHL slice. *Family (i): CHL-averaged paramodular weights*, $\text{wt}(\Delta_1^{(N)}) = (5, 4, 3, 2, 1)$ via Gritsenko 1999 Thm. 1.2 (additive lift of the weight- $k(N)$ index-1 Jacobi input; the $(5, 4, 3, 2, 1)$ tuple cited in item (i) above). *Family (ii): twined Borcherds weights*, $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2 \in (5, 2, 1, 1, 1)$ with $(c_N(o)) = (10, 4, 2, 2, 2)$ via Gritsenko–Nikulin 1998 Thm. 2.1 (singular-theta Borcherds lift of the g_N -twined weight-0 Jacobi form $\phi_{o,1}^{(g_N)}$). The comparison tuple $(5, 2, 1, 1, \tfrac{1}{2}, 1, \tfrac{1}{4}, 0)$ belongs to a different row-map problem and is not the Gritsenko–Cléry catalogue without extra data. The two CHL families coincide at $N = 1$ (both give 5 on Δ_5) and diverge at $N \in \{2, 3, 4, 6\}$ because the Jacobi inputs differ. Every formula identifying κ_{BKM} with $c_N(o)/2$ cites the appropriate scope; the scope is always stated. See Chapter 19 for the CHL derivation and [96] (Theorem 32.8.1) for the full $\{1, \dots, 8\}$ enlargement.

31.1 THE CY_3 COLLISION RESIDUE

The collision residue is a single algebraic operation extracted from the universal Maurer–Cartan element Θ_A of a chiral algebra. In the CY setting, this operation acquires geometric meaning: the residue is

computed against the holomorphic CY volume form, and the resulting binary operation is the classical limit of the quantum vertex chiral group braiding.

Definition 31.1.1 (Binary collision residue, CY version). Let C be a smooth proper Calabi–Yau category of dimension d with holomorphic volume form Ω_C , and suppose the stage-1 object $\Phi_d^{\text{FA}}(C) \in E_d\text{-HolFA}(X)$ has been constructed on the chosen locus (Chapter 5, §5.1.1). Let A_C denote its stage-2 specialisation $\text{Sp}_{\Sigma_{d-1}, C}^{\text{ch}}(\Phi_d^{\text{FA}}(C))$, the chiral algebra on a curve C (Theorem CY-A₂ at $d = 2$; at $d = 3$ only after choosing the framed Φ_3 -specialisation datum of Theorem 5.11.1). Let $\Theta_{A_C} \in \text{MC}(\mathfrak{g}_{A_C}^{\text{mod}})$ denote its universal Maurer–Cartan element (cf. Vol I, Theorem 21.16). The *binary CY collision residue* is

$$r_{CY}(z) := \text{Res}_{0,2}^{\text{coll}}(\Theta_{A_C}) \in A_C \otimes A_C [[z^{-1}]],$$

the genus-0, degree-2 residue along the collision divisor of $\overline{C}_2(\text{Spec } \mathbb{C})$, paired against Ω_C in the CY direction.

Remark 31.1.2 (The CY direction is a separate slot). The collision residue extracts the z^{-1} part of Θ along the chiral curve direction. In the CY setting, Θ has *two* gradings: degree in the chiral direction (controlled by the curve X) and Hodge weight in the CY direction (controlled by O_C). The CY volume form Ω_C kills the Hodge weight by integration; what remains is a chiral binary operation valued in $A_C \otimes A_C$. This is the precise sense in which r_{CY} couples the two directions.

Remark 31.1.3 (Three invariants are distinct). For any chiral algebra A , the binary residue carries three *distinct* numerical invariants which the CY setting will illuminate:

- (i) $p_{\max}(A)$, the maximal pole order of generator-on-generator OPEs (cf. Vol I, Definition 30.10);
- (ii) $k_{\max}(A) = p_{\max}(A) - 1$, the collision depth of r_{CY} itself, after d log-absorption (cf. Vol I, Definition 30.10);
- (iii) $r_{\max}(A)$, the shadow depth, the degree at which the obstruction tower $\Theta_A^{\leq r}$ terminates (Vol I, Definition 30.10).

The $\beta\gamma$ system is the archetypal witness of their independence: $p_{\max}(\beta\gamma) = 1$, $k_{\max}(\beta\gamma) = 0$, $r_{\max}(\beta\gamma) = 4$ (class C). Conflating these produces incorrect classifications, and the seven-face programme will distinguish them at every face.

31.2 FACE I: THE CY BAR-COBAR TWISTING MORPHISM

Face I places the binary residue the universal twisting morphism between $\text{arB}(A_C)C$ the *chiral bar – cobar adjunction*. The CY – to – chiral functor sends a Calabi – Yau category C to a chiral algebra A_C , and the bar construction sends A_C to a factorization coalgebra $\overline{B}(A_C)$ on $\text{Ran}(X)$. The collision residue is the binary component of the universal twisting morphism between $\overline{B}(A_C)$ and A_C .

Coordinates. Level 2 (Stage-2 chart-shadow read through bar twisting), with descent from level 1 (Stage-1 factorisation bar) via the two-bar comparison of Remark 31.2.1; chart any (Σ_{d-1}, C) on the verified locus; ambient ordinary chain complex at $d = 2$, weight-completed for class M on $\overline{B}$ at $d = 3$ (ambient qualifier).

Remark 31.2.1 (Two bar constructions, one per stage). Face I uses two distinct bar constructions, one per stage of $\Phi_d = \text{Sp}_{\Sigma_{d-1}, C}^{\text{ch}} \circ \Phi_d^{\text{FA}}$, and each statement of this section labels which lane it occupies.

- (i) **Stage-1 factorisation bar.** On $\Phi_d^{\text{FA}}(C) \in E_d\text{-HolFA}(X)$ the relevant bar is the E_d -hFA factorisation bar: the homotopy E_d -coalgebra $\overline{B}_{E_d}^{\text{fact}}(\Phi_d^{\text{FA}}(C))$ computed by the factorisation-algebra

cobar resolution in $E_d\text{-HolFA}(X)$. This is an invariant of C before any curve-specialisation and records the native operadic level $n_{\text{native}}(d)$ of Proposition 5.1.3.

- (ii) **Stage-2 chiral ordered bar.** After specialising to a curve $C \subset X$ via $\text{Sp}_{\Sigma_{d-1}, C}^{\text{ch}}$, the E_1 -chiral ordered bar of Vol I applies to $A_C \in E_n\text{-HolFA}(C)$: the tensor-coalgebra $T^c(s^{-1}A_C)$ on the augmentation ideal, with the deconcatenation coproduct. This is the bar complex featured in Volume I and the object on which the Vol I Koszul reflection acts.

The binary CY collision residue $r_{CY}(z)$ is extracted at stage 2 from the universal twisting morphism between the stage-2 chiral ordered bar $\overline{B}(A_C)$ and A_C ; its existence as a stage-1 aspect of $\Phi_d^{\text{FA}}(C)$ is the statement that this residue descends from the factorisation bar through the Sp^{ch} -specialisation. The stage-1 factorisation bar records the native E_d -coalgebra structure on X ; the stage-2 chiral ordered bar records the E_1 -coalgebra structure on C ; each carries the bar invariant at its own level of the two-stage factorisation.

THEOREM 31.2.2 (*Face 1: CY bar-cobar realization, $d = 2$*). Let A_C be the chiral algebra of a CY_2 category C produced by the CY-to-chiral correspondence Φ_2 (Theorem CY-A₂). Then:

- (i) The convolution dg Lie algebra $\mathfrak{g}_{A_C}^{\text{mod}}$ identifies with the homotopy Lie algebra of twisting morphisms $\text{hom}_\alpha(\overline{B}(A_C), A_C)$ between bar coalgebra and chiral algebra (cf. Vol I, Theorem 21.16);
- (ii) The universal MC element Θ_{A_C} is the universal twisting morphism;
- (iii) The binary collision residue $r_{CY}(z) = \text{Res}_{0,2}^{\text{coll}}(\Theta_{A_C})$ is the leading degree-2 component of this twisting morphism, evaluated in the CY direction against Ω_C .

Proof sketch. For (i), the cyclic bar complex $\text{CC}_\bullet(C)$ identifies with $\overline{B}(A_C)$ as a factorization coalgebra (Proposition 29.1.1). The convolution identification is the application of Vol I's master twisting morphism theorem to this coalgebra-algebra pair. For (ii), Θ_{A_C} satisfies the MC equation $D\Theta + \frac{1}{2}[\Theta, \Theta] = 0$ at all levels, with the bar-intrinsic construction $\Theta = D - d_o$. For (iii), the collision residue is computed from Θ by restricting to genus 0, degree 2, and pairing against the holomorphic volume form. $\square$

THEOREM 31.2.3 (*Face 1: CY bar-cobar realization, $d = 3$*). The statement of Theorem 31.2.2 extends to $d = 3$ on the framed CY_3 locus of Theorem 5.11.1. If C is a smooth proper CY_3 category equipped with a framed specialisation datum (Σ_3, C) for which $A_C := \text{Sp}_{\Sigma_3, C}^{\text{ch}}(\Phi_3^{\text{FA}}(C))$ is defined, then the convolution identification, the universal MC element, and the binary collision residue extraction of Theorem 31.2.2(i)–(iii) hold for this framed output A_C .

Remark 31.2.4 (*Bar-cobar inversion and the seven-face programme: distinct constructions on the boundary*). The cobar functor Ω inverts the bar complex: $\Omega(\overline{B}(A)) \simeq A$ (Vol I, Theorem B). This is a round-trip that recovers A itself. The seven-face programme realises the single algebraic object $r_{CY}(z)$ in seven distinct geometric languages, all on the boundary algebra A_C ; the closed-string / bulk side is a distinct construction, the chiral derived centre $\mathcal{Z}_{\text{ch}}^{\text{der}}(A_C)$ at the next level of the universal arrow (Vol I, Theorem H).

Remark 31.2.5 (*BPS shadow depth and the CY holographic datum*). The holographic modular Koszul datum in the CY setting assembles the six pieces of the seven-face programme into a single package:

$$H_{CY}(T) = (A_{CY}, A_{CY}^!, C_{CY}, r_{CY}(z), \Theta_{CY}, \nabla_{CY}^{\text{hol}}),$$

where A_{CY} is the constructed stage-2 CY-to-chiral image A_C , $A^!_{CY}$ is its Verdier/Koszul dual boundary algebra, C_{CY} is the line category of the HT theory, $r_{CY}(z)$ is the binary CY collision residue of Definition 31.1.1, Θ_{CY} is the universal Maurer–Cartan element (Theorem 31.2.2), and ∇_{CY}^{hol} is the holomorphic Knizhnik–Zamolodchikov connection on the chiral curve direction. This is the CY specialization of the Vol I datum $H(T) = (A, A^!, C, r(z), \Theta_A, \nabla^{\text{hol}})$; the additional datum is the CY direction Ω_C (Remark 31.1.2). The BPS/Hilbert-space clauses in this paragraph are mathematical statements only after the protected physical comparison datum of Definition 31.2.10 has been supplied.

Dimofte’s framework (PIRSA 25110067) attaches to $H_{CY}(T)$ a single numerical invariant, the *BPS complexity* of the boundary Hilbert space, measured by the K -matrix $K_{A_{CY}}(z)$ of equation (8.1) (cf. Chapter 8, Remark 8.3.6, and *Vol II*, remark 8.3.6 in [97]). As a physics-motivated heuristic (Dimofte framework, no chiral-algebra proof), the boundary Hilbert space of the HT theory decomposes as

$$\mathcal{H}_\partial(T) \simeq \mathcal{H}_\partial^{\text{free}} \otimes \mathcal{H}_\partial^{\text{BPS}},$$

where $\mathcal{H}_\partial^{\text{free}}$ is the $\mathfrak{u}(1)^r$ free-boson factor (the class $\mathbf{G}$ summand) and $\mathcal{H}_\partial^{\text{BPS}}$ records the BPS corrections. Under the CY-to-chiral correspondence programme $\{\Phi_d\}$, this decomposition is the Vol I shadow partition $\mathbf{G} + (\mathbf{L}/\mathbf{C}/\mathbf{M})$: the free-boson summand is exactly class $\mathbf{G}$, and the BPS summand carries the higher shadow depth.

CY₂ (K_3 , protected sector). For a CY_2 category C admitting a chiral algebraization via Φ , the protected BPS Hilbert space is modelled by the associated Borcherds–Kac–Moody superalgebra after the physical comparison datum is supplied, $\mathfrak{g}_{\text{BKM}}(C)$, and the K -matrix encodes its denominator identity. Concretely, for $C = D^b(\text{Coh}(K_3))$ the BKM denominator formula (Gritsenko–Nikulin, Borcherds) identifies the primitive denominator algebra with $\mathfrak{g}_{\Delta_5}$, whose signed root supermultiplicities are the Fourier coefficients of the Jacobi input $\phi_{0,1}$. The dyonic scalar partition function uses the OP-normalised square $\Phi_{10}^{\text{OP}} = D_5^2 = 4096^{-1}\Delta_5^2$; the K -matrix modes $\{\alpha_n\}$ read root multiplicities from the primitive denominator, not from the scalar square alone.

Automorphic product normalisation. The numerical identity

$$\text{wt}(\Phi_{10}^{\text{OP}}) = 2 \kappa_{\text{BKM}} = 10$$

factors as two separate primary-source statements. First, by Borcherds 1998 (*Invent. Math.* 132, Theorem 13.3) the BKM weight formula gives $\kappa_{\text{BKM}}(\Phi_N) = c_N(\mathfrak{o})/2$; at $N = 1$ the Gritsenko paramodular form Δ_5 of weight 5 has $c_1(\mathfrak{o}) = 10$, so $\kappa_{\text{BKM}} = 5$. The primitive denominator remains Δ_5 ; the monic Gritsenko–Nikulin product is $D_5 = 64^{-1}\Delta_5$. In the Oberdieck–Pandharipande/Oberdieck–Pixon scalar normalisation,

$$\Phi_{10}^{\text{OP}} = D_5^2 = 4096^{-1}\Delta_5^2, \quad Z_{\text{DT}}^X = Z_{\text{OP}}^X = -(\Phi_{10}^{\text{OP}})^{-1} = -4096 \Delta_5^{-2}.$$

The factor of 2 in $\text{wt}(\Phi_{10}^{\text{OP}})/\kappa_{\text{BKM}}$ is this squaring, not Serre duality; the factor $4096 = 64^2$ is a scalar normalisation and carries no compact Hall or Pfaffian orientation data. This matches entry $\kappa_{\text{BKM}}(K_3 \times E) = 5$ in the Vol III κ_{BKM} -spectrum and the weight $\text{wt}(\Phi_{10}^{\text{OP}}) = 10$ recorded in Chapter 19.

CY₃ (framed Φ_3 locus). For a CY_3 category the BPS Hilbert space should be the module over the Donaldson–Thomas Hall algebra (Kontsevich–Soibelman, Davison–Meinhardt), and the K -matrix should be

the generating function of the cohomological Hall algebra $\mathcal{H}(Q, W)$ attached to a quiver-with-potential presentation. For toric CY_3 without compact 4-cycles (Chapter 34) this is explicit: Schiffmann–Vasserot identify $\mathcal{H}(\mathbb{C}^3)$ with the positive half of the affine Yangian $Y^+(\widehat{\mathfrak{gl}}_1)$, and the K -matrix is its character $M(q)^2 \cdot P(q)$ (Theorem 8.3.4). All statements in this paragraph whose proof chain passes through $\mathcal{A}_C$ at $d = 3$ are restricted to the chosen framed Φ_3 -specialisation locus of Theorem 5.11.1.

Shadow–BPS dictionary. The four-class partition of CY boundary algebras is:

Shadow class	BPS complexity	$K_{ACY}(z)$	Example
G	0 BPS corrections	1	trivial CY fiber, $\mathfrak{u}(1)^r$
L	1 BPS level	polynomial, simple pole	rank-one CY Heisenberg deformation
C	2 BPS levels	polynomial, double pole	toric CY_3 ($\mathbb{C}^3$, conifold)
M	infinite BPS tower	infinite expansion	K_3 , $K_3 \times E$

The shadow-depth classification of the CY boundary algebra is therefore the algebraic counterpart of the BPS complexity of the HT boundary Hilbert space under the protected CY-to-chiral comparison programme $\{\Phi_d\}$. The K -matrix modifies the coproduct, not the product, so the level- k vanishing check does not apply directly; the companion r -matrix check is the level check on the affine r -matrix at $k_{\text{ch}} = 0$, which vanishes as required and returns class **G**. Primary references for BPS Hall algebras and the denominator identity: Dimofte PIRSA 25110067, Kontsevich–Soibelman, Davison–Meinhardt, Gritsenko–Nikulin. Vol II cross-references: 8.3.6 in [97] and the BPS/shadow discussion in [97].

Remark 31.2.6 (Δ_5 as Borchers theorem and one-loop physics witness). The paramodular weight $\text{wt}(\Delta_5) = 5$ recorded in Remark 31.2.5 is the Borchers–Gritsenko weight theorem: $\kappa_{\text{BKM}}(\mathfrak{g}_{\Delta_5}) = c_1(0)/2 = 5$. Twisted 11D supergravity supplies a matching one-loop physics witness from paramodular anomaly cancellation on $K_3 \times T^2$ with Ω -deformation, supporting 24 M5-branes wrapping the I_1 Kodaira fibres of the elliptic K_3 . The weight arithmetic reads

$$\text{wt}(\Delta_5) = \chi(\mathcal{O}_{K_3}) + \sum_{24 \text{ fibres}} \text{Res}(I_1) = 2 + 3 = 5,$$

where the $\chi(\mathcal{O}_{K_3}) = 2$ summand is the Mukai doubling of the holomorphic Euler characteristic (the source of the $\kappa_{\text{fiber}} = 24$ of Chapter 19) and the $+3$ summand records the orbifold residue of the I_1 Kodaira stratum summed over the 24-section of the elliptic fibration. Four duality frames independently witness the same $\text{wt} = 5$ output: heterotic $K_3 \times T^2$ (Harvey–Moore 1996 threshold correction); Type IIB on $K_3 \times S^1$ with D1–D5 bound states (Dijkgraaf–Verlinde–Verlinde 1996–97); Type IIA DMVV symmetric products (Dijkgraaf–Moore–Verlinde–Verlinde 1997); M-theory on $K_3 \times T^3$ (Witten 1995). The Vol I bar–cobar bridge (Chapter 29) realises this number as the degree-2 shadow coefficient of the Φ_2 -image chiral algebra on the K_3 fibre; Face 4 of the present seven-face master (§31.5) realises the same number as the Borchers weight $c_1(0)/2 = 5$ of Δ_5 , confirming that the genus-stratification of the CY-to-chiral correspondence programme $\{\Phi_d\}$ and the paramodular anomaly calculation agree at the checked one-loop weight level. The physics comparison is not used as a proof of the Borchers weight identity, nor as an all-orders quantisation theorem.

Definition 31.2.7 (Pure mathematical holographic bridge datum). Let X be a CY_3 target for which the positive Hall side and a framed $d = 3$ chiral output are both defined. A *pure mathematical holographic bridge datum* is the following package:

$$\mathfrak{S}_X^{\text{mat}} = (\text{BPS}_X, \text{Bdry}_X, \mathcal{H}_X, \lambda_X, \text{ch}_X, \omega_X, \eta_X).$$

Here BPS_X is a charge-graded stable category of BPS objects with Kontsevich–Soibelman Hall product and orientation line $\mathcal{L}_{\text{or}}$; Bdry_X is the boundary factorisation category of the chiral algebra $\mathcal{A}_X = \text{Sp}_{\Sigma_2, C}^{\text{ch}}(\Phi_3^{\text{FA}}(\text{Perf } X))$ on the chosen framed locus;

$$\mathcal{H}_X: \text{BPS}_X \longrightarrow \text{Bdry}_X$$

is an exact charge-preserving functor; λ_X is an isometry from the numerical charge lattice of BPS_X to the root/weight lattice seen by $\mathcal{A}_X$; ch_X is an index-character map

$$K_0(\text{BPS}_X, \mathcal{L}_{\text{or}}) \longrightarrow K_0(\text{Bdry}_X)$$

intertwining the BPS index with the graded chiral character; ω_X is a trivialisation of the orientation line compatible with Hall convolution; and η_X is the coherence square asserting that wall-crossing on BPS_X maps to Maurer–Cartan gauge equivalence of $\Theta_{\mathcal{A}_X}$.

The datum is *complete* only if $\mathcal{H}_X$ carries the Hall product to the boundary OPE/factorisation product and intertwines the bulk coproduct with the chiral Drinfeld-centre half-braiding, with all trace maps taken in compactly supported K -theory. For non-proper BPS stacks this means the same Borel–Moore or renormalised $!$ -pushforward used in the Hall product. The charge lattice and index-character components alone are arithmetic shadows of the bridge; they are not the bridge.

Definition 31.2.8 (Finite Rees hCS–Hall comparison datum). Let X be a CY_3 target and fix a Harder–Narasimhan height filtration $F_{\leq N}$ on the effective charge cone. A *finite Rees hCS–Hall comparison datum* is a compatible family

$$\mathcal{R}_{X, \leq N}^{\text{hCS–Hall}}: \text{Rees}_F(F_{\leq N} \text{Obs}_{\text{hCS}}(X)) \longrightarrow \text{Rees}_F(F_{\leq N} \text{CoHA}_{\text{eff}}(X))$$

intertwining the tree hCS bracket, the finite Hall correspondence, and the orientation line on every truncated correspondence stack. The datum is *finite*: it compares actual finite windows before the compact-support completion, before the Hall coproduct is promoted to a bialgebra, and before the Drinfeld double is mapped to a BKM denominator algebra.

Its compact realisation obstruction is the ordered tuple

$$\mathfrak{o}_X^{\text{comp}} = (o_{\text{prop}}, o_{\text{or}}, o_{\Delta}, o_{\widehat{F}}, o_{\text{BKM}}),$$

where the components respectively measure failure of proper or renormalised Hall pushforward, failure of orientation-line descent, failure of the coproduct to preserve compact support, failure of the Rees filtration to complete without adding uncontrolled charge sectors, and failure of the completed Hall–Drinfeld double to carry the Borchers denominator normalisation.

PROPOSITION 31.2.9 (Finite Rees comparison versus compact Hall double). A finite Rees hCS–Hall comparison datum on X proves only the truncated hCS/Hall compatibility on the finite windows $F_{\leq N}$. It produces a compact BKM-valued trace precisely when

$$\mathfrak{o}_X^{\text{comp}} = 0$$

and the resulting compact Hall algebra admits a Drinfeld double map

$$\mathcal{D}_h(\text{CoHA}_X^c) \longrightarrow \mathfrak{g}_{\Delta_5}$$

whose denominator is normalised by $\text{den}(\mathfrak{g}_{\Delta_5}) = D_5(2Z) = 64^{-1}\Delta_5(2Z)$.

Proof. The Rees datum is built before completion. It records, for each finite height, the compatibility of two filtered products: the hCS tree bracket and the Hall convolution product on the corresponding finite correspondence stacks. Passing from these finite products to a compact trace requires the !-pushforward defining Hall multiplication to exist in the same compact-support theory used by the trace; this is exactly $\mathcal{O}_{\text{prop}}$. The BPS index is oriented, so descent of the orientation line is $\mathcal{O}_{\text{or}}$. The Drinfeld double requires a coproduct compatible with the compact support condition, giving $\mathcal{O}_{\Delta}$. Completion in charge height can add sectors invisible in every finite window; $\mathcal{O}_{\widehat{F}}$ is the assertion that it does not. After those four obstructions vanish, the target is still only a compact Hall double. The final map to $\mathfrak{g}_{\Delta_5}$ and the denominator normalisation are the separate obstruction $\mathcal{O}_{\text{BKM}}$. Thus finite Rees compatibility is necessary for the compact bridge but never sufficient for the compact CoHA/Drinfeld-double/BKM conclusion. $\square$

Definition 31.2.10 (Protected trace functor package). Let X be as in Definition 31.2.7. A *protected trace functor package* over X is an extension

$$\mathfrak{T}_X^{\text{prot}} = (P_X^{\text{prot}}, \mathfrak{H}_X^{\text{mat}}, \text{Tr}_X^{\text{prot}}, \rho_X).$$

Here P_X^{prot} is either the physical Q -cohomology projection or an idempotent projection from the full BPS Hilbert sector to the protected sector before any trace is taken;

$$\text{Tr}_X^{\text{prot}} : \text{Phys}_X^{\text{prot},c} \longrightarrow \text{Tr}^{\text{ch},c}(A_X)$$

is an exact symmetric monoidal functor from compactly supported protected sectors to the compactly supported trace category of A_X ; and ρ_X identifies the induced map on oriented Grothendieck groups with ch_X . Completeness means that the following five diagrams commute: protected-sector projection, Hall-convolution/OPE product, orientation-line trivialisation, Kontsevich–Soibelman wall-crossing versus MC gauge equivalence, and compact-support pushforward. The package is BKM-valued only after the Hall–Drinfeld double is mapped to the BKM bialgebra and the denominator is normalised by $\kappa_{\text{BKM}}(\Phi_N) = c_N(\mathfrak{o})/2$.

THEOREM 31.2.11 (Holographic bridge gate). Let X be as in Definition 31.2.7. If a complete pure mathematical holographic bridge datum $\mathfrak{H}_X^{\text{mat}}$ is supplied, then every identity of oriented BPS indices in BPS_X transfers functorially to an identity of graded characters and collision residues on the boundary chiral algebra A_X . In particular the denominator/product formula, wall-crossing invariance, and large-charge asymptotic statement become theorems of the CY-to-chiral programme.

Conversely, the transfer from a physical holographic statement to a pure CY-to-chiral theorem is not derivable from the CY-to-chiral axioms unless the product comparison, orientation-line compatibility, and wall-crossing coherence parts of $\mathfrak{H}_X^{\text{mat}}$ are present. Thus AdS/CFT, black-hole, M-theory, or celestial arguments may supply proved identities in the physical theory, but their CY-to-chiral consequences require the explicit bridge datum above.

Proof. The first assertion is functoriality. The Hall product on BPS_X is a convolution product built from the correspondence stack of short exact triangles. The boundary product on Bdry_X is the factorisation/OPE product along the collision strata of the chosen curve. If $\mathcal{H}_X$ carries the Hall correspondence to the collision correspondence and ω_X trivialises the orientation line compatibly with convolution, then the equality of oriented indices is preserved by the induced map on K_o . The index-character map ch_X turns the same equality into a graded character equality. The Drinfeld-centre compatibility identifies the coproduct/half-braiding side with the collision residue $\text{Res}_{o,2}^{\text{coll}}(\Theta_{A_X})$. The wall-crossing square η_X says that a Kontsevich–Soibelman wall-crossing automorphism on the BPS side maps to MC gauge equivalence of Θ_{A_X} ; hence the transferred character and residue are chamber-independent.

For the converse, remove any one of the three load-bearing components. Without the product comparison there is no morphism carrying Hall multiplication to OPE multiplication. Without the orientation trivialisation the BPS index and the chiral trace live in different twisted Grothendieck groups. Without wall-crossing coherence the transferred class depends on a chamber and therefore cannot be a global CY-to-chiral invariant. A physics duality may still compute the BPS index, but no pure mathematical implication to A_X has been constructed. This proves the gate criterion. $\square$

THEOREM 31.2.12 (*Protected index versus protected trace functor*). Let X be a CY_3 target on a framed $d = 3$ locus, and let

$$\text{ind}_X^{\text{BPS}}: K_o^\epsilon(\text{BPS}_X, \mathcal{L}_{\text{or}}) \longrightarrow R_X$$

be the compactly supported oriented protected index. A complete protected trace functor package $\mathfrak{T}_X^{\text{prot}}$ promotes protected-index identities to functorial chiral trace identities: products, orientation signs, wall-crossing, charge gradings, and compact-support pushforwards are preserved, and the BKM-valued trace is available precisely when the Hall–Drinfeld double and Borchers denominator normalisation are also part of the package.

Conversely, an equality of scalar protected indices

$$\text{ind}_X^{\text{BPS}}(\alpha) = \text{tr}_X^{\text{ch}}(\beta) \quad (\alpha \in K_o^\epsilon(\text{BPS}_X, \mathcal{L}_{\text{or}}))$$

does not determine a functor $\text{Tr}_X^{\text{prot}}$, nor a Hall-to-OPE product comparison, nor a BKM trace. Any argument factoring only through the scalar character ring is blind to classes in $\ker(\text{ind}_X^{\text{BPS}})$, to orientation-line twists, to compact-support failures of the Hall !-pushforward, and to chamber changes killed by the numerical index. Hence protected-index equality is a character-level statement unless the full package of Definition 31.2.10 is supplied.

Proof. Assume first that $\mathfrak{T}_X^{\text{prot}}$ is complete. Exactness gives a map on compactly supported Grothendieck groups. Symmetric monoidality sends external tensor products of protected sectors to external tensor products of chiral trace objects, and the product diagram identifies the pushforward defining Hall convolution with the collision pushforward defining the boundary OPE. The orientation diagram removes the twist by $\mathcal{L}_{\text{or}}$; the wall-crossing diagram identifies Kontsevich–Soibelman automorphisms with MC gauge transformations of Θ_{A_X} ; and the compact-support diagram says that the trace is taken after the same !-pushforward on both sides. The induced identity in $K_o^\epsilon(\text{Tr}^{\text{ch}}(A_X))$ is therefore functorial and product-preserving. If the target is BKM-valued, the Hall–Drinfeld double map supplies the algebra target and the $\kappa_{\text{BKM}} = c_N(o)/2$ normalisation fixes the denominator trace.

For the converse, let an argument use only the equality of scalar indices. The scalar map factors through the quotient of $K_o^\epsilon(\text{BPS}_X, \mathcal{L}_{\text{or}})$ by the kernel of $\text{ind}_X^{\text{BPS}}$. It therefore cannot distinguish α from $\alpha + u$ for u in that kernel. Such a quotient forgets the Hall correspondence, the orientation line, the

compact-support pushforward, and the chamber action unless separate commuting diagrams remember them. The missing diagrams are exactly the projection, orientation, product, wall-crossing, compact-support, charge-lattice, and BKM-double gates in Definition 31.2.10. The index equality can be a proved character identity; it is not, by itself, a functorial protected trace. $\square$

Remark 31.2.13 ($K_3 \times E/\text{CHL}$ bridge obstruction). For the $K_3 \times E$ CHL tower the charge-lattice piece λ_X , the index-character equality for the DVV/DMZ BPS generating series, and the large-charge Rademacher/Sen asymptotics are available as arithmetic or physics witnesses. The complete pure mathematical bridge datum is not yet present: the functor $\mathcal{H}_X: \text{BPS}_{K_3 \times E} \rightarrow \text{Bdry}_{K_3 \times E}$, the Hall-product/OPE comparison, and the orientation-line coherence have not been constructed. Hence the holographic and quantum-gravity consequences in this volume are read as conditional theorems under Definition 31.2.7, not as unconditional pure mathematical identifications.

31.3 FACE 2: COHA AND PERVERSE COHERENT SHEAVES

Face 2 identifies the binary residue the leading non-trivial structure constant of the cohomological Hall algebra of $\mathcal{C}$, or equivalently, the Yoneda product on perverse coherent sheaves. This face is the natural home of Donaldson–Thomas invariants.

Coordinates. Level 1 (Stage-1 invariant of the CoHA on the moduli stack) crossing to level 2 through CY-C; chart toric T^d on $\mathbb{C}^3$, conifold, local $\mathbb{P}^2$, quasi-NCCR for $K_3 \times E$; ambient derived $(\infty, 1)$ -categorical with critical cohomology (Kontsevich–Soibelman, Davison–Meinhardt).

Conjecture 31.3.1 (Face 2: CoHA realization of r_{CY}). Let $\mathcal{C}$ be a smooth proper CY_3 category with quiver-with-potential presentation (Q, W) at a stable point of the moduli of stability conditions. Let $\mathcal{H}(Q, W)$ denote the critical cohomological Hall algebra (Definition 34.2.1). Then the binary collision residue of $\mathcal{A}_{\mathcal{C}}$ admits a CoHA realization

$$r_{CY}^{\text{CoHA}}(z) = \mu_{\mathcal{H}(Q, W)}^{(2)} \otimes z^{-1} \in \mathcal{H}(Q, W) \otimes \mathcal{H}(Q, W) [[z^{-1}]],$$

where $\mu^{(2)}$ is the binary CoHA product, paired with the d log-propagator on $\overline{\mathcal{C}}_2$.

Remark 31.3.2 (Obstruction in Conjecture 31.3.1). The CoHA $\mathcal{H}(Q, W)$ exists unconditionally (Kontsevich–Soibelman, Davison–Meinhardt). The chiral algebra $\mathcal{A}_{\mathcal{C}}$ exists at $d = 2$ (CY- $\mathcal{A}_2$); at $d = 3$ it is the output of a chosen framed $\text{Sp}_{\Sigma, \mathcal{C}}^{\text{ch}}$ -specialisation of $\Phi_3^{\text{FA}}(\mathcal{C})$ (Theorem 5.11.1). What remains conjectural is CY-C: the identification with r_{CY} via Φ_d requires $\{\Phi_d\}$ to commute with critical cohomology. CY-C is proved for the toric CY_3 examples (Theorems 34.3.1, 34.4.1). In those cases the identification reduces to the Schiffmann–Vasserot and Rapcak–Soibelman–Yang–Zhao theorems.

Remark 31.3.3 (Perverse coherent sheaves). For a CY_3 category arising as $D^b(\text{Coh}(X))$ for X a smooth CY_3 variety, the CoHA description above is equivalent to a description in terms of perverse coherent sheaves on X (Bridgeland, Bayer–Macri). The Yoneda product on $\text{Ext}^\bullet$ of perverse coherent sheaves is the binary CoHA product, and the binary collision residue extracts its leading Ext^1 component. This is the geometric face: the residue r_{CY} is a piece of the deformation theory of the CY_3 .

Remark 31.3.4 (CoHA is not the full quantum vertex chiral group). The critical CoHA is an associative algebra: the positive (or E_1 -ordered) half of the conjectural quantum vertex chiral group $G(X)$. The braided E_2 object belongs to the Drinfeld double/derived-centre completion, with braiding supplied by the R -matrix of the affine super Yangian (Section 31.6). The CoHA face captures the *shadow* of r_{CY} on the ordered E_1 side; faces 4 and 5 record the centre/double data.

31.4 FACE 3: CLASSICAL CY POISSON COISSON (GENUS 0 ONLY)

Face 3 inscribes the classical avatar of 867 In the CY setting, the binary residue r_{CY} has a classical avatar: a coisson bracket on the sheafification of A_C , the chiral version of the holomorphic Poisson bracket arising from the CY $(2,0)$ -form (at $d = 2$) or the holomorphic top form via contraction (at $d = 3$).

Coordinates. Level 2 classical limit $\hbar \rightarrow 0$ of the Stage-2 chart-shadow; chart any (Σ_{d-1}, C) on the verified locus, genus 0 only (higher-genus quantum corrections obstruct); ambient PVA / coisson bracket on $\mathcal{Z}_{\text{ch}}^{\text{der}}(A_C^{\text{cl}})$.

THEOREM 31.4.1 (*Face 3: classical Poisson coisson, $d = 2$ (genus 0 only)*). Let C be a CY_2 category and let A_C be its chiral algebraization (Theorem CY-A₂). Let $\hbar$ denote a quantization parameter. Then:

- (i) The classical limit $A_C^{\text{cl}} := \lim_{\hbar \rightarrow 0} A_C$ is a Poisson vertex algebra (PVA) with bracket $\{\cdot, \cdot\}_{\lambda}$ valued in $A_C^{\text{cl}} \otimes \mathbb{C}[\lambda]$;
- (ii) The leading coefficient $\{\cdot, \cdot\}_{\lambda}^{(0)}$ of the PVA bracket is a chiral Poisson bracket whose classical r -matrix is exactly $r_{CY}(z)$ at $\hbar = 0$;
- (iii) This identifies r_{CY}^{cl} as the coisson bracket constructed from the CY volume form Ω_C via the Poisson structure on $\mathcal{Z}_{\text{ch}}^{\text{der}}(A_C^{\text{cl}})$ (cf. Vol I, Theorem 30.10).

Proof sketch. For a CY_2 category, Φ_2 is the proved CY-to-chiral correspondence at $d = 2$ (Chapter 5). The PVA structure on A_C^{cl} is the classical limit of the chiral OPE. The leading λ coefficient of the λ -bracket is the contraction of two factors along the binary collision divisor; this is exactly $\text{Res}_{0,2}^{\text{coll}}$ computed in the classical limit, hence r_{CY}^{cl} . The identification with the coisson bracket arising from Ω_C is the coisson–PVA dictionary (cf. Vol I, Theorem 30.10, applied to the specialization $C \mapsto A_C$). $\square$

Conjecture 31.4.2 (*Face 3: classical Poisson coisson, $d = 3$ (genus 0 only)*). The statement of Theorem 31.4.1 extends to $d = 3$ on a framed Φ_3 -specialisation locus (Theorem 5.11.1): if A_C is the framed CY_3 chiral algebraization of C , then items (i)–(iii) of Theorem 31.4.1 hold for A_C^{cl} with the CY_3 volume form $\Omega_C \in H^0(C, \omega_C)$ supplying the coisson pairing.

Remark 31.4.3 (*Convention: λ -brackets vs OPE modes*). Vol I uses OPE modes $a_{(n)}b$. Vol II uses λ -brackets $\{a_{\lambda}b\} = \sum_n \lambda^{(n)} a_{(n)}b$ with the divided power $\lambda^{(n)} = \lambda^n/n!$. Vol III uses motivic and categorical language. When transcribing r_{CY} between volumes, the $1/n!$ factor must be tracked: the λ^3 coefficient of a λ -bracket is $a_{(3)}b/3! = a_{(3)}b/6$, not $a_{(3)}b$. The cross-volume λ -bracket / mode dictionary is recorded in the Vol I concordance.

31.5 FACE 4: THE MAULIK–OKOUNKOV R -MATRIX AS GLUING-COCYCLE RESIDUE

The fourth face presents the binary residue as a residue of the universal positive-half gluing cocycle of the Maulik–Okounkov stable envelope across an equivariant chamber wall. The stable envelope $\text{Stab}_{\mathcal{K}}^+$ exists unconditionally on the equivariant K -theory $K_T^{\bullet}(\text{Hilb}^{\bullet}(K_3))$ (Maulik–Okounkov 2012, Theorem 4.6.1) and its transition matrices between adjacent chambers $\mathcal{K}_1, \mathcal{K}_2$ are, by construction, the Maulik–Okounkov R -matrices. Face 4 places this transition data on a single meromorphic cocycle and extracts r_{CY} as its residue.

Coordinates. Level 2 (Stage-2 chart-shadow); chart (Σ_2, C) on $K_3 \times E$ in the reduced $\mathbb{C}^{\times} + \text{Aut}$ equivariance stratum; ambient E_n -HolFA(C) at the recalled depth $n(3) = 1$ with E_2 -braiding lifted to $\mathcal{Z}(\text{Rep}^{E_1}(A_C))$.

THEOREM 31.5.1 (*Face 4: Maulik–Okounkov R -matrix as cocycle residue*). Let $\mathcal{C} = D^b\text{Coh}(K_3 \times E)$ and let $\mathcal{F}_X = \Phi_3^{\text{FA}}(\mathcal{C}) \in E_3\text{-HolFA}(K_3 \times E)$ be the canonical Stage-1 datum on the framed CY_3 locus of Theorem 5.11.1. Let T be the torus preserving the CY_3 structure, $\mathcal{W} \subset \mathfrak{t}_{\mathbb{C}}^*$ the equivariant wall arrangement, and ϕ_{UV}^+ the UV positive-half gluing cocycle of Construction 10.5.5. The Maulik–Okounkov R -matrix is the residue of ϕ_{UV}^+ across an equivariant chamber wall,

$$R^{\text{MO}}(u) = \text{Res}_{u=u_{\star}} \phi_{UV}^+(u), \quad u = u_1 - u_2, \quad (31.1)$$

at any chamber wall $u_{\star}$, independent of the chamber choice up to unitarity. The Maulik–Okounkov axiom (quantum Yang–Baxter equation + unitarity) is the Čech-cocycle condition for ϕ_{UV}^+ on the codimension-two and codimension-one wall intersections respectively (Theorem 10.5.6). The binary CY collision residue is the classical limit

$$r_{CY}^{K_3 \times E}(z) = \lim_{\hbar \rightarrow 0} \hbar^{-1} (R^{\text{MO}}(z) - \text{id}) = \lim_{\hbar \rightarrow 0} \hbar^{-1} \text{Res}_{z=z_{\star}} \phi_{UV}^+(z), \quad (31.2)$$

the rational/elliptic stable envelope of Maulik–Okounkov evaluated on the Hilbert scheme of points on K_3 along the elliptic direction E , paired against the holomorphic volume form $\Omega_{K_3 \times E}$.

Proof. The cocycle–residue identification (31.1) is Theorem 10.5.6 (i)–(iii) on $K_3^{\bullet}(\text{Hilb}^{\bullet}(K_3))$: the residue of the meromorphic 1-form ϕ_{UV}^+ at a wall α equals the hyperbolic-restriction r_{α} , which is the chamber-transition matrix $\text{Stab}_{\mathcal{K}_2}^+ \circ (\text{Stab}_{\mathcal{K}_1}^+)^{-1} = R^{\text{MO}}(\alpha)$ [156, Theorem 4.6.1]. The quantum Yang–Baxter equation is the cocycle condition at codimension-two wall triple-intersections; unitarity is the cocycle-reversal identity. The classical-limit identification (31.2) is Definition 31.1.1 applied after specialising to the elliptic direction. $\square$

Conjecture 31.5.2 (*Face 4: MO realization for $K_3 \times E$*). For the CY_3 specialization $X = K_3 \times E$, the binary CY collision residue identifies with the classical limit of the Maulik–Okounkov R -matrix:

$$r_{CY}^{K_3 \times E}(z) = \lim_{\hbar \rightarrow 0} \hbar^{-1} (R_{\text{MO}}^{K_3 \times E}(z) - \text{id}).$$

The right-hand side is the rational/elliptic stable envelope of Maulik–Okounkov, evaluated on the Hilbert scheme of points on K_3 along the elliptic direction E . The conjecture is equivalent to Conjecture CY-C for $K_3 \times E$.

Remark 31.5.3 (*The CY involution $g(z)g(-z) = 1$*). For $K_3 \times E$, the MO R -matrix is governed by a single Yangian generator $g(z)$ satisfying $g(z)g(-z) = 1$ (Theorem 17.4.1). This CY involution is the $\mathbb{S}^2$ -framing of the CY-to-chiral correspondence programme $\{\Phi_d\}$ seen at the level of the binary residue: the $z \mapsto -z$ involution is the chiral analogue of the CY Serre functor $\mathbb{S} \simeq [d]$. In particular the CY involution forces the residue to be of *odd* pole order, in agreement (the d log-absorption sends even-order poles to odd-order poles in the residue).

Remark 31.5.4 (*Class- $\mathcal{S}$ A_1 on $\Sigma_{0,24}$ is the 4d $\mathcal{N} = 2$ parent of Δ_5*). The Face 4 identification of $r_{CY}^{K_3 \times E}$ with the MO R -matrix sits inside a larger 4d $\mathcal{N} = 2$ parent picture whose boundary 2d chiral side is exactly the Φ_2 -image chiral algebra of Chapter 20. The parent theory is Gaiotto’s class- $\mathcal{S}$ construction (Gaiotto 2008) for type A_1 on the punctured sphere $\Sigma_{0,24}$, whose 24 regular punctures register the 24 Kodaira I_1 fibres of the elliptic K_3 . Chacaltana–Distler (2010) anomaly arithmetic at $(g, n) = (0, 24)$ gives

$$c_{4d} = \frac{5n-13}{6} = \frac{107}{6}, \quad a_{4d} = \frac{403}{24},$$

with Coulomb-branch rank 21 and flavour symmetry $\mathfrak{su}(2)^{24}$ (Chapter 20, Remark 20.10.5, Proposition 20.10.3). The Beem–Lemos–Liendo–Peelaers–Rastelli–van Rees chiral-algebra correspondence then gives the associated Schur-VOA central charge

$$c_{2d} = -12 c_{4d} = -214,$$

and the Drinfeld–Sokolov/BRST gluing of the 22 trinions along the 21 tubes preserves this number after the affine $\widehat{\mathfrak{sl}}_2$ ghost subtraction. The value -214 is the $4d/2d$ Schur central charge, sitting at level 3 of the universal arrow alongside the companion Stage-2 scalars $\kappa_{\text{ch}}(K_3 \times E) = 0$ (compact CY_3 Hodge supertrace) and $\kappa_{\text{BKM}}(\Delta_5) = 5$ (Borcherds weight). It enters the Vol I conductor through the Schur-to-Borcherds comparison map below. The 24-point configuration on $\mathbb{P}^1$ is the Steiner system $S(5, 8, 24)$: the unique 5-transitive arrangement of 24 points on $\mathbb{P}^1$ with Mathieu-group symmetry M_{24} (Conway–Sloane 1988, *Sphere Packings, Lattices, and Groups*), whose rigidity forces the paramodular Δ_5 output of Remark 31.2.6 to be unique. Face 4 in this setting is the K_3 -fibre slice of the class- $\mathcal{S}$ parent; $r_{CY}^{K_3 \times E}(z) = \lim_{\hbar \rightarrow 0} \hbar^{-1}(R_{\text{MO}} - \text{id})$ is the $4d \rightarrow 2d$ reduction of the class- $\mathcal{S}$ chiral-algebra extraction applied at the 24-section.

PROPOSITION 31.5.5 (*Class- $\mathcal{S}$ central charge and Drinfeld–Sokolov gluing*). For the class- $\mathcal{S}$ theory $\mathcal{T}[A_1, \Sigma_{0,24}]$ with 24 maximal regular $\mathfrak{su}(2)$ -punctures,

$$(n_v, n_h) = (63, 88), \quad c_{4d} = \frac{2n_v + n_h}{12} = \frac{107}{6}, \quad a_{4d} = \frac{5n_v + n_h}{24} = \frac{403}{24}.$$

The Beem–Lemos–Liendo–Peelaers–Rastelli–van Rees functor to the Schur chiral algebra gives

$$c_{2d} = -12c_{4d} = -214.$$

The same number is obtained from the Drinfeld–Sokolov/BRST presentation of the pants decomposition: 22 copies of the T_2 trinion are glued by 21 diagonal $\mathfrak{su}(2)$ -gaugings, and the affine-current plus ghost central-charge balance is precisely the two-dimensional image of the four-dimensional anomaly computation.

Proof. The pants decomposition of a 24-punctured sphere has $n - 2 = 22$ trinions and $n - 3 = 21$ tubes. For the A_1 maximal regular puncture normalisation used in Remark 31.5.4, Chacaltana–Distler give $(n_v, n_h) = (63, 88)$. Substitution in the Shapere–Tachikawa anomaly formula gives

$$c_{4d} = (2 \cdot 63 + 88)/12 = 214/12 = 107/6, \quad a_{4d} = (5 \cdot 63 + 88)/24 = 403/24.$$

The BLLPR correspondence sends a four-dimensional $\mathcal{N} = 2$ SCFT to its Schur vertex algebra with $c_{2d} = -12c_{4d}$, hence $c_{2d} = -214$. The Drinfeld–Sokolov/BRST gluing is the two-dimensional realisation of the same gauging: each tube imposes the diagonal $\widehat{\mathfrak{sl}}_2$ constraint and contributes the standard ghost subtraction. Gauge anomaly cancellation in the four-dimensional pants decomposition is exactly the vanishing of the BRST anomaly in the two-dimensional complex, so the central charge computed before and after gluing agrees with the BLLPR value. $\square$

Definition 31.5.6 ($K_3 \times E$ six-layer holographic tower). The $K_3 \times E$ six-layer holographic tower is the ordered package

$$\mathcal{T}_{K_3 \times E}^{\text{hol}} = (\mathcal{C}_S, \mathcal{C}_{\text{Schur}}, \mathcal{C}_{\text{hCS}}, \mathcal{C}_{\text{Miki}}, \mathcal{C}_{\text{AdS}}, \mathcal{C}_{\text{GC}}),$$

with layers:

- (1) $\mathcal{C}_S$: the class- $\mathcal{S}$ A_1 -theory on $\Sigma_{0,2,4}$;
- (2) $\mathcal{C}_{\text{Schur}}$: the BLLPR Schur/DS vertex algebra with $c_{2d} = -214$;
- (3) $\mathcal{C}_{\text{hCS}}$: the Costello–Paquette hCS boundary layer, read as E_1 -chiral at $d = 3$;
- (4) $\mathcal{C}_{\text{Miki}}$: the Miki-triality local toroidal chart, with parameters (q_1, q_2, q_3) , $q_1 q_2 q_3 = 1$;
- (5) $\mathcal{C}_{\text{AdS}}$: the AdS_3 /dyon layer whose protected scalar partition function is governed by Φ_{10}^{OP} ;
- (6) $\mathcal{C}_{\text{GC}}$: the Gritsenko–Clery lattice-polarised throat atlas with Borcherds weights $(5, 2, 3, 1, 2, 1/2, 3/2, 1)$ in the triple-indexed Gritsenko–Clery order.

The tower is a tower of comparison maps, not six equal objects.

THEOREM 31.5.7 ($K_3 \times E$ six-layer tower stratification). For $X = K_3 \times E$, the six layers of Definition 31.5.6 decompose into proved inputs and compatibility obstructions.

layer	proved input	compatibility obstruction
$\mathcal{C}_S$	$c_{4d} = 107/6$, $a_{4d} = 403/24$	Schur-to-Borcherds averaging map
$\mathcal{C}_{\text{Schur}}$	$c_{2d} = -214$	BRST-to-BKM character comparison
$\mathcal{C}_{\text{hCS}}$	Costello–Paquette local E_1 boundary	$\mathfrak{S}_{K_3 \times E}^{\text{mat}}$
$\mathcal{C}_{\text{Miki}}$	S_3 -triality of local toroidal charts	global Hall–Borcherds centre compatibility
$\mathcal{C}_{\text{AdS}}$	$\Phi_{10}^{\text{OP}} = D_5^2 = 4096^{-1} \Delta_5^2$, $\text{wt}(\Phi_{10}^{\text{OP}}) = 10$	BPS-to-boundary product functor
$\mathcal{C}_{\text{GC}}$	$\kappa_{\text{BKM}}(\Phi_m) = c_m(0, 0)/2$	CY hosts for non-CHL throat cells

In particular,

$$\kappa_{\text{BKM}}(\mathfrak{g}_{\Delta_5}) = c_1(0)/2 = 10/2 = 5, \quad \text{wt}(\Phi_{10}^{\text{OP}}) = 10,$$

and these two numbers are different readings of the primitive denominator Δ_5 and the OP-normalised scalar square Φ_{10}^{OP} . The constants $c_{2d} = -214$, $\kappa_{\text{ch}} = 0$, $\kappa_{\text{ch}}^{\text{Heis}} = 3$, $\kappa_{\text{BKM}} = 5$, and $\kappa_{\text{fiber}} = 24$ are five projections of different structures on the same geometric input.

Proof. The first layer is Proposition 31.5.5. The second is BLLPR central-charge transport together with the Drinfeld–Sokolov/BRST gluing calculation of the same proposition. The third is the Costello–Paquette local boundary theorem quoted in Proposition 31.11.4; its pure CY-to-chiral use is gated by the bridge datum of Definition 31.2.7. The fourth is Miki’s S_3 -triality for the local quantum toroidal/affine-Yangian chart, written in the Omega-background parameters with $q_1 q_2 q_3 = 1$; it is local because global compact $K_3 \times E$ requires the Hall–Borcherds centre comparison. The fifth is the DVV/DMZ/Sen arithmetic theorem for the $1/4$ -BPS partition function, combined with the Gritsenko–Nikulin monic product $D_5 = 64^{-1} \Delta_5$ and the OP scalar square $\Phi_{10}^{\text{OP}} = D_5^2$. The sixth is the Gritsenko–Clery 8-form atlas and the Borcherds singular-theta weight formula.

The displayed decomposition is therefore a formal consequence of already separated inputs: central-charge transport, local hCS boundary theory, local toroidal triality, dyonic automorphic arithmetic, and Borcherds weight theory. The third column is exactly the data not supplied by those theorems: a Schur-to-Borcherds averaging map, a BRST character comparison with the BKM denominator, the pure mathematical holographic bridge datum, global centre compatibility for Miki triality, the BPS-to-boundary product functor, and CY hosts for the non-CHL Gritsenko–Clery cells. $\square$

Remark 31.5.8 (*Self-dual Gepner trivialization*). At the Gepner point of K_3 , where the chiral algebra has $\mathcal{N} = (4, 4)$ enhancement, the MO R -matrix trivializes (Conjecture 17.4.2), so r_{CY} vanishes. This is consistent with the seven-face master statement: at the self-dual point of any face, all seven realizations

vanish simultaneously. For $K_3 \times E$ this is a statement about the vanishing of the collision residue in the enhanced-symmetry limit, not an identification of the global modular characteristic with zero.

31.6 FACE 5: THE AFFINE SUPER YANGIAN $Y(\widehat{\mathfrak{gl}}_1)$ FOR TORIC CY_3

Face 5 covers the toric case: when the CY_3 is toric and admits a quiver-with-potential presentation, the binary residue is the classical r -matrix of the affine super Yangian $Y(\widehat{\mathfrak{gl}}_1)$ (for $\mathbb{C}^3$, the Jordan quiver) or more generally $Y(\widehat{\mathfrak{gl}}_{Q_X})$ (for the toric quiver of X).

Coordinates. Level 2 on the toric chart, descended from the level-3 Drinfeld double of the level-1 CoHA $Y^+(X)$; chart toric T^d on X without compact 4-cycles, Σ_2 a toric codimension-1 cycle, C the toric reference curve; ambient rational shuffle algebra + Drinfeld–Yangian double.

THEOREM 31.6.1 (*Face 5 for toric CY_3 via RSYZ*). Let X be a toric CY_3 without compact 4-cycles, with toric quiver (Q_X, W_X) and affine super Yangian $Y(\widehat{\mathfrak{gl}}_{Q_X})$ (Theorem 34.4.1). Then the binary CY collision residue identifies with the classical r -matrix:

$$r_{CY}^X(z) = r_{Y(\widehat{\mathfrak{gl}}_{Q_X})}^{\text{cl}}(z) = \frac{\Psi \Omega_{Y(\widehat{\mathfrak{gl}}_{Q_X})}}{z} + (\text{higher poles dictated by } p_{\max}(W_X)),$$

where $\Omega_{Y(\widehat{\mathfrak{gl}}_{Q_X})}$ is the Casimir tensor of the affine super Yangian. At the Jordan-quiver specialization $X = \mathbb{C}^3$, the CoHA input is the positive half $Y^+(\widehat{\mathfrak{gl}}_1)$; the $\mathcal{W}_{1+\infty}$ vertex algebra appears only after passing to the Drinfeld double/centre and evaluating the vacuum module at the self-dual level.

Remark 31.6.2 (*Proof support for face 5*). Theorem 31.6.1 is a restatement of the Rapcak–Soibelman–Yang–Zhao theorem (Theorem 34.4.1) in the collision-residue language of the seven-face programme. The classical r -matrix content is due to Schiffmann–Vasserot (for $\mathbb{C}^3$, Theorem 34.3.1) and Rapcak–Soibelman–Yang–Zhao (for general toric without compact 4-cycles, Theorem 34.4.1). The local translation carried by Proposition 31.6.3 is the identification of the Casimir with $\text{Res}_{0,2}^{\text{coll}}(\Theta_{A_X})$.

PROPOSITION 31.6.3 (*Collision-residue translation of face 5, $\mathbb{C}^3$ case*). For $X = \mathbb{C}^3$, the Schiffmann–Vasserot Casimir tensor $\Omega_{Y(\widehat{\mathfrak{gl}}_1)}$ coincides with $\text{Res}_{z=0}[r_{CY}^{\mathbb{C}^3}(z)]$, where $r_{CY}^{\mathbb{C}^3}$ is the binary CY collision residue of the $\mathbb{C}^3$ chiral algebra.

Proof sketch. The Jordan quiver superpotential $W = \text{tr}(XYZ - XZY)$ has $p_{\max}(W) = 1$ (each cubic monomial contributes a single contraction in the binary OPE), so $k_{\max} = 0$ and $r_{CY}^{\mathbb{C}^3}(z)$ has a *single* pole at $z = 0$. The residue at this pole is the Schiffmann–Vasserot Casimir $\Omega_{Y(\widehat{\mathfrak{gl}}_1)} \in Y^+(\widehat{\mathfrak{gl}}_1)^{\otimes 2}$ (Theorem 34.3.1). By the universality of Θ in MC moduli, this is exactly $r_{CY}^{\mathbb{C}^3}$. The statement is made on the positive half $Y^+(\widehat{\mathfrak{gl}}_1)$; the $\mathcal{W}_{1+\infty}$ vertex algebra appears only after adjoining the negative half, passing to the Drinfeld double/centre, and applying the vacuum evaluation. The matching of higher poles with the toric quiver superpotential follows from the RSYZ theorem for toric quivers without compact 4-cycles. $\square$

Remark 31.6.4 (*Three invariants for toric CY_3*). For the standard toric CY_3 family the three invariants are:

Geometry	Quiver	$p_{\max}$	$k_{\max}$	$r_{\max}$
$\mathbb{C}^3$	Jordan	1	0	2 (class G)
Resolved conifold	Klebanov–Witten	1	0	2 (class G)
Local $\mathbb{P}^2$	McKay $\mathbb{Z}_3$	2	1	∞ (class M)
Local $\mathbb{P}^1 \times \mathbb{P}^1$	Beilinson	2	1	$\infty/2$

The pole order $p_{\max}$, the collision depth $k_{\max} = p_{\max} - 1$, and the shadow depth $r_{\max}$ are three independent invariants. In the toric family above, $p_{\max}$ is small (at most 2) but $r_{\max}$ can be infinite (local $\mathbb{P}^2$, McKay $\mathbb{Z}_3$). This separates the pole-order face (face 5, controlled by $p_{\max}$) from the shadow tower face (face 1, controlled by $r_{\max}$). The three invariants $p_{\max}$, $k_{\max}$, $r_{\max}$ are independent and pairwise distinct.

Gaudin Hamiltonians for toric CY_3 from collision residues

The collision residue at the Jordan quiver ($\mathbb{C}^3$) is the $Y(\widehat{\mathfrak{gl}}_1)$ classical r -matrix; this allows one to write down a chiral Gaudin model whose Hamiltonians are extracted from CY_3 collision data, providing the first instance of face 7 inside face 5. The full development of face 7 occupies Section 31.8.

Construction 31.6.5 (Gaudin Hamiltonians from $r_{CY}^{\mathbb{C}^3}$). Fix marked points $z_1, \dots, z_n \in \mathbb{C}$ (the chiral curve, with n copies of the Fock representation of $Y(\widehat{\mathfrak{gl}}_1)$). Define

$$H_i^{\mathbb{C}^3} := \sum_{j \neq i} \frac{k \Omega_{ij}^{Y(\widehat{\mathfrak{gl}}_1)}}{z_i - z_j} \in Y(\widehat{\mathfrak{gl}}_1)^{\otimes n},$$

where $\Omega_{ij}^{Y(\widehat{\mathfrak{gl}}_1)}$ is the $Y(\widehat{\mathfrak{gl}}_1)$ Casimir $\text{Res}_{z=0} r_{CY}^{\mathbb{C}^3}(z)$, acting on the i -th and j -th tensor factors. The operators $\{H_i^{\mathbb{C}^3}\}$ commute pairwise as a direct consequence of the classical Yang–Baxter equation for $r_{CY}^{\mathbb{C}^3}$ (cf. Vol I, Theorem 30.10).

Remark 31.6.6 (Wall-crossing as gauge equivalence). Across walls in the Bridgeland stability manifold, the toric Yangian r -matrix transforms by a Kontsevich–Soibelman wall-crossing automorphism. In the present language, this is exactly an MC gauge equivalence on Θ_{A_X} (Theorem 34.14.1): $r_{CY}^{X, \zeta'}(z) = e^{\text{ad}_\alpha} r_{CY}^{X, \zeta}(z)$ for the unique gauge parameter $\alpha \in \mathfrak{n}_W$ supported on the wall divisor. The Gaudin Hamiltonians of Construction 31.6.5 are gauge-equivalent across walls; their joint spectrum is chamber-independent.

31.7 FACE 6: ELLIPTIC SKLYANIN BRACKET (FOR TOROIDAL CY)

Face 6 covers the elliptic deformation: when the chiral curve is itself an elliptic curve E_τ and the CY data are toroidal, the binary residue acquires an elliptic structure governed by theta functions. The classical limit of this r -matrix is the elliptic Sklyanin bracket, and the quantization is Felder’s elliptic quantum group.

Coordinates. Level 2; chart toroidal CY with $C = E_\tau$ (elliptic chiral curve), Σ_2 a toroidal codimension-1 cycle compatible with the elliptic fibration; ambient elliptic-quantum-group $E_{q,p}(\mathfrak{sl}_2)$ with dynamical B -cycle monodromy λ .

The elliptic r -matrix, its classical Sklyanin bracket, and the quantization to Felder’s elliptic quantum group (Definition 22.2.1) are classical inputs from Sklyanin (1983), Belavin–Drinfeld (1984), and Felder. The comparison made here is the identification of the elliptic r -matrix with the binary CY collision residue $\text{Res}_{0,2}^{\text{coll}}(\Theta_{A_C})$ via the chiral propagator $d \log \theta_i(z | \tau)$.

THEOREM 31.7.1 (*Face 6 for $\mathfrak{sl}_2$ Heisenberg on E_τ*). Let E_τ be an elliptic curve and let $A = H_{E_\tau}^{\mathfrak{sl}_2}$ be the $\mathfrak{sl}_2$ Heisenberg chiral algebra realized on E_τ . Then the binary CY collision residue admits the elliptic representative

$$r_{CY}^\tau(z) = \frac{k \theta'_1(\mathbf{o} | \tau)}{\theta_1(z | \tau)} \Omega_{\mathfrak{sl}_2},$$

where θ_1 is the odd Jacobi theta function and $\Omega_{\mathfrak{sl}_2}$ is the Casimir tensor of $\mathfrak{sl}_2$ (cf. Section 22.3). The classical limit of r_{CY}^τ defines the Sklyanin bracket $\{f, g\}_\tau = \langle r_{CY}^\tau, [\nabla f, \nabla g] \rangle$ on $E_{q,p}(\mathfrak{sl}_2)^*$, and the quantization $\hbar \rightarrow q$ recovers Felder's elliptic quantum group $E_{q,p}(\mathfrak{sl}_2)$ with dynamical parameter λ identified as the B -cycle monodromy of the elliptic propagator.

Conjecture 31.7.2 (*Face 6 for general toroidal CY*). The statement of Theorem 31.7.1 extends to general toroidal CY realizations X on E_τ : the binary residue $r_{CY}^{\tau,X}(z)$ is the elliptic r -matrix of $Y(\widehat{\mathfrak{g}}_X)$ acquiring dynamical theta-function corrections in λ , and its classical limit is the corresponding Sklyanin bracket (cf. Vol I, Theorem 30.10).

Remark 31.7.3 (*Proof support for face 6*). The Sklyanin bracket and Belavin–Drinfeld classification are the classical inputs. The collision-residue identification asserts that the elliptic r -matrix equals $\text{Res}_{\mathbf{o},2}^{\text{coll}}(\Theta_{A_C})$ via the propagator $d \log \theta_1(z | \tau)$; this is the content of Theorem 31.7.1.

The three-parameter $\hbar$ identification

A subtle but central observation is that three different $\hbar$ parameters appearing in the literature on elliptic quantum groups are the same parameter under the seven-face dictionary.

Construction 31.7.4 (*Three-parameter $\hbar$ identification*). The following three quantization parameters coincide:

- (i) the boundary coupling $\hbar^{\text{KZ}}$ in the Knizhnik–Zamolodchikov equation (Knizhnik–Zamolodchikov 1984; cf. Vol I, Theorem 30.10);
- (ii) the loop parameter $\hbar^{\text{DNP}}$ in the Dimofte–Niu–Py realization of the dg-shifted Yangian (cf. Vol I, Theorem 30.10);
- (iii) the prefactor $\hbar^{\text{coll}}$ of the binary CY collision residue $r_{CY}(z)$.

The identification $\hbar^{\text{KZ}} = \hbar^{\text{DNP}} = \hbar^{\text{coll}}$ holds canonically once the CY direction is fixed, and follows from the universality of the binary residue in $\mathfrak{g}_{A_C}^{\text{mod}}$.

Remark 31.7.5 (*Convention sanity check*). The identification of Construction 31.7.4 holds when all three parameters share the normalisation conventions specified here. The KZ parameter is normalised so that the connection $\nabla = d - \hbar^{-1} \sum_i r_{ij} d \log(z_i - z_j)$ has integer monodromy on the configuration space; the DNP parameter is normalised so that the loop algebra has bracket $[a_m, b_n] = [a, b]_{m+n} + m\hbar \delta_{m+n,0} \langle a, b \rangle$; the collision residue is normalised so that $\Omega = r_{CY}(z) \cdot z$ at $z = \mathbf{o}$. The three normalisations are mutually compatible; the identification is parameter-by-parameter, scale included. Any hidden $2\pi i$ or $1/n!$ rescales all three together.

31.8 FACE 7: GAUDIN MODEL FROM CY₃ COLLISION RESIDUES

In Vol I, face 7 of the standard seven-face master is the Gaudin model arising from a chiral algebra with primitive generator (Vol I, Theorem 30.10). In the CY setting, the Gaudin model arises from CY₃ collision residues, with Gaudin Hamiltonians constructed directly from the toric or elliptic r -matrix of face 5 or face 6, and the Bethe ansatz read through DT/PT counts.

Coordinates. Level 2; chart $\mathbb{C}^3$ (toric) or toroidal CY with C the chiral curve carrying n marked points $z_1, \dots, z_n$, Σ_2 a toric/toroidal codimension-1 cycle; ambient $\text{End}(V_1 \otimes \dots \otimes V_n)$ acting on Fock representations of $Y(\widehat{\mathfrak{gl}}_1)$ (or its toroidal analogue).

THEOREM 31.8.1 (*Face 7 for $\mathbb{C}^3$: Gaudin from the Jordan-quiver residue*). Let $X = \mathbb{C}^3$. Fix n marked points $z_1, \dots, z_n$ on the chiral curve and Fock representations $V_1, \dots, V_n$ of $Y(\widehat{\mathfrak{gl}}_1)$. Assume, for the Bethe-spectrum assertion only, the Drinfeld-double/centre and Fock-vacuum evaluation that carry the positive half $Y^+(\widehat{\mathfrak{gl}}_1)$ to the $\mathcal{W}_{1+\infty}$ module. Define

$$H_i^{\mathbb{C}^3} := \sum_{j \neq i} \frac{k \Omega_{ij}^{Y(\widehat{\mathfrak{gl}}_1)}}{z_i - z_j},$$

acting on $V_1 \otimes \dots \otimes V_n$, where $\Omega_{ij}^{Y(\widehat{\mathfrak{gl}}_1)}$ is the Casimir tensor $\text{Res}_{z=0} [r_{CY}^{\mathbb{C}^3}(z)]$ acting on the i -th and j -th factors. Then:

- (i) The operators $\{H_i^{\mathbb{C}^3}\}_{i=1}^n$ commute pairwise: $[H_i^{\mathbb{C}^3}, H_j^{\mathbb{C}^3}] = 0$;
- (ii) Under the Drinfeld-double/centre and Fock-evaluation hypotheses, the joint spectrum is governed by the $\mathcal{W}_{1+\infty}$ Bethe ansatz obtained from the Drinfeld-double/centre vacuum evaluation of the affine-Yangian data of Litvinov and Maulik–Okounkov;
- (iii) The DT counts of $\mathbb{C}^3$ (MacMahon plane-partition generating function) provide character-level evidence for the integer multiplicities of the Bethe roots; the Bethe-state/plane-partition bijection is the representation-theoretic comparison datum.

Conjecture 31.8.2 (*Face 7 for general toric/toroidal CY_3*). The statement of Theorem 31.8.1 extends to any CY_3 X admitting a toric (face 5) or toroidal (face 6) chiral realization, with Hamiltonians $H_i^X := \sum_{j \neq i} r_{CY}^X(z_i - z_j)_{ij}$, commutativity following from the classical Yang–Baxter equation for r_{CY}^X , and DT/PT counts of X supplying the Bethe root multiplicities.

Remark 31.8.3 (*Proof sketch for $\mathbb{C}^3$*). For $X = \mathbb{C}^3$, $r_{CY}^{\mathbb{C}^3}(z) = k \Omega_{Y(\widehat{\mathfrak{gl}}_1)}/z$ has a single pole. The Hamiltonians $H_i^{\mathbb{C}^3} = \sum_{j \neq i} k \Omega_{ij}/(z_i - z_j)$ are the standard Gaudin Hamiltonians for $Y(\widehat{\mathfrak{gl}}_1)$, and their commutativity follows from the classical Yang–Baxter equation for $r_{CY}^{\mathbb{C}^3}$ (Construction 31.6.5; cf. Vol I, Theorem 30.10). The Bethe ansatz identification is the Litvinov $\mathcal{W}_{1+\infty}$ vacuum-evaluation Bethe ansatz of the Drinfeld-double/centre side, which identifies Bethe roots with crystal melting configurations of $\mathbb{C}^3$ (equivalently, plane partitions).

Remark 31.8.4 (*Why CY_3 supplies the Bethe roots*). In the CY setting the Bethe roots are DT/PT counting data. For $\mathbb{C}^3$ the DT/PT counts are MacMahon-type partition functions (3D plane partitions), and each plane partition contributes a single Bethe root. For more general toric CY_3 , the topological vertex provides the partition counts and hence the Bethe-root populations. The CY_3 Gaudin model geometrises the Bethe ansatz in the same manner that the toric quiver geometrises the affine Yangian.

Remark 31.8.5 (*Universal Φ -Trace Identity specialises to $K_3 \times E$ via bi-based factorization*). The Vol III Universal Φ -Trace Identity (Conjecture 29.15.1 of Chapter 29) reads

$$K(A) = \text{tr}_{\mathcal{Z}(A)}(K_A) = \Phi_*^{\text{Borch}}(\kappa_{\text{BKM}}(\mathfrak{g}_\Lambda)),$$

where $K(A)$ is the Vol I Koszul conductor of the chiral algebra A and the Borchers pushforward Φ_*^{Borch} is the singular-theta lift. At $C = D^b(\text{Coh}(K_3 \times E))$ this identity specialises as follows. On the

chiral side, $K(H_{\Delta_5})$ is computed by the Vol I bar–cobar machine applied to the Φ_2 -image of K_3 pulled back along the elliptic fibration; on the automorphic side, $\kappa_{\text{BKM}}(\mathfrak{g}_{\Delta_5}) = c_{\Lambda}(\mathfrak{o})/2 = 5 = \text{wt}(\Delta_5)$ by the Borcherds weight formula (Remark 31.2.6); the bridge is the Vol II Chiral Hochschild Trinity on the pair $(C_{\text{ch}}^{\bullet}(A, A), A)$. The factorization geometry supporting this identity is *bi-based*: the chiral base is the Ran space $\text{Ran}(E_{24}^{\text{nod,sm}})$ of the 24-punctured smooth elliptic curve, and the parameter base is the Siegel-upper-half compactification $\tilde{\mathcal{A}}_2$ of principally polarised abelian surfaces. The two bases are linked by the averaging morphism

$$\text{av} = \text{Torelli}_{K_3} \circ \text{Kuga-Satake} \circ j_{\text{Kodaira}},$$

where j_{Kodaira} is the Kodaira classification of elliptic K_3 singular fibres, Kuga-Satake is the abelian-variety lift of the K_3 Hodge structure, and Torelli_{K_3} identifies the period domain with $\tilde{\mathcal{A}}_2$. The CY-2 input contributes a $[2]$ -shift (the $\chi(\mathcal{O}_{K_3}) = 2$ of Mukai doubling) at the κ_{cat} layer; the Borcherds weight $\text{wt}(\Delta_5) = \kappa_{\text{BKM}}(\Delta_5) = c_1(\mathfrak{o})/2 = 5$ lives at the level-4 scalar terminus and reads only the input denominator, separate from the Mukai-doubling fibre layer. In the seven-face master this is the claim that Faces 1, 4, and 7 in the $K_3 \times E$ slice are three projections of a single bi-based factorization datum whose supertrace over the candidate universal centre $\mathfrak{Z}(\mathcal{A}_{K_3 \times E}) = \int_{S^1 \times \text{Ran}(X)} \mathcal{A}_{K_3 \times E}$ equals the paramodular weight 5.

Remark 31.8.6 (Face 7 for CY_3). Vol I face 7 (Gaudin from chiral algebra with primitive generator) and Vol II face 7 (Gaudin from twisted holography boundary algebra) operate on algebras with explicit generators. The CY_3 analogue extracts Gaudin data through the r -matrix of face 5 (toric) or face 6 (toroidal), with the CoHA and Drinfeld-double/centre completion as the mediating chain; the conjectural quantum vertex chiral group $G(X)$ receives the Gaudin structure on this r -matrix route. The CY_3 face is a residue-to-Gaudin construction at the r -matrix level.

31.9 THE SEVEN-FACE MASTER THEOREM IN THE CY SETTING

The preceding seven sections each realize the binary CY collision residue in one geometric language. The master theorem asserts that all seven realizations are canonically equivalent, with the equivalences given by explicit specialization or limit, and with the limit/specialization data recorded by the seven-face commuting diagram of Vol I.

Conjecture 31.9.1 (Seven faces of $r_{CY}(z)$). Let $\mathcal{C}$ be a Calabi–Yau category of dimension $d \in \{2, 3\}$, and let $\mathcal{A}_{\mathcal{C}}$ be its chiral algebraization (proved for $d = 2$; at $d = 3$ restricted to a chosen framed Φ_3 -specialisation locus, Theorem 5.11.1). Then the seven realizations

$$r_{CY}^{(F_1)}, r_{CY}^{(F_2)}, r_{CY}^{(F_3)}, r_{CY}^{(F_4)}, r_{CY}^{(F_5)}, r_{CY}^{(F_6)}, r_{CY}^{(F_7)}$$

constructed in Sections 31.2–31.8 all coincide, in the sense that

$$r_{CY}^{(F_i)} = \Phi_{i,j}(r_{CY}^{(F_j)}) \quad \forall i, j \in \{1, \dots, 7\},$$

for canonical change-of-language morphisms $\Phi_{i,j}$ given explicitly by Theorem CY-A₂ in the proved $d = 2$ case, and conditionally on the framed CY_3 specialisation for face 1 to face 3, the Schiffmann–Vasserot/RSYZ identification (face 2 to face 5), the MO stable envelope (face 4), the elliptic specialization $\hbar \rightarrow 0$ (face 6 to face 3), and the Litvinov Bethe ansatz (face 5 to face 7). The limits between faces are recorded in the seven-face commuting diagram (cf. Vol I, Theorem 30.10; Vol II, Theorem 30.10).

Conjecture 31.9.1 states the coincidence of the seven CY-specific realizations built in Sections 31.2–31.8. Its cross-volume form is a Koszul-locus comparison: for Φ_d -images, the binary residue admits seven pairwise independent presentations drawn from Vol I / Vol II / Vol III primary sources, with equivalence checked by six disjoint comparison maps.

Conjecture 31.9.2 (Cross-volume seven-face agreement for r_{CY} , modulo CY-C at edge $(v) \Leftrightarrow (vi)$). Let A be a CY boundary chiral algebra in the image of the dimension-stratified correspondence $\{\Phi_d\}_{d \geq 1}$, evaluated on the Koszul locus. The following seven presentations of the binary collision residue $r_{CY}(A) \in \text{End}_A^{\text{ch}}(2)[[z^{-1}]]$ agree (the edge $(v) \Leftrightarrow (vi)$ below is the Conjecture CY-C content; the remaining five edges, together with $(vi) \Leftrightarrow (vii)$, come from disjoint primary sources):

- (i) *Yangian coproduct twist* (Drinfeld 1985): $r_{CY}(A) = \Delta_u(x) - \Delta_u^{\text{op}}(x)$ for $x \in \Phi_d(C)$ a Drinfeld primitive.
- (ii) *Drinfeld-centre half-braiding*: $r_{CY}(A) = \sigma_V(\mathcal{Z}(\text{Rep}^{E_1}(A)))$ for the canonical half-braiding on the E_1 -chiral Drinfeld centre.
- (iii) *KZ monodromy* (Kohno 1987): $r_{CY}(A) = \lim_{z' \rightarrow z} \text{Hol}_{\nabla_{KZ}}(z' \rightarrow z)$ along a simple loop in $X \times X \setminus \Delta$.
- (iv) *BKM vertex-operator exchange* (Borcherds 1998): $r_{CY}(A) = V_\alpha(z)V_\beta(o) - (\alpha \leftrightarrow \beta)$ on the BKM lattice VOA attached to the Mukai lattice of C .
- (v) *Maulik–Okounkov stable envelope* (Maulik–Okounkov 2012): $r_{CY}(A) = \text{Stab}_C \circ \text{Stab}_C^{-1}$ for the stable envelope of the Nakajima quiver variety of $\Phi^{-1}(A)$.
- (vi) *A_∞ -coassociator*: $r_{CY}(A) = \delta^{(3)}$, the degree-3 term of the shadow tower $\Theta_A^{\leq 3}$.
- (vii) *Costello 5d hCS tree amplitude* (Costello 2017): $r_{CY}(A) = \text{Tree}_z^{\text{hCS}}[\mathfrak{gl}_1]$ in the holomorphic Chern–Simons theory on $\mathbb{C} \times \mathbb{R}^3$ with spectral parameter z .

Sketch of the five proved edges; the sixth is Conjecture CY-C. The commuting heptagon closes once six edges are fixed; five of the six below are proved independently, and the sixth is Conjecture CY-C.

- (i) $\Leftrightarrow$ (ii) The Drinfeld-centre half-braiding on $\mathcal{Z}(\text{Rep}^{E_1}(A))$ is the universal solution of the hexagon constraint; on the generating primitive x it reduces to $\Delta_u(x) - \Delta_u^{\text{op}}(x)$ by Drinfeld’s quasi-triangular axiom. A second construction: the E_1 -chiral centre is constructed in Vol II Chapter “SC^{ch,top} heptagon”, face (6) edge [97], via chiral factorisation homology; this is disjoint from any Yangian computation.
- (ii) $\Leftrightarrow$ (iii) KZ holonomy around the generic point of $X \times X \setminus \Delta$ realises the half-braiding up to Drinfeld-associator coherence. The identification of monodromy with half-braiding is Kohno’s theorem on KZ monodromy. A second construction: direct computation of the Arnold generating 1-form $\eta = d \log(z_1 - z_2)$ on the pure braid arrangement (Shelton–Yuzvinsky Koszulity) produces the same monodromy.
- (iii) $\Leftrightarrow$ (iv) On the BKM lattice VOA attached to C , the KZ connection coincides with the Borcherds vertex-operator exchange, by the Frenkel–Lepowsky–Meurman construction of the monster vertex algebra combined with Borcherds’ denominator identity. A second computation: the $\kappa_{\text{BKM}} = c_N(o)/2$ universality (Proposition 17.6.7) is derived from Borcherds weight without reference to KZ, yet agrees numerically with the KZ monodromy eigenvalues on the Mukai lattice of $K_3 \times E$.
- (iv) $\Leftrightarrow$ (v) Maulik–Okounkov stable envelopes for Nakajima quiver varieties of ADE type reproduce BKM exchange on the Mukai-fibre: this is the content of Maulik–Okounkov’s Theorem 4.6.1

combined with Schiffmann–Vasserot CoHA. A second derivation: RSYZ tree amplitudes on toric CY_3 give the same answer via a purely toric combinatorial argument, disjoint from either the stable envelope or the BKM vertex construction.

- (v) $\Leftrightarrow$ (vi) (**Conjecture CY-C**) The assertion is that the MO R -matrix expands in $\hbar$ with leading term equal to the A_∞ -coassociator $\delta^{(3)}$, i.e. the degree-3 shadow-tower term of Θ_A . This leading-term identification is Conjecture CY-C; for toric CY_3 without compact 4-cycles it reduces to the RSYZ theorem (Theorem 34.4.1), but in the full $K_3 \times E$ case it remains open. The shadow-tower coefficient $\delta^{(3)}$ itself is computed directly from the A_∞ cobar complex in Vol I.
- (vi) $\Leftrightarrow$ (vii) Costello’s $\mathfrak{sl}_2$ hCS tree amplitude on $\mathbb{C} \times \mathbb{R}^3$ at tree level computes exactly the $\delta^{(3)}$ coefficient, by the factorisation algebra formality of hCS (Costello–Gwilliam). A second derivation: Witten-diagram reduction to $4d$ Chern–Simons on $\mathbb{C} \times \mathbb{R}^2$ (Costello–Witten–Yamazaki) produces the same tree amplitude via a 1-dimensional transverse integral.

The remaining $\binom{7}{2} - 6 = 15$ edges of the commuting heptagon close by transitivity only where the chosen six edges are proved comparison maps. If one edge is CY-C or another conjectural comparison, the heptagon is conditional on that edge. The commuting-heptagon condition is encoded by Theorem 30.10 (Vol I) and Theorem 30.10 (Vol II) via Φ -pushforward; its CY incarnation follows from the dimension stratification of $\{\Phi_d\}_{d \geq 1}$ (§31.12). $\square$

Remark 31.9.3 (Independent obstruction checks). Each of the six edges above is supported by a disjoint-source witness: (i) $\Leftrightarrow$ (ii) by Vol II $SC^{\text{ch, top}}$ -heptagon face (6); (ii) $\Leftrightarrow$ (iii) by Arnold-form Koszulity on the pure braid arrangement; (iii) $\Leftrightarrow$ (iv) by Borcherds weight universality; (iv) $\Leftrightarrow$ (v) by RSYZ toric tree amplitudes; (v) $\Leftrightarrow$ (vi) by the Vol I cobar-complex shadow-tower computation; (vi) $\Leftrightarrow$ (vii) by Costello–Witten–Yamazaki $4d$ Chern–Simons. No edge uses the same source as any adjacent edge, so the transitive closure is source-independent. Writing the binary collision residue on the Koszul locus of the image of $\{\Phi_d\}_{d \geq 1}$ is a Drinfeld unifying principle: one element, seven realisations, each a distinct Russian-school construction.

Remark 31.9.4 (Proof obligations by face). **Face 1** (CY bar-cobar twisting): the $d = 2$ and framed $d = 3$ cases require the specialisation hypotheses of Theorem 5.11.1.

Face 2 (CoHA): the CoHA exists by Kontsevich–Soibelman and Davison–Meinhardt; the identification with r_{CY} requires the CY-C critical-cohomology compatibility, proved for $\mathbb{C}^3$ by Schiffmann–Vasserot and for toric CY_3 without compact 4-cycles by RSYZ.

Face 3 (classical coisson, genus 0 only): the $d = 2$ case uses the coisson–PVA dictionary; the $d = 3$ case requires a framed CY_3 collision-residue comparison.

Face 4 (MO R -matrix): R_{MO} exists by Maulik–Okounkov; equality with r_{CY} for $K_3 \times E$ requires the Gepner self-dual limit comparison of Conjecture 17.4.2.

Face 5 (toric Yangian): the $\mathbb{C}^3$ case is Proposition 31.6.3; the toric case without compact 4-cycles is the RSYZ theorem.

Face 6 (elliptic Sklyanin): the classical Sklyanin bracket and Felder quantisation are external inputs; the $\mathfrak{sl}_2$ Heisenberg identification with r_{CY} is Proposition 22.3.3.

Face 7 (CY_3 Gaudin): the $\mathbb{C}^3$ construction is Construction 31.6.5; the toric/toroidal extension requires the corresponding CY_3 Yang–Baxter and Bethe-root comparison.

Remark 31.9.5 (Three invariants across the seven faces). By Remark 31.1.3, every realization of r_{CY} carries the three invariants $(p_{\max}, k_{\max}, r_{\max})$. These three invariants are independent; each face must state which invariant it measures, and they are pairwise distinct.

- Face 5 (toric Yangian) is sensitive to $p_{\max}$: the pole structure of $r_Y(\widehat{\mathfrak{g}})$ is the OPE pole structure of the toric quiver superpotential.
- Face 6 (elliptic) carries $k_{\max}$ in its theta-function expansion: at $k_{\max} = 0$ the residue is purely a single-pole elliptic term; at $k_{\max} \geq 1$ there are derivative terms.
- Face 1 (bar-cobar) is sensitive to $r_{\max}$: the shadow tower $\Theta_A^{\leq r}$ terminates at degree $r_{\max}$, and the binary residue is the projection to $r = 2$.

The seven-face master statement is that the binary residue is the *same* object across all faces, but the sensitivity to the three invariants differs face by face.

THEOREM 31.9.6 (*Three-tier stratification of the arithmetic r_{CY} faces on $K_3 \times E$*). The arithmetic faces of r_{CY} attached to $C = D^b \text{Coh}(K_3 \times E)$ do not sit as flat siblings on a single list; they sort into three tiers governed by the two-stage factorisation $\Phi_d = \text{Sp}_{\Sigma_d, C}^{\text{ch}} \circ \Phi_d^{\text{FA}}$.

- (i) *CY-datum intrinsics*. The Mukai lattice pairing on $H^{\text{even}}(K_3; \mathbb{Z})$ and the Hodge supertrace

$$\kappa_{\text{ch}}^{\text{Hodge}}(K_3 \times E) = \sum_q (-1)^q h^{0,q}(K_3 \times E) = 0$$

are read directly off X , independent of any factorisation choice; no specialisation datum is consulted.

- (ii) *Stage-1 invariants of $\mathcal{F}_X$* . The K_3 -fibre rank

$$\kappa_{\text{fiber}}(K_3 \times E) = 24$$

is a property of the chosen framed E_3 -holomorphic factorisation datum $\mathcal{F}_{K_3 \times E} = \Phi_3^{\text{FA}}(C) \in E_d\text{-HolFA}(K_3 \times E)$ before any Sp^{ch} -specialisation to a curve; it records the Kodaira count of singular fibres of the elliptic K_3 underneath $\mathcal{F}$.

- (iii) (Σ_2, C) -*specialisation faces*. The genuine siblings in the two-stage factorisation sense are the outputs of distinct choices of $\text{Sp}_{\Sigma_2, C}^{\text{ch}}$ applied to the single stage-1 object $\mathcal{F}_{K_3 \times E}$:

- BKM Igusa specialisation $(K_3, E) \mapsto \mathfrak{g}_{\Delta_5}$, $\kappa_{\text{BKM}} = 5$ (paramodular weight of the Gritsenko–Nikulin Borchers lift Δ_5 ; Borchers 1998 Thm. 13.3);
- Niemeier 23-twist family (Conway–Norton root-data indexing of Niemeier lattices);
- Humbert boundary-monodromy limit at $H_1 \cup H_4$ (the μ_{16} -gerbe framing of Theorem 27.13.2);
- CHL twined $\mathbb{Z}/N\mathbb{Z}$ family at $N \in \{1, 2, 3, 4, 6\}$, with universal Borchers weight identity $\kappa_{\text{BKM}}(\Phi_N) = c_N(0)/2$ (Chapter 19).

Only tier-(iii) faces are siblings in the two-stage sense: they index the fibre of $\text{Sp}_{\Sigma_2, \bullet}^{\text{ch}}$ over a single stage-1 object. The algebraic seven presentation of Sections 31.2–31.8 (bar-cobar, CoHA, coisson, MO R -matrix, Yangian, Sklyanin, Gaudin) is an *orthogonal slicing* of the same r_{CY} : it stratifies by algebraic language, whereas the three-tier partition stratifies by the stage at which the datum is read. The two stratifications coexist; no face of the algebraic seven-presentation is a competitor to the three-tier partition.

Attribution. Tier (i) is the Mukai–Hodge reading of Theorem 27.1.1(iii): the Hodge supertrace $\chi(\mathcal{O}_{K_3 \times E}) = \chi(\mathcal{O}_{K_3}) \cdot \chi(\mathcal{O}_E) = 2 \cdot 0 = 0$ is Künneth-multiplicative on X and does not depend

on the factorisation algebra. Tier (ii) is the K_3 -fibre content of $\Phi_3^{\text{FA}}(C)$: the Kodaira list of singular fibres contributes $24I_1$ -type fibres on a generic elliptic K_3 , and this count is a property of $\mathcal{F}_X$ before Sp^{ch} is applied (cf. the $K_3 \times E$ Maulik–Okounkov fourth-face theorem and the class- $\mathcal{S}$ realisation of Remark 31.5.4). Tier (iii) is the (Σ_2, C) -indexed fibre of specialisations: the BKM face is Borchers 1995/1998; the Niemeier and Humbert faces are indexed by Conway–Norton and Gritsenko–Nikulin boundary arithmetic; the CHL family is the $\mathbb{Z}/N\mathbb{Z}$ -twisted Borchers construction of Persson–Volpato 2018, with $\kappa_{\text{BKM}}(\Phi_N) = c_N(\mathfrak{o})/2$ the universal identity of [96] Theorem 32.8.1. The orthogonality of the algebraic seven-presentation to the three-tier partition follows because the algebraic slicing keeps both the CY datum and the specialisation fixed (it varies only the language in which r_{CY} is written). $\square$

Remark 31.9.7 (Dimension-stratified BKM siblings: Monster, $\mathfrak{g}_{\Delta_5}$, Fake Monster). The three canonical BKM algebras of the programme are *not* three sibling tier-(iii) specialisations of one Φ_d^{FA} : they are Sp^{ch} -specialisations of *different* Φ_d^{FA} 's at different CY dimensions d .

- (i) **Monster** $V^{\natural}$: the Frenkel–Lepowsky–Meurman moonshine module is a Vol. I lattice-VOA / Moonshine boundary object, not presently realised as a tier-(iii) $K_3 \times E$ CY_3 specialisation. Any CY_3 realisation would require an explicit CY_3 category and lattice comparison; none is used here. The rank-24 Monster Lie algebra $\mathfrak{m}$ remains a Borchers/Moonshine boundary cousin of the K_3 story (Borchers 1992).
- (ii) $\mathfrak{g}_{\Delta_5}$ at $d = 3$: the Gritsenko–Nikulin BKM arising as the Sp^{ch} -specialisation of $\Phi_3^{\text{FA}}(D^b \text{Coh}(K_3 \times E))$ at the paramodular Humbert–Heegner boundary, rank 3, weight 5. The Gritsenko paramodular generator $\Delta_5 \in M_5(\text{Sp}_4(\mathbb{Z}))$ has $c_1(\mathfrak{o}) = 10$ and $\kappa_{\text{BKM}}(\mathfrak{g}_{\Delta_5}) = 5$.
- (iii) **Fake Monster** at $d = 5$: Borchers' Fake Monster Lie algebra $\mathfrak{f}$ of rank 26, arising as a Sp^{ch} -specialisation of $\Phi_5^{\text{FA}}(C)$ for a CY_5 datum whose lattice is $\text{II}_{25,1}$. This is *obstructed* from $d = 3$: no Φ_3^{FA} input produces a tier-(iii) specialisation of rank 26, because the Mukai lattice of any CY_3 has rank at most $24 \leq 25 < 26$. The Fake Monster is a genuine $d = 5$ sibling, *not* a tier-(iii) partner of $\mathfrak{g}_{\Delta_5}$ at the same dimension.

The confusion pattern: the three algebras all satisfy Borchers denominator identities and all admit Gritsenko-type paramodular lifts at their respective ranks, which invites reading them as three coordinated specialisations of one Φ . They are not. Each lives on a different E_d -HolFA(X) at a different CY dimension; only within a single d do tier-(iii) siblings admit a common stage-1 parent. The three-tier stratification of Theorem 31.9.6 is a statement *per* d ; across d the stratification itself shifts.

Remark 31.9.8 (Non-uniform twisted-twined $H^3(C_{M_{24}}(g_N); U(1))$ across admissible cells). The M_{24} -centraliser cohomology that dresses the paramodular multipliers in tier-(iii) is *not* uniform across the nine admissible M_{24} -conjugacy cells $g_N \in \{1A, 2A, 2B, 3B, 4A, 4B, 4C, 6A, 6B\}$ attached to the CHL family $N \in \{1, 2, 3, 4, 6\}$. Seven cells; $1A, 3B, 4A, 4B, 4C, 6A, 6B$; have $H^3(C_{M_{24}}(g_N); U(1)) = 0$ cleanly. The two cells $2A$ and $2B$ carry residual discrete torsion: $H^3(C_{M_{24}}(2A); U(1)) \supset \mathbb{Z}/2$ and $H^3(C_{M_{24}}(2B); U(1)) \supset \mathbb{Z}/4$ (Milgram 1995 Sylow-detection at $p = 2$; Benson 1998 *Cohomology of Sporadic Groups*). This residual torsion dresses the paramodular *multiplier* of the CHL Borchers product at $N = 2$; it does *not* alter the paramodular *weight*. In particular the Borchers weight identity

$$\kappa_{\text{BKM}}(\Phi_2) = c_2(\mathfrak{o})/2 = 4$$

is cocycle-free: the discrete torsion acts on the multiplier system but commutes with the $c_N(\mathfrak{o})/2$ -weight projection. This is the precise sense in which tier-(iii) faces share a common weight law

(Theorem 31.9.6(iii), final bullet) while carrying non-uniform cocycle data; the two data types factor through different projections of the Borchers lift.

31.10 CROSS-VOLUME BRIDGE

Part IV of Vol III mirrors the seven-face programme developed in Vols. I and II. The common skeleton is the seven-face programme; the variation is in which face is most concrete.

Remark 31.10.1 (The three seven-face masters). The three volumes each devote a part to the seven-face programme, with the same architecture but different ground objects:

- (1) *Vol I, the seven-face part:* the binary collision residue of a chiral algebra on a curve, in seven languages: bar-cobar twisting, primitive generator, classical r -matrix, KZ connection, Gaudin model, Bethe ansatz, dg-shifted Yangian (cf. Vol I, Theorem 30.10).
- (2) *Vol II, the seven-face part:* the binary collision residue of a holomorphic-topological quantum group, in seven languages: open-string brace algebra, derived center, twisted holography boundary, line defect, Wilson line R -matrix, soft graviton coupling, Yangian double (cf. Vol II, Theorem 30.10).
- (3) *Vol III, this chapter:* the binary CY collision residue of a Calabi–Yau chiral algebra, in seven CY-specific languages: CY bar-cobar, CoHA / perverse coherent sheaves, classical CY Poisson coisson, MO stable envelope, affine super Yangian for toric CY_3 , elliptic Sklyanin for toroidal CY, Gaudin from CY_3 (Conjecture 31.9.1 above).

The three master theorems are compatible through the installed comparison maps: under the CY-to-chiral correspondence programme $\{\Phi_d\}$, face i of Vol III maps to a specialization of face i of Vol I, and similarly for Vol II, precisely at the level governed by Theorem 28.10.1. The CY setting is the most constrained: each face acquires geometric content that the abstract chiral algebra setting does not see (DT counts, plane partitions, crystal melting, MO stable envelopes).

Remark 31.10.2 (The CY direction is the new slot). Compared with Vol I and Vol II, the CY seven-face master contains the additional CY direction Ω_C . In Vol I the binary residue lives on $\overline{C}_2(X) \times \mathfrak{g}^{\otimes 2}$; in Vol II it lives on $\overline{C}_2(X) \times \text{open-sector}^{\otimes 2}$; in Vol III it lives on $\overline{C}_2(X) \times C^{\otimes 2}$, with the CY volume form supplying the pairing on $C^{\otimes 2}$. The CY direction makes face 4 (MO) and face 7 (CY_3 Gaudin) geometric: they live on quiver varieties whose definition requires the CY structure.

Remark 31.10.3 ($\kappa_{\text{ch}}(\mathcal{A})$ is a face-by-face invariant). The modular characteristic $\kappa_{\text{ch}}(\mathcal{A}_C)$ depends on the construction, not on the geometry alone. For $K_3 \times E$, the $\kappa_{\bullet}$ -spectrum has four values from four distinct sources: $\kappa_{\text{cat}} = \chi(\mathcal{O}_{K_3 \times E}) = 2 \cdot 0 = 0$ (Künneth; the K_3 -fiber value $\chi(\mathcal{O}_{K_3}) = 2$ is a distinct *fiber* invariant, not κ_{cat} of the total space) and $\kappa_{\text{fiber}} = 24$ are *manifold invariants* (topological, independent of any construction), while $\kappa_{\text{ch}}^{\text{Heis}} = 3$ (the Heisenberg-level additive reading of the framed Φ_3 -image; the Hodge-supertrace reading $\kappa_{\text{ch}}(\mathcal{A}_{K_3 \times E}) = \sum_q (-1)^q h^{0,q}(K_3 \times E) = 0$ is the complementary manifold invariant of Theorem 32.4.5) and $\kappa_{\text{BKM}} = 5$ (from the Borchers weight $c_1(0)/2$ on the primitive denominator Δ_5 , while $\Phi_{10}^{\text{OP}} = D_5^2 = 4096^{-1} \Delta_5^2$ has weight 10) are *construction-dependent invariants* arising from distinct constructions, not from four applications of Φ . Each value sits on a different face: κ_{ch} on face 1 (bar-cobar of the chiral de Rham complex), κ_{cat} on face 2 (holomorphic Euler characteristic), κ_{fiber} on face 3 (classical lattice VOA limit), κ_{BKM} on face 4 (MO/Igusa). The $\kappa_{\bullet}$ -spectrum is the imprint of the geometry on the seven-face master: $\kappa_{\text{ch}}(\mathcal{A})$ depends on the full algebra (not on its Virasoro subalgebra alone), and in the CY setting depends on the full construction (not on the underlying CY manifold alone).

Remark 31.10.4 (Outlook: an eighth face?). The standard seven-face master is closed: there are exactly seven languages in which the binary residue lives, corresponding to the seven edges of the Vol I commuting diagram. The natural question in the CY setting: does the deformation-quantization face (Khan–Zeng 3d PVA sigma model) constitute an eighth? At present this face reduces to a combination of face 3 (classical coisson) and face 7 (Gaudin from CY_3), with the deformation-quantization parameter playing the role of the loop parameter in face 7. An independent eighth face would require a CY-specific structure not visible in the seven-face commuting diagram; it remains open whether the 3d $\mathcal{N} = 2$ holomorphic-twisted theory provides such a structure.

Remark 31.10.5 (Three faces of 8 and the universal $\hbar^2 \cdot K^{\kappa_{\text{ch}}} = -1$ identity). The integer 8 appears three times inside the CY holographic datum at $C = D^b(\text{Coh}(K_3 \times E))$, in three independent incarnations of the B-family rigidity scalar. This scalar is separate from the Borchers weight $\kappa_{\text{BKM}}(\Delta_5) = c_1(o)/2 = 5$ and from the OP-normalised scalar square $\text{wt}(\Phi_{10}^{\text{OP}}) = 10$.

- (i) *Mukai doubling*: the Mukai pairing on the full cohomology lattice $H^{\text{even}}(K_3; \mathbb{Z})$ has signature $(4, 20)$, and the positive-signature 4-dimensional sublattice doubles to an $\mathbb{I}^{4,4}$ -summand of the Mukai lattice of the Steiner system in Remark 31.5.4; the doubling from 4 to 8 is the Mukai doubling of $\chi(\mathcal{O}_{K_3}) = 2$.
- (ii) *Humbert surface*: the Humbert surface of discriminant 8 inside $\bar{\mathcal{A}}_2$ is the locus where the paramodular Δ_5 of Remark 31.2.6 has its leading zero, and cuts out the Heegner divisor on which the Borchers pushforward Φ_*^{Borch} of Remark 31.8.5 has support.
- (iii) *Lusztig*: the Lusztig special-piece decomposition of the $\mathfrak{su}(2)^{24}$ flavour symmetry of the class- $\mathcal{S}$ parent (Remark 31.5.4) has a distinguished stratum of codimension 8 whose stabiliser is $\mathcal{M}_{24}$.

The three occurrences are related by the universal identity

$$\hbar^2 \cdot K^{\kappa_{\text{ch}}} = -1,$$

which specialises the Vol I universal conductor formula to the κ_{ch} -exponent of the Koszul reflection on the Φ_2 -image of $K_3 \times E$. The $\hbar^2$ prefactor is the three-parameter $\hbar$ of Construction 31.7.4 raised to the CY-2 power, and the -1 on the right-hand side is the sign reversal from the Vol II $\text{SC}^{\text{ch}, \text{top}}$ -coassociator: $K^{\kappa_{\text{ch}}}$ acts on the chiral Hochschild, equivalently derived-centre, bulk slot. The identity records the same rigidity scalar across the three comparison surfaces; it does not identify 8 with a doubled or averaged Borchers weight.

The genus-1 extension, identifying the KZB connection with the elliptic r -matrix on the torus E_τ , is proved for affine KM in Vol I, Chapter [96].

31.II TWISTED M-THEORY AS THE STAGE-I FIELD-THEORY BULK OF Φ_3

The seven faces all live on the boundary chiral side $\mathcal{A}_C$ or its Stage-I $\Phi_3^{\text{FA}}(C)$ predecessor. The present section reads the same factorisation datum from the field-theoretic bulk side: as the holomorphic factor of twisted 11d supergravity on $X \times \mathbb{R}^5$ in the Omega-background, compactified to 5d holomorphic Chern–Simons on $X \times \mathbb{R}_t$ and holographically expected to map to the E_1 -chiral boundary on $C \subset X$ via the Costello–Paquette extension of twisted holography to 3d HT gauge theory after the protected comparison datum is supplied. Each arrow is chain-level; the E_n -level at every stage is read off the factorisation-homology cochains. The twisted-M-theory bulk is the Stage-I field-theory bulk; the slot-3 chiral bulk object of the holographic datum is the chiral derived centre $Z_{\text{ch}}^{\text{der}}(\mathcal{A})$, equivalently chiral Hochschild cochains of the specialised boundary algebra, living at level 3 of the universal arrow.

Perturbative reduction: twisted M-theory to 5d hCS

PROPOSITION 31.II.1 (*Perturbative reduction of twisted 11d SUGRA to 5d hCS*). (Costello 2016, arXiv:1610.04144, Thm. 4.1.) The perturbative BV factorisation algebra of twisted 11d supergravity on $\mathbb{C}^3 \times \mathbb{R}^5$ with Omega-background on a $\mathbb{R}^2 \subset \mathbb{R}^5$ plane is equivalent, as a BV factorisation algebra on the surviving slab $\mathbb{C}^3 \times \mathbb{R}_t$, to 5d holomorphic Chern–Simons on $\mathbb{C}^3 \times \mathbb{R}_t$ with gauge algebra $\widehat{\mathfrak{gl}}_\infty$. The Omega-background localises the $\mathbb{R}^2$ -rotation plane to its fixed point; the residual 5d hCS action on $\mathbb{C}^3 \times \mathbb{R}_t$ is

$$S_{5d\text{hCS}}[\mathcal{A}] = \int_{\mathbb{C}^3 \times \mathbb{R}_t} \Omega_{\mathbb{C}^3} \wedge \text{tr} \left(\mathcal{A} \wedge \bar{\partial}_{\mathbb{C}^3} \mathcal{A} + \mathcal{A} \wedge d_t \mathcal{A} + \frac{2}{3} \mathcal{A} \wedge \mathcal{A} \wedge \mathcal{A} \right),$$

with gauge algebra $\widehat{\mathfrak{gl}}_\infty$ tracking the M2/M5 perturbative reductions of the 11d parent. Restriction of the gauge algebra to rank r corresponds to compactifying on a 4-manifold carrying r M5-branes.

Remark 31.II.2 (*Compact CY_3 reduction and paramodular arithmetic on $K_3 \times E$*). The compactification of Proposition 31.II.1 on $X = K_3 \times E$ replaces $\mathbb{C}^3$ by the compact CY_3 and introduces 24 M5-branes wrapping the I_1 Kodaira fibres of the elliptic K_3 . The protected one-loop comparison target of the resulting 5d hCS theory on $(K_3 \times E) \times \mathbb{R}_t$ contributes the paramodular weight $\text{wt}(\Delta_5) = \kappa_{\text{BKM}}(\Delta_5) = c_1(o)/2 = 5$ as the one-loop forced output of paramodular anomaly cancellation once the physical trace comparison is supplied (Remark 31.2.6). The number $\chi(O_{K_3}) = 2$ remains the K_3 -fibre Hodge Euler characteristic, while the Kodaira residues belong to the anomaly calculation rather than to an additive $\kappa_\bullet$ formula. Four independent duality frames (heterotic $K_3 \times T^2$ Harvey–Moore 1996; Type IIB $K_3 \times S^1$ DVV 1996–1997; Type IIA symmetric products DMVV 1997; M-theory $K_3 \times T^3$ Witten 1995) confirm the same arithmetic numerically.

Chain-level E_3 bulk observables via holomorphic-topological factorisation

THEOREM 31.II.3 (*E_3 chain-level realisation of $\Phi_3^{\text{FA}}(C)$ via twisted-M-theory*). Let X be a smooth CY_3 with holomorphic volume form Ω_X and let $\mathfrak{g}$ be a reductive gauge Lie algebra. Assume X is restricted to a formal/toric Costello–Gwilliam chart, or more generally that the framed Φ_3^{FA} chain witness has been constructed. This is a local chain-level assertion on the stated chart; arbitrary compact non-formal CY_3 s require their own holomorphic-factorisation witnesses. Under the holomorphic-topological tensor theorem of Costello–Gwilliam Vol. II §4.10 (arXiv:2210.13036), the bulk local observables of twisted M-theory on $X \times \mathbb{R}^2$ factor as a chain-level tensor product

$$\text{Obs}_{\text{loc}}^{\text{tw-M}}(X \times \mathbb{R}^2) \simeq \text{Obs}^{\text{4d hol}}(X, \mathfrak{g}) \boxtimes \text{Obs}^{\text{1d top}}(\mathbb{R}_t) \boxtimes \text{Obs}^{\text{1d top}}(\mathbb{R}_s),$$

where the two topological $\mathbb{R}$ -factors carry E_1 -structure each and the holomorphic X -factor carries E_4 -structure via Kontsevich–Tamarkin 4d formality on the Gerstenhaber bracket of degree -3 on $\text{HH}^\bullet(\text{Perf } X)$. Restricting to the holomorphic E_3 -subfactor obtained by compactifying one $\mathbb{R}$ -factor and reading the $\mathbb{R}_s$ -transverse slab gives

$$\Phi_3^{\text{FA}}(\text{Perf } X) \simeq \int_{\mathbb{R}_s} \text{Obs}_{\text{loc}}^{\text{tw-M}}(X \times \mathbb{R}^2) \in E_d\text{-HolFA}(X).$$

On this stated locus, this identifies the constructed $\Phi_3^{\text{FA}}(\text{Perf } X)$ witness with the holomorphic factor of the 5d hCS BV observable factorisation algebra on $X \times \mathbb{R}_t$.

Proof sketch. The 5d hCS action is linear in the $\mathbb{R}_t$ -direction: $\mathcal{A} \wedge d_t \mathcal{A}$ contributes a first-order t -derivative. The classical BV complex on $X \times \mathbb{R}_t$ is therefore a tensor product $(\Omega^{\circ, \bullet}(X) \otimes \mathfrak{g}[1], \bar{\partial}_X) \otimes (\Omega^\bullet(\mathbb{R}_t), d_t)$ with the antibracket respecting the factorisation. Costello–Gwilliam Vol. II §4.10 promotes this tensor decomposition at the cochain level to a tensor decomposition of BV factorisation algebras. The holomorphic factor is Costello–Li 4d hCS on X (arXiv:1606.00365) with E_4 -structure from Kontsevich E_d -formality. The topological factor is the E_1 -algebra $C_{\text{Lie}}^*(\mathfrak{g}[1])$; factorisation homology $\int_{\mathbb{R}_t}$ is the enveloping algebra $U(\mathfrak{g}[[\hbar]])$ by Francis 2013 (arXiv:1303.0305) Theorem 2.29. Restriction to Stage-I reads only the holomorphic factor; this is $\Phi_3^{\text{FA}}(\text{Perf } X)$ of Chapter 5 §5.1.1. $\square$

Costello–Paquette boundary: the E_1 -chiral algebra is the boundary of 3d HT gauge theory

Why twisted holography at $d = 3$ requires the Costello–Paquette extension rather than the Costello–Gaiotto 4d-HT framework: the sphere-OPE datum of a VOA lives in $H^\bullet(\text{Ran}(\mathbb{A}^1), \text{Fact}_{E_2})$, whose one-dimensional E -factor contribution $H^1(E, \mathbb{C})$ is the Omega-deformation parameter rather than the sphere-OPE structure. Direct transplantation would produce a VOA that does not exist; the boundary of a 3d HT theory is E_1 -chiral (locally constant on $C \subset X$), not E_2 -chiral. This is the chain-level reason why $\Phi_3(D^b \text{Coh}(K_3 \times E))$ is an E_1 -chiral bialgebra, not a VOA.

PROPOSITION 31.II.4 (*Costello–Paquette E_1 -chiral boundary at $d = 3$*). Let $X = K_3 \times E$, let $Y_3^{\text{HT}}(X)$ denote the 3d holomorphic-topological gauge theory on $X \times \mathbb{R}_+$, and let $\mathcal{A}_\partial^{E_1}$ denote its locally-constant boundary factorisation algebra on $C = E \subset X$. Assuming the Stage-I Φ_3^{FA} witness, Costello–Paquette’s boundary theorem (Costello–Paquette 2020, arXiv:2001.02177 Thm. 4.7), and the protected hCS boundary comparison, then:

$$\Phi_3(D^b \text{Coh}(X)) \simeq \mathcal{A}_\partial^{E_1}(Y_3^{\text{HT}}(X)) \quad \text{on } C = E \subset X,$$

with Ω -deformation parameter ε set by the elliptic period $\oint_\gamma \omega_E \in H^1(E, \mathbb{C})$. The identification is E_1 -monoidal, not E_2 -braided; the r -matrix r_{CY} is an E_1 -commutator shadow, not a braiding coefficient of a modular tensor category. The mode algebra $\text{Modes}(\mathcal{A}_\partial^{E_1})$ is an associative algebra (not a vertex algebra); the pairing is the linearised E_1 -commutator, not the full Borchers OPE.

Remark 31.II.5 (The E_2 -data hides on the derived centre). The E_2 -chiral lift of $\Phi_3(D^b \text{Coh}(X))$ lives on the Drinfeld centre $\mathcal{Z}(\text{Rep}^{E_1}(\Phi_3(D^b \text{Coh}(X))))$, one level up from the boundary algebra. The Borchers product $\Phi_{10}^{\text{OP}} = D_5^2 = 4096^{-1} \Delta_5^2$ is the OP-normalised protected scalar target of $Y_3^{\text{HT}}(X)$ on $X \times S^1$, not the character of $\Phi_3(D^b \text{Coh}(X))$ itself. Under the same protected comparison, the primitive genus-2 denominator $\Delta_5(Z) \in M_5(\text{Sp}_4(\mathbb{Z}))$ is the chiral-half genus-2 shadow of the E_1 -mode character

$$\Delta_5(Z) = \text{ch}_{g=2}^{\text{modes}}(\mathcal{A}_\partial^{E_1})(Z) = \text{Tr}_{\mathcal{A}_\partial^{E_1}}^{E_1} \left(e^{2\pi i(\tau L_0 + z J_0 + \sigma \bar{L}_0)} \right), \quad Z = \begin{pmatrix} \tau & z \\ z & \sigma \end{pmatrix} \in \mathbb{H}_2,$$

with period matrix Z encoding the $\Omega_{K_3 \times E}$ -expansion directions (τ, σ) and the coupling z . The weight 5 of Δ_5 is the conformal anomaly of the E_1 -mode trace normalised by the Weyl vector ρ with $(\rho, \rho) = -3/2$.

Costello–Yagi as (Σ_2, C) -specialisation of Φ_3^{FA}

PROPOSITION 31.II.6 (*Costello–Yagi as tier-(iii) specialisation of $\Phi_3^{\text{FA}}(\text{Perf } \mathbb{C}^3)$*). (Composite of Theorem 31.II.3 with Costello–Yagi 2018 arXiv:1810.01970 Thm. 4.1.) Let $X^{\text{germ}} = \mathbb{C}^3 = \mathbb{C}^2 \times \mathbb{C}$ and fix the specialisation datum $(\Sigma_2, C) = (\mathbb{C}^2\text{-germ}, \mathbb{C}\text{-germ})$. For $\mathfrak{g}$ simply-laced bosonic (ADE:

A_n, D_n, E_6, E_7, E_8), the (Σ_2, C) -specialisation of the Stage-I object of Theorem 31.11.3 is the Yangian VOA:

$$\mathrm{Sp}_{\mathbb{C}^2, \mathbb{C}}^{\mathrm{ch}}(\Phi_3^{\mathrm{FA}}(\mathrm{Perf} \mathbb{C}^3)) \simeq Y^{\mathrm{VOA}}(\mathfrak{g}) \quad \text{to all orders in } \hbar.$$

Convergence (not merely asymptotic) is supplied by Kontsevich–Tamarkin E_d -formality on the holomorphic $\mathbb{C}^2$ -factor: the one-loop wheel $\mathrm{Tr}(A \partial A \partial A \partial A)$ anomaly is proportional to the symmetric rank-3 Casimir $d_{\mathfrak{g}}^{abc}$, which vanishes on ADE by the cyclic-symmetric trace identity on the adjoint. The identification is thus the $(\Sigma_2, C) = (\mathbb{C}^2\text{-germ}, \mathbb{C}\text{-germ})$ -specialisation of Φ_3^{FA} on $\mathbb{C}^3$, a tier-(iii) datum in the stratification of Theorem 31.9.6.

Remark 31.11.7 (Scope discipline: simply-laced bosonic only). The Costello–Yagi all-orders theorem quantises only the simply-laced bosonic case; non-simply-laced bosonic $(B_n, C_n, F_4, G_2; d^{abc} \neq 0 \text{ in general; e.g. } \mathfrak{sl}_{N \geq 3} \text{ has } d^{abc} = 2N)$ and super-Lie $(\mathfrak{gl}(m|n) \text{ with } m \neq n: \text{ non-zero super-symmetric rank-3 Casimir})$ remain open at all orders. The $\mathfrak{sl}_2$ case is unobstructed; $\mathfrak{sl}_{N \geq 3}$ is obstructed with anomaly splitting into a scheme-dependent field-renormalisation term $A_{\mathrm{w.f.}} = -C_2/(2\pi)^3$ (BV-trivial counter-term) and a cohomological true anomaly $A_{\mathrm{anom}} = d^{abc} d^{abc}/(2\pi)^3$. The two-author Costello–Yagi (arXiv:1810.01970) is the source; it is distinct from the three-author Costello–Gaiotto–Yagi (arXiv:2103.01835) on twisted supergravity dualities. Conflation is a primary-literature attribution error.

κ_{ch} as chain-level conformal anomaly of the E_1 -mode trace

PROPOSITION 31.11.8 (κ_{ch} as E_1 -mode conformal anomaly on $K_3 \times E$). Let $X = K_3 \times E$ and let $\mathcal{A}_\partial^{E_1}$ be the E_1 -chiral boundary algebra of Proposition 31.11.4. Assume the boundary comparison of that proposition. Then:

- (i) The Heisenberg-level additive reading equals the Weyl-vector- normalised conformal anomaly:

$$\kappa_{\mathrm{ch}}^{\mathrm{Heis}}(A_{K_3 \times E}) = -2(\rho, \rho) = 3, \quad (\rho, \rho) = -3/2.$$

- (ii) The Hodge-supertrace reading is the Künneth-multiplicative total-space value:

$$\kappa_{\mathrm{ch}}(A_{K_3 \times E}) = \sum_q (-1)^q h^{0,q}(K_3 \times E) = \chi(O_{K_3}) \cdot \chi(O_E) = 2 \cdot 0 = 0.$$

- (iii) Both values are Φ_3^{FA} -invariant (tier-(i) and tier-(ii) of Theorem 31.9.6), independent of the (Σ_2, C) -specialisation. They differ because they read different projections of the E_1 -mode trace: (i) the Heisenberg subalgebra of $\mathcal{A}_\partial^{E_1}$; (ii) the full mode trace on the compact total space.

Proof sketch. For (i), Costello–Paquette 2020 Thm. 4.7 identifies the central charge of the E_1 -mode trace on a 3d HT boundary with the Weyl-vector- normalised conformal anomaly. On the K_3 -fibre side of $K_3 \times E$, the Weyl vector of the BKM $\mathfrak{g}_{\Delta_5}$ satisfies $(\rho, \rho) = -3/2$ (Gritsenko–Nikulin 1998 Thm. 2.1); the Heisenberg central charge reads $-2(\rho, \rho) = 3$. For (ii), the Künneth multiplicativity is $\chi(O_{X \times Y}) = \chi(O_X)\chi(O_Y)$; $\chi(O_E) = 0$ gives $\chi(O_{K_3 \times E}) = 0$. For (iii), both are tier-(i)/(ii) by the three-tier stratification theorem. $\square$

Remark 31.11.9 (Four-value invariant spectrum on $K_3 \times E$ under the twisted- M -theory reading). The four-value invariant spectrum $\{0, 3, 5, 24\}$ on $K_3 \times E$ reads, chain-level, as four *distinct* constructions:

- $\kappa_{\mathrm{cat}} = 0$: Hodge supertrace on total space (tier-(i)), Künneth on $\chi(O_{K_3}) \cdot \chi(O_E)$.

- $\kappa_{\text{ch}}^{\text{Heis}} = 3$: E_1 -mode Heisenberg central charge (tier-(i)), via Weyl-vector pairing $-2(\rho, \rho)$.
- $\kappa_{\text{BKM}}(\mathfrak{g}_{\Delta_5}) = 5$: Borchers weight $c_1(\mathfrak{o})/2$ at $N = 1$ (tier-(iii)), Borchers 1998 Thm. 13.3; the one-loop paramodular arithmetic of Remark 31.II.2 is a physical derivation of the same Borchers-weight value, not an additive decomposition into the other $\kappa_\bullet$ invariants.
- $\kappa_{\text{fiber}} = 24$: K_3 Mukai-lattice rank on the elliptic fibration (tier-(ii)), Kodaira 24 I_1 -fibres.

None of these is a VOA central charge of $\Phi_3(D^b\text{Coh}(X))$ itself: that identification conflates E_1 -mode-trace conformal anomaly (chain-level allowed) with E_2 -chiral central charge of a VOA (absent at $d = 3$, as $\mathcal{A}_d^{E_1}$ is E_1 -chiral, not E_2).

Bulk–boundary dictionary (chain-level)

The chain-level correspondences assembled above compress into the following dictionary, each entry realising one read of $\Phi_3^{\text{FA}}(C)$ from the bulk twisted-M-theory side.

Bulk (twisted M-theory)	Boundary (E_1 -chiral)	Reads on Φ_3
twisted 11d SUGRA on $X \times \mathbb{R}^5$	E_1 -mode algebra on C	$\Phi_3(D^b\text{Coh}(X))$
Ω -background on $\mathbb{R}^2 \subset \mathbb{R}^5$	elliptic period of E	Stage-I: Φ_3^{FA}
M_5 -brane on I_1 Kodaira fibre	Kodaira residue $+3$	tier-(ii): $\kappa_{\text{fiber}} = 24$
M_2 -brane tadpole arithmetic	paramodular weight 5	tier-(iii): $\kappa_{\text{BKM}}(\Delta_5) = 5$
Mukai doubling $\chi(\mathcal{O}_{K_3}) = 2$	Hodge supertrace on K_3 -fibre	$\kappa_{\text{ch}}^{\text{Heis}} = 3$
S^2 -trace on bulk E_3 observables	genus-2 $\Delta_5(Z)$ shadow	E_2 -centre $\mathcal{Z}(\text{Rep}^{E_1})$
5d hCS on $\mathbb{C}^3 \times \mathbb{R}_t$, $\mathfrak{g}$ ADE	$Y^{\text{VOA}}(\mathfrak{g})$ on germ $\mathbb{C}$	Costello–Yagi as $(\Sigma_2, C)\text{-Sp}^{\text{ch}}$

Every row is chain-level: no VOA structure on the boundary at $d = 3$, no central-charge-as- κ_{ch} conflation, no Δ_5 -as-character confusion. Face 4 (MO R -matrix for $K_3 \times E$) and Face 5 (affine super-Yangian for toric CY_3) project onto the bottom two rows; Face 7 (CY_3 Gaudin) projects onto the sixth row through the E_2 -centre.

Coherence with Costello–Francis–Gwilliam topological envelope

PROPOSITION 31.II.10 (*Coherence with the CFG topological envelope*). Let $M^3 = \mathbb{R}_t \times \mathbb{C}$ denote the topological slab of $X \times \mathbb{R}_t$ after transverse holomorphic quotient (reducing X onto the $\mathbb{C}$ -direction; for $X = \mathbb{C}^3$ this is the projection onto one holomorphic coordinate; for $X = K_3 \times E$, onto the E -direction).

- The Costello–Francis–Gwilliam 2026 envelope $\mathcal{U}^{\text{CFG}}(\mathfrak{g}, M^3)$ is an E_3 -pre-factorisation algebra on M^3 , sheafifying to a genuine E_3 -factorisation algebra by Weiss-cover descent (Costello–Gwilliam Vol. I Def. 6.1.0.6).
- Holomorphic compactification of 5d hCS on $X \times \mathbb{R}_t$ along X reduces the E_4 -holomorphic factor to its $H^\bullet(X)$ -cohomology (Costello–Li 2016 Prop. 5.2, with one-loop coefficient $\alpha_{\text{BCOV}} = \chi(X)/24 \cdot [\Omega_X]^{\text{or},1}$ vanishing on $K_3 \times E$ by $\chi(K_3 \times E) = 0$), absorbing the X -holomorphic data into the gauge algebra $\widehat{\mathfrak{gl}}_\infty$ of Costello 2016.
- The two envelopes agree on their common Gerstenhaber/BV core: both select the Kontsevich–Tamarkin E_3 -formality output of the Gerstenhaber bracket of degree -3 on $\text{HH}^\bullet(\text{Perf } X)$ at the Costello–Li $\text{GRT}_1(\mathbb{Q})$ -point.

The twisted-M-theory construction *geometrises* the CFG envelope by supplying the CY_3 -datum input and the gauge algebra $\widehat{\mathfrak{gl}}_\infty$ from the iid parent; conversely, the CFG envelope provides the E_3 -operadic structure canonically.

Remark 31.11.11 (The bulk-boundary picture is $\mathrm{Sp}^{\mathrm{ch}}$ -natural across (Σ_2, C)). The (Σ_2, C) -specialisation fibres of $\Phi_3^{\mathrm{FA}}(\mathrm{Perf} X)$ produce tier-(iii) siblings in the two-stage factorisation sense; the twisted-M-theory reading naturalises the choice by identifying (Σ_2, C) with a holomorphic sub-4-cycle of X (for $X = \mathbb{C}^3$: $\Sigma_2 = \mathbb{C}^2$ -germ; for $X = K_3 \times E$: $\Sigma_2 = K_3$ -fibre) together with a reference curve $C \subset X$ transverse to Σ_2 . Each (Σ_2, C) realises a distinct boundary theory $\mathcal{A}_\partial^{E_1}$ under Costello–Paquette, and hence a distinct face in the tier-(iii) seven-face slice. The six routes to $G(K_3 \times E)$ of Chapter 23 are six (Σ_2, C) -specialisations of one Stage-I object (Remark 31.0.2), not six applications of Φ_3 ; the twisted-M-theory reading identifies each with a distinct choice of sub-4-cycle and reference curve inside the compact CY_3 .

Cross-references across the seven-face programme

The twisted-M-theory reading intersects the seven faces as follows.

Face 1 (CY bar-cobar). The bar complex $\overline{B}(\mathcal{A}_C)$ coacts on the holomorphic factor of Theorem 31.11.3; the binary CY collision residue $r_{CY}(z) = \mathrm{Res}_{0,2}^{\mathrm{coll}}(\Theta_{\mathcal{A}_C})$ is the degree-2 component of the universal twisting morphism between the E_1 -chiral mode bar $\overline{B}(\mathcal{A}_\partial^{E_1})$ and $\mathcal{A}_\partial^{E_1}$.

Face 4 (MO R -matrix for $K_3 \times E$). The Maulik–Okounkov stable-envelope R -matrix $R_{\mathrm{MO}}^{K_3 \times E}(z)$ is the bulk E_3 -observable trace of the Ω -deformed boundary E_1 -chiral mode algebra against the configuration space of two marked points on C ; the classical limit $\lim_{\hbar \rightarrow 0} \hbar^{-1}(R_{\mathrm{MO}} - \mathrm{id})$ is the $r_{CY}^{K_3 \times E}$ of Conjecture 31.5.2.

Face 5 (affine super Yangian for toric CY_3). Proposition 31.11.6 identifies the $(\mathbb{C}^2$ -germ, $\mathbb{C}$ -germ)-specialisation of $\Phi_3^{\mathrm{FA}}(\mathrm{Perf} \mathbb{C}^3)$ with the Yangian VOA $Y^{\mathrm{VOA}}(\mathfrak{g})$ for simply-laced bosonic $\mathfrak{g}$; tied to Theorem 31.6.1 via the Rapcak–Soibelman–Yang–Zhao CoHA identification.

Face 7 (Gaudin from CY_3). The Drinfeld-centre E_2 -shadow of Remark 31.11.5 is the bulk-side source of the Gaudin Hamiltonians: the E_2 -centre acts on the Fock-representation tensor product through the (Σ_2, C) -framed factorisation homology integral, yielding the commuting Hamiltonians of Theorem 31.8.1 via the Ω -background coupling to the reference curve.

Seven-face master. Faces 1–7 project onto distinct slices of the bulk E_3 -observable pre-factorisation algebra $\mathrm{Obs}_{\mathrm{loc}}^{\mathrm{tw-M}}(X \times \mathbb{R}^2)$ under different choices of specialisation datum (Σ_2, C) and different centre-complementarity operations. This is the seven-face content of Conjecture 31.9.1 read from the bulk side: one chosen framed stage-I $\Phi_3^{\mathrm{FA}}(C)$; seven tier-(iii) boundary projections via $\mathrm{Sp}_{\Sigma_2, C}^{\mathrm{ch}}$; one family of bulk observables in twisted M-theory.

31.12 EXPLICIT CROSS-VOLUME BRIDGES

The CY holographic datum $H_{CY}(T) = (\mathcal{A}_{CY}, \mathcal{A}_{CY}^!, C_{CY}, r_{CY}(z), \Theta_{CY}, \nabla_{CY}^{\mathrm{hol}})$ of Remark 31.2.5 is the CY incarnation of the Vol I holographic datum $H(T) = (A, A^!, C, r(z), \Theta_A, \nabla^{\mathrm{hol}})$. The seven CY faces constructed above are Φ -pushforwards of load-bearing Vol I / Vol II structures. Four bridges carry the load.

Bridge to Vol I Koszul Reflection ([96]). The Vol I bar-cobar adjunction $(\Omega_X, \bar{B}_X)$ on $\text{Kosz}(X)$ defines an involutive Koszul reflection $\mathfrak{R}_A: A \mapsto A^\dagger$. Under the CY-to-chiral correspondence programme $\{\Phi_d\}$ (CY- A_2 proved at $d = 2$ as Φ_2 ; the $d = 3$ statement restricted to the framed Φ_3 locus of Theorem 5.11.1), Face 1 (CY bar-cobar twisting morphism, §31.2) IS the Φ -image of the Koszul reflection: the binary CY collision residue $r_{CY}(z) = \text{Res}_{0,2}^{\text{coll}}(\Theta_{A_C})$ is the leading degree-2 component of the universal twisting morphism between $\bar{B}(A_C)$ and A_C . The arrow:

$$r_{CY}(z) = \Phi_*(\text{Res}_{0,2}^{\text{coll}}(\mathfrak{R}_{\Phi(C)})).$$

Bridge to Vol III 32.4.5. The Vol III dimension-stratified κ_{ch} formula (Theorem 32.4.5 of [96]) identifies $\kappa_{\text{ch}}(A_C)$ with the Hodge supertrace $\sum_q (-1)^q h^{o,q}(X)$ for compact CY_d . Under the seven faces:

- Face 1 (bar-cobar): κ_{ch} is the degree-2 shadow invariant $S_2 = \kappa_{\text{ch}}$ (convention-independent; the $c/12$ coefficient sometimes seen in λ -bracket conventions is $(c/2)/3! = \kappa_{\text{ch}}/6$, not S_2 itself).
- Face 2 (CoHA): κ_{ch} is the dimension shift of the perverse-coherent shadow.
- Face 4 (MO): the K_3 -fibered case gives $\kappa_{\text{BKM}} = c_N(o)/2$ via the Borchers weight (17.6.7; see also Remark 31.10.3 above).

The four-value $\kappa_\bullet$ -spectrum $\{\kappa_{\text{cat}}, \kappa_{\text{ch}}^{\text{Heis}}, \kappa_{\text{BKM}}, \kappa_{\text{fiber}}\}$ splits into manifold invariants (topological, Φ -invariant: $\kappa_{\text{cat}}, \kappa_{\text{fiber}}$) and construction-dependent invariants (face-dependent: $\kappa_{\text{ch}}^{\text{Heis}}$ on Face 1, κ_{BKM} on Face 4); the distinction is preserved at every cross-reference.

Bridge to Vol II universal holography master ([97]). Vol II universal celestial holography establishes that the $\text{SC}^{\text{ch,top}}$ -structure on the bulk-boundary pair $(C_{\text{ch}}^\bullet(A, A), A)$ equals chiral factorization homology, with shadow-tower coefficients matching the soft-factor hierarchy. The CY image is the seven-face master: under Φ , the seven CY incarnations of $r_{CY}(z)$ correspond to seven projections of the Vol II $\text{SC}^{\text{ch,top}}$ -structure on $(C_{\text{ch}}^\bullet(A_C, A_C), A_C)$. The Universal Trace Identity (Conjecture 29.15.1, §29.15 of the bar-cobar bridge chapter) predicts that the supertrace of the Koszul reflection on the candidate universal centre $\mathfrak{Z}(A_C) := \int_{S^1 \times \text{Ran}(X)} A_C$ equals the Vol I κ_{ch} -conductor $K(A_C)$ AND, on the K_3 -fibered $\mathfrak{g}_\Lambda$ branch, equals the BKM weight $\kappa_{\text{BKM}}(\mathfrak{g}_\Lambda) = c_\Lambda(o)/2$. The Φ -pushforward identity $\mathfrak{B}_X = \Phi_*(\mathfrak{R}_{\Phi^{-1}(X)})$ (item (3) of 29.15.1) makes the seven-face master a projection of one universal involution.

Remark 31.12.1 (Bi-based factorization realises $\text{SC}^{\text{ch,top}}$ on the Hochschild pair). The Vol II $\text{SC}^{\text{ch,top}}$ -structure on $(C_{\text{ch}}^\bullet(A_C, A_C), A_C)$ is not a structure on $\bar{B}(A_C)$ alone (which is an E_1 coassociative coalgebra; the bar coalgebra is not itself an $\text{SC}^{\text{ch,top}}$ -coalgebra); $\text{SC}^{\text{ch,top}}$ emerges on the bulk-boundary pair in which the chiral Hochschild cochain algebra is paired with A_C through the Chiral Hochschild Trinity (Vol II). For $C = D^b(\text{Coh}(K_3 \times E))$ the pair is bi-based: the boundary A_C is factorised over the chiral base $\text{Ran}(E_{24}^{\text{nod,sm}})$ (Remark 31.8.5) and the bulk $C_{\text{ch}}^\bullet(A_C, A_C)$ is factorised over the parameter base $\tilde{\mathcal{A}}_2$ through the Kuga–Satake–Torelli averaging morphism. Under this bi-based factorization, the seven-face projections of Remark 31.9.5 are the seven ways of slicing the $\text{SC}^{\text{ch,top}}$ -heptagon:

- Face 1 (bar-cobar) projects the chiral base;
- Face 4 (MO stable envelope) projects the parameter base via the Torelli identification $H^2(K_3; \mathbb{Z}) \simeq \Pi^{3,19}$;
- Face 7 (CY₃ Gaudin) projects the joint base $\text{Ran}(E_{24}^{\text{nod,sm}}) \times_{\text{av}} \tilde{\mathcal{A}}_2$, with Bethe roots of the chiral side pulled back to lattice points of the Borchers automorphic side along av .

The programme expects each projection to preserve the Universal Φ -Trace Identity of Remark 31.8.5. The proved value-level input is the Borchers weight $\kappa_{\text{BKM}}(\Delta_5) = 5$. The assertion that the Koszul reflection supertrace on $\mathfrak{Z}(A_C)$ equals this value in every slice is the universal-trace comparison and requires the stated projection compatibility.

Bridge to Vol I climax + universal conductor + shadow quadrichotomy. The three Vol I master structures map face-by-face under Φ :

- *Climax* ([96]): $\bar{\partial}_X = \text{KZ}^*(\nabla_{\text{Arnold}})$ controls Face 1 (bar-cobar) at the level of the bar differential.
- *Universal conductor* ([96]): $K(A_C) = -c_{\text{ghost}}(\text{BRST}(A_C))$ provides the single scalar invariant attached to each face (face-dependent $\kappa_\bullet$ -values agree under appropriate normalisation).
- *Shadow quadrichotomy* ([96]): the G/L/C/M shadow class of A_C controls which faces are nonvanishing and at what degree (Remark 31.9.5: p_{max} for Face 5, k_{max} for Face 6, r_{max} for Face 1).

Each bridge is a Φ -pushforward of a Vol I or Vol II structure, carries the distinction between manifold-level and construction-level invariants, and replaces any informal “X gives Y” with an explicit Φ_* arrow.

31.13 CY HOLOGRAPHIC DATUM MASTER AT THE K_3 BASE

Remark 31.13.1 (CY holographic datum master at the K_3 base). The CY holographic datum master diagram on the K_3 base has the source datum

$$\mathcal{H}^{\text{CY}}(K_3) = (D^b \text{Coh}(K_3), D^b \text{Coh}(K_3)^\dagger, \text{Hoch}^\bullet(K_3), \Omega_{\text{Calabi–Yau}}, \Theta^{\text{CY}}, \nabla^{\text{GM}}),$$

and, conditional on the CY-to-chiral comparison, the boundary-linear Hall–Borchers bridge data, and the chosen $\text{Sp}_{\Sigma_2, C}^{\text{ch}}$ -specialisation, targets the chiral holographic datum master

$$\mathcal{H}^{\text{ch}}(\mathbf{H}_{\Delta_5}) = (\mathbf{H}_{\Delta_5}, \mathbf{H}_{\Delta_5}^{(!)}, \mathcal{Z}_{\text{ch}}^{\text{der}}(\mathbf{H}_{\Delta_5}) \simeq \mathcal{C}_{\text{ch}}^\bullet(\mathbf{H}_{\Delta_5}, \mathbf{H}_{\Delta_5}), R_{\text{Sieg, dyn}}, \Theta_{\mathbf{H}_{\Delta_5}}, \nabla_{\tilde{\mathcal{A}}_2}^{\text{KZB}}).$$

The ordered bar complex $B_{\text{ch}}^{\text{ord}}(\mathbf{H}_{\Delta_5})$ is the chain model used to construct $\Theta_{\mathbf{H}_{\Delta_5}}$ and the binary residue $R_{\text{Sieg, dyn}}$; it is not the bulk slot. The Gauss–Manin connection ∇^{GM} on the CY side is required, under the same bridge datum, to match the KZB connection on the chiral side through the Kuga–Satake period lift and the Torelli identification of the relevant K_3 Hodge data; no literal morphism $K_3 \hookrightarrow \tilde{\mathcal{A}}_2$ is supplied by the base datum alone. The six-tuple master equation $D \cdot \Theta + \frac{1}{2}[\Theta, \Theta] = 0$ is the conditional compatibility equation on the two sides, not an unconditional consequence of the K_3 base datum alone. Cross-ref Vol. I, §[96] (Vol I), and Vol. III, Chapter 20.

Part V

The Calabi–Yau Landscape

Definition 31.13.2 (Equivariance strata of CY_d-Cat at the Stage-2 chart). The Stage-2 chart datum factors as

$$\text{equivariance stratum} \times (\Sigma_{d-1}, C) \times \text{boundary vacuum } b \times \text{admissibility window}.$$

The four equivariance strata of CY_d-Cat are:

- *Toric* T^d . X admits an effective algebraic T^d -action with isolated fixed points; the Stage-1 factorisation algebra $\Phi_d^{\text{FA}}(C)$ is computed via T^d -equivariant localisation on X , and the Stage-2 chiral output is the K-theoretic critical CoHA on the T^d -fixed locus. Worked $d = 3$ examples: $\mathbb{C}^3$ (Schiffmann–Vasserot CoHA($\mathbb{C}^3$) = $Y^+(\widehat{\mathfrak{gl}}_1)$, Theorem 34.3.1), local $\mathbb{P}^2 = \text{Tot}(\omega_{\mathbb{P}^2})$ via the $[\mathbb{C}^3/\mathbb{Z}_3]$ McKay quiver and Bridgeland–King–Reid equivalence (Theorem 34.11.1; Beasley–Plesser cubic superpotential $W = \text{tr}(XYZ - XZY)$ on the Beilinson 9-arrow quiver), resolved conifold $\tilde{X}_{\text{con}} = \text{Tot}(\mathcal{O}(-1)^{\oplus 2} \rightarrow \mathbb{P}^1)$ via the Czech atlas $U_+, U_- = \mathbb{C}^3$ with Klebanov–Witten potential $W_{\pm} = \text{tr}(x[y, z])$ (Theorem 34.0.1) and the Szendrői 2-vertex global NCCR with reduced topological Euler $\chi(\tilde{X}_{\text{con}}) = 2$ and Maulik–Nekrasov–Okounkov–Pandharipande partition function $Z^{\text{DT}} = M(-q)^2 \prod_{k \geq 1} (1 - Q(-q)^k)^k$.
- *Reduced* $\mathbb{C}^{\times} + \text{Aut}$. X admits a $\mathbb{C}^{\times}$ -action on a fibre or transverse cycle together with a finite automorphism group fixing the CY structure; the central stratum at $d = 3$ is $K_3 \times E$, with a reduced elliptic-translation action on E and the K_3 polarisation automorphisms acting on the K_3 factor. At $(\Sigma_2, C) = (K_3, E)$ the Stage-2 specialisation produces the K_3 BKM superalgebra $\mathfrak{g}_{\Delta_5}$ on the rank-3 hyperbolic lattice $U \oplus \langle -2 \rangle$ (Gritsenko–Nikulin 1998, *IMRN* 1998 no. 11, 525–547; Borchers 1998, *Invent. Math.* 132, 491–562), with Stage-2 Borchers-weight identity $\kappa_{\text{BKM}}(\Delta_5) = c_1(o)/2 = 5$. The full $K_3 \times E$ five-spectrum from five distinct constructions (Remark 26.32.2) is

$$\{\kappa_{\text{cat}}, \kappa_{\text{ch}}^{\text{Hodge}}, \kappa_{\text{ch}}^{\text{Heis}}, \kappa_{\text{BKM}}(\Delta_5), \kappa_{\text{fiber}}\}(K_3 \times E) = \{0, 0, 3, 5, 24\}.$$

Sibling reduced-stratum entries: abelian threefold E^3 with $\kappa_{\text{cat}}(E^3) = 0$ and full automorphism torus T^3 acting on the universal cover; elliptic K_3 fibration $X \rightarrow \mathbb{P}^1$ with E -translation along each fibre.

- *Orbifold inertia* $I(X/G)$. $X = Y/G$ for a finite $G \subset \text{SU}(d)$ acting on a smooth Calabi–Yau Y , with the inertia stack $I(X)$ supplying the chart datum. At $d = 3$, $\mathbb{C}^3/\Gamma$ for $\Gamma \subset \text{SU}(3)$ finite produces the McKay critical CoHA on the Bridgeland–King–Reid crepant resolution $G\text{-Hilb}(\mathbb{C}^3)$ (Bridgeland–King–Reid 2001, *J. Amer. Math. Soc.* 14, 535–554). The Mathieu-moonshine sibling at $d = 2$ is the orbifold K_3 elliptic genus enriched by M_{24} (Eguchi–Ooguri–Tachikawa 2010, *Exp. Math.* 20, 91–96); the Conway/Leech sibling at $d = 4$ via the fermionic Conway module $V^{\mathfrak{f}}_{\mathfrak{h}}$ with Co_0 -action (Frenkel–Lepowsky–Meurman 1988 *Vertex Operator Algebras and the Monster*, Academic Press; Duncan 2007, *Duke Math. J.* 139, 255–315).
- *Lattice-polarised period domain*. X has reduced period map into a type-IV symmetric domain Ω_L for an even lattice L of signature $(2, n)$; the Stage-2 chiral output is a Borchers lift on Ω_L . At $d = 3$, the quintic $X_5 \subset \mathbb{P}^4$ has period in $\Omega_{H^3(X_5)}$ of signature $(2, 100)$; Z -manifolds and abelian quotients (Kummer, Borcea–Voisin) inherit lattice-polarised period from their parents. At $d = 5$, the Fake-Monster sibling lives on $\text{II}_{25,1} \subset \text{II}_{26,2}$ via Borchers 1992 (Chapter 40).

The four strata exhaust the inputs for which a Stage-2 chiral output is constructed in Vol III.

Cross-stratum sibling census across d . The Stage-2 output of Φ_d at the canonical reference curve C produces a sibling family across CY dimension:

d	representative X	Stage-2 chiral output on C	lattice / chart data
1	E (elliptic curve)	H_1 (free Heisenberg lattice VOA)	$\tilde{H}(E, \mathbb{Z}) = U \oplus U$ (rank 4, sign. (2, 1))
2	K_3	$Y_h(\mathfrak{so}(4, 20))$ (Mukai-self-mirror)	$\tilde{H}(K_3, \mathbb{Z}) = U^4 \oplus E_8(-1)^2$ (rank 26)
3	$K_3 \times E$	$\mathfrak{g}_{\Delta_5}$ (K_3 BKM, Hall–Drinfeld double)	$U \oplus \langle -2 \rangle$ (rank 3, sign. (2, 1))
3	$V^{\mathfrak{h}}$ (Monster moonshine module)	$\mathbb{M}$ -action on $V^{\mathfrak{h}}$ (Borcherds Monster Lie algebra)	$\Pi_{1,1}$ Cartan rank 2 (not 26)
4	Conway / Leech bridge $V^{f^{\mathfrak{h}}}$	$N = 1$ Conway moonshine module (Co_0)	Λ_{Leech} (rank 24, Niemeier-root)
5	$K_3 \times K_3 \times E$	$\mathfrak{g}^{\text{FM}}$ (Fake Monster, Borcherds 1992)	$\Pi_{25,1}$ via $E_5 \simeq E_2 \otimes E_2 \otimes E_1$

At $d = 1$ the chiral target is E_{∞} -native; at $d = 2$ it is E_2 (the K_3 Yangian face of Part III); at $d \geq 3$ it is E_1 via the Dunn–Lurie additivity $E_3 \simeq E_2 \otimes E_1$ (Lurie, *Higher Algebra*, 5.1.2.6). The Borcherds–Monster Cartan rank is 2 on $\Pi_{1,1}$, not 26 on $\Pi_{25,1}$; the rank-26 object is the Fake Monster at $d = 5$, on the iterated tensor decomposition $E_5 \simeq E_2 \otimes E_2 \otimes E_1$ realised geometrically by $K_3 \times K_3 \times E$ (Chapter 40).

Two distinct fives, one common cell. The CY landscape carries two five-element scalar collections that share one entry but are otherwise distinct.

The $K_3 \times E$ five $\{0, 0, 3, 5, 24\}$ enumerates five readings of *one CY datum* through five distinct constructions: κ_{cat} Künneth-multiplicative on the total space; $\kappa_{\text{ch}}^{\text{Hodge}} = \Xi(K_3 \times E) = 0$ the Hodge supertrace (Theorem 32.2.1, $\Xi(E) = 0$ kills the product); $\kappa_{\text{ch}}^{\text{Heis}} = 3 = \dim_{\mathbb{C}}(K_3 \times E)$ the Heisenberg–Mukai specialisation (Vol I Theorem D); $\kappa_{\text{BKM}}(\Delta_5) = c_1(\mathfrak{o})/2 = 5$ the primitive Borcherds weight of Gritsenko’s paramodular cusp form Δ_5 ; $\kappa_{\text{fiber}}(K_3) = \text{rank}(\tilde{H}(K_3, \mathbb{Z})) = 24$ the Mukai lattice rank of the K_3 fibre. The five values inhabit five distinct cohomology theories on a single Calabi–Yau threefold; no two coincide by definition.

The G/L/C/M/B five-archetype landmark $\{0, 8, 13, 250/3, 98/3\}$ enumerates the derived-centre complementarity ceiling $K^{\kappa_{\text{ch}}} = \kappa_{\text{ch}} + \kappa_{\text{ch}}^1$ across *five different chiral-algebra archetypes*: Heisenberg (G, $K^{\kappa} = 0$), affine Kac–Moody (L, $K^{\kappa} = 0$), $\beta\gamma_{\lambda}$ (C, $K^{\kappa} = 0$), Virasoro Vir_c with Verdier partner Vir_{26-c} (M, $K^{\kappa} = 13$), principal $\mathcal{W}_3^k$ via Drinfeld–Sokolov (M, $K^{\kappa} = 250/3$; Bershadsky–Polyakov on the non-principal $\mathfrak{sl}_3$ orbit, $K^{\kappa} = 98/3$). The fifth archetype B is the Mukai-doubling face on K_3 , with $K^{\kappa_{\text{ch}}} = 8 = 2c_+(\text{Mukai}(K_3))$ (Vol I derived-centre complementarity theorem, parts (b)–(c) [96]).

The two fives intersect on a single cell. The $K_3 \times E$ five carries no $K^{\kappa} = 8$ entry; the G/L/C/M/B five carries the B-row $K^{\kappa_{\text{ch}}} = 8$ as the K_3 Mukai-doubling witness. The K_3 Mukai-doubling $K^{\kappa_{\text{ch}}} = 8$ is the common cell: the B-row archetype above sits on the K_3 fibre of the $K_3 \times E$ chart, and its Mukai–Heisenberg realisation $\kappa_{\text{ch}}^{\text{Mukai}} = 4 = K^{\kappa_{\text{ch}}}/2$ is the same fibre datum read at half complementarity. The two fives are otherwise non-overlapping. The $\kappa_{\text{cat}} = 0$ entry of the $K_3 \times E$ five counts a total-space Euler characteristic; the G-row $K^{\kappa} = 0$ of the archetype five counts a Heisenberg complementarity sum.

Per-dimension Hodge-supertrace skeleton (Theorem 32.4.5). The constructed- Φ_d Hodge-supertrace $\kappa_{\text{ch}}^{\text{Hodge}}(\mathcal{A}_X) = \Xi(X) = \sum_{q=0}^d (-1)^q h^{\mathfrak{o},q}(X)$ fixes the Stage-2 shadow invariant on every compact X in

the constructed locus. The dimension stratifies by Beauville–Bogomolov holonomy:

d	family	$\kappa_{\text{ch}}^{\text{Hodge}}(\mathcal{A}_X)$	target E_n	stratum (Thm 32.3.1)
1	E (elliptic curve)	o	E_∞ native / E_1^{curve}	(I) odd- d
2	K_3	2	E_2	(II) strict CY, $\text{SU}(2) = \text{Sp}(1)$
2	abelian surface	o	E_2	(III) holomorphic-symplectic
2	bielliptic	o	E_2	(III) (étale $\mathbb{Z}/n$ quotient)
2	Enriques	o	E_2	(II) strict CY (free $\mathbb{Z}/2$ quotient)
3	quintic $X_5 \subset \mathbb{P}^4$	o	E_1	(I) odd- d , strict CY
3	$K_3 \times E$	o	E_1	(I) odd- d , five-spectrum above
3	E^3	o	E_1	(I) odd- d
3	local $\mathbb{P}^2$	3/2	E_1	non-compact; chain-level McKay
3	conifold $\tilde{X}_{\text{con}}$	1	E_1	non-compact; direct $\mathbb{P}^1$ cycle
4	sextic $\text{CY}_4 \subset \mathbb{P}^5$	2	E_1	(II) strict CY
4	$K_3^{[2]}$	3	E_1	(III) hyper-Kähler $n+1=3$
4	$K_3 \times K_3$	o	E_1	p_1 -twisted cascade
4	T^8	o	E_1	maximal abelian
5	generic CY_5	o	E_1	(I) odd- d , universal Serre
5	$K_3 \times K_3 \times E$	o	E_1	(I) odd- d , Fake-Monster host

Three caveats are marked. The conifold is not a local surface, so $\kappa_{\text{ch}}^{\text{loc}} = \chi(S)/2$ fails (Corollary 32.7.1); the chain-level reading uses the Klebanov–Witten Kronecker quiver and gives $\kappa_{\text{ch}}^{\text{loc}}(\mathcal{A}_{\tilde{X}_{\text{con}}}) = 1$. $K_3 \times K_3$ is p_1 -twisted with non-trivial obstruction class $p_1(T_{K_3 \times K_3}) \in H^4(K_3 \times K_3, \mathbb{Z})$, so the naive E_4 cascade breaks at the E_3 level. Generic CY_5 means $h^{p,q}(X) = \delta_{p,q}$ outside the Hodge diamond's symmetry; isolated loci carry extra classes (Theorem 32.6.2, Universal Serre Cancellation).

Beauville–Bogomolov tri-stratum. Compact Calabi–Yau manifolds with $h^{1,0} = 0$ partition into three holonomy strata (Theorem 32.3.1, Beauville 1983, *J. Differential Geom.* 18, 755–782):

stratum	condition	$\kappa_{\text{ch}}^{\text{Hodge}}(\mathcal{A}_X)$
(I) odd- d	d odd, $\omega_X = \mathcal{O}_X$	o by Serre pairing $h^{0,q} = h^{0,d-q}$
(II) strict CY even- d	$\text{Hol}(X) = \text{SU}(d)$, $h^{2,0} = 0$	2
(III) holomorphic-symplectic	$\text{Hol}(X) = \text{Sp}(n)$, $d = 2n$	$n+1$ on $K_3^{[n]}$

Strata (II) and (III) overlap exactly at $d = 2$, where $\text{SU}(2) = \text{Sp}(1)$ and both strata assign $\Xi(K_3) = 2$; for $d \geq 4$ the strata are disjoint. Stratum (I) absorbs every odd- d entry of the dimension table above; stratum (II) absorbs the strict even- d entries (sextic $\subset \mathbb{P}^5$, decic $\subset \mathbb{P}(1^5, 5)$, Enriques double cover); stratum (III) absorbs the hyper-Kähler entries (K_3 , $K_3^{[n]}$, Beauville–Donagi $F(Y)$).

Other Calabi–Yau category constructions.

- *Matrix factorisations.* For $W: \mathbb{A}^n \rightarrow \mathbb{A}^1$ with isolated critical point at the origin, $\text{MF}(W)$ is a CY_{n-2} category (Orlov 2009, *Russian Math. Surveys* 64 no. 3, 537–553); the ADE classification at $n = 4$ produces CY_2 structures connecting to Drinfeld–Sokolov $\mathcal{W}_N$. Chapter 36.
- *Fukaya categories.* $\text{Fuk}(X)$ with A_∞ -structure from J -holomorphic disks (Fukaya–Oh–Ohta–Ono 2009); the symplectic input to Φ_d via the Landau–Ginzburg / CY correspondence. Chapter 37.

- *Super-Yangian general rank.* $Y_h(\mathfrak{sl}(m \mid n))^{\text{ch}}$ with super-Riccati recurrence and rank-stratified shadow class; the parity-sign recurrence yields super-complementarity $\kappa_{\text{ch}}^{\text{Mukai}}(Y) + \kappa_{\text{ch}}^{\text{Mukai}}(Y^\dagger) = \max(m, n)$ on the small-rank cases proved (Section 38.5; Wang–Wen–Jing 2022, *J. Algebra* 596, 313–345). Chapter 38.
- *Wall-crossing CoHA and bar coalgebra.* The Kontsevich–Soibelman wall-crossing identity at the bar level on $B^{\text{ord}}(\text{MH}(C))$ (Kontsevich–Soibelman 2008, arXiv:0811.2435, Theorem 1); the chiral upgrade of the motivic Hall pentagon to a bar-level identity. Chapter 35.
- *Quantum group representations.* Kazhdan–Lusztig theory at roots of unity (where $\text{Rep}_q(\mathfrak{g})$ is non-semisimple and the modular tensor category structure is non-trivial), affine Yangians, critical CoHAs. The representation categories Rep^{E_2} are the targets of the CY-C derived-centre comparison. Chapter 39.

The landscape closes with the existence-obstruction theorem beyond $K_3 \times E$: the single-chart NCCR obstruction (Theorem 26.1.1) and the Serre-equivariant quasi-NCCR substitute (Definition 26.1.2).

THE κ_{ch} STRATIFICATION BY CY DIMENSION

The two-stage factorisation functor

$$\Phi_d = \text{Sp}_{\Sigma_{d-1}, C}^{\text{ch}} \circ \Phi_d^{\text{FA}}: \text{CY}_d\text{-Cat} \longrightarrow E_d\text{-HolFA}(X) \longrightarrow E_n\text{-HolFA}(C)$$

(see [96], Definitions 5.1.1–5.1.17) assigns to a CY_d category C first a holomorphic factorisation algebra $\Phi_d^{\text{FA}}(C)$ on the CY_d target X , then a chiral algebra $\text{Sp}_{\Sigma_{d-1}, C}^{\text{ch}}(\Phi_d^{\text{FA}}(C))$ on a curve. In this chapter the Hodge-supertrace computations are unconditional Hodge theory; their interpretation as κ_{ch} of a chiral output is proved on the constructed $d \leq 3$ loci and is conditional for $d \geq 4$. The specialisation is factorisation homology over Σ_{d-1} . Five scalar invariants of distinct provenance attach to this two-stage datum; four inhabiting the main text (κ_{ch} , κ_{cat} , κ_{BKM} , κ_{fiber}) plus the one-loop Costello–Li BCOV curving coefficient $\kappa_{\text{ch}, \text{BV}}$ valued on the compactly-supported side; and no two coincide in general. The discipline of never conflating them is the unit of analysis of this chapter.

Definition 32.0.1 (The four $\kappa_{\bullet}$ -invariants). For a CY_d manifold X with CY_d category $C = D^b(\text{Coh}(X))$, the following four scalar invariants, jointly denoted $\kappa_{\bullet} \in \{\kappa_{\text{ch}}, \kappa_{\text{cat}}, \kappa_{\text{BKM}}, \kappa_{\text{fiber}}\}$, are defined.

- (i) $\kappa_{\text{ch}}(\mathcal{A}_X)$. The degree-two shadow coefficient of the chiral algebra $\mathcal{A}_X = \Phi_d(C)$, computed as the Hodge supertrace on compact CY_d at even d :

$$\kappa_{\text{ch}}(\mathcal{A}_X) = \Xi(X) := \sum_{q=0}^d (-1)^q h^{0,q}(X) \quad (\text{Theorem 32.2.1}).$$

Native to the $\Phi_d^{\text{FA}}(C)$ stage; at odd d read chain-level (Remark 32.0.2).

- (ii) $\kappa_{\text{cat}}(C) = \chi(\mathcal{O}_X)$. The categorical Euler characteristic of the structure sheaf, Künneth-multiplicative on products: $\kappa_{\text{cat}}(X \times Y) = \kappa_{\text{cat}}(X) \cdot \kappa_{\text{cat}}(Y)$. Native to the variety X , independent of the Φ_d^{FA} stage.
- (iii) $\kappa_{\text{BKM}}(\Phi) = c(o)/2$. The weight of a Borchers product Φ , equal to half the constant term $c(o)$ of the Borchers-input principal part (Theorem 32.8.1). Attached to the Sp^{ch} specialisation cycle, not to the Φ_d^{FA} output.
- (iv) κ_{fiber} . The rank or Euler characteristic of the fibering data attached to the Sp^{ch} map; for a $K3$ fibration it is the Mukai-lattice rank 24 of the fibre.
- (v) $\kappa_{\text{ch}, \text{BV}}(\mathcal{A}_X)$. The Costello–Li one-loop BCOV curving coefficient at $\beta\gamma$ -ghost central charge $c = -2$, valued on compact X in $H^1(X, \mathcal{O}_X)$ against the $\beta\gamma$ -ghost supertrace sign and on non-compact X in $H_c^1(X, \mathcal{O}_X)$ (or equivalently, via Alexander duality, in the boundary trace on the link ∂X). Concretely, the Atiyah–BCOV dilaton cocycle is the class

$$\alpha_{\text{BCOV}} = \frac{\chi_{\text{top}}(X)}{24} \cdot \text{tr At}(T_X) \in H^1(X, \mathcal{O}_X),$$

where $\text{At}(T_X) \in \text{Ext}^1(T_X, T_X \otimes \Omega_X^1)$ is the Atiyah class and tr is the trace pairing $\Omega_X^1 \otimes T_X \rightarrow \mathcal{O}_X$; for strict CY, although $c_1(T_X) = 0$ in $H^{1,1}(X)$, the Dolbeault component $\text{tr At}(T_X) \in H^{0,1}(X, \mathcal{O}_X)$ need not vanish (the $c_1 = 0$ CY condition lives in $H^{1,1}$, not in $H^{0,1}$; the two are distinct Hodge components of the Chern-class data). The class is computed via the Atiyah-class extension of the tangent sheaf (Kapranov math/9811023) and pairs through the BV one-loop Quantum Master Equation of Costello–Li (arXiv:1606.00365 Prop. 5.2) with the $\beta\gamma$ -ghost zero mode ω_{ghost} to produce the BCOV dilaton free energy of BCOV (hep-th/9309140 Eq. (5.11)). Native to the stratum-(ii–iv) BCOV sector on $\Phi_d^{\text{FA}}(C)$; vanishes on stratum-(i) toric cells with zero-dimensional T -fixed locus by the Atiyah-retraction $X \simeq X^T$ collapsing $\text{At}(T_X)$ to the T -weight-balanced zero class (Kapranov math/9811023). Scope: $\kappa_{\text{ch}, \text{BV}}$ targets $H^1(X, \mathcal{O}_X)$ on compact X and $H_c^1(X, \mathcal{O}_X)$ on non-compact X , *not* $H^\bullet(C)$; it is a first-principles Atiyah-class-of- T_X coefficient on the geometric target, not a Hochschild invariant of the category.

These are five construction-distinct invariants of a single CY datum (C, X) ; four are native to the main text (κ_{ch} , κ_{cat} , κ_{BKM} , κ_{fiber}) and the fifth $\kappa_{\text{ch}, \text{BV}}$ is activated when the one-loop BCOV curving is non-trivial; i.e. when the dilaton cocycle $\text{tr At}(T_X)$ survives as a nonzero class in $H^1(X, \mathcal{O}_X)$ on compact X , or equivalently when the boundary link ∂X of a non-compact X supports a nontrivial $\beta\gamma$ -ghost zero mode. Any identity relating two or more of the five is a theorem about the specific construction; no pair coincides by definition.

Odd- d failure via Serre involution. At odd d the Serre involution $\sigma: q \mapsto d - q$ acts on $h^{\circ, \bullet}(X)$ with character $(-1)^d = -1$, so Serre duality $h^{\circ, q} = h^{\circ, d-q}$ pairs each $q < d/2$ with its sign-opposite partner and the pairs cancel uniformly: $\Xi(X) = 0$ for every compact CY_d at odd d (Theorem 32.3.1, stratum (I)). The Hodge-supertrace formula $\kappa_{\text{ch}}(\mathcal{A}_X) = \Xi(X)$ is vacuous on this stratum and must be replaced by direct chain-level computation: $\kappa_{\text{ch}}(\text{loc } \mathbb{P}^2) = 3/2$ via the $\mathbb{Z}/3$ -McKay quiver (Theorem 34.11.1) and $\kappa_{\text{ch}}(\text{conifold}) = 1$ via direct McKay (Corollary 32.7.1) are the two canonical chain-level readings at $d = 3$ that expose the Serre-silent algebraic content. Hence: at even d , κ_{ch} is the Hodge supertrace; at odd d , κ_{ch} reads chain-level through the McKay quiver or the direct shadow computation of the relevant non-compact toric CY_3 .

Canonical $K_3 \times E$ five-spectrum. The Calabi–Yau threefold $K_3 \times E$ carries the canonical five-valued spectrum

$$\{\kappa_{\text{cat}}, \kappa_{\text{ch}}^{\text{Hodge}}, \kappa_{\text{ch}}^{\text{Heis}}, \kappa_{\text{BKM}}(\mathfrak{g}_{\Delta_5}), \kappa_{\text{fiber}}\}(K_3 \times E) = \{0, 0, 3, 5, 24\}$$

from five distinct constructions on the same Calabi–Yau datum.

- $\kappa_{\text{cat}}(K_3 \times E) = \chi(\mathcal{O}_{K_3}) \cdot \chi(\mathcal{O}_E) = 2 \cdot 0 = 0$ by Künneth multiplicativity for coherent cohomology (Hartshorne, Chapter III, Proposition 8.5).
- $\kappa_{\text{ch}}^{\text{Hodge}}(K_3 \times E) = \Xi(K_3 \times E) = 0$ via $\Xi(K_3 \times E) = \Xi(K_3) \cdot \Xi(E) = 2 \cdot 0$ on the Hodge supertrace, with $\Xi(E) = 1 - 1 = 0$ killing the product.
- $\kappa_{\text{ch}}^{\text{Heis}}(K_3 \times E) = 3$ from the Heisenberg–Mukai specialisation, with the Mukai-enhanced Hodge supertrace giving $\kappa_{\text{ch}}^{\text{Heis}}(K_3) = 2$ on the K_3 fibre and $\kappa_{\text{ch}}^{\text{Heis}}(E) = 1$ on the elliptic factor (Remark 32.5.9).
- $\kappa_{\text{BKM}}(\mathfrak{g}_{\Delta_5}) = c_1(0)/2 = 5$ from the Borchers weight of Gritsenko’s paramodular cusp form Δ_5 (Theorem 32.8.1).
- $\kappa_{\text{fiber}}(K_3) = \text{rank}(\tilde{H}(K_3, \mathbb{Z})) = 24$ the Mukai-lattice rank of the K_3 fibre.

The five values inhabit five distinct cohomology theories on a single Calabi–Yau threefold; no two coincide by definition. The two zeros $\kappa_{\text{cat}} = 0$ and $\kappa_{\text{ch}}^{\text{Hodge}} = 0$ vanish for distinct reasons: Künneth on the structure-sheaf Euler for the first, Serre cancellation on the elliptic factor for the second. The value 2 is the K_3 fibre $\kappa_{\text{cat}}(K_3) = \chi(\mathcal{O}_{K_3}) = 1 + 1$ and not a total-space entry; misreading the fibre as the total space is the confusion the five-invariant discipline forestalls.

Universal Borcherds weight at two scopes. The identity $\kappa_{\text{BKM}}(\Phi) = c(0)/2$ holds in two canonical parametrisations of the paramodular simplest-divisor family. *Scope (A): CHL-averaged paramodular ladder.* On the five-entry CHL ladder $N \in \{1, 2, 3, 4, 6\}$; the orders with an elliptic curve automorphism of matching order fixing the origin; the Gritsenko–Nikulin 1995 Pt II Theorem 2.1 construction (additive lift of the g_N -twined weight-0 weak Jacobi form $\phi_{0,1}^{(g_N)}$) yields paramodular cusp forms $\Delta_{k(N)}^{(N)}$ of weights $\text{wt}(\Delta_{k(N)}^{(N)}) = k(N) = (5, 4, 3, 2, 1)$ with $(c_N(0)) = (10, 8, 6, 4, 2)$; this is the convention deployed in Theorem 32.8.1 below. Scope (A) extends to the Mukai-admissible orders $N \in \{5, 7, 8\}$ via Gritsenko 1994 Proposition 3.1 with $\text{Sp}_4(\mathbb{Z})$ -paramodular weight $(2, 1, 1)$ (Corollary 32.8.7); at $N \in \{5, 7, 8\}$ the missing datum is a smooth $K_3 \times E$ CHL quotient of matching order. *Scope (B): Gritsenko–Cléry 2008 Theorem 1.4 classification.* The eight dd-modular forms with divisor equal to the diagonal $\mathcal{H}_1 \subset \mathbb{H}_2$ of vanishing order 1 on $\Gamma_t(N)$, indexed by triples $(t, N; k) \in \{(1, 1; 5), (2, 1; 2), (1, 2; 3), (3, 1; 1), (1, 3; 2), (4, 1; \frac{1}{2}), (1, 4; \frac{3}{2}), (2, 2; 1)\}$, each satisfying $\kappa_{\text{BKM}}(F_{t,N}) = \text{wt}(F_{t,N}) = k_{t,N}$ by the cusp-weighted Borcherds automorphic product formula of Gritsenko–Cléry 2008 Theorem 3.1 (Theorem 32.8.2). Six integer-weight entries live on $\Gamma_t(N)$ -paramodular subgroups; two half-integer-weight entries carry multiplier systems of orders 8 and 4 respectively, using the Shimura 1975 holomorphic-square-root convention, not a metaplectic cover of $\text{Sp}_4(\mathbb{Z})$. The two scopes coincide at $(t, N) = (1, 1)$ (the common entry $F_{1,1} = \Delta_5$, weight 5) and otherwise enumerate distinct Borcherds products on distinct paramodular groups. The twice-weight tuple of the GC catalogue is $(10, 4, 6, 2, 4, 1, 3, 2)$, not the CHL constant table $(10, 8, 6, 4, 2)$. Scalar-square identities therefore have to be read row-by-row with their own levels, covers, branches, and denominator data; they do not identify the CHL $N \in \{2, 3, 4\}$ ladder with the GC $(1, N)$ rows.

Refutation of the additive identity. The additive identity

$$\kappa_{\text{BKM}}(\Phi_N) = \kappa_{\text{ch}}(\mathcal{A}_{X_N}) + \chi(\mathcal{O}_{\text{fiber}_N})$$

fails at every $N \in \{1, 2, 3, 4, 6\}$: at $N = 1$, LHS = 5 while RHS = $0 + 0 = 0$; at $N = 2$, LHS = 4 while RHS = $1 + 0 = 1$. The apparent decomposition $5 = 2 + 3$ at $N = 1$ (K_3 fibre $\chi(\mathcal{O}_{K_3}) = 2$ plus Heisenberg–Mukai $\kappa_{\text{ch}}^{\text{Heis}} = 3$) is a coincidence of two distinct Stage-2 constructions, not a structural identity; the universal formula is $\kappa_{\text{BKM}}(\Phi_N) = c_N(0)/2$ throughout, with κ_{BKM} read off the Borcherds weight of the paramodular form, not summed from supertraces on the product.

Root cause at odd d . The invariant κ_{ch} is additive under direct sums but not under fibre products: for $X = Y \times_Z W$ of CY dimensions $(\dim Y, \dim W, \dim Z)$, the Hodge supertrace $\Xi(X)$ is not determined by $\Xi(Y), \Xi(W), \Xi(Z)$ alone at odd fibre-product dimension. The same fact forces the chain-level reading at odd d : on compact CY_d with d odd, Serre cancellation collapses every Φ -output Hodge column uniformly to $\Xi = 0$ regardless of the algebraic richness of $\mathcal{A}_X$, and the true invariant is the chain-level McKay shadow of the non-compact toric model or the direct Hochschild computation on the quiver (Remark 32.0.2).

Canonical conifold row and the Polyakov ghost-mode balance. On the non-compact CY_3 frontier, the resolved conifold $X_{\text{con}} = \text{Tot}(\mathcal{O}(-1)^{\oplus 2} \rightarrow \mathbb{P}^1)$ carries the canonical four-subscript row

$$(\kappa_{\text{ch}}, \kappa_{\text{cat}}, \kappa_{\text{vertex}}, \kappa_{\text{ch,BV}})(X_{\text{con}}) = (+1, 0, +1, -1)$$

(Theorem 32.7.2). The fifth invariant $\kappa_{\text{ch},\text{BV}}$ is the Costello–Li one-loop BCOV curving coefficient against the $\beta\gamma$ -ghost supertrace sign at $\beta\gamma$ -system central charge $c = -2$ (Costello–Li arXiv:1606.00365 Prop. 5.2; BCOV hep-th/9309140 Eq. (5.11); the $c = -2$ $\beta\gamma$ -system is the Kausch hep-th/9510149 holomorphic avatar of the critical-dimension argument); on compact X with $H^1(X, \mathcal{O}_X) \neq 0$ it is the Atiyah-dilaton pairing $(\chi_{\text{top}}(X)/24) \cdot \text{tr At}(T_X) \in H^1(X, \mathcal{O}_X)$ integrated against the $\beta\gamma$ -ghost zero mode, and on non-compact X whose ambient $H^1(X, \mathcal{O}_X)$ and $H_c^1(X, \mathcal{O}_X)$ both vanish (e.g. the resolved conifold, §32.7) it is the ζ -regularised $\beta\gamma$ Casimir energy on the Sasaki–Einstein boundary link ∂X . The three apparent conifold values $+1, 0, -1$; the DT count on the compact curve class, the structure-sheaf Euler on the non-compact total space, and the Costello–Li one-loop BV curving as Casimir energy on the Sasaki–Einstein boundary link $T^{\text{st}} \cong S^2 \times S^3$ of the conifold (Klebanov–Witten hep-th/9807080); inhabit three distinct cohomology theories (Kontsevich–Soibelman DT/motivic, ordinary $H^*(X, \mathcal{O}_X)$, and $\beta\gamma$ -ghost vacuum-energy on ∂X), and the Polyakov ghost-mode balance

$$\kappa_{\text{ch}}(X_{\text{con}}) + \kappa_{\text{ch},\text{BV}}(X_{\text{con}}) = \kappa_{\text{cat}}(X_{\text{con}}), \quad (+1) + (-1) = 0,$$

registers critical-dimension ghost cancellation in the $\beta\gamma$ -ghost system at $c = -2$ (Polyakov 1981 *Gauge Fields and Strings*; Ch. 9 critical-dimension paradigm; $c = -2$ avatar via Kausch hep-th/9510149), instantiated on non-compact CY_3 via Costello–Li holomorphic BV quantisation. The balance is a G-class non-compact CY_3 theorem, not the Theorem C ceiling $\kappa_{\text{ch}} + \kappa_{\text{ch}}^! \in \{0, 8, 13, 250/3, 98/3\}$ and not a universal identity across strata; see Remark 32.7.3 for the precise scope.

This chapter evaluates the Hodge supertrace dimension by dimension for $d \in \{1, 2, 3, 4, 5\}$ and stratifies the comparison between κ_{ch} and κ_{cat} by Beauville–Bogomolov holonomy type. The companion engine is `compute/lib/cy_d_kappa_d3.py` with stratification test `compute/tests/test_cy_d_kappa_stratification.py`.

Remark 32.0.2 (Odd- d κ_{ch} reads chain-level). At odd complex dimension d the Hodge-supertrace identification $\kappa_{\text{ch}}(\mathcal{A}_X) = \Xi(X)$ collapses to 0 by Serre, and the substantive algebraic content of $\mathcal{A}_X$ is read instead through the chain-level McKay quiver attached to the non-compact toric CY_3 model (or directly through the Hochschild cohomology of the path algebra). At $d = 3$ the two canonical chain-level readings are:

- *Local* $\mathbb{P}^2 = \text{Tot}(\omega_{\mathbb{P}^2})$. The $\mathbb{Z}/3$ -McKay quiver of $\mathbb{C}^3/\mathbb{Z}_3$ (three arrows, three nodes) gives $\kappa_{\text{ch}}(\mathcal{A}_{\text{loc } \mathbb{P}^2}) = \frac{1}{2}\chi_{\text{top}}(\mathbb{P}^2) = 3/2$ via the compactly-supported Dolbeault supertrace on the base (Theorem 34.11.1).
- *Resolved conifold* $\text{Tot}(\mathcal{O}(-1)^{\oplus 2} \rightarrow \mathbb{Q}^1)$. The Kronecker quiver with two arrows in each direction gives $\kappa_{\text{ch}}(\mathcal{A}_{\text{conifold}}) = 1$ via direct McKay (Corollary 32.7.1).

Both values are Serre-silent on the $h^{\circ, \bullet}$ column – the local $\mathbb{P}^2$ has $h^{\circ, \bullet}$ column not well-defined as a compact CY datum, and the conifold contribution 1 comes from the single compact cycle $\mathbb{Q}^1$ rather than from a Hodge sum.

32.1 SETUP: κ_{ch} , $\chi(\mathcal{O}_X)$, AND THE HODGE SUPERTRACE

Let X be a compact Calabi–Yau manifold of complex dimension d , so that $\omega_X \simeq \mathcal{O}_X$ and the Serre functor on $D^b(\text{Coh}(X))$ is the shift $[d]$. Write $h^{p,q} = h^{p,q}(X) = \dim_{\mathbb{C}} H^q(X, \Omega_X^p)$ for its Hodge numbers and $\chi_p = \chi_p(X) = \sum_q (-1)^q h^{p,q}$ for its holomorphic Euler characteristics (the $p = 0$ case recovers $\chi(\mathcal{O}_X)$).

Fix the CY-to-chiral correspondence Φ_d and write $\mathcal{A}_X = \Phi_d(D^b(\text{Coh}(X)))$ for the chiral algebra associated to X . The *algebraization scalar* $\kappa_{\text{ch}}(\mathcal{A}_X)$ is the degree-two shadow invariant of Vol I: the coefficient of $[b \mid b]$ in the quadratic piece of the Maurer–Cartan obstruction on $B^{\text{ord}}(\mathcal{A}_X)$. It is an algebraization invariant: a second algebraization of the same topological CY_d manifold can produce a different κ_{ch} . The companion invariants $\kappa_{\text{cat}}(X)$ and $\kappa_{\text{fiber}}(X)$ are topological manifold invariants; κ_{BKM} depends on the Borchers frame shape.

Three candidate comparators

We compare κ_{ch} against three Hodge-derived scalars:

- The *holomorphic Euler characteristic* $\chi(\mathcal{O}_X) = \sum_q (-1)^q h^{o,q}(X) = \chi_o(X)$.
- The *Hodge-filtered supertrace* of the structure sheaf column

$$\Xi(X) := \sum_{q=0}^d (-1)^q h^{o,q}(X).$$

Because $h^{o,q}$ counts antiholomorphic forms of pure type (o, q) , $\Xi(X)$ and $\chi(\mathcal{O}_X)$ agree as numbers. The distinction is structural: the κ_{ch} route produces the supertrace $\Xi(X)$ via the chiral bar complex on the $(o, \bullet)$ column, agreeing with $\chi(\mathcal{O}_X)$ on inputs where Serre cancellation has not already collapsed the latter. The notation Ξ records the supertrace view; the identification $h^{o,q} = h^{d,d-q}$ via Serre then expresses Ξ in terms of $\chi(\mathcal{O}_X)$ when both are in scope.

- The *explicit algebraic Hochschild sum* $\text{HH}_{\text{alg}}(X) = \sum_{p,q} (-1)^{p-q} h^{p,q}(X)$. This is the signed Hodge sum appearing in the HKR–Caldararu formula; on compact Kähler X one has $(-1)^{p-q} = (-1)^{p+q}$, so $\text{HH}_{\text{alg}}(X) = \sum_p (-1)^p \chi_p(X) = \chi_{\text{top}}(X)$.

Theorem 32.2.1 identifies κ_{ch} with the supertrace $\Xi(X)$, computed from the chiral/categorical side through the (o, q) anti-holomorphic column independently of Kodaira vanishing or Serre cancellation. The Serre antisymmetry $h^{o,q} = h^{o,d-q}$ then acts at odd d : pairwise cancellation in the supertrace forces $\kappa_{\text{ch}} = 0$, separating it from the $\chi(\mathcal{O}_X)$ -track which is itself zero on the same input.

Running examples and their Hodge columns

For every CY manifold below, we record d , the column $(h^{o,0}, h^{o,1}, \dots, h^{o,d})$, and the topological Euler characteristic. The engine `cy_d_kappa_d3.py` supplies these numerically.

Family	d	Column $h^{\circ, \bullet}$	χ_{top}	κ_{ch}	Side
Elliptic curve E	1	(1, 1)	0	0	Φ_d^{FA}
K_3 surface	2	(1, 0, 1)	24	2	Φ_d^{FA}
Abelian surface $E \times E$	2	(1, 2, 1)	0	0	Φ_d^{FA}
Bielliptic surface	2	(1, 1, 0)	0	0	Φ_d^{FA}
Quintic threefold	3	(1, 0, 0, 1)	-200	0	Φ_d^{FA}
$K_3 \times E$	3	(1, 1, 1, 1)	0	0	Φ_d^{FA}
E^3	3	(1, 3, 3, 1)	0	0	Φ_d^{FA}
Local $\mathbb{P}^2 = \text{Tot}(\omega_{\mathbb{P}^2})$	3	open toric column	$\chi_{\text{top}}(\mathbb{P}^2) = 3$	3/2	Φ_d^{FA}
Resolved conifold $\text{Tot}(\mathcal{O}(-1)^{\oplus 2} \rightarrow \mathbb{P}^1)$	3	open toric	-	1	Φ_d^{FA}
CY ₄ sextic $\subset \mathbb{P}^5$	4	(1, 0, 0, 0, 1)	2610	2	Φ_d^{FA}
Septic CY ₅ $X_7 \subset \mathbb{P}^6$	5	(1, 0, 0, 0, 0, 1)	;	0	Φ_d^{FA}
$K_3 \times X_5$ (quintic)	5	(1, 0, 1, 1, 0, 1)	0	0	Φ_d^{FA}
Generic strict CY ₅	5	(1, 0, 0, 0, 0, 1)	;	0	Φ_d^{FA}
<i>Specialisation-side invariants (not Φ_d^{FA} outputs):</i>					
$\kappa_{\text{cat}}(X) = \chi(\mathcal{O}_X)$	all d	manifold	-	(topological)	variety
$\kappa_{\text{BKM}}(\Phi_N) = c_N(\mathfrak{o})/2$	3	Borcherds	-	(automorphic)	Sp^{ch}
κ_{fiber}	3	fibre rank	-	(lattice)	Sp^{ch} cycle

Column key: “Side” records whether the invariant is native to the Φ_d^{FA} factorisation-algebra stage (all rows above the rule) or to the $\text{Sp}_{\Sigma_{d-1}, C}^{\text{ch}}$ specialisation stage (rows below). κ_{ch} values above are computed via the Hodge supertrace $\Xi(X) = \sum_q (-1)^q h^{\circ, q}(X)$ (Theorem 32.2.1); they do not depend on which Sp^{ch} specialisation is chosen. The three specialisation-side invariants are construction-dependent: they change when the Borcherds lift or fibre changes, while κ_{ch} does not.

These values are the skeleton of the stratification theorem. The κ_{ch} column is populated by Künneth multiplicativity of the Hodge supertrace, $\Xi(X \times Y) = \Xi(X) \cdot \Xi(Y)$ (the value at $t = -1$ of the Poincaré polynomial of the $h^{\circ, \bullet}$ column is a homomorphism from products of compact Kähler manifolds to $\mathbb{Z}$), and by the independent supertrace evaluation for non-product families (quintic, local $\mathbb{P}^2$, sextic). On the product entries of the table above at least one factor carries $\Xi = 0$, so Künneth multiplicativity and the naive additive rule $\Xi(X \times Y) = \Xi(X) + \Xi(Y)$ happen to give the same value; the two diverge on products with both factors even-dimensional and supertrace-nonzero (e.g., $K_3 \times K_3$: multiplicative $2 \cdot 2 = 4$, additive $2 + 2 = 4$ coincides; $K_3 \times K_3^{[2]}$: multiplicative $2 \cdot 3 = 6$, additive $2 + 3 = 5$ disagrees). The coincidences $\kappa_{\text{ch}} = \chi(\mathcal{O}_X)$ hold only for $(d, h^{\circ, \bullet}) = (2, 0)$: K_3 sits alone as the honest match.

LEMMA 32.1.1 (*Künneth multiplicativity of the Hodge supertrace*). For compact Kähler manifolds X and Y ,

$$\Xi(X \times Y) = \Xi(X) \cdot \Xi(Y).$$

Proof. The Künneth formula for sheaf cohomology gives $H^q(X \times Y, \mathcal{O}_{X \times Y}) = \bigoplus_{i+j=q} H^i(X, \mathcal{O}_X) \otimes H^j(Y, \mathcal{O}_Y)$, hence $h^{\circ,q}(X \times Y) = \sum_{i+j=q} h^{\circ,i}(X) \cdot h^{\circ,j}(Y)$. Summing with signs,

$$\Xi(X \times Y) = \sum_q (-1)^q \sum_{i+j=q} h^{\circ,i}(X) h^{\circ,j}(Y) = \left(\sum_i (-1)^i h^{\circ,i}(X) \right) \left(\sum_j (-1)^j h^{\circ,j}(Y) \right) = \Xi(X) \cdot \Xi(Y).$$

□

Lemma 32.1.1 reads the table: $\Xi(K_3 \times E) = \Xi(K_3) \cdot \Xi(E) = 2 \cdot \circ = \circ$; $\Xi(E^3) = \circ^3 = \circ$; $\Xi(K_3 \times K_3) = 4$; $\Xi(K_3 \times K_3 \times E) = \circ$.

32.2 THE HODGE SUPERTRACE IDENTIFICATION

THEOREM 32.2.1 (κ_{ch} is the Hodge supertrace of the $h^{\circ,\bullet}$ column). The Hodge supertrace is an unconditional Hodge-theoretic invariant. Its interpretation as κ_{ch} is asserted only on the constructed Φ_d -locus, in particular on the CY- A_d locus for $d \geq 4$. Let X be a compact Calabi–Yau manifold of complex dimension d and let $\mathcal{A}_X = \Phi_d(D^b(\text{Coh}(X)))$ be the chiral algebra of Theorem 5.11.1 (for $d = 3$) or the analogous CY- A_d construction (for other d , conditional for $d \geq 4$). Then, on that constructed locus,

$$\kappa_{\text{ch}}(\mathcal{A}_X) = \Xi(X) = \sum_{q=0}^d (-1)^q h^{\circ,q}(X),$$

while $\Xi(X)$ itself is an unconditional Hodge-theoretic supertrace. At $d = 2$ with $h^{1,\circ}(X) = \circ$ the right-hand side collapses to $\chi(\mathcal{O}_X)$, recovering Proposition 5.3.13.

Proof. The argument proceeds in three steps.

Step 1. HKR and the CY trace. By Theorem 16.1.3, the Hochschild homology of $D^b(\text{Coh}(X))$ decomposes as

$$\text{HH}_\bullet(D^b(\text{Coh}(X))) \simeq \bigoplus_{p+q=\bullet} H^q(X, \Omega_X^p),$$

intertwining the Connes B -operator on the left with the de Rham differential on the right up to the Caldararu twist. The CY structure determines the negative cyclic lift $\text{HC}_d^-(D^b(\text{Coh}(X)))$ of the trace class, which is the S^d -framing datum required by Φ_d .

Step 2. The shadow scalar from HC_d^- . The Vol I shadow construction evaluates the degree-two shadow S_2 of $\mathcal{A}_X$ on the composition $\text{HC}_d^- \rightarrow \text{HH}_\bullet \rightarrow \bigoplus_{p+q} H^q(\Omega_X^p)$. The r -matrix on $\mathcal{A}_X$ is the Mukai pairing (Proposition 16.1.2), graded by the Hodge filtration $F^\bullet$ on $\text{HH}_\bullet$. By construction κ_{ch} is the value of S_2 on the first graded piece $F^0/F^{-1} \cong \bigoplus_q H^q(X, \mathcal{O}_X)$, the structure-sheaf column $(\circ, \bullet)$. The higher Hodge columns $H^q(X, \Omega_X^p)$ with $p \geq 1$ enter the full categorical trace on $\text{HH}_\bullet$ and contribute to κ_{ch} through the graded projection to F^0/F^{-1} ; the chiral shadow is the $(\circ, \bullet)$ filtered piece of this projection. When the middle columns $h^{1,\circ}, h^{2,\circ}, \dots$ vanish, Hodge symmetry $h^{p,q} = h^{q,p}$ collapses the $(\circ, q)$ supertrace to $\chi(\mathcal{O}_X)$.

Step 3. Supertrace through the $(\circ, q)$ column. The surviving $p = 0$ column contributes $H^q(X, \mathcal{O}_X)$ with sign $(-1)^q$, the cohomological sign from the chiral bar complex. Summing over q , $\kappa_{\text{ch}}(\mathcal{A}_X) = \sum_q (-1)^q h^{\circ,q}(X) = \Xi(X)$.

The three steps together establish the supertrace identity unconditionally at Φ -generic parameters. At $d = 2$ with $h^{1,\circ} = \circ$ the column $(1, \circ, 1)$ gives $\Xi(K_3) = 2 = \chi(\mathcal{O}_{K_3})$ and we recover Proposition 5.3.13. Outside that scope $\chi(\mathcal{O}_X) = \circ$ is forced by Serre (Lemma 32.2.3), and the same supertrace identity gives $\Xi(X) = \kappa_{\text{ch}}(\mathcal{A}_X) = \circ$ on compact odd-dimensional CY inputs. Non-zero odd-dimensional scalars belong to distinct shadow, BCOV, Heisenberg, or BKM lanes, not to the compact Hodge supertrace. □

Remark 32.2.2 (Stage-I supertrace scope: κ_{ch} vs. $\kappa_{\text{ch,BV}}$). Theorem 32.2.1 identifies $\kappa_{\text{ch}}(\mathcal{A}_X)$ with the Hodge supertrace $\Xi(X)$ of the $h^{\circ,\bullet}$ column: the Stage-I shadow on $\Phi_d^{\text{FA}}(C)$ against ordinary $H^q(X, \mathcal{O}_X)$. The one-loop BCOV curving coefficient $\kappa_{\text{ch,BV}}$ is a separate Stage-I datum, living on the dilaton-class cohomology: $H^1(X, \mathcal{O}_X)$ via the dilaton cocycle $\text{tr At}(T_X)$ on compact X , and the ζ -regularised $\beta\gamma$ Casimir energy on the boundary link ∂X at $c = -2$ on non-compact X . It sources from the Costello–Li holomorphic BV action (arXiv:1606.00365), distinct from Ξ . On compact CY_d where the actual dilaton class vanishes (the quintic, the four $d = 4$ families of Section 32.5, and the $d = 5$ families of Section 32.6), the dilaton cocycle $\text{tr At}(T_X)$ vanishes in $H^1(X, \mathcal{O}_X)$ and $\kappa_{\text{ch,BV}} = 0$, so the two invariants coincide numerically by zero. For $K_3 \times E$ and E^3 , $h^{\circ,1}$ is respectively 1 and 3; the compact Hodge supertrace still vanishes by Serre/Künneth, but the argument is not an $h^{\circ,1} = 0$ argument. The scope separation is substantive on the non-compact CY_3 frontier where the boundary link ∂X supports a nontrivial $\beta\gamma$ -ghost zero mode; e.g. the conifold with link $T^{1,1} \simeq S^2 \times S^3$, and local $\mathbb{Q}^2$ with link $S^5/\mathbb{Z}_3$; so $\kappa_{\text{ch,BV}} \neq 0$ through the boundary-link ζ -regularised Casimir pairing. The canonical conifold row $(+1, 0, +1, -1)$ of Theorem 32.7.2 exhibits the non-trivial balance $\kappa_{\text{ch}} = -\kappa_{\text{ch,BV}}$ per the Polyakov $c = -2$ ghost-cancellation identity on G-class non-compact CY_3 with single compact curve class; the two invariants remain two separate Stage-I data evaluated against two distinct cohomology theories.

LEMMA 32.2.3 (Serre-enforced vanishing of $\chi(\mathcal{O}_X)$ at odd d). For any compact Calabi–Yau X of odd complex dimension d , $\chi(\mathcal{O}_X) = 0$. The proof is Serre pairwise cancellation: $h^{\circ,q}(X) = h^{\circ,d-q}(X)$ and, for d odd, $(-1)^q + (-1)^{d-q} = 0$ for every pair $(q, d-q)$ with $q \neq d-q$; there is no middle term. See Griffiths–Harris, *Principles of Algebraic Geometry*, Ch. 0 and the engine routine `cy_d_kappa_d3.chi_0_vanishes_odd_d`.

Remark 32.2.4 (Why the identification $\kappa_{\text{ch}} = \chi(\mathcal{O}_X)$ survives only at $(d, h^{1,0}) = (2, 0)$). The supertrace $\Xi(X)$ and the number $\chi(\mathcal{O}_X)$ are computationally identical (both are $\sum_q (-1)^q h^{\circ,q}$). The distinction is that the supertrace is a well-defined invariant of the CY category (it is the degree-two shadow $S_2(\mathcal{A}_X)$ passing through HC_d^-), whereas the phrase “ $\chi(\mathcal{O}_X)$ ” invokes Serre cancellation whenever d is odd. At E with $(d, h^{\circ,\bullet}) = (1, (1, 1))$ the Serre pairing $h^{\circ,0} = h^{\circ,1} = 1$ cancels the two contributions in the written-out sum, so $\Xi(E) = 1 - 1 = 0 = \chi(\mathcal{O}_E)$; the independent chiral computation $\kappa_{\text{ch}}(\mathcal{A}_E) = 0$ agrees, coming from the abelian π_1 -cohomology of E , not from a pairing with the vacuum. Supertrace and chiral calculation agree at the elliptic curve ($0 = 0$); the supertrace value records a cancellation between the two nonzero entries of the $h^{\circ,\bullet}$ column. K_3 sits at the unique even- q -only locus: every nonzero entry of $h^{\circ,\bullet}(K_3)$ lies at even q , and the supertrace records a sum of two nonzero contributions ($1 + 1 = 2$). This locates $(d, h^{1,0}) = (2, 0)$ as the structural home of the K_3 chiral algebra.

32.3 DIMENSION-BY-DIMENSION STRATIFICATION

The Hodge-filtered supertrace formula (Theorem 32.2.1) collapses the entire CY-D landscape into three structural strata, discriminated by the parity of d and by the presence of a holomorphic-symplectic form. This unifies Theorem B at $d = 2$ (K_3), the $d = 3$ case study $K_3 \times E$, the $d = 4$ sextic and hyperkähler examples, the $d = 5$ Universal Serre Cancellation, and every higher-dimensional example below.

THEOREM 32.3.1 (CY-D tri-stratum theorem). Let X be a compact CY_d manifold with Hodge column $h^{\circ,\bullet}(X) = (h^{\circ,0}, h^{\circ,1}, \dots, h^{\circ,d})$. The Hodge-filtered supertrace $\Xi(X) := \sum_{q=0}^d (-1)^q h^{\circ,q}(X)$ takes one of three forms, determined by the parity of d and the holomorphic-symplectic structure of X :

- (I) *Odd d stratum.* If d is odd, then $\Xi(X) = 0$ for every compact CY_d . Mechanism: Serre duality $h^{\circ,q} = h^{\circ,d-q}$ pairs every term with its sign-opposite, and d odd means there is no middle term ($q = d/2$ is non-integral); pairs cancel uniformly.
- (II) *Even d strict-CY stratum.* If d is even and X has holonomy exactly $SU(d)$ (so $h^{\circ,k} = 0$ for $0 < k < d$; the unique global holomorphic form is the Calabi–Yau volume), then $\Xi(X) = 2$. Examples: sextic fourfold in $\mathbb{P}^5$, decic 5-fold in $\mathbb{P}(1^5, 5)$, and every strict CY of even dimension.
- (III) *Even d holomorphic-symplectic stratum.* If d is even and X is irreducible holomorphic-symplectic (holonomy $Sp(d/2)$, with $h^{\circ,k} = 1$ for every even $0 \leq k \leq d$ and $h^{\circ,k} = 0$ for k odd), then $\Xi(X) = (d/2) + 1$. In particular: $K_3^{[n]}$ at $d = 2n$ has $\Xi = n + 1$, recovering $\Xi(K_3) = 2$ at $n = 1$ and $\Xi(K_3^{[2]}) = 3$ at $n = 2$.

Strata (II) and (III) overlap precisely when $SU(d) = Sp(d/2)$, which occurs only at $d = 2$ (where $SU(2) = Sp(1)$; both strata assign $\Xi(K_3) = 2$). For $d \geq 4$ the strata are disjoint, and together with (I) they exhaust the Beauville–Bogomolov classification of compact CY holonomies on connected simply-connected X with $h^{1,0} = 0$.

Proof. Stratum (I) is direct Serre cancellation: for d odd, $h^{\circ,q} = h^{\circ,d-q}$ pairs each $q < d/2$ with $d - q > d/2$, contributing $(-1)^q + (-1)^{d-q} = (-1)^q + (-1)^{d-q}$; since $(-1)^{d-q} = (-1)^d (-1)^{-q} = -(-1)^q$ for d odd, each pair contributes 0. No middle term exists since $d/2$ is non-integral.

Stratum (II) uses the strict-CY definition: for X with holonomy exactly $SU(d)$, the holonomy representation on Ω^q has no trivial summand for $0 < q < d$, so $h^{\circ,q} = 0$ in this range. The only nonzero $h^{\circ,q}$ are $q = 0$ (constants) and $q = d$ (the Calabi–Yau volume form). A second holomorphic form at $q = d/2$ would reduce the holonomy to $Sp(d/2)$, placing X in stratum (III) instead. Hence $\Xi(X) = h^{\circ,0} + (-1)^d h^{\circ,d} = 1 + 1 = 2$, since d is even.

Stratum (III) uses the holomorphic-symplectic Hodge structure of Beauville–Bogomolov: for X irreducible holomorphic-symplectic of complex dimension $d = 2n$, the holomorphic-symplectic form σ and its powers σ^k for $k = 0, 1, \dots, n$ generate the only nonzero $h^{\circ,q}$ with q even. Specifically $h^{\circ,2k} = 1$ for $0 \leq k \leq n$ and $h^{\circ,q} = 0$ for q odd. The supertrace is $\Xi = \sum_{k=0}^n h^{\circ,2k} = n + 1 = (d/2) + 1$.

Mutual exclusivity follows from Beauville–Bogomolov: every compact Kähler CY manifold with $c_1 = 0$ admits a finite étale cover that decomposes as $T^d \times \prod_i HK_i \times \prod_j Y_j$ where T^d is a torus, HK_i are irreducible holomorphic-symplectic, and Y_j are strict CYs. Restricting to $h^{1,0} = 0$ (the universal hypothesis on the present chapter) eliminates the torus factor; restricting to one Bogomolov factor gives one of the three strata exclusively. $\square$

Remark 32.3.2 (The κ_{ch} landscape has structure only at even d). Stratum (I) collapses the entire odd- d landscape to the single value $\kappa_{\text{ch}}(\mathcal{A}_X) = 0$. The algebraic richness of the chiral output $\mathcal{A}_X$ at odd d lives on other invariants — shadow-tower depth, BCOV partition function, Maulik–Okounkov stable-envelope R -matrix — each computing its own structural content beyond the linear Hodge supertrace. The κ_{ch} landscape proper sits at even d , distributed across strata (II) and (III) by the holomorphic-symplectic form.

This is the structural reason that the K_3 chiral algebra at $d = 2$ is the canonical exemplar: the two stratifying formulas agree on K_3 . Stratum (III) gives $\Xi = (d/2) + 1 = 2$ at $d = 2, n = 1$. Stratum (II) with the K_3 column $h^{\circ,\bullet}(K_3) = (1, 0, 1)$ and the $h^{\circ,d/2} = h^{\circ,1} = 0$ middle term gives $\Xi = 1 + (-1)^1 \cdot 0 + 1 = 2$. Both routes land on the same value because K_3 is simultaneously strict CY (holonomy $SU(2)$) and irreducible holomorphic-symplectic (holonomy $Sp(1) = SU(2)$), an accident of low dimension: $SU(2) = Sp(1)$. In higher even dimension the two holonomy classes are distinct and the two stratum formulas

diverge, with stratum (II) giving 2 (at vanishing middle holomorphic form) and stratum (III) giving $n + 1$ for $K_3^{[n]}$.

COROLLARY 32.3.3 (*BCOV F_g vanishing across all even d*). Theorems 32.5.2 ($d = 4$) and 32.6.2 ($d = 5$) are the chain-level expressions of Theorem 32.3.1: the BCOV F_g holomorphic anomaly equation respects the underlying Serre symmetry of stratum (I) and the holomorphic-symplectic Hodge structure of stratum (III), so the supertrace is the COMPLETE answer in both strata. At stratum (II), the BCOV F_g contribution is similarly forced to zero by the constancy $F_1 = \chi/24$ on the BTT moduli of strict CYs.

32.4 SHADOW-CLASS STRATIFICATION BY CY HOLONOMY

Theorem 32.3.1 controls the scalar $\kappa_{\text{ch}}(\mathcal{A}_X)$ by the Hodge column $h^{\circ, \bullet}$. A complementary, logically independent question is: what is the *shadow class* $\text{Cl}(\mathcal{A}_X) \in \{G, L, C, M\}$ of the chiral algebra $\mathcal{A}_X = \Phi_d(D^b(\text{Coh}(X)))$ per stratum? The shadow class is determined by the higher shadow coefficients $(S_3, S_4, \dots)$ (the OPE-pole structure of the chiral r -matrix), not by $\kappa_{\text{ch}} = S_2$ alone. The classification below uses the Vol I shadow-depth hierarchy $G < L < C < M$ indexed by $r_{\text{max}} \in \{2, 3, 4, \infty\}$ together with the Vol III closed $\kappa_{\bullet}$ menu.

THEOREM 32.4.1 (*CY- D shadow-class stratification by holonomy*). The statement is read at the level of the tree-level Hodge-supertrace input to the shadow tower. It is supplied unconditionally for $d \in \{1, 2, 3\}$ by CY- A_2 and by the ∞ -categorical CY- A_3 resolution of Theorem 5.11.1; for $d \geq 4$ it assumes the CY- A_d construction. The BCOV F_g -instanton promotion in stratum (I_{BCOV}) is unconditional on the cited cases (quintic, sextic-double cover at $d = 3$); compact non-product non-toric CY₃ with a verified non-vanishing leading Gopakumar–Vafa invariant supplies the promotion case by case. Let X be a compact CY _{d} manifold with $h^{1,0}(X) = 0$ and $\mathcal{A}_X = \Phi_d(D^b(\text{Coh}(X)))$, all statements at generic parameters of Φ and ambient-qualified per stratum below:

- (I_{tree}) *Odd d stratum, tree level.* If d is odd, the Hodge-supertrace input to the shadow tower is $S_2 = \Xi(X) = 0$ by Serre pairwise cancellation. This statement does not compute the higher shadow coefficients $S_3, S_4, \dots$; those require OPE/BRST/BCOV input beyond the linear Hodge supertrace. The tree-level shadow class is therefore G only on the additional vanishing locus for the higher tree coefficients.
- (I_{BCOV}) *Odd d stratum, BCOV-promoted.* At compact odd- d CY with nontrivial Gopakumar–Vafa spectrum, the BCOV instanton corrections promote the shadow class to M (depth $r_{\text{max}} = \infty$). The quintic $X_5 \subset \mathbb{P}^4$ realizes this promotion: classical $S_4 = 0$ gives tree-level class L once the $\sigma_3 = 5$ triple-intersection Yukawa is retained, but the Gopakumar–Vafa genus-zero invariants n_d^0 are nonzero for every $d \geq 1$, driving $S_4^{\text{instanton}} \neq 0$ and hence class M (Proposition 29.9.7, with the quintic $\kappa_{\text{ch}}^{\text{BCOV}} = \chi/24 = -25/3$ separately; see Remark 32.4.2 below for the supertrace-vs-BCOV disambiguation).
- (II) *Even d , strict CY stratum.* If X has holonomy exactly $\text{SU}(d)$ (strict CY, $h^{\circ, k} = 0$ for $0 < k < d$), then the tree-level algebra $\mathcal{A}_X$ is the rank-2 lattice VOA on the holomorphic $(0, 0)$ and $(0, d)$ sector (the vacuum and the Calabi–Yau volume form), which is a free-field algebra. Free-field algebras have $S_3 = S_4 = 0$ and shadow class G with $r_{\text{max}} = 2$. Sextic $X_6 \subset \mathbb{P}^5$ and decic $\subset \mathbb{P}(1^5, 5)$ (with $\kappa_{\text{ch}} = 2$) are canonical class- G representatives.
- (III) *Even $d = 2n$, holomorphic-symplectic stratum.* If X is irreducible holomorphic-symplectic (holonomy $\text{Sp}(n)$), then $h^{\circ, 2k} = 1$ for $0 \leq k \leq n$ and the tree-level algebra $\mathcal{A}_X$ is the rank- $(n + 1)$ lattice VOA generated by the σ^k tower (the $n + 1$ powers of the holomorphic-symplectic form).

This is a free-field algebra: $S_3 = S_4 = 0$, shadow class G , $r_{\max} = 2$. K_3 ($n = 1$), $K_3^{[n]}$, and the Beauville–Donagi Fano variety of lines $F(Y)$ on a cubic fourfold are canonical class- G representatives, with $\kappa_{\text{ch}} = n + 1$. At $n = 1$ (K_3), strata (II) and (III) coincide and both yield class G on the Φ_2 -output vertex algebra, consistent with the Mukai lattice VOA computation (Chapter 17, $S_3 = S_4 = 0 \Rightarrow \Delta = 0 \Rightarrow \text{class } G$).

The tree-level shadow class is thus uniformly G across every compact CY_d stratum (I_{tree}), (II), (III). Promotion to higher shadow classes requires either (a) compact odd- d BCOV F_g instanton corrections (I_{BCOV}), (b) non-compact toric promotion via McKay quiver $\mathbb{Z}/N$ -symmetry (see Theorem 34.11.1: local $\mathbb{P}^2$ is class M with $r_{\max} = \infty$ by $\mathbb{Z}/3$ -McKay), or (c) K_3 *sigma-model* enhancement of the Φ_2 -output lattice VOA to an $\widehat{\mathfrak{su}}_2^{\oplus n}$ subalgebra at level 1 (Kummer point, Chapter 17: enhanced subalgebra is class L with $r_{\max} = 3$).

Proof. We prove each stratum separately.

Stratum (I_{tree}). At odd d with $h^{1,0} = 0$, the Hodge column $(1, h^{0,1}, \dots, h^{0,1}, 1)$ paired by Serre produces, at tree level (before BCOV F_g corrections), a free-field lattice VOA structure on $\mathcal{A}_X$: the paired generators $\{1, \omega_d\}$ at degrees 0 and d , together with the Serre-dual pairs $\{\eta_q, \eta_{d-q}\}$ at intermediate degrees $q \in \{1, \dots, d-1\}$, mutually commute at tree level because (a) Serre duality pairs η_q with η_{d-q} in a degree-zero pairing $\langle \eta_q, \eta_{d-q} \rangle = \int_X \eta_q \wedge \eta_{d-q} = \text{vol}_X$, giving a symplectic (d odd, so η -pair is in antisymmetric position) rank-2 block per pair, and (b) cross-pairs between distinct q, q' vanish by bigrading conservation. The total structure is a rank- $(d+1)$ symplectic lattice VOA, which is free-field (Frenkel–Ben-Zvi *Vertex algebras and algebraic curves* 2001 Chapter 3, free-field lattice VOA construction). Free-field lattice VOAs have $S_3 = S_4 = 0$ (no cubic or quartic OPE pole; every OPE has at most a double pole by free-field Wick contraction), so $\Delta = 8\kappa_{\text{ch}}S_4 = 0$ and the shadow class is G with $r_{\max} = 2$. Equivalently: $\kappa_{\text{ch}} = 0$ from the Serre-cancellation of $\Xi(X)$ (stratum (I) of Theorem 32.3.1), and the higher shadow coefficients are zero from the free-field structure. The two inputs (vanishing scalar; free-field higher) converge on class G .

Stratum (I_{BCOV}). At compact odd- d CY with nontrivial Gopakumar–Vafa spectrum, the BCOV holomorphic-anomaly equation (Bershadsky–Cecotti–Ooguri–Vafa 1994, Theorem 11.1) propagates to the shadow tower via $S_4^{\text{instanton}} = \sum_{d \geq 1} n_d^0 / \kappa_{\text{ch}}^{\text{BCOV}}$ (Proposition 29.9.7, clause (iii)). For the quintic: $n_1^0 = 2875 \neq 0$ (Candelas–de la Ossa–Green–Parkes 1991), forcing $S_4^{\text{instanton}} \neq 0$ and hence class M with $r_{\max} = \infty$. The class- M conclusion applies conditionally: (i) to the quintic unconditionally, via the explicit nonzero $n_1^0 = 2875$ computation; (ii) to compact non-product CY_3 families with a nonvanishing leading Gopakumar–Vafa invariant at degree 1 or at some higher degree for which the BCOV mirror-symmetry series is known to be nontrivial. Each such case proceeds by an explicit GV-invariant verification; universal nonvanishing of the GV spectrum across all compact non-product CY_3 is an open conjecture, treated case-by-case here. The open frontier of Remark 32.7.5 is the locus of compact non-product non-toric CY_3 awaiting an independent GV-nonvanishing witness.

The BCOV promotion produces the leading shadow-tower coefficient. For the quintic it proves the first LCS obstruction coefficient $S_{4,1}^{\text{inst}} = 2875/(-25/3) = -345$, with leading sign $(\kappa_{\text{ch}}^{\text{BCOV}})^3 S_{4,1}^{\text{inst}} > 0$. The Booth–Lazarev vanishing theorem operates at a separate level: the residual sewing obstruction $O_3^{\text{BL}} \in \varprojlim_g^1 \mathcal{A}^{\text{sew},g}$ vanishes through the full BCOV Borel sign lemma on the entire genus tower; the Ran-space obstruction $O_1^{\text{BL}} \in H^1(\text{Ran}(C), \text{Aut}_{\otimes}(\text{Gen}_{\text{BL}}))$ is the Smith-recognition complex. Each obstruction carries its own vanishing locus, with the scalar shadow calculation supplying the leading-order check.

Stratum (II). At strict CY_d with holonomy exactly $\text{SU}(d)$ (even d), the nontrivial Hodge column is $\{h^{\circ,0}, h^{\circ,d}\} = \{1, 1\}$ with $h^{\circ,k} = 0$ for $0 < k < d$. The chiral algebra $\mathcal{A}_X$ at tree level is generated by the $H^0(X, \mathcal{O}_X) = \mathbb{C}$ vacuum $|0\rangle$ and the $H^d(X, \mathcal{O}_X) = \mathbb{C}\omega$ volume form, giving a Fock-module structure of Heisenberg type: the pair $(|0\rangle, \omega)$ generates a rank-1 Heisenberg VOA $\mathcal{H}_1$ via the mode expansion of $\omega(z) = \sum_n \omega_n z^{-n-1}$ with canonical commutation $[\omega_m, \omega_n] = m\delta_{m+n,0}$ (the standard Heisenberg relation, Frenkel–Ben-Zvi 2001 Proposition 2.2.1). The shadow tower of a Heisenberg VOA $\mathcal{H}_k$ has $\kappa_{\text{ch}} = k$, $S_3 = 0$ (no cubic pole: Heisenberg OPE is $\omega(z)\omega(w) \sim k/(z-w)^2$, a pure double pole with no cubic term), and $S_4 = 0$ (no quartic pole either). The critical discriminant $\Delta = 8\kappa_{\text{ch}}S_4 = 0$ gives class G with $r_{\text{max}} = 2$ (Vol I shadow-class- G criterion: $S_3 = S_4 = 0 \Leftrightarrow \Delta = 0$ and shadow tower terminates at degree 2). The Hodge supertrace $\kappa_{\text{ch}} = \Xi(X) = 2$ from Stratum (II) of Theorem 32.3.1 identifies the Heisenberg level $k = 2$. The sextic $X_6 \subset \mathbb{P}^5$, decic $\subset \mathbb{P}(1^5, 5)$, and every higher even- d strict CY realize this Heisenberg pattern at tree level.

Stratum (III). At irreducible holomorphic-symplectic X of complex dimension $d = 2n$, the Hodge column has $h^{\circ,2k} = 1$ for $0 \leq k \leq n$ and $h^{\circ,q} = 0$ otherwise (Beauville–Bogomolov decomposition). The chiral algebra $\mathcal{A}_X$ at tree level is generated by the $n+1$ classes $\sigma^k \in H^{\circ,2k}(X, \mathbb{C})$ ($k = 0, \dots, n$) with corresponding bosonic modes $\sigma^k(z) = \sum_m \sigma_m^k z^{-m-1}$. The Fujiki relations (Fujiki *Hodge structures on hyperkähler manifolds*, Publ. Inst. Math. IHES 1987, cubic Fujiki constant c_X) give the pairing $\int_X \sigma^k \wedge \bar{\sigma}^{n-k} = c_X \cdot \text{vol}(X)$ pairwise, and orthogonality for distinct Hodge weights (k, k') with $k + k' \neq n$. The induced mode commutator is $[\sigma_m^k, \sigma_p^{n-k}] = m \cdot c_X \cdot \delta_{m+p,0}$ (pure Heisenberg central-charge relation with σ^k and σ^{n-k} forming a conjugate pair), and $[\sigma_m^k, \sigma_p^{k'}] = 0$ for $k + k' \neq n$. This is exactly the defining commutator of the rank- $(n+1)$ Heisenberg VOA $\mathcal{H}^{\otimes(n+1)}_{c_X}$ at level c_X (equivalently: $n+1$ mutually-commuting free-boson generators, each a copy of $\mathcal{H}_{c_X}$). The shadow coefficients of a tensor product of free-boson VOAs are $S_3 = S_4 = 0$ and $\kappa_{\text{ch}} = \sum_{k=0}^n c_X = (n+1)c_X$ at the standard normalization $c_X = 1$, recovering $\kappa_{\text{ch}} = n+1$ from Stratum (III) of Theorem 32.3.1. The critical discriminant $\Delta = 0$ gives class G with $r_{\text{max}} = 2$. K_3 ($n = 1$, rank-2 Heisenberg tensor), $\text{K}_3^{[2]}$ ($n = 2$, rank-3 Heisenberg tensor), and the Beauville–Donagi cubic-4-fold lines $F(Y) \sim_{\text{deform}} \text{K}_3^{[2]}$ (Beauville–Donagi 1985) all realize this pattern; the full rank-24 Mukai lattice VOA on K_3 of Chapter 17 is an enlargement to the full Mukai lattice but the class- G conclusion is preserved ($S_3 = S_4 = 0 \Rightarrow \Delta = 0 \Rightarrow \text{class } G$).

Overall conclusion. The tree-level shadow class is G uniformly across strata. Promotion mechanisms (a) compact odd- d BCOV, (b) non-compact toric McKay $\mathbb{Z}/N$ -symmetry, (c) K_3 -sigma-model enhancement are the three documented routes out of class G ; each is explicit in the indicated chapter or stratum. $\square$

Remark 32.4.2 (Disambiguation: $\kappa_{\text{ch}}^{\text{Hodge}}$ vs $\kappa_{\text{ch}}^{\text{BCOV}}$ at the quintic). The quintic threefold carries two distinct invariants that each go by the name κ_{ch} ; the Φ -output invariant must be distinguished from the construction-level invariant.

- (i) $\kappa_{\text{ch}}^{\text{Hodge}}(\mathcal{A}_{X_5}) = \Xi(X_5) = 0$, the Hodge supertrace of the $(0, \bullet)$ column $(1, 0, 0, 1)$: vanishes by Serre (Theorem 32.2.1).
- (ii) $\kappa_{\text{ch}}^{\text{BCOV}}(\mathcal{A}_{X_5}) = \chi(X_5)/24 = -25/3$, the BCOV F_1 one-loop free energy divided by the universal Euler coefficient: nonzero, fractional (Proposition 29.9.5).

Both are “ κ_{ch} ” of “the quintic chiral algebra”, but they are invariants of *different constructions*: (1) is the supertrace trace on HC_3^- of the shadow tower of $\mathcal{A}_{X_5} = \Phi_3(D^b(\text{Coh}(X_5)))$ (the categorical Φ_3 output), while (2) is the BCOV-genus-1 coefficient of the topological-string partition function on the quintic (a separately constructed worldsheet invariant). These two invariants are both legitimate and

both denoted κ_{ch} in the standard literature (Vol III [96] at Proposition 29.9.5 for the BCOV route, and this chapter Section 32.3 for the Hodge supertrace route), but they are not the same number and are distinct. Six routes to $G(K_3 \times E)$ are six different constructions, not six Φ applications; the same discipline applies here: $\kappa_{\text{ch}}^{\text{Hodge}}$ and $\kappa_{\text{ch}}^{\text{BCOV}}$ are two-route analogs at the quintic.

The shadow-class stratification of Theorem 32.4.1 uses the Hodge supertrace input (tree level, stratum (I_{tree})), and promotes to class M via BCOV instanton corrections to S_4 (stratum (I_{BCOV})). The two routes converge on the same shadow-class outcome at the quintic (class M) but differ on the degree-2 scalar: $\kappa_{\text{ch}}^{\text{Hodge}} = 0$ from stratum- (I_{tree}) Serre cancellation, $\kappa_{\text{ch}}^{\text{BCOV}} = -25/3$ from F_1 -constant-map formula.

COROLLARY 32.4.3 (*Shadow class and CY dimension: the universal compact class- G signature at tree level*). Assume the tree-level Φ_d -shadow is constructed in the sense of Theorem 32.4.1. For every compact CY_d with $h^{1,0} = 0$, the tree-level shadow class $\text{Cl}^{\text{tree}}(\mathcal{A}_X)$ is G uniformly across $d \in \{2, 3, 4, 5\}$. (At $d = 1$, the $h^{1,0} = 0$ scope is vacuous: every elliptic curve has $h^{1,0} = 1$, so there is no compact $d = 1$ CY with $h^{1,0} = 0$ to classify; the $d = 1$ entry is treated separately at Theorem 32.4.5 via the $\Xi(E) = 0$ Serre cancellation.) The tree-level shadow depth is $r_{\text{max}}^{\text{tree}} = 2$ throughout the $d \in \{2, 3, 4, 5\}$ scope. Higher shadow classes L, C, M appear only through (a) compact odd- d BCOV F_g instanton promotion, (b) non-compact toric McKay $\mathbb{Z}/N$ -enhancement, or (c) K3-sigma-model $\widehat{\mathfrak{su}}_2^{\oplus n}$ enhancement. Equivalently: the CY dimension d alone does not determine the shadow class; the shadow class is determined by the compactness, the holonomy, and the presence/absence of a promotion mechanism, not by d directly.

Proof. Strata (I_{tree}) , (II), (III) of Theorem 32.4.1 each yield class G at tree level, and the three strata exhaust the compact CY_d landscape with $h^{1,0} = 0$ per Beauville–Bogomolov (Theorem 32.3.1). Hence class G is universal at tree level across d . The three documented promotion mechanisms are enumerated in the last paragraph of Theorem 32.4.1; each is conditional on auxiliary data (BCOV instanton spectrum, McKay quiver symmetry, K3 sigma-model enhancement) beyond the raw CY dimension. $\square$

Remark 32.4.4 (*Cross-volume implication: Vol I four-class landscape*). The Vol I four-class landscape $\{G, L, C, M\}$ is populated by four archetype vertex algebras: Heisenberg $\mathcal{H}_k$ (class G), affine Kac–Moody $V_k(\mathfrak{g})$ (class L), $\beta\gamma$ (class C), Virasoro Vir_c (class M). The Vol III Φ_d -output stratification of Theorem 32.4.1 realizes class G universally at tree level; classes L, C, M are accessed only through the three promotion mechanisms. In particular:

- Class L (affine Kac–Moody) is accessed from Φ_d only via the K3 $N = 4$ sigma-model enhancement to $\widehat{\mathfrak{su}}_2^{\oplus n}$ at level 1 on the Kummer point (Chapter 17).
- Class C ($\beta\gamma$) is accessed from Φ_d only at non-compact local surfaces (Theorem 34.11.1: local $\mathbb{P}^2$ via the $\beta\gamma$ boundary algebra is class C at $r_{\text{max}} = 4$; see also the conifold bichamber computation of Chapter 34).
- Class M (Virasoro-type) is accessed via BCOV instanton corrections at compact odd- d CY (quintic, $K_3 \times E$, non-product CY_3) or via the K3 sigma-model full $N = 4$ superconformal enhancement (Chapter 17, full sigma model class M).

This population pattern is the Vol III-specific analog of the Vol I averaging-map principle: the averaging map $\text{av} : \mathfrak{g}^{E_1} \rightarrow \mathfrak{g}^{\text{mod}}$ collapses every standard chiral algebra into one of four archetypes; the Φ_d -output tree-level algebra $\mathcal{A}_X$ lands on the Heisenberg archetype (class G) uniformly, and higher classes require ambient-category enhancement beyond the bare Φ_d output.

THEOREM 32.4.5 (*Stratification of κ_{ch} by $(d, h^{\circ, \bullet})$*). On the constructed Φ_d -locus, with the $d \geq 4$ entries read under $\text{CY-}A_d$, the following table is the Hodge-supertrace stratification. Let X be a compact CY_d and $\mathcal{A}_X$ the associated chiral algebra. For the standard families of Vol III, the invariant $\kappa_{\text{ch}}(\mathcal{A}_X)$ is determined by the Hodge column $h^{\circ, \bullet}(X)$ via Theorem 32.2.1 and takes the following values.

$d = 1$ (**elliptic curve** E). Column $h^{\circ, \bullet} = (1, 1)$, so $\Xi(E) = 1 - 1 = 0$ and $\kappa_{\text{ch}}(\mathcal{A}_E) = 0$. Two Heisenberg invariants must be distinguished: the shadow scalar κ_{ch} of the chiral output $\mathcal{A}_E = \Phi_1(D^b(\text{Coh}(E)))$, which vanishes by the supertrace $1 - 1 = 0$; and the Heisenberg level $\kappa_{\text{Heis}} = k$, which parametrizes the free-boson lattice VOA H_k of rank 1 and equals 1 at the basic representation H_1 . The lattice VOA H_1 is a separate construction from $\Phi_1(D^b(\text{Coh}(E)))$, so $\kappa_{\text{Heis}}(H_1) = 1$ and $\kappa_{\text{ch}}(\Phi_1(D^b(\text{Coh}(E)))) = 0$ are invariants of different algebras. In this chapter κ_{ch} always denotes the supertrace on the Φ_d output; the $d = 1$ value is $\kappa_{\text{ch}}(\Phi_1(D^b(\text{Coh}(E)))) = 0$.

$d = 2$, **K3** ($h^{1,0} = 0$). Column $(1, 0, 1)$, so $\Xi(K_3) = 2$ and $\kappa_{\text{ch}}(\mathcal{A}_{K_3}) = 2 = \chi(\mathcal{O}_{K_3})$. This is the honest case where the supertrace and the naive $\chi(\mathcal{O}_X)$ agree.

$d = 2$, **abelian surface**. Column $(1, 2, 1)$, so $\Xi(E \times E) = 1 - 2 + 1 = 0$ and $\kappa_{\text{ch}}(\mathcal{A}_{E \times E}) = 0$. The cancellation is pairwise: the two $h^{0,1}$ forms subtract exactly from $h^{0,0} + h^{0,2} = 2$.

$d = 2$, **bielliptic surface**. Column $(1, 1, 0)$, so $\Xi(\text{biell}) = 1 - 1 + 0 = 0$ and $\kappa_{\text{ch}}(\mathcal{A}_{\text{biell}}) = 0$. No holomorphic 2-form; $h^{1,0} = 1$ forces a cancellation at $q = 1$.

$d = 3$, **generic quintic**. Column $(1, 0, 0, 1)$, so $\Xi(X_5) = 1 - 0 + 0 - 1 = 0$ and $\kappa_{\text{ch}}(\mathcal{A}_{X_5}) = 0$.

$d = 3$, **K3 $\times$ E** . Kunneth gives the column $(1, 1, 1, 1)$: $h^{0,0} = 1$, $h^{0,1} = h_{K_3}^{0,0} \cdot h_E^{0,1} + h_{K_3}^{0,1} \cdot h_E^{0,0} = 1 + 0 = 1$, $h^{0,2} = 0 + 1 = 1$, $h^{0,3} = 1$. Then $\Xi = 1 - 1 + 1 - 1 = 0$. $\kappa_{\text{ch}}(\mathcal{A}_{K_3 \times E}) = 0$.

$d = 3$, **local toric**. For a non-compact toric CY_3 , the $h^{\circ, \bullet}$ column is not the correct input: Serre duality on compact X is replaced by compactly-supported duality on the total space. The supertrace evaluates instead on the Dolbeault column of the base: for local $\mathbb{Q}^2 = \text{Tot}(\omega_{\mathbb{Q}^2})$ this is $\frac{1}{2}\chi_{\text{top}}(\mathbb{Q}^2) = \frac{3}{2}$, matching Theorem 34.11.1.

$d = 4$, **CY₄**. Column $(1, h^{0,1}, h^{0,2}, h^{0,3}, h^{0,4})$ with $h^{0,4} = h^{4,0} = 1$ and $h^{0,q} = h^{0,4-q}$ by Serre. The supertrace $\Xi(X) = 1 - h^{0,1} + h^{0,2} - h^{0,3} + h^{0,4} = 2 - 2h^{0,1} + h^{0,2}$, using $h^{0,3} = h^{0,1}$ and $h^{0,4} = 1$. For the sextic $X_6 \subset \mathbb{Q}^5$ with $h^{0,1} = 0$ and $h^{0,2} = 0$, $\Xi(X_6) = 2$.

$d = 5$, **odd case**. Column $(1, h^{0,1}, h^{0,2}, h^{0,3}, h^{0,4}, h^{0,5})$ with $h^{0,q} = h^{0,5-q}$ and $h^{0,5} = 1$. The supertrace $\Xi = 1 - h^{0,1} + h^{0,2} - h^{0,3} + h^{0,4} - h^{0,5} = (1 - 1) + (-h^{0,1} + h^{0,4}) + (h^{0,2} - h^{0,3}) = 0$ term by term under Serre. So $\kappa_{\text{ch}} = 0$ for every compact CY_5 , just as at $d = 1, 3$.

Proof. Each case reduces to plugging the Hodge column into Theorem 32.2.1. The K_3 calculation reproduces Proposition 5.3.13. The abelian surface, bielliptic surface, quintic, $K_3 \times E$, and E^3 values are verified independently by K nneth multiplicativity of the Hodge supertrace, $\Xi(X \times Y) = \Xi(X) \cdot \Xi(Y)$, using $\Xi(\Phi_1(E)) = 0$ and $\Xi(\Phi_2(K_3)) = 2$: every product entry has a factor with vanishing supertrace and therefore collapses to zero. The local $\mathbb{Q}^2$ value $3/2$ is Theorem 34.11.1 and agrees with $\frac{1}{2}\chi_{\text{top}}(\mathbb{Q}^2) = 3/2$. The sextic value $\Xi(X_6) = 2$ is independently $\chi(\mathcal{O}_{X_6})$ since $h^{1,0} = h^{2,0} = h^{3,0} = 0$ at $d = 4$ with $h^{4,0} = 1$. The odd $d = 5$ vanishing is purely Serre: every pair cancels. $\square$

THEOREM 32.4.6 (*Local $\mathbb{Q}^2/E_{27}$ arithmetic obstruction*). Let

$$E_{27}: y^2 + y = x^3$$

be the conductor-27 elliptic curve with CM by $\mathbb{Z}[\zeta_3]$. Its Hecke eigenvalues satisfy

$$a_2(E_{27}) = 0, \quad a_7(E_{27}) = -1, \quad \dim S_2^{\text{new}}(\Gamma_0(27)) = 1, \quad \dim S_2(\Gamma_0(9)) = 0.$$

Hence the T_2 condition is a consistency check, not a falsifier: $\beta a_2 = 0$ for every scalar β . The first split-prime falsifier is $p = 7$: on the Skoruppa–Zagier target $S_2(\Gamma_0(27)) = \mathbb{C}f_{27,a_3}$, the source coefficient map

$$[q^7]SZ(\xi^{\text{loc}}\mathbb{Q}^2) \mapsto \beta a_7(E_{27}) = -\beta$$

forces $\beta = 0$ once the local $\mathbb{Q}^2$ chain-level source coefficient $[q^7]SZ(\xi^{\text{loc}}\mathbb{Q}^2)$ is zero.

Proof. The computation is executable in `compute/lib/local_p2_four_kappa_engine.py` and tested in `compute/tests/test_lp2_E27_falsifier.py`. Direct enumeration of $E_{27}(\mathbb{F}_p)$ gives $a_p = p + 1 - \#E_{27}(\mathbb{F}_p)$ for every good prime in the stored table; at $p = 2$ this full enumeration is necessary because the discriminant shortcut divides by 2. The result is $a_2 = 0$ and $a_7 = -1$.

The CM verification is independent. For $p \equiv 2 \pmod{3}$ the prime is inert in $\mathbb{Z}[\zeta_3]$ and $a_p = 0$. For split primes $p \equiv 1 \pmod{3}$, the equation

$$4p = L^2 + 27M^2$$

gives $|a_p| = L$; at $p = 7$, $28 = 1^2 + 27 \cdot 1^2$, hence $|a_7| = 1$, and the direct point count fixes the sign $a_7 = -1$.

The target space is unique. Riemann–Hurwitz gives $[SL_2(\mathbb{Z}) : \Gamma_0(27)] = 36$ and six cusps on $X_0(27)$, hence $\dim S_2(\Gamma_0(27)) = 1$; the same formula gives $\dim S_2(\Gamma_0(9)) = 0$, so no old-form sector survives at level 27. The arithmetic target is therefore the line $\mathbb{C}f_{27,a_3}$. The only remaining non-arithmetic map is the source-side chain construction of the coefficient $[q^7]SZ(\xi^{\text{loc}}\mathbb{Q}^2)$ from the local $\mathbb{Q}^2$ Pentagon complex; the E_{27} arithmetic and the source/target falsifier constant are unconditional. $\square$

32.5 $d = 4$ EXPLICIT EXAMPLES AND THE BCOV F_2 ZERO-CORRECTION THEOREM

The $d = 4$ entry of Theorem 32.4.5 records the supertrace $\Xi(X_6) = 2$ for the sextic. This section develops the full $d = 4$ stratum: explicit computation across five families (sextic, octic double cover, decic, $K_3^{[2]}$, $F(Y)$ Beauville–Donagi cubic-4-fold lines) plus the new structural *BCOV F_2 zero-correction theorem* establishing that the leading Hodge supertrace is the COMPLETE answer at $d = 4$.

The five $d = 4$ families

X	$h^{\circ,\bullet}$	$\Xi(X) = \kappa_{\text{ch}}$	F_2 corr.	mechanism	reference
Sextic $X_6 \subset \mathbb{Q}^5$	(1, 0, 0, 0, 1)	2	0	strict CY honest	KPo7 Tab. 1
Octic double X_8	(1, 0, 149, 0, 1)	151	0	non-trivial $h^{\circ,2}$	HKTY95 App. B
Decic in $\mathbb{Q}(1^5, 5)$	(1, 0, 0, 0, 1)	2	0	strict CY honest	HKT96
$K_3^{[2]}$	(1, 0, 1, 0, 1)	3	0	hyper-Kähler σ	Beauville83+Göttsche90
$F(Y)$ cubic-4-fold lines	(1, 0, 1, 0, 1)	3	0	deformation $\sim K_3^{[2]}$	Beauville–Donagi85

The five families partition into three patterns: (i) *strict-CY honest match* (sextic and decic, $h^{\circ,q} = 0$ for $q \in \{1, 2, 3\}$, $\Xi = 2$); (ii) *non-trivial middle column* (octic double cover, $h^{\circ,2} = 149$, $\Xi = 151$); (iii) *hyper-Kähler* ($K_3^{[2]}$ and $F(Y)$, $h^{\circ,2} = 1$ from holomorphic-symplectic form σ , $\Xi = 3 = n + 1$ from Beauville–Göttsche). The agreement between $K_3^{[2]}$ and $F(Y)$ is the deformation invariance of κ_{ch} within the hyper-Kähler family.

THEOREM 32.5.1 ($d = 4$ stratification of κ_{ch}). For each compact CY_4 family X in the table above, the algebraization scalar $\kappa_{\text{ch}}(\mathcal{A}_X)$ equals the $h^{\circ,\bullet}$ -supertrace

$$\kappa_{\text{ch}}(\mathcal{A}_X) = \Xi(X) = \sum_{q=0}^4 (-1)^q h^{\circ,q}(X),$$

taking values $\Xi(X_6) = \Xi(\text{decic}) = 2$, $\Xi(X_8) = 151$, and $\Xi(K_3^{[2]}) = \Xi(F(Y)) = 3$. The final equality $\Xi(K_3^{[2]}) = 3 = n + 1$ at $n = 2$ recovers the Beauville–Göttsche $n + 1$ rule for the $K_3^{[n]}$ series.

Proof. Each entry follows by direct evaluation of the Hodge supertrace formula (Theorem 32.2.1) on the $h^{\circ,\bullet}$ column tabulated above. The Hodge data is taken from: Klemm–Pandharipande *Enumerative geometry of Calabi–Yau 4-folds* (2007) Table 1 for the sextic; Hosono–Klemm–Theisen–Yau *Mirror symmetry* (1995) Appendix B for the octic double cover; Hosono–Klemm–Theisen (1996) for the decic in $\mathbb{P}(1^5, 5)$; Göttsche *Hilbert schemes of zero-dimensional subschemes* (1990) for the $K_3^{[2]}$ generating function; Beauville–Donagi *La variété des droites d’une hypersurface cubique de dimension 4* (1985) for the deformation equivalence $F(Y) \sim K_3^{[2]}$. The agreement $\Xi(K_3^{[2]}) = 3 = n + 1$ at $n = 2$ matches the Beauville 1983 Hilbert-scheme classification.

The absence of any F_2 correction is Theorem 32.5.2 below. $\square$

The BCOV F_2 zero-correction theorem

THEOREM 32.5.2 (BCOV F_2 contributes zero to κ_{ch} at $d = 4$). For any compact CY_4 manifold X , the BCOV genus-2 holomorphic anomaly contributes identically zero to the algebraization scalar:

$$\kappa_{\text{ch}}^{F_2\text{-correction}}(\mathcal{A}_X) = 0.$$

The full $\kappa_{\text{ch}}(\mathcal{A}_X)$ at $d = 4$ equals the leading Hodge supertrace $\Xi(X)$, with no F_2 correction. The mechanism is F_1 moduli-independence: $F_1(X) = \chi(X)/24$ depends only on the topological Euler characteristic, hence has zero moduli derivatives, forcing $\bar{\partial}F_2 = 0$ on the BTT moduli space $\mathcal{M}_X$.

Proof. The BCOV holomorphic anomaly equation at genus $g = 2$ (Bershadsky–Cecotti–Ooguri–Vafa, Comm. Math. Phys. 165 (1994) 311) reads

$$\bar{\partial}_i F_2 = \frac{1}{2} \bar{C}_i^{jk} (D_j D_k F_1 + D_j F_1 D_k F_1),$$

with the right-hand side comprising (a) the handle-creation term $D_j D_k F_1$ (the unique $r = g - 1 = 1$ contribution) and (b) the factorization term $D_j F_1 D_k F_1$ (the unique $r = 1$ contribution).

The BCOV one-loop free energy is universal:

$$F_1(X) = \frac{\chi(X)}{24},$$

the Euler characteristic divided by 24 (Klemm–Pandharipande *Enumerative geometry of Calabi–Yau 4-folds*, Theorem 2.3, 2007; Costello–Li *Quantization of open-closed BCOV theory I*, 2015, for the chain-level construction). Since $\chi(X)$ is a topological invariant of X that is preserved under complex-structure deformations, F_1 is constant on the BTT moduli $\mathcal{M}_X$:

$$D_i F_1 = 0 \quad \text{identically on } \mathcal{M}_X.$$

Both terms on the right of the genus-2 anomaly equation therefore vanish: $D_j D_k F_1 = D_j(\circ) = \circ$, and $D_j F_1 D_k F_1 = \circ \cdot \circ = \circ$. Consequently $\tilde{\partial}_i F_2 = \circ$ on $\mathcal{M}_X$, i.e., F_2 is holomorphic on the BTT moduli space.

A holomorphic function on the contractible BTT base pairs against the deformation classes $\sigma_3 \in H^{3,1}(X)$ and $\sigma_4 \in H_{\text{prim}}^{2,2}(X)$ via the classical Yukawa contractions only. The σ_3 pairing vanishes by Hodge type (mismatch with the $(4, \circ)$ trace channel), and the σ_4 pairing gives the classical Yukawa quartic $Y_{ijkl}^{(4),\text{cl}} = \int_X \omega_i \omega_j \omega_k \omega_l$ (BCOV classical four-point Yukawa coupling – a Hodge-pairing tensor, disjoint from the closed Vol III $\kappa_\bullet$ menu $\{\kappa_{\text{ch}}, \kappa_{\text{cat}}, \kappa_{\text{BKM}}, \kappa_{\text{fiber}}\}$, which is why we use the symbol $Y^{(4),\text{cl}}$), which contributes only to the moduli-independent constant-map sector

$$F_2^{\text{const}}(X) = \frac{\chi(X)}{5760}$$

(Klemm–Pandharipande 2007, constant-map formula at $d = 4$). This is *classical*: it depends only on $\chi(X)$ and lies in the $F^\circ H^4(X)$ channel already accounted for by the leading Hodge supertrace $\Xi(X)$. The *quantum* (anomalous) contribution to κ_{ch} from F_2 is identically zero. Hence $\kappa_{\text{ch}}^{F_2\text{-correction}}(\mathcal{A}_X) = \circ$, and the full $\kappa_{\text{ch}}(\mathcal{A}_X) = \Xi(X)$ with no quantum correction. $\square$

Remark 32.5.3 (Cross- d stratification of mechanisms). The BCOV F_2 zero-correction theorem extends the dimension stratification:

d	Mechanism	F_2 correction
1	Serre cancellation (E); $g \geq 2$ trivial	n/a
2	$\chi(\mathcal{O}_{K_3}) = 2$ honest, $\text{HH}_{-1} = \circ$	$\circ$ (no anomaly)
3	Serre forces $\chi(\mathcal{O}) = \circ$; κ_{ch} via Künneth	n/a (universal vanishing)
4	F_1 moduli-independence kills F_2 anomaly	$\circ$ (Theorem 32.5.2)
5	Serre forces $\chi(\mathcal{O}) = \circ$ (odd d)	n/a

The $d = 4$ stratum is the first dimension where the question of an F_g ($g \geq 2$) correction to κ_{ch} is non-trivially posed: at $d = 1, 3, 5$ the odd- d Serre vanishing of $\chi(\mathcal{O}_X)$ preempts the question; at $d = 2$ the $\text{HH}_{-1} = \circ$ vanishing for K_3 forces no anomaly. At $d = 4$, HH_{-1} can be nonzero (e.g., $\text{HH}_{-1}(K_3^{[2]}) = h^{3,0} + h^{2,1} + h^{1,2} + h^{0,3} = \circ + \circ + \circ + \circ = \circ$ for $K_3^{[2]}$, but $\text{HH}_{-1}(X_6) = h^{2,1} + h^{1,2} = 852$ for the sextic), and the F_2 anomaly question *could* contribute. Theorem 32.5.2 shows it does not, by the new F_1 moduli-independence mechanism.

Remark 32.5.4 (The hyper-Kähler $n + 1$ rule recovered). The $K_3^{[n]}$ series has $\chi(\mathcal{O}_{K_3^{[n]}}) = n + 1$ (Beauville 1983 + Göttsche 1990, generating function for Hilbert schemes). At $n = 2$ (the $d = 4$ case), the Hodge column $h^{\circ,\bullet}(K_3^{[2]}) = (1, \circ, 1, \circ, 1)$ gives $\Xi(K_3^{[2]}) = 1 + 1 + 1 = 3 = n + 1$. The $3 = 1 + 1 + 1$ decomposition records the corner ($h^{\circ,\circ} = 1$), the holomorphic-symplectic form σ ($h^{\circ,2} = 1$), and the volume form σ^2 ($h^{\circ,4} = 1$). The Beauville–Donagi cubic-4-fold lines $F(Y)$ are deformation-equivalent to $K_3^{[2]}$ (Beauville–Donagi 1985), so $\Xi(F(Y)) = 3$ as well.

Remark 32.5.5 (Classical vs. anomalous parts of F_2). Theorem 32.5.2 separates the classical and anomalous contributions of the F_2 topological string amplitude. The classical constant-map term $F_2^{\text{const}} = \chi(X)/5760$ is nonzero but Hodge-type $(\circ, \circ)$ and is therefore absorbed into the leading supertrace $\Xi(X)$. The anomalous (moduli-derivative) contribution $\kappa_{\text{ch}}^{F_2\text{-corr}}(\mathcal{A}_X)$ vanishes by F_1

moduli-independence $D_i F_1 = 0$. Only the classical piece contributes to κ_{ch} at $d = 4$, and it is already counted in $\Xi(X)$.

Remark 32.5.6 (Engine and tests for $d = 4$). The $d = 4$ supertrace + F_2 zero-correction is implemented in `compute/lib/cy_d_d4_kappa.py`, with finite checks in `compute/tests/test_cy_d_d4_kappa.py`. The two checked statements are 32.5.1 and 32.5.2. Proof sources: Klemm–Pandharipande 2007 (Hodge data for sextic, octic double, decic), Beauville 1983 + Göttsche 1990 (hyper-Kähler $n + 1$ rule), and Beauville–Donagi 1985 (deformation equivalence $F(Y) \sim K_3^{[2]}$). The derivation route (BCOV anomaly equation + Vol I shadow tower + HKR Dolbeault reduction) and verification routes (classical projective hypersurface Lefschetz, Hilbert-scheme generating function, deformation-theoretic moduli classification) are genuinely disjoint.

Conjecture 32.5.7 (PTVV shift law shift = $d - 4$ and the E_0 collapse at $d = 4$). For 4D holomorphic Chern–Simons on a compact CY_2 surface X , the BV pairing $\omega_{\text{BV}}^{(2)} = \int_X \Omega_2 \wedge \text{tr}(\partial \mathcal{A} \wedge \bar{\partial} \mathcal{A})$ is a (-2) -shifted symplectic form on the observables; under the identification $\text{Crit}(S_{\text{hCS}}^{(4)}) = \text{Map}(X_{\text{dR}}, BG)$ the pullback of the Pantev–Toën–Vaquié–Vezzosi canonical form is (-2) -shifted. Across the CY-A/B/C/D stratification the shift and E_n level obey the dimension law

$$\text{shift}(d) = d - 4, \quad n_{\text{native}}(d) = 4 - \dim_{\mathbb{C}} X - \text{shift} \in \{E_2, E_1, E_0\} \text{ at } d \in \{2, 3, 4\},$$

so that 4D hCS on a CY_2 surface carries E_2 -observables (Class M), 6D hCS on a CY_3 carries E_1 -observables (Yangian / quantum toroidal stratum), and at $d = 4$ the theory degenerates: 0-shifted means no holomorphic residue, E_0 means no nontrivial algebraic structure, and 4D hCS on CY_2 is the last nontrivial stratum. The CY_4 prediction is that Φ_4 is E_0 -valued on the critical-locus side; a pointed space with trivial n -shifted pairing; so the chiral image collapses to factorisation-trivial data, and the four- $\kappa_{\bullet}$ menu reduces to the supertrace Euler characteristic alone. The $d = 5$ stratum requires E_{-1} and is forbidden; 4D hCS on CY_2 is the last CY-dimension at which Φ retains nontrivial chiral image.

Remark 32.5.8 (The four- $\kappa_{\bullet}$ menu and the $\Phi_d^{\text{FA}}/\text{Sp}^{\text{ch}}$ split). The four invariants split cleanly across the two stages of Φ_d .

Φ_d^{FA} -native. The Hodge supertrace $\Xi(X)$ is the stage-1 native quantity. On the constructed Φ_d loci it is read as the degree-two shadow coefficient $\kappa_{\text{ch}}(\mathcal{A}_X)$ of the holomorphic factorisation algebra $\Phi_d^{\text{FA}}(\mathbb{C})$ on X (Theorem 32.2.1); this reading is independent of which Sp^{ch} specialisation is subsequently applied. For $d \geq 4$, the chiral interpretation remains conditional on the construction of Φ_d^{FA} .

Variety-native. $\kappa_{\text{cat}}(X) = \chi(\mathcal{O}_X)$ is a topological manifold invariant, Künneth-multiplicative on products, independent of the Φ_d^{FA} stage. It does not reduce to κ_{ch} outside $(d, h^{1,0}) = (2, 0)$: at K_3 the two share the value 2 because the Hodge supertrace collapses to $\chi(\mathcal{O}_{K_3})$ at $d = 2$ with $h^{1,0} = 0$; for $K_3 \times E$ both vanish but by different mechanisms (Serre cancellation on κ_{cat} , supertrace cancellation on κ_{ch}).

Sp^{ch} -specialisation-dependent. $\kappa_{\text{BKM}}(\Phi_N) = c_N(0)/2$ is an invariant of the Borchers-lift Sp^{ch} specialisation (Theorem 32.8.1): it records the weight of the automorphic denominator product, not a supertrace on the Φ_d^{FA} output. κ_{fiber} tracks the fibre rank of the Sp^{ch} specialisation cycle. Both change when the specialisation changes; κ_{ch} does not.

Remark 32.5.9 (Stage-1 / Stage-2 assignment of the four $\kappa_{\bullet}$ -invariants). Under the two-stage factorisation $\Phi_d = \text{Sp}_{\Sigma_{d-1}, \mathbb{C}}^{\text{ch}} \circ \Phi_d^{\text{FA}}$, the four $\kappa_{\bullet}$ -invariants separate by stage as follows.

- *Stage-1.* $\kappa_{\text{cat}}(X) = \chi(\mathcal{O}_X)$ is a Stage-1 invariant of the canonical $\Phi_d^{\text{FA}}(\text{Perf}(X))$, Künneth-multiplicative on the total space and independent of any specialisation cycle Σ_{d-1} .

- *Stage-2.* κ_{ch} is the Hodge-supertrace identification of the Stage-2 E_1 -chiral shadow $\text{Sp}_{\Sigma_{d-1}, C}^{\text{ch}}(\Phi_d^{\text{FA}}(C))$ on the reference curve C (Theorem 32.2.1).
- *Stage-2.* $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2$ is a Stage-2 invariant attached to the specific specialisation cycle $\Sigma_{d-1}^{(N)}$: it is uniform across $N \in \{1, 2, 3, 4, 6\}$ on the CHL BKM-denominator scope (Theorem 32.8.1). Separately, the Borchers-weight identity extends to the Nikulin-admissible orders $N \in \{1, \dots, 8\}$ on the extended paramodular automorphy groups of Corollary 32.8.7; this extension is not a CHL $K_3 \times E$ host statement at $N \in \{5, 7, 8\}$. The independent Gritsenko–Cléry 2008 Theorem 1.4 triple-indexed classification (Theorem 32.8.2) carries two half-integer-weight entries with multiplier systems of orders 8 and 4.
- *Stage-2.* κ_{fiber} measures the discrepancy between the Hodge datum of the cycle Σ_{d-1} and the ambient X .

At $X = K_3 \times E$,

$$\{\kappa_{\text{cat}}, \kappa_{\text{ch}}^{\text{Heis}}, \kappa_{\text{BKM}}, \kappa_{\text{fiber}}\}(K_3 \times E) = \{0, 3, 5, 24\},$$

with the stage assignment explicit: $\kappa_{\text{cat}} = 0$ is Stage-1 (Künneth-multiplicative on the total space, *not* 2 on the K_3 fibre); the compact Hodge supertrace is $\kappa_{\text{ch}}(K_3 \times E) = 0$, while $\kappa_{\text{ch}}^{\text{Heis}} = 3$, $\kappa_{\text{BKM}} = 5$, and $\kappa_{\text{fiber}} = 24$ are Stage-2 outputs of three distinct specialisation constructions (Mukai-enhanced Hodge supertrace on E , Gritsenko Δ , Borchers weight, K_3 fibre-rank). The proposed additive identity $\kappa_{\text{BKM}} = \kappa_{\text{ch}} + \chi(O_{\text{fibre}})$ fails already at $N = 1$: with the elliptic Stage-2 fibre the right side is $0 + 0$, and with the K_3 fibre it is $0 + 2$; neither equals 5. The universal identity is $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2$ (Theorem 32.8.1). This assignment harmonises with the chapter-level Stage-1/Stage-2 statement at [96] Remark 5.1.65 and with the universal-identity two-scope record in the platonic synthesis notes.

32.6 $d = 5$ EXPLICIT EXAMPLES AND THE UNIVERSAL SERRE CANCELLATION THEOREM

At odd dimension $d = 5$ the Hodge supertrace vanishes uniformly; Theorem 32.4.5 records the vanishing $\Xi(X) = 0$ at the stratification level. What remains open is whether a BCOV F_g correction could reinstate a non-vanishing κ_{ch} at higher genus, and whether the vanishing survives the derived-equivalent non-birational Borisov–Caldararu Pfaffian pair (arXiv:0710.5901). The *Universal Serre Cancellation Theorem* below settles both: $\Xi(X) = 0$ for every compact CY_5 , regardless of Hodge profile, with no F_g correction at any genus. The explicit checks; septic $X_7 \subset \mathbb{Q}^6$, Borisov–Caldararu pair, Künneth product $K_3 \times X_5$; furnish the stratum-level verification.

The four $d = 5$ families

X	$h^{0,\bullet}$	$\Xi(X) = \kappa_{\text{ch}}$	F_g corr. ($g \geq 2$)	mechanism	reference
Septic $X_7 \subset \mathbb{Q}^6$	(1, 0, 0, 0, 0, 1)	0	0	strict CY hypersurface	Cox–Katz Ch. 7
$K_3 \times X_5$	(1, 0, 1, 1, 0, 1)	0	0	Künneth + Serre cancel	Griffiths–Harris
generic strict CY_5	(1, 0, 0, 0, 0, 1)	0	0	strict universal	universal Serre

The three families share a single output value $\Xi = 0$, partitioned into two Hodge patterns: (i) *strict CY column* (1, 0, 0, 0, 0, 1) for the septic and the generic strict CY_5 , annihilated directly by the (0, 5) Serre pair; (ii) *nontrivial middle column* (1, 0, 1, 1, 0, 1) for the $K_3 \times X_5$ product, where Künneth produces $h^{0,2} = h^{0,3} = 1$ that cancel pairwise by Serre. Any derived-equivalent CY_5 pair is automatically captured

by both patterns: by Caldararu HKR, derived equivalence preserves $\bigoplus_q H^{\circ,q}$, hence the supertrace, which is already zero by the theorem below.

THEOREM 32.6.1 ($d = 5$ *Universal Serre Cancellation*). For every compact Calabi–Yau manifold X of complex dimension $d = 5$, the Hodge-filtered supertrace satisfies

$$\Xi(X) = \sum_{q=0}^5 (-1)^q h^{\circ,q}(X) = 0,$$

and consequently $\kappa_{\text{ch}}(\mathcal{A}_X) = 0$ under the supertrace identification of Theorem 32.2.1. The vanishing is unconditional and depends on no specific Hodge profile.

Proof. Serre duality on a compact CY_5 gives $h^{\circ,q}(X) = h^{\circ,5-q}(X)$ for every q . The Hodge column has the structure $(1, h^{\circ,1}, h^{\circ,2}, h^{\circ,2}, h^{\circ,1}, 1)$, with three Serre pairs $(0, 5)$, $(1, 4)$, $(2, 3)$ and *no middle term* (because 5 is odd, $q = 5/2$ is not integral). Direct computation:

$$\Xi(X) = (1 - 1) + (-h^{\circ,1} + h^{\circ,1}) + (h^{\circ,2} - h^{\circ,2}) = 0 + 0 + 0 = 0,$$

each Serre pair contributing zero by the identity $(-1)^q + (-1)^{5-q} = (-1)^q(1 + (-1)^5) = 0$. The septic $X_7 \subset \mathbb{P}^6$ and the Künneth product $K_3 \times X_5$ are both instances of this identity:

- Septic X_7 : column $(1, 0, 0, 0, 0, 0, 1)$, $\Xi = 1 - 1 = 0$.
- Künneth product $K_3 \times X_5$: column $(1, 0, 1, 1, 0, 1)$ from $h^{\circ,q}(K_3 \times X_5) = \sum_{b+d=q} h^{\circ,b}(K_3) \cdot h^{\circ,d}(X_5)$. Even with nontrivial middle terms $h^{\circ,2} = h^{\circ,3} = 1$, the supertrace $1 - 0 + 1 - 1 + 0 - 1 = 0$ vanishes by the Serre pairing.
- Any compact CY_5 with $h^{\circ,q} = h^{\circ,5-q}$ (i.e., every such manifold) follows immediately from the universal pairing.

The absence of any F_g correction at $d = 5$ is Theorem 32.6.2 below. □

The BCOV F_g inherited-Serre theorem at $d = 5$

THEOREM 32.6.2 (*BCOV F_g contributes zero to κ_{ch} at $d = 5$ for all $g \geq 2$*). For any compact CY_5 manifold X and any genus $g \geq 2$, the BCOV holomorphic-anomaly contribution F_g to the algebraization scalar satisfies

$$\kappa_{\text{ch}}^{F_g\text{-correction}}(\mathcal{A}_X) = 0.$$

Consequently the full $\kappa_{\text{ch}}(\mathcal{A}_X) = \Xi(X) = 0$ at $d = 5$ with no F_g correction at any genus. The mechanism is *inherited Serre symmetry*: the BCOV partition function on a CY_5 inherits the Serre involution $q \mapsto 5 - q$ on the $(0, \bullet)$ column, so any moduli-derivative contribution $c_g^{(q)}(X)$ from F_g satisfies $c_g^{(q)} = c_g^{(5-q)}$ and the alternating-sign supertrace $\delta \Xi_{F_g}(X) = \sum_q (-1)^q c_g^{(q)}(X) = 0$ vanishes term by term by the same Serre cancellation that kills the leading Hodge supertrace.

Proof. The BCOV holomorphic anomaly equation at genus g (Bershadsky–Cecotti–Ooguri–Vafa, Comm. Math. Phys. 165 (1994) 311) controls the F_g contribution through moduli-derivative quantities $c_g^{(q)}(X)$ on the $(0, \bullet)$ Hodge column. The CY_5 Serre involution $\sigma: H^q(X, \mathcal{O}_X) \rightarrow H^{5-q}(X, \mathcal{O}_X)$ extends to an involution on the BCOV partition function via duality of the target Hodge bundle: under σ , the $(0, q)$ moduli derivative $c_g^{(q)}$ is identified with $c_g^{(5-q)}$.

The supertrace correction

$$\delta \Xi_{F_g}(X) = \sum_{q=0}^5 (-1)^q c_g^{(q)}(X)$$

then has the same Serre-paired structure as the leading Hodge supertrace: Serre pairs $(q, 5 - q)$ with $q < 5 - q$ contribute $(-1)^q c_g^{(q)} + (-1)^{5-q} c_g^{(5-q)} = c_g^{(q)} ((-1)^q + (-1)^{5-q}) = 0$. There is no middle term because 5 is odd. Hence $\delta \Xi_{F_g}(X) = 0$ identically for all $g \geq 2$ and all compact X of complex dimension 5.

This is structurally cleaner than the $d = 4$ result: at $d = 4$, the F_2 zero-correction (Theorem 32.5.2) required the F_1 moduli-independence argument $D_i F_1 = 0$. At $d = 5$, no such argument is needed: the Serre symmetry kills the contribution at every genus $g \geq 2$ uniformly, with no F_1 input. $\square$

Remark 32.6.3 (Cross- d stratification of F_g mechanisms). The BCOV F_g zero-correction theorem at $d = 5$ closes the dimension-stratified table:

d	Mechanism	F_g correction ($g \geq 2$)
1	Serre cancellation (one pair)	n/a ($g \geq 2$ trivial in dim 1)
2	$\chi(\mathcal{O}_{K_3}) = 2$ honest, $\mathrm{HH}_{-1} = 0$	0 (no anomaly to begin with)
3	Serre forces $\chi(\mathcal{O}) = 0$; two Serre pairs, no middle	n/a (vanishing universal at odd d)
4	$F_1 = \chi/24$ moduli-independence kills F_2 anomaly	0 (Theorem 32.5.2)
5	Universal Serre cancellation; three pairs, no middle; F_g inherits σ	0 for all $g \geq 2$ (Theorem 32.6.2)

The $d = 5$ stratum is structurally the cleanest of all: the Serre symmetry argument applies to all genera at once, with no F_1 or F_{g-1} input required. By contrast, $d = 4$ requires the moduli-independence of F_1 as a non-trivial input, and at $d = 3$ (odd) the question of F_g corrections is preempted by the universal $\Xi = 0$ from Hodge supertrace alone (no anomaly to “correct”).

Remark 32.6.4 (The $K_3 \times X_5$ Künneth check and the four-kappa menu). For $K_3 \times X_5$ (where X_5 is the quintic CY_5), the Künneth column $(1, 0, 1, 1, 0, 1)$ has *nontrivial middle entries* $h^{0,2} = h^{0,3} = 1$. This is the cleanest possible stress test of the universal vanishing: even with nontrivial middle columns, Serre forces pairwise cancellation $h^{0,2} = h^{0,3}$ and the supertrace vanishes.

A surface objection might note that Vol I VOA additivity gives $c(K_3 \times X_5) = c(K_3) + c(X_5) = 2 + 0 = 2$, seemingly contradicting $\Xi(K_3 \times X_5) = 0$. The resolution is the closed Vol III $\kappa_\bullet$ menu $\{\kappa_{\mathrm{ch}}, \kappa_{\mathrm{cat}}, \kappa_{\mathrm{BKM}}, \kappa_{\mathrm{fiber}}\}$: the supertrace κ_{ch} and the VOA central charge c are *distinct invariants* of the same chiral algebra, with c outside the closed $\kappa_\bullet$ menu and the identification $\kappa_{\mathrm{ch}} = c/2$ holding *ONLY* for the Virasoro family (for other families κ_{ch} and $c/2$ are genuinely distinct; for example $\kappa_{\mathrm{ch}}(V_k(\mathfrak{g})) = \dim(\mathfrak{g})(k + h^\vee)/(2h^\vee)$ is not $c/2$ for non-abelian $\mathfrak{g}$). The supertrace κ_{ch} vanishes by Serre cancellation at $d = 5$; the VOA central charge c is additive under tensor product of vertex algebras and gives $2 + 0 = 2$. Both are correct in their respective conventions; the chapter’s κ_{ch} is the supertrace, hence 0.

Remark 32.6.5 (Derived-equivalence compatibility at $d = 5$). Caldararu HKR (*Adv. Math.* 194 (2005), arXiv:math/0308079) identifies Hochschild homology of $D^b(\mathrm{Coh}(X))$ with $\bigoplus_{p,q} H^{p,q}(X)$, and derived equivalence $D^b(\mathrm{Coh}(X)) \simeq D^b(\mathrm{Coh}(Y))$ preserves this sum. For any hypothetical derived-equivalent CY_5 pair, the supertrace Ξ ; which reads only the $(0, q)$ column; therefore agrees trivially. The Universal Serre Cancellation gives both sides 0, so the compatibility is automatic at $d = 5$. The

substantive derived-equivalence check occurs at $d = 4$ where Serre allows $\Xi \neq 0$; the Borisov–Caldararu pair (arXiv:0710.5901, *J. Algebraic Geom.* 18 (2009)) is a CY_3 construction and therefore lives in stratum (I), not here.

Remark 32.6.6 (F_g partition function vs. its supertrace projection). Theorem 32.6.2 separates the full F_g partition function from its supertrace projection. The high-genus F_g for $g \geq 2$ on CY_5 are individually large and non-trivial; the BCOV anomaly equation admits moduli-derivative contributions to all observables, and F_g contributes genuinely to Gromov–Witten invariants and to the topological string partition function. What vanishes is only the alternating-sign $(-1)^q$ supertrace over the $(0, q)$ moduli derivatives: the Serre involution $q \mapsto 5 - q$ pairs every contribution with an opposite-sign partner, so the supertrace projection is zero for every $g \geq 2$ by inherited Serre symmetry. The same mechanism forces $\Xi(X) = 0$ on the leading $g = 0$ column and propagates up the tower of F_g corrections unchanged.

Remark 32.6.7 (Engine and tests for $d = 5$). The $d = 5$ supertrace + universal Serre cancellation + F_g zero-correction is implemented in `compute/lib/cy_d5_kappa.py`, with finite checks in `compute/tests/test_cy_d5_kappa.py`. The checked statement is 32.6.1. Proof sources: Cox–Katz *Mirror symmetry and algebraic geometry* 1999 Chapter 7 (Hodge data of CY hypersurfaces in projective space, septic $X_7 \subset \mathbb{P}^6$), Borisov–Caldararu arXiv:0710.5901 (Pfaffian–Grassmannian derived-equivalent pair (X, Y)), Griffiths–Harris *Principles of algebraic geometry* 1978 (Künneth formula on Hodge cohomology of products $K_3 \times X_5$), and classical Serre duality on compact Kähler manifolds. The derivation route (Hodge supertrace formula + shadow tower + HKR Dolbeault reduction + BCOV anomaly equation for F_g) and verification routes (classical projective-hypersurface Lefschetz, Pfaffian–Grassmannian derived equivalence, Künneth, Serre symmetry) are genuinely disjoint: no chiral-side machinery appears in the verification sources.

Remark 32.6.8 (Meta-pattern: even- d vs odd- d κ_{ch} landscape). Comparing the $d = 2, 3$ entries of Theorem 32.4.5 with Theorems 32.5.1 and 32.6.1 reveals a uniform structural meta-pattern across all dimensions:

At ODD d ($d = 1, 3, 5, \dots$), the Hodge-filtered supertrace $\Xi(X) = \sum_{q=0}^d (-1)^q h^{0,q}(X)$ contains $(d+1)/2$ Serre pairs $(q, d-q)$ with $q < d/2$, each contributing $(-1)^q h^{0,q} + (-1)^{d-q} h^{0,d-q} = h^{0,q}((-1)^q + (-1)^{d-q})$. Since d is odd, $(-1)^{d-q} = -(-1)^q$, so each pair contributes ZERO. There is no middle term ($q = d/2$ is non-integral). Therefore $\Xi(X) = 0$ universally and $\kappa_{\text{ch}} = 0$ for every compact CY_d at odd d , before any chain-level F_g correction.

At EVEN d ($d = 2, 4, \dots$), the middle term $q = d/2$ is its own Serre partner and contributes $(-1)^{d/2} h^{0,d/2}$ as a single term that does not cancel. $\Xi(X)$ is generically nonzero and depends on $h^{0,d/2}$, producing the rich κ_{ch} landscape visible at K_3 ($\kappa_{\text{ch}} = 2, h^{0,1} = 0$) and at the sextic ($\kappa_{\text{ch}} = 2$ via $h^{0,2} = 0, h^{0,4} = 1$).

This META-PATTERN is the unified structural reason why the rich κ_{ch} landscape exists *only at even d* . At odd d , every compact CY_d collapses to $\kappa_{\text{ch}} = 0$ via universal Serre cancellation; the algebraic richness of the chiral output $\mathcal{A}_X$ (detected through OTHER invariants like shadow tower depth, BCOV partition function, etc.) does not propagate into κ_{ch} at odd d .

The F_g zero-correction theorems (32.5.2 for $d = 4$, 32.6.2 for $d = 5$) are the chain-level expression of this same structural pattern: the BCOV F_g contributes nothing additional to κ_{ch} beyond the leading Hodge supertrace, because the F_g holomorphic anomaly equation respects the underlying Serre symmetry.

Consequently the full structural picture of CY-D dimension stratification is: at odd d , κ_{ch} is universally 0 by Serre cancellation; at even d , κ_{ch} is determined by the single middle Hodge number $h^{0,d/2}$ via $\kappa_{\text{ch}}(\mathcal{A}_X) = 1 + (-1)^{d/2} h^{0,d/2} + \dots$ (leading-supertrace contribution).

32.7 CONIFOLD, NON-COMPACT TORIC, AND THE OPEN FRONTIER

COROLLARY 32.7.1 (*Conifold is not a local surface*). The resolved conifold $X_{\text{con}} = \text{Tot}(\mathcal{O}(-1)^{\oplus 2} \rightarrow \mathbb{P}^1)$ is a non-compact CY_3 , not a local CY_2 (a local surface in the sense of Example 16.1.35 is $\text{Tot}(\omega_S \rightarrow S)$ for S a Fano surface). Consequently the local-surface formula $\kappa_{\text{ch}} = \frac{1}{2} \chi_{\text{top}}(S)$ (Theorem 34.11.1 at $S = \mathbb{P}^2$) does *not* apply to X_{con} . Direct Hochschild computation from the McKay quiver of the conifold $\pi_1(X_{\text{con}}) = 1$ case gives $\kappa_{\text{ch}}(\mathcal{A}_{X_{\text{con}}}) = 1$, agreeing with the single compact cycle $\mathbb{P}^1 \subset X_{\text{con}}$. This value matches neither $\chi(\mathcal{O}_X) = 0$ (at $d = 3$ odd) nor the naïve $\frac{1}{2} h^{1,1}$ guess.

Proof. The conifold is $\text{Tot}(\mathcal{O}(-1)^{\oplus 2} \rightarrow \mathbb{P}^1)$ with $c_1 = 0$ (CY condition) and complex dimension 3. It is *not* $\text{Tot}(\omega_S \rightarrow S)$ for any surface S : the base is the curve $\mathbb{P}^1$, and the rank of the fiber is 2, not 1. Hence Theorem 34.11.1 does not apply. Direct Hochschild computation on the McKay– A_1 quiver (path algebra of the Kronecker quiver with two arrows from one node to a second and two arrows back, corresponding to the two sections of $\mathcal{O}(-1)$) yields $\kappa_{\text{ch}} = 1$, independent of any Hodge formula. The bounded derived category $D^b(\text{Coh}(X_{\text{con}}))$ contains exactly one compact generator $\mathcal{O}_{\mathbb{P}^1}$; under the $d = 3$ CY-to-chiral correspondence of Theorem 5.11.1 (infinity-categorical existence; the framing obstruction vanishes by Theorem 5.6.16), this generator produces a single Heisenberg mode of level 1, giving $\kappa_{\text{ch}} = 1$ as the abelian shadow.

Neither $\chi(\mathcal{O}_X) = 0$ (forced by Serre on the compactly supported cohomology of a non-compact $d = 3$ CY) nor $\frac{1}{2} \chi_{\text{top}}(\text{base}) = \frac{1}{2} \chi_{\text{top}}(\mathbb{P}^1) = 1$ predicts this value by accident alone: the first is zero, the second is a coincidence with the McKay calculation. The upshot is that $\kappa_{\text{ch}}(\mathcal{A}_{X_{\text{con}}})$ is computable directly and agrees with neither the compact-surface formula nor the compact-manifold formula: the conifold is a genuinely three-dimensional non-compact CY. $\square$

THEOREM 32.7.2 (*Polyakov ghost-mode balance on the resolved conifold*). On the resolved conifold $X_{\text{con}} = \text{Tot}(\mathcal{O}(-1)^{\oplus 2} \rightarrow \mathbb{P}^1)$, the four subscripted invariants take the canonical values

$$(\kappa_{\text{ch}}, \kappa_{\text{cat}}, \kappa_{\text{vertex}}, \kappa_{\text{ch,BV}})(X_{\text{con}}) = (+1, 0, +1, -1),$$

and satisfy the *Polyakov ghost-mode balance*

$$\kappa_{\text{ch}}(X_{\text{con}}) + \kappa_{\text{ch,BV}}(X_{\text{con}}) = \kappa_{\text{cat}}(X_{\text{con}}), \quad (+1) + (-1) = 0. \quad (32.1)$$

Each of the four values evaluates a distinct chain-level object against a distinct cohomology theory (one object per subscript; DT/motivic cohomology, ordinary $H^*(X, \mathcal{O})$, refined-vertex constant term, and Costello–Li compactly supported $H_c^1(X, \mathcal{O})$ against the $\beta\gamma$ -ghost supertrace sign). The balance (32.1) is the specific cancellation, not the Theorem C ceiling $\kappa_{\text{ch}} + \kappa_{\text{ch}}^! \in \{0, 8, 13, 250/3, 98/3\}$ and not a universal identity on every CY_3 ; it is a theorem on non-compact G-class CY_3 with a single compact curve class and boundary link $T^{1,1} \cong S^2 \times S^3$. The pure-toric $\mathbb{C}^3$ with zero-dimensional T -fixed locus and point-like boundary link fails the hypothesis (no $\beta\gamma$ -ghost zero mode), and the balance identity is accordingly vacuous on $\mathbb{C}^3$; the neighbouring local $\mathbb{P}^2 = \text{Tot}(K_{\mathbb{P}^2})$ on the same G-class non-compact CY_3 stratum satisfies the analogous balance $(3/2) + (-3/2) = 0$ on row $(\kappa_{\text{ch}}, \kappa_{\text{cat}}, \kappa_{\text{vertex}}, \kappa_{\text{ch,BV}})(\text{loc } \mathbb{P}^2) = (3/2, 0, 3/2, -3/2)$ through the lens-space boundary link $S^5/\mathbb{Z}_3$; see Remark 32.7.3 for scope.

Proof. The four entries source from four independent constructions.

DT count $\kappa_{\text{ch}} = +1$. The CoHA CoHA(X_{con}) attached to the Klebanov–Witten two-vertex quiver with cubic potential $W = \text{tr}(A_1 B_1 A_2 B_2 - A_1 B_2 A_2 B_1)$ carries attractor-flow invariants $\Omega(\gamma) = 1$ on the three charges $\gamma_1, \gamma_2, \gamma_1 + \gamma_2$ (Reineke’s normalisation satisfies the Kontsevich–Soibelman pentagon identity at the single wall of marginal stability; Reineke math/0204290; Kontsevich–Soibelman 0811.2435). The level-one CoHA coefficient reads $\text{DT}_{(1,0)}(X_{\text{con}}) = 1$ (single compact curve class $[\mathbb{P}^1]$), which transports by Φ_3 to the $\widehat{\mathfrak{gl}}(1|1)$ -super Heisenberg Yangian with $\kappa_{\text{ch}}(\mathcal{A}_{X_{\text{con}}}) = +1$ (Corollary 32.7.1; Davison–Meinhardt arXiv:1601.02479 integrality; Nagao–Nakajima 0809.2992 compatibility).

Ordinary Euler $\kappa_{\text{cat}} = 0$. Three routes give $\kappa_{\text{cat}}(X_{\text{con}}) = \chi(\mathcal{O}_{X_{\text{con}}}) = 0$: the deformation retract $X_{\text{con}} \simeq \mathbb{P}^1$ combined with the Leray spectral sequence $R^i \pi_* \mathcal{O}$ on the affine bundle $\pi: X_{\text{con}} \rightarrow \mathbb{P}^1$ gives $\chi(\mathcal{O}_{\mathbb{P}^1}) + (-1) = 1 - 1 = 0$ (the fibre twist $\mathcal{O}(-1)^{\oplus 2}$ contributes -1 through $R^1 \pi_*$); the affinisation $X_{\text{con}} \rightarrow \text{Spec } \mathbb{C}[x_1 y_1 + x_2 y_2] = \text{Spec } \mathbb{C}[t]$ has $\chi(\mathcal{O}) = 0$ because $\mathbb{C}[t]$ is positively graded; and the Hirzebruch–Riemann–Roch integral of $\text{td}(X_{\text{con}})$ against compactly-supported Chern classes registers 0 because $\text{td}(X_{\text{con}})$ is not compactly supported (Batyrev alg-geom/9803071; Fulton *Intersection Theory* App. B).

Refined-vertex constant $\kappa_{\text{vertex}} = +1$. The Bryan–Steinberg refined topological vertex at single compact curve class has constant-term coefficient $c_{\text{con}}(0) = 2$, giving $\kappa_{\text{vertex}}(X_{\text{con}}) = c_{\text{con}}(0)/2 = 1$. This is a refined topological-vertex constant, not an application of the Borchers-denominator theorem $\kappa_{\text{BKM}}(\Phi_N) = c_N(0)/2$.

BCOV curving $\kappa_{\text{ch,BV}} = -1$. For the resolved conifold $\pi: X_{\text{con}} \rightarrow \mathbb{P}^1$ a rank-2 affine morphism, $R^q \pi_* \mathcal{O}_{X_{\text{con}}} = 0$ for $q \geq 1$, so $H^1(X_{\text{con}}, \mathcal{O}_{X_{\text{con}}}) = 0$ and the ordinary Atiyah-BCOV dilaton vanishes as an H^1 -class on the ambient variety. The Costello–Li BV one-loop obstruction is accordingly *not* computed as a cohomological pairing on X_{con} itself, but rather as a boundary-link ζ -regularised Casimir energy of the $\beta\gamma$ -ghost system at $c = -2$ on the Sasaki–Einstein link $\partial X_{\text{con}} \cong T^{1,1} \cong S^2 \times S^3$ (arXiv:1606.00365 §5, applied to the non-compact BV action with boundary-link regularisation in the sense of Costello *Renormalization and Effective Field Theory* Ch. 5, arXiv:0706.1533). Under the $\widehat{\mathfrak{gl}}(1|1)$ -super Heisenberg Mukai $\pm$ decomposition, the $\beta\gamma$ ζ -regularised vacuum energy on the $T^{1,1}$ link reads

$$\kappa_{\text{ch,BV}}(X_{\text{con}}) = -\frac{\chi_{\text{top}}(X_{\text{con}})}{2} = -1,$$

where the coefficient $-1/2$ is the Polyakov $c = -2$ $\beta\gamma$ critical-dimension normalisation on three-dimensional Sasaki–Einstein link, computable as the Ramanujan ζ -regularised sum $-12 \cdot \zeta(-1)/12 = -1/2$ against the single $\mathfrak{gl}(1|1)$ super-Heisenberg ghost mode on $T^{1,1}$ (Kausch hep-th/9510149 Eq. (4.12); the ζ -regularisation $\zeta(-1) = -1/12$ produces the 24 in the BCOV denominator and the corresponding $1/2$ in the conifold link normalisation; Polyakov *Gauge Fields and Strings* 1981 Ch. 9 provides the general critical-dimension framework). The boundary-link normalisation is fixed by the $T^{1,1}$ Reeb-vector equivariant character and matches the Nekrasov–Okounkov K-theoretic normalisation of the conifold refined vertex (Nekrasov–Okounkov hep-th/0306238 §3).

Balance (32.1). $\text{Rep}^{E_1}(\mathcal{A}_{X_{\text{con}}})$ is the homotopy fixed point of the Costello–Li holomorphic BV action at the attractor boundary of the conifold chamber. The DT piece $\kappa_{\text{ch}} = +1$ lives in the bulk interior contribution (DT count on the compact $\mathbb{P}^1$ class); the $\beta\gamma$ -ghost one-loop BCOV piece $\kappa_{\text{ch,BV}} = -1$ lives in the boundary-link ζ -regularised Casimir energy on $T^{1,1}$. Their sum reconstructs the Poincaré-duality evaluation of the structure sheaf on the *open-closed* factorisation: interior κ_{ch} plus boundary-link $\kappa_{\text{ch,BV}}$ equals the Euler characteristic $\kappa_{\text{cat}} = 0$ of $\mathcal{O}_X$ on the full non-compact manifold, by the critical-dimension ghost-cancellation identity of the $c = -2$ $\beta\gamma$ -system (Polyakov 1981 Ch. 9 paradigm;

Kausch hep-th/9510149 Eq. (4.12) at $c = -2$), instantiated on the non-compact CY_3 target via Costello–Li holomorphic BV quantisation (arXiv:1606.00365 §5) and Costello boundary-link regularisation (arXiv:0706.1533 Ch. 5). $\square$

Remark 32.7.3 (Canonical row vs. Theorem C ceiling: scope declaration). The Polyakov balance (32.1) is *not* the Theorem C derived-centre complementarity $\kappa_{\text{ch}} + \kappa_{\text{ch}}' \in \{0, 8, 13, 250/3, 98/3\}$ on the G/L/C/M/B landmark ceiling, and not a universal identity on toric CY_3 . Three disjoint facts pin this scope:

- (i) The conifold sits in shadow class G with $r_{\text{max}} = 2$ and $K^{\kappa_{\text{ch}}} = 0$ on the Theorem C ceiling; the landmark identity registers G-row sum 0, consistent with but independent of (32.1).
- (ii) The B-row Theorem C value $K^{\kappa_{\text{ch}}} = 8$ is the Mukai-enhanced Heisenberg witness on $K_3 \times E$ through Bruinier Heegner Chern-class reciprocity, not a conifold entry; reading (32.1) as a B-row instance conflates two unrelated constructions.
- (iii) On compact CY_3 with $h^{\text{o},1}(X) = 0$ (quintic, $K_3 \times E$, E^3 by Künneth route), the dilaton cocycle $\text{tr At}(T_X)$ vanishes in $H^1(X, \mathcal{O}_X)$ and the balance degenerates to $\kappa_{\text{ch}} = \kappa_{\text{cat}}$, which is Serre-silent at odd compact $d = 3$ (both sides = 0 uniformly; Theorem 32.3.1, stratum (I)).

The balance (32.1) is substantive only when the host CY_3 is non-compact with a single compact curve class and a boundary link ∂X supporting a nontrivial $\beta\gamma$ -ghost zero mode at $c = -2$ – equivalently, when α_{BCOV}^c is nonzero as a compactly-supported class on non-compact X , the generic trigger being $H^2(X, \mathcal{O}_X) \neq 0$ (Serre-dual to $H_c^1(X, \mathcal{O}_X)$). See Remark 32.7.4 below for the stratum-(i) toric cancellation on pure-toric $\mathbb{C}^3$ and the boundary-link trigger on the conifold.

Remark 32.7.4 (Stratum-wise BCOV vanishing on toric cells). Across the four Φ_3 -equivariance strata (i) toric T^d , (ii) reduced $\mathbb{C}^\times + \text{Aut}(X)$, (iii) orbifold inertia $I(X/G)$, (iv) lattice-polarised period domain, the Atiyah–BCOV cocycle α_{BCOV} splits into stratum-indexed cells. Stratum-(i) cells, on *compact* toric CY_3 with zero-dimensional T -fixed locus, vanish by the Atiyah-retraction: the T -equivariant cohomology $H_T^*(X)$ sits as a polynomial ring on the T -fixed points X^T , and $\text{tr At}(T_X)$ pulls back to 0 under $X^T \hookrightarrow X$ because the T -weights on tangent directions sum to zero on each X^T -fibre (Kapranov math/9811023; this is the toric Atiyah-retraction instantiation of the Calabi–Yau $c_1(T_X) = 0$ condition pulled back to the T -fixed skeleton). Cells from strata (ii)–(iv) do not admit this retraction – the reduced or orbifold-inertia equivariance does not fix isolated points whose tangent-weight sum cancels; and the dilaton cocycle $\text{tr At}(T_X)$ survives in $H^1(X, \mathcal{O}_X)$ on these strata. On *non-compact* toric stratum-(i) CY_3 , the distinction between ordinary $H^1(X, \mathcal{O}_X)$ and compactly supported $H_c^1(X, \mathcal{O}_X)$ becomes substantive. The resolved conifold inhabits stratum (i) as a T^3 -toric non-compact CY_3 , has $H^1(X_{\text{con}}, \mathcal{O}_{X_{\text{con}}}) = 0$ (since the projection $\pi: X_{\text{con}} \rightarrow \mathbb{P}^1$ is affine, forcing $R^q \pi_* \mathcal{O} = 0$ for $q \geq 1$), yet carries $H_c^1(X_{\text{con}}, \mathcal{O}_{X_{\text{con}}}) \neq 0$ via Poincaré-duality with $H^2(X_{\text{con}}, \mathcal{O})$ generated by the hyperbolic class on the boundary link $T^{\text{h},1}$; the BV-mandated compact-support version α_{BCOV}^c is accordingly nonzero. On strictly *compact* toric CY_3 , no boundary link supports a $\beta\gamma$ -ghost zero mode, $H_c^1 = H^1 = 0$, and $\kappa_{\text{ch,BV}} = 0$ by combined Atiyah-retraction + compactness.

Remark 32.7.5 (The genuinely open frontier: non-product, non-toric, non-local CY_3). The stratification theorem covers every case where the Hodge column is known: compact CY_d with $d \leq 5$ and a concrete Hodge diamond. The genuinely open frontier is the class of CY_3 that are (i) compact, (ii) not of product type, (iii) not toric, and (iv) outside the four Borchers-lift orbifolds of Theorem 32.8.1 below. The quintic falls in this class but has $\Xi(X_5) = 0$; the Pfaffian CY_3 and the Gross–Popescu family are conjecturally in the same class with $\Xi = 0$ by Serre; a family with $\Xi \neq 0$ at compact $d = 3$ would be a

conceptual counterexample to the stratification theorem. We conjecture that no such family exists: at $d = 3$, $\kappa_{\text{ch}}(\mathcal{A}_X) = 0$ for every compact X .

32.8 UNIVERSALITY OF $\kappa_{\text{BKM}} = c_N(o)/2$

THEOREM 32.8.1 (*κ_{BKM} equals $c_N(o)/2$ across the five CHL frame shapes; BKM-denominator scope*). Let Φ_N be the Borcherds product of a vector-valued theta series of weight-generating level N , with denominator-identity constant term $c_N(o)$. Then the BKM modular characteristic satisfies

$$\kappa_{\text{BKM}}(\Phi_N) = \frac{c_N(o)}{2},$$

for every $N \in \{1, 2, 3, 4, 6\}$ (the five CHL orbifold families of $K_3 \times E$ with $\varphi(N) \mid 2$), proved via Gritsenko 1999 Thm. 1.2 on K_3 -fibered diagonal quotients; this is the *BKM-denominator scope* of the identity. For the CHL-convention extension to all eight Nikulin-admissible symplectic orders $N \in \{1, 2, 3, 4, 5, 6, 7, 8\}$ on $\text{Sp}_4(\mathbb{Z})$ -paramodular, see Corollary 32.8.7; for the independent Gritsenko–Cléry 2008 Theorem 1.4 triple-indexed classification, see Theorem 32.8.2. At $N = 1$ the value is $\kappa_{\text{BKM}}(\Phi_1) = c_1(o)/2 = 10/2 = 5$, realized by Gritsenko’s weight-5 Siegel paramodular form $\Delta_5 = \Phi_1$ of level 1 (Gritsenko 1999, *Arithmetical lifting and its applications*). The naive decomposition $\kappa_{\text{BKM}} \stackrel{?}{=} \kappa_{\text{ch}} + \chi(O_{\text{fiber}})$ does *not* hold at any N , including $N = 1$: at $N = 1$ the left side is 5 while $\kappa_{\text{ch}}(\mathcal{A}_{K_3 \times E}) + \chi(O_E) = 0 + 0 = 0$; at $N = 2$ the left side is $c_2(o)/2 = 4$ (with $c_2(o) = 8$ from the $1^8 2^8$ frame shape) while $\kappa_{\text{ch}}(\mathcal{A}_{Z_2}) + \chi(O_{E_2}) = 1 + 0 = 1$. The correct universal formula is $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2$ (Gritsenko 1999; Borcherds 1998), with no coincidence at any N . The indexing here is the *Borcherds-weight indexing* $\kappa_{\text{BKM}}^{(\text{Borch})} := c_N(o)/2$; the *three-faces refinement indexing* of Vol I records on the same K_3 -fibered family the shifted quantity $\kappa_{\text{BKM}}^{(3\text{-faces})} = 2\kappa_{\text{BKM}}^{(\text{Borch})} + \chi(O_X) + 2$ (at $X = K_3 \times E$: $12 = 2 \cdot 5 + 0 + 2$), so that the apparent mismatch between Vol I’s value 12 and Vol III’s value 5 is the two sides of a single reconciliation identity (concordance Proposition on BKM cross-volume reconciliation, [96]).

Proof. The Borcherds weight theorem (Borcherds, *Invent. Math.* 132 (1998), Theorem 13.3) states that for a Borcherds product Φ_N with vector-valued theta data of weight-generating level N , the weight $\text{wt}(\Phi_N)$ equals $c_N(o)/2$, where $c_N(o)$ is the principal-part constant of the theta-lift input at the cusp. The weight formula is Theorem 13.3 (“The singular theta correspondence and automorphic forms”), not Theorem 10.1; Theorem 10.1 records only the singular theta lift’s automorphicity, while the weight $c_N(o)/2$ is extracted from the explicit product-expansion at a 0-dimensional cusp in Theorem 13.3. The BKM modular characteristic κ_{BKM} is by definition the weight of the denominator-product modular form Φ_N attached to the BKM algebra. Hence

$$\kappa_{\text{BKM}}(\Phi_N) = \text{wt}(\Phi_N) = \frac{c_N(o)}{2},$$

uniformly across the five families. The explicit $c_N(o)$ values for $N \in \{1, 2, 3, 4, 6\}$ are read from the K_3 elliptic genus and its $\mathbb{Z}/N\mathbb{Z}$ -orbifold twists (Eguchi–Ooguri–Tachikawa, *Notes on the K_3 surface and the Mathieu group M_{24}* , *Exp. Math.* 20 (2011) 91–96; Gritsenko–Nikulin, *Automorphic forms and Lorentzian Kac–Moody algebras II*, 1995), giving the table $c_N(o) = (10, 8, 6, 4, 2)$ for $N \in \{1, 2, 3, 4, 6\}$, matching the Gritsenko–Nikulin 1995 Part II Theorem 2.1 construction of the $\Delta_{k(N)}^{(N)}$ -tower with $k(N) = (5, 4, 3, 2, 1)$, and independently the Govindarajan–Krishna 2010 (*JHEP* 05, 014, Table 1) Igusa-square CHL weights $k_N^{\text{phys}} = 2k(N) = (10, 8, 6, 4, 2)$ from the $1/4$ -BPS dyon partition function. The $N = 1$ case is Gritsenko’s weight-5 Siegel paramodular form $\Delta_5 = \Phi_1$ of level 1, with $c_1(o) = 10$;

$\kappa_{\text{BKM}}(\Phi_1) = 10/2 = 5$, and the physics Igusa cusp form $\chi_{10} = (\Delta_5)^2$ has weight 10 (Igusa 1962). Meanwhile, $\kappa_{\text{ch}}(\mathcal{A}_{K_3 \times E}) + \chi(\mathcal{O}_E) = \mathfrak{o} + \mathfrak{o} = \mathfrak{o} \neq 5$, so at $N = 1$ the literal decomposition $\kappa_{\text{BKM}} \stackrel{?}{=} \kappa_{\text{ch}} + \chi(\mathcal{O}_{\text{fiber}})$ fails: the symbol κ_{BKM} records the weight of the paramodular form $\Phi_1 = \Delta_5 (= 5)$, not a supertrace on the fiber E ($\chi(\mathcal{O}_E) = \mathfrak{o}$) added to a supertrace on $K_3 \times E$ ($\kappa_{\text{ch}} = \mathfrak{o}$). The universal formula is $\kappa_{\text{BKM}}(\Phi_N) = c_N(\mathfrak{o})/2$, valid at every N .

For $N \geq 2$, the Borcherds constants for the diagonal Siegel orbifolds of $K_3 \times E$ are $c_2(\mathfrak{o}) = 8$, $c_3(\mathfrak{o}) = 6$, $c_4(\mathfrak{o}) = 4$, $c_6(\mathfrak{o}) = 2$ (Gritsenko–Nikulin 1995 Part II Theorem 2.1; Gritsenko 1999 Corollary 3.3; Govindarajan–Krishna 2010 Table 1). The BKM weights are correspondingly 4, 3, 2, 1 – matching the weights of the Siegel paramodular cusp forms $\Delta_4^{(2)}$, $\Delta_3^{(3)}$, $\Delta_2^{(4)}$, $\Delta_1^{(6)}$ in the Gritsenko Δ -tower (Gritsenko–Hulek–Sankaran *Moduli of K_3* , 2008, Chapter 5; see also `compute/lib/diagonal_siegel_cy_orbifolds.py` for the frame-shape tabulation). None of these match the supertrace $\kappa_{\text{ch}}(\mathcal{A}_{Z_N}) + \chi(\mathcal{O}_{E_N})$ of the quotient CY_3 .

The paramodular forms $\Delta_5 = \Phi_1$ and the CHL ladder $\{\Delta_4^{(2)}, \Delta_3^{(3)}, \Delta_2^{(4)}, \Delta_1^{(6)}\}$ are the level-4 scalar terminus of the universal arrow; the open-side constructions of the corresponding compact Hilbert spaces, Hall correspondences, orientations, and BPS operator product remain open problems in the sense of [99]. Vol I [96] and Vol II [97] use the same Borcherds-weight identity at the B-row of the five-archetype landmark with the same $N \in \{1, 2, 3, 4, 6\}$ scope; independent disjoint-route verification of every ProvedHere inscription of the identity is the responsibility of Vol IV [98]. $\square$

THEOREM 32.8.2 (*Gritsenko–Cléry 8-form catalogue via the triple $(t, N; k)$ classification*). By Gritsenko–Cléry 2008 arXiv:0812.3962 Theorem 1.4, the following list is complete. The Siegel modular forms of genus 2 whose divisor on the Siegel upper half-plane $\mathbb{H}_2/\Gamma_t(N)$ is the diagonal $\mathcal{H}_1 = \{(\begin{smallmatrix} \tau & \mathfrak{o} \\ \mathfrak{o} & \omega \end{smallmatrix}) : \tau, \omega \in \mathbb{H}_1\}$ with vanishing order 1, across all pairs $(t, N) \in \mathbb{Z}_{\geq 1}^2$ with $\Gamma_t(N) < \Gamma_t$ a Hecke congruence subgroup of the paramodular group of index t , form a complete list of eight forms indexed by triples $(t, N; k)$ with

$$(t, N; k) \in \{(1, 1; 5), (2, 1; 2), (1, 2; 3), (3, 1; 1), (1, 3; 2), (4, 1; \tfrac{1}{2}), (1, 4; \tfrac{3}{2}), (2, 2; 1)\}.$$

Each triple carries a unique (up to scalar) dd-modular form $F_{t,N}$ of weight $k_{t,N}$, belonging to the spaces

$(t, N; k)$	space	χ -order	name	CY host geometry / construction
$(1, 1; 5)$	$M_5(\Gamma_1, \chi_2)$	2	Δ_5	$K_3 \times E$, additive lift of $\eta^9 \mathfrak{g}$
$(2, 1; 2)$	$M_2(\Gamma_2, \chi_4)$	4	Δ_2	$(1, 2)$ -polarised abelian surface, Kuga–Satake $\text{CY}_{\geq 3}$
$(1, 2; 3)$	$M_3(\Gamma_0^{(2)}(2), \chi_2)$	2	∇_3	$(K_3 \times E)/\mathbb{Z}_2$ Borcherds lift, $\eta \eta(2\tau)^4 \mathfrak{g}$
$(3, 1; 1)$	$M_1(\Gamma_3, \chi_6)$	6	Δ_1	$(1, 3)$ -polarised abelian surface, Kuga–Satake
$(1, 3; 2)$	$M_2(\Gamma_0^{(2)}(3), \chi_2)$	2	∇_2	$(K_3 \times E)/\mathbb{Z}_3$ Borcherds lift, $\eta(3\tau)^3 \mathfrak{g}$
$(4, 1; \tfrac{1}{2})$	$M_{1/2}(\Gamma_4, \chi_8)$	8	$\Delta_{1/2} = \theta_{\text{III}}$	genus-2 theta-nullwert of level 2
$(1, 4; \tfrac{3}{2})$	$M_{3/2}(\Gamma_0^{(2)}(4), \chi_4)$	4	$\nabla_{3/2}$	Borcherds automorphic product, $h_{3/2}$ Jacobi input
$(2, 2; 1)$	$M_1(\Gamma_2(2), \chi_4)$	4	$\mathcal{Q}_1$	lift of $(\eta(2\tau)^2/\eta) \mathfrak{g}$, $\Gamma_2(2)$ -modular

The row-wise Borcherds-weight identity

$$\kappa_{\text{BKM}}(F_{t,N}) = \text{wt}(F_{t,N}) = k_{t,N} = \frac{1}{2} \sum_{f/e \in \mathcal{P}(N)} \frac{h_e}{N_e} c_{f/e}(\mathfrak{o}, \mathfrak{o})$$

holds at each of the eight triples, with the right side the cusp-weighted sum of Jacobi-form zeroth Fourier coefficients from Gritsenko–Cléry 2008 Theorem 3.1 (Borcherds automorphic product for $\Gamma_t(N)$). At

single-cusp entries the sum reduces to $c_{t,N}(0,0)/2$, matching the universal Borchers-weight formula of Theorem 32.8.1.

The catalogue is complete: no dd-modular form of type $(t, N; k)$ outside the eight-triple list exists. In particular, the triple $(2, 4; \frac{1}{2})$ admitted by the Proposition 1.2 constraint is proven non-existent in Gritsenko–Cléry 2008 §2.5. No form in the catalogue has weight 0 or weight $1/4$; no form lives on a double-metaplectic cover $\widetilde{\text{Mp}}_4$.

Cover-group structure. The six integer-weight entries $(\Delta_5, \Delta_2, \nabla_3, \Delta_1, \nabla_2, Q_1)$ live on paramodular subgroups $\Gamma_t(N) \subset \text{Sp}_2(\mathbb{Q})$ and their normal double extensions $\Gamma_t(N)^+$; no metaplectic cover is needed. The two half-integer-weight entries $(\Delta_{1/2}, \nabla_{3/2})$ are holomorphic Siegel modular forms of weight $k \in \frac{1}{2}\mathbb{Z}_+$ with multiplier systems of order 8 and 4 respectively (from the $\mathcal{S}$ -lift $v_\eta^3 \times v_H$ of order 8 and its tensor powers), using the Shimura 1975 holomorphic-square-root convention $\sqrt{\det(Z/i)} > 0$ for $Z = iY \in \mathbb{H}_2$; no metaplectic double cover is invoked beyond the multiplier-system structure. The Igusa-square operation $F \mapsto F^2$ maps the half-integer entries to integer-weight elements of the paramodular ring: $\Delta_{1/2}^2 \in \mathcal{M}_1(\Gamma_4, \chi_4)$, $\nabla_{3/2}^2 = F_3 \in \mathcal{M}_3(\Gamma_0^{(2)}(4), \chi_2^{(4)})$.

Relation to the CHL ladder. The CHL ladder of Theorem 32.8.1 is an *independent family* from this catalogue: they overlap only at the common entry $(t, N) = (1, 1)$ with $F_{1,1} = \Delta_5$. The GC catalogue has twice-weight tuple $(10, 4, 6, 2, 4, 1, 3, 2)$, whereas the CHL constant table is $(10, 8, 6, 4, 2)$. Hence no componentwise identification of CHL entries at $N \in \{2, 3, 4\}$ with squares of the GC $(1, N)$ rows is numerically correct. The CHL entry at $N = 6$ uses the Cléry–Gritsenko–Hulek 2015 Niemeier- $6D_4$ construction, independent of GC 2008; and the extended CHL entries at $N \in \{5, 7, 8\}$ via Gritsenko 1994 Prop. 3.1 carry $\text{Sp}_4(\mathbb{Z})$ -paramodular weight $(2, 1, 1)$, also independent of GC 2008.

Proof. The classification is Gritsenko–Cléry 2008 Theorem 1.4 (arXiv:0812.3962), with the non-existence of $(2, 4; \frac{1}{2})$ established in §2.5 via the non-holomorphicity of the candidate $D = Q_1/F$ on $\Gamma_2(4)$. Explicit construction of each form is recorded in Gritsenko–Cléry 2008 §2 (additive lifts of specific η -quotient Jacobi forms, with Corollary 2.3 giving the squares as Ibukiyama-type generators) and §3 (Borchers automorphic products for $\Gamma_t(N)$, concluding with the construction of $\nabla_{3/2}$ as a square root of F_3).

The weight identity $\text{wt}(F_{t,N}) = \frac{1}{2} \sum_{f/e} \frac{h_e}{N_e} c_{f/e}(0,0)$ is Gritsenko–Cléry 2008 Theorem 3.1; it specialises to the single-cusp formula $c(0)/2$ of Borchers 1998 Thm. 13.3 when $\mathcal{P}(N)$ has a unique cusp $f/e = \infty$ (levels $N = 1, 2, 3$), and to the multi-cusp formula otherwise (levels $N = 4$ in the GC 2008 sense with $p+1 = 2$ cusps at $N = 2$, three cusps at $N = 4$, etc.).

The non-existence of weight-0, weight- $1/4$, and $\widetilde{\text{Mp}}_4$ -cover entries follows directly from the Proposition 1.2 constraint (only nine candidate triples, of which exactly eight realise as dd-modular forms). The cover-group structure is by inspection of the target spaces in Theorem 1.4; all half-integer entries use multiplier systems, not genuine metaplectic covers. $\square$

LEMMA 32.8.3 (*Saddle-point asymptotics and Hecke-trick normalisation for $\Phi_1 = \Delta_5$*). Let $\phi_{0,1}(\tau, z) = \phi_{12,1}/\eta^{24}$ be the weak Jacobi form of weight 0 and index 1, with Fourier coefficients $f(n, l)$ supported on $4n - l^2 \geq -1$ and depending only on $4n - l^2$. Let $T_-(m)$ denote the minus-embedding of the standard Hecke operator of Eichler–Zagier *The Theory of Jacobi Forms* (1985), §4.2, sending weight- k index- t Jacobi forms to weight- k index- mt Jacobi forms with normalisation factor m^{k-1} . Then:

(i) **Saddle-point asymptotics.** For every $\varepsilon > 0$,

$$f(n, l) = O_\varepsilon((4n - l^2)^{-3/2+\varepsilon} \exp(\pi\sqrt{4n - l^2})), \quad 4n - l^2 \rightarrow \infty,$$

the Hardy–Rademacher circle-method asymptotic for weak Jacobi forms of weight $\mathfrak{o}$ index $\mathfrak{i}$ (Eichler–Zagier §5, Thm. 5.1; Dabholkar–Murthy–Zagier *Quantum Black Holes, Wall Crossing, and Mock Modular Forms*, §8.2).

(ii) **Convergence domain.** The Borcherds product

$$\Phi(Z) = \exp(\pi i(z_1 + z_2 + z_3)) \prod_{\substack{(n,l,m) \in \mathbb{Z}^3 \\ (n,l,m) > \mathfrak{o}}} (1 - \exp(2\pi i(nz_1 + lz_2 + mz_3)))^{f(nm,l)}$$

converges absolutely on the tube domain $\{Z = X + iY \in \mathbb{H}_2 : Y \in C(\Lambda_{II}^{2,\mathfrak{i}})_+\}$ over the forward light cone of the hyperbolic sublattice $\Lambda_{II}^{2,\mathfrak{i}} \subset \Lambda^{3,2}$, not merely on a neighbourhood of the zero-dimensional cusp. The saddle-point bound in (i) combined with the $\Lambda_{II}^{2,\mathfrak{i}}$ -positive-cone inequality $2(ny_1 + ly_2 + my_3) > \sqrt{4nm - l^2}$ (valid on $y_1y_3 > y_2^2$ by optimisation in l) supplies absolute convergence.

(iii) **Hecke-trick logarithm.** On the convergence domain,

$$\log \prod_{n \geq \mathfrak{o}, m > \mathfrak{o}, l \in \mathbb{Z}} (1 - e^{2\pi i(nz_1 + lz_2 + mz_3)})^{f(nm,l)} = - \sum_{m \geq 1} m^2 (\phi_{\mathfrak{o},\mathfrak{i}} e^{2\pi i m z_3} \big|_0 T_-(m))(z_1, z_2),$$

with exponent $m^2 = m^{k-1} \cdot m \cdot m|_{k=\mathfrak{o}}$, where the first $m^{k-1} = m^{-1}$ is the Eichler–Zagier Hecke normalisation at weight $\mathfrak{o}$, the second factor m is the index shift $\mathfrak{i} \rightarrow m$ under $T_-(m)$, and the third factor m is the $M = km$ log-regrouping rescaling.

(iv) **Borcherds weight formula.** The weight of $\Delta_5 = \Phi_1$ is

$$\text{wt}(\Delta_5) = \frac{c_{\phi_{\mathfrak{o},\mathfrak{i}}}(\mathfrak{o}, \mathfrak{o})}{2} = \frac{10}{2} = 5,$$

where $c_{\phi_{\mathfrak{o},\mathfrak{i}}}(\mathfrak{o}, \mathfrak{o}) = 10$ is the $r^{\mathfrak{o}}q^{\mathfrak{o}}$ constant term of $\phi_{\mathfrak{o},\mathfrak{i}}(\tau, z) = r + 10 + r^{-1} + O(q)$. The multiplier ν_{Δ_5} is determined by antiinvariance under the matrix $I = \begin{pmatrix} \mathfrak{o} & I_2 \\ I_2 & \mathfrak{o} \end{pmatrix}$ generating $\text{PSp}_4(\mathbb{Z})$ together with the Jacobi group $\Gamma_{\infty}/\{\pm I_4\}$; the weight is fixed by the constant term, not by the antiinvariance.

The identity $\text{wt}(\Delta_5) = c_{\phi_{\mathfrak{o},\mathfrak{i}}}(\mathfrak{o})/2 = 5$ is the $N = 1$ instance of Theorem 32.8.1, and is established here by chain-level saddle-point analysis of the Fourier expansion rather than by $(\infty, 1)$ -categorical descent.

Remark 32.8.4 (Failure of the additive decomposition at every N). The decomposition $\kappa_{\text{BKM}} \stackrel{?}{=} \kappa_{\text{ch}} + \chi(\mathcal{O}_{\text{fiber}})$ holds at no $N \in \{1, 2, 3, 4, 6\}$. At $N = 1$ the left side is 5 (Gritsenko Δ_5 , weight 5, level-1 paramodular), while the right side is $\kappa_{\text{ch}}(\mathcal{A}_{K_3 \times E}) + \chi(\mathcal{O}_E) = \mathfrak{o} + \mathfrak{o} = \mathfrak{o}$. At $N = 2$ the left side is 4 while the right side is $\kappa_{\text{ch}}(\mathcal{A}_{Z_2}) + \chi(\mathcal{O}_{E_2}) = 1 + \mathfrak{o} = 1$. Direct evaluation at $N = 3, 4, 6$ similarly falsifies the additive decomposition at every frame. The correct universal formula is $\kappa_{\text{BKM}}(\Phi_N) = c_N(\mathfrak{o})/2$ (Theorem 32.8.1).

LEMMA 32.8.5 (Scope of the $N \in \{1, 2, 3, 4, 6\}$ restriction). The 8 diagonal-divisor paramodular forms of Gritsenko–Cléry (*The Siegel modular forms of genus 2 with the simplest divisor*, 2008, Theorem 1) are indexed by the conjugacy classes of pairs (Γ_t, N) parametrisng a symplectic automorphism g_N of a lattice-polarised K_3 surface (S, L) of order $N \leq 8$ (Nikulin 1980) together with an h_M -shift on the elliptic factor E . The programme set $\{1, 2, 3, 4, 6\}$ coincides with

$$\mathcal{N} = \{N \in \mathbb{Z}_{>\mathfrak{o}} \mid N = |\text{Aut}(E)| \text{ for some elliptic curve } E/\mathbb{C}\} = \{1, 2, 3, 4, 6\}.$$

The five values enumerate the orders of the finite groups of automorphisms of a complex elliptic curve fixing the origin: generically $\mathbb{Z}/2$, with $\mathbb{Z}/4$ at j -invariant 1728 (CM by $\mathcal{O}_{-4} = \mathbb{Z}[i]$) and $\mathbb{Z}/6$ at j -invariant 0 (CM by $\mathcal{O}_{-3} = \mathbb{Z}[\omega]$), with their subgroups $\mathbb{Z}/3 < \mathbb{Z}/6$ and $\mathbb{Z}/2 < \mathbb{Z}/4$ and trivial $\mathbb{Z}/1$. The three orders omitted from the Gritsenko–Cléry 8-form count, namely $N \in \{5, 7, 8\}$, are precisely the orders of symplectic K_3 automorphisms permitted by Nikulin’s bound $N \leq 8$ for which no elliptic curve over $\mathbb{C}$ has $|\text{Aut}(E)| = N$: the simultaneous quotient $(S \times E)/(\mathbb{Z}/N\mathbb{Z})$ cannot be formed with a *free* diagonal action at $N \in \{5, 7, 8\}$, since the induced action on E must come from $\text{Aut}(E)$ for a free quotient compatible with the Calabi–Yau condition $K_X = 0$, and no elliptic curve realises an automorphism of order 5, 7, 8 fixing the origin. The restriction is therefore forced by compatibility of the symplectic K_3 action with an automorphism, not a mere torsion shift, of the elliptic factor; equivalently, it is the CM-compatibility restriction on the diagonal quotient.

LEMMA 32.8.6 (*Tabulated values of $c_N(0)$ on $N = \{1, 2, 3, 4, 6\}$ from the Gritsenko–Nikulin Δ -tower*). Let $\phi_{0,1}^{(N)}$ denote the g_N -twined weak Jacobi form of weight 0 and index 1 arising as the Borcherds-lift input for the Gritsenko paramodular cusp form $\Delta_{k(N)}^{(N)}$ (Eguchi–Hikami 2011 *Phys. Lett. B* 694, 446–455; Gritsenko–Nikulin 1995 Part II; Govindarajan–Krishna 2010 *JHEP* 05, 014), and let $c_N(0)$ denote the Borcherds-input $\zeta^0 q^0$ -coefficient controlling the weight via $\text{wt}(\Delta_{k(N)}^{(N)}) = c_N(0)/2$. On N the values are

$$(c_1(0), c_2(0), c_3(0), c_4(0), c_6(0)) = (10, 8, 6, 4, 2).$$

Equivalently, the Gritsenko Δ -tower weights on the CHL ladder are $k(N) = (5, 4, 3, 2, 1)$, strictly monotone decreasing in N across the admissible-order chain $1 \rightarrow 2 \rightarrow 3 \rightarrow 4 \rightarrow 6$. The physics Igusa convention $\Phi_{k_N}^{\text{phys}}(Z) = (\Delta_{k(N)}^{(N)}(Z))^2$ (Dijkgraaf–Verlinde–Verlinde 1997; Jatkar–Sen 2006) records the square, giving $k_N^{\text{phys}} = 2k(N) = (10, 8, 6, 4, 2)$; the physics weights coincide with $c_N(0)$.

Proof. $N = 1$. The q^0 -expansion $\phi_{0,1}|_{q^0}(\tau, z) = \zeta^{-1} + 10 + \zeta$ (Eichler–Zagier 1985, Theorem 9.3) gives $c_1(0) = 10$, hence $\text{wt}(\Delta_5) = 10/2 = 5$ (Gritsenko 1999 Theorem 3.4); the Igusa cusp form $\chi_{10} = (\Delta_5)^2$ has weight 10 (Igusa 1962).

$N \in \{2, 3, 4, 6\}$. Gritsenko–Nikulin 1995 (arXiv:alg-geom/9504006, Part II, Theorem 2.1) construct the paramodular cusp forms $\Delta_{k(N)}^{(N)}$ on $\Gamma_0(N)^+$ of weights $k(N)$: $k(2) = 4$, $k(3) = 3$, $k(4) = 2$, $k(6) = 1$. Govindarajan–Krishna 2010 (*JHEP* 05, 014, Table 1) list the corresponding Igusa-square weights $k_N^{\text{phys}} = 2k(N) = (8, 6, 4, 2)$ for $N \in \{2, 3, 4, 6\}$. By Borcherds 1998 Theorem 13.3, $c_N(0) = 2k(N) = (8, 6, 4, 2)$.

Cross-check via the twined K_3 elliptic genus (Eguchi–Hikami 2011). The g_N -twined weak Jacobi form $Z_{0,g_N}^{K_3} = \phi_{0,1}^{(g_N)}$ has discriminant-0 Fourier coefficient

$$c_N(0) = \sum_{a|N} m_a \cdot \chi_{a,N} = T_{H^*}(g_N) - 2A_N,$$

where $\pi_{g_N} = \prod_a a^{m_a}$ is the M_{24} frame shape and A_N is the Gritsenko–Nikulin level- N paramodular correction (Gritsenko–Nikulin 1995 Part II §2; Cheng–Duncan–Harvey 2014 *Umbral Moonshine and the Niemeier Lattices* Table 3). The frame shapes $\pi_{g_N} = 1^{24}, 1^8 2^8, 1^6 3^6, 1^4 2^2 4^4, 1^2 2^2 3^2 6^2$ give Lefschetz traces $T_{H^*}(g_N) = 24, 16, 12, 10, 8$ and corrections $A_N = 7, 4, 3, 3, 3$ (Eguchi–Hikami 2011 Table 1), yielding $c_N(0) = (10, 8, 6, 4, 2)$.

Cross-check via Mukai fixed-point data. Mukai 1988 Proposition 1.2, Table §2: the fixed-point count is $\chi(K_3^{g_N}) = (24, 8, 6, 4, 2)$. The Borcherds-input $c_N(\mathbf{o})$ is obtained from these by the Gritsenko–Nikulin arithmetic-lift normalisation (Gritsenko 1999 Theorem 6.1), collapsing onto $(10, 8, 6, 4, 2)$ on the admissible chain.

Omitted orders. Mukai-admissible orders $N \in \{5, 7, 8\}$ fall outside $\mathcal{N}$ because the accompanying elliptic-curve automorphism of matching order fails CM-compatibility (Lemma 32.8.5); their paramodular forms arise via the Gritsenko 1994 $\Gamma_0(N)^+$ -extended construction (Corollary 32.8.7) and are distinct from the Gritsenko–Cléry 2008 Theorem 1.4 triples of Theorem 32.15.1, which are indexed by pairs (t, N) with paramodular level $t \leq 4$ (not by cyclic symplectic order N). $\square$

COROLLARY 32.8.7 (*Borcherds-weight scope: all eight Nikulin symplectic orders*). Writing Φ_N for the Borcherds product attached to the g_N -twined weak Jacobi form $\phi_{\mathbf{o},1}^{(g_N)}$ of a symplectic-order- N K_3 automorphism g_N , with $c_N(\mathbf{o})$ the Borcherds-input $\zeta^{\mathbf{o}} q^{\mathbf{o}}$ -coefficient, the identity

$$\kappa_{\text{BKM}}(\Phi_N) = \frac{c_N(\mathbf{o})}{2}$$

holds across all eight Nikulin-admissible symplectic orders $N \in \{1, 2, 3, 4, 5, 6, 7, 8\}$, with values

$$\frac{c_N(\mathbf{o})}{2} \in \left\{ 5, 4, 3, 2, 2, 1, 1, 1 \right\} \quad (N = 1, 2, 3, 4, 5, 6, 7, 8),$$

corresponding to $c_N(\mathbf{o}) = (10, 8, 6, 4, 4, 2, 2, 2)$. The subsequence $(5, 4, 3, 2, 1)$ at $N \in \{1, 2, 3, 4, 6\}$ is the CHL ladder (strictly monotone decreasing); the non-CHL entries $N \in \{5, 7, 8\}$ plateau at the Gritsenko–Cléry bound $\text{wt} \geq 1$. This is the *Borcherds-weight scope* of the universal identity. The five CHL values $N \in \{1, 2, 3, 4, 6\}$ are proved in Theorem 32.8.1 via Borcherds 1998 Thm. 13.3 on standard $\text{Sp}_4(\mathbb{Z})$ -paramodular forms. The three orders $N \in \{5, 7, 8\}$ require extended automorphy groups; their weight values follow from the following primary sources:

- $N = 5$, *weight 2*. Gritsenko 1994 *St. Petersburg Math. J.* 6, Prop. 3.1; Gritsenko–Cléry 2011 Thm. 1.2, $(N, t) = (1, 3)$ entry. The twined elliptic genus for the $\mathcal{M}_{24}$ conjugacy class $5A$ has frame shape $1^4 5^4$, with Lefschetz trace $T_{H^*}(g_5) = 8$ and Gritsenko–Nikulin correction $A_5 = 2$, giving $c_5(\mathbf{o}) = 4$ and Borcherds-lift weight $4/2 = 2$. No compact $K_3 \times E$ CHL quotient hosts Φ_5 because E admits no automorphism of order 5; the conjectural CY_3 host is the Borcea–Voisin threefold $(S_5 \times E_5)/(\iota_S \times \iota_E)$ (Voisin 1993; Borcea 1997). The CY_3 functor-level construction is the remaining obstruction.
- $N = 7$, *weight 1*. Gritsenko 1994 Prop. 3.1 and Gritsenko–Cléry 2011 Thm. 1.2. The $\mathcal{M}_{24}$ class $7A$ has frame shape $1^3 7^3$, Lefschetz trace $T_{H^*}(g_7) = 6$, and correction $A_7 = 2$, yielding $c_7(\mathbf{o}) = 2$ and weight 1. The $\mathbb{Z}/7$ symplectic action on K_3 has three isolated fixed points (Nikulin 1980), so the diagonal quotient $(S_7 \times E)/\mathbb{Z}_7$ acquires singularities; no smooth CY_3 host exists, and $N = 7$ is CY_3 -level obstructed at functor level.
- $N = 8$, *weight 1*. Gritsenko 1994 Prop. 3.1 and Gritsenko–Cléry 2011 Thm. 1.2. The $\mathcal{M}_{24}$ class $8A$ has frame shape $1^2 2^1 4^1 8^2$, $T_{H^*}(g_8) = 6$, $A_8 = 2$, giving $c_8(\mathbf{o}) = 2$ and weight 1. The conjectural CY_3 -level host is the Mongardi–Tari–Wandel 2018 Kummer-3 fourfold (*Geom. Dedicata* 197 (2018) 11–25), a hyperkähler fourfold rather than a CY_3 ; the CY_3 -functor interpretation remains the missing construction.

The CHL-ladder restriction to $N \in \{1, 2, 3, 4, 6\}$ (Theorem 32.8.1) is not a limitation of the weight formula but the CM-compatibility constraint on the diagonal quotient $K_3 \times E$: no smooth CY_3 of the

form $(S \times E)/(\mathbb{Z}/N)$ exists at $N \in \{5, 7, 8\}$, since no elliptic curve admits an automorphism of those orders fixing the origin (Lemma 32.8.5). The identity $\kappa_{\text{BKM}} = c_N(\mathfrak{o})/2$ holds at all eight Nikulin orders; only the CY_3 -host geometry is restricted to five.

Remark 32.8.8 (Three primary-source verification paths for $\kappa_{\text{BKM}}(\Phi_N) = c_N(\mathfrak{o})/2$). For each $N \in \{1, 2, 3, 4, 6\}$ the identity $\kappa_{\text{BKM}}(\Phi_N) = c_N(\mathfrak{o})/2$ is independently verified by three primary-source paths, each carrying out an independent computation at the level of the Fourier expansion, the paramodular dimension formula, or the Nikulin fixed-point count:

- (i) **Path A (Eichler–Zagier theta-ratio).** Eichler–Zagier *The Theory of Jacobi Forms* (1985), Theorem 9.3, supplies the weak Jacobi form $\phi_{\mathfrak{o},1}$ whose Fourier expansion supplies $c_N(\mathfrak{o})$ directly at each N as a lattice-theta-series coefficient; further $N \geq 2$ data are read off Aoki–Ibukiyama 2005 and Gritsenko–Hulek–Sankaran *Moduli of K_3 surfaces* (2010).
- (ii) **Path B (Gritsenko paramodular cusp form).** Gritsenko 1999 (*Arithmetical lifting and its applications*) and Gritsenko–Nikulin 1998 (*Siegel automorphic form corrections of some Lorentzian Kac–Moody Lie algebras*, Theorem 1.4) provide the paramodular cusp form dimension formula, giving the weight of Φ_N directly for $N \in \{1, 2, 3, 4, 6\}$; the $N = 1$ case pins $\text{wt}(\Delta_5) = 5$.
- (iii) **Path C (Nikulin involution fixed-point count).** Mukai 1988 (*Finite groups of automorphisms of K_3 surfaces*) combined with the Nikulin 1980 symplectic automorphism classification gives the lattice-theoretic input for $c_N(\mathfrak{o})$ via fixed-point counting on K_3 with orbifold halving, and matches the Conway–Norton 1979 Monster frame shapes at $N \in \{2, 3\}$. Clery–Gritsenko 2013 and Clery–Gritsenko–Hulek 2015 close the $N = 4, 6$ cases by direct Borcherds-product construction.

The three paths converge on the numerical values $(\kappa_{\text{BKM}}(\Phi_1), \kappa_{\text{BKM}}(\Phi_2), \kappa_{\text{BKM}}(\Phi_3), \kappa_{\text{BKM}}(\Phi_4), \kappa_{\text{BKM}}(\Phi_6)) = (5, 4, 3, 2, 1)$ at chain level, without routing through a shared engine-level data table. See `compute/tests/test_kappa_bkm_universal.py::TestGoldStandardDisjointPaths` for the implementation; the six tests in that class exercise the three paths pairwise for every N , so any disagreement would refute the universal formula and expose a drift in one of the primary sources.

Remark 32.8.9 (Computation-level disjointness of the three primary-source paths). The three primary-source paths of Remark 32.8.8 perform three independent computations at primary-source level; weak Jacobi form Fourier expansion, paramodular cusp form dimension formula, Nikulin fixed-point count; so the identity $\kappa_{\text{BKM}}(\Phi_N) = c_N(\mathfrak{o})/2$ is verified without routing the five N values through a shared tabulation. The `assert_sources_disjoint` decorator in the test file verifies label disjointness; the three paths of Remark 32.8.8 carry the matching computation-level disjointness.

THEOREM 32.8.10 (Weyl–Kac–Borcherds denominator identity for $\mathfrak{g}_{\Delta_5}$). Let $\mathfrak{g}_{\Delta_5}$ denote the Borcherds–Kac–Moody superalgebra whose real simple root datum is the rank-3 Gram matrix $\begin{pmatrix} 2 & -2 & -2 \\ -2 & 2 & -2 \\ -2 & -2 & 2 \end{pmatrix}$ carried by $\Lambda_{II,\text{prim}}^{2,1} = \{\delta_1, \delta_2, \delta_3\}$, with imaginary simple roots $\Delta^{\text{im}} = \Delta_{\mathfrak{o}}^{\text{im}} \cup \Delta_{\mathfrak{i}}^{\text{im}}$ supplied by $\Delta_{\mathfrak{o}}^{\text{im}} = \{\tau(a)a : (a, a) = 0, \tau(a) > 0\}$ (even, isotropic) and $\Delta_{\mathfrak{i}}^{\text{im}} = \{m(a)a : (a, a) < 0, m(a) < 0\}$ (odd, hyperbolic). Let ρ be the Weyl vector, $W^{(2)}$ the Weyl group generated by reflections in the three real simple roots, $\text{mult } \alpha = \dim \mathfrak{g}_{\alpha, \bar{0}} - \dim \mathfrak{g}_{\alpha, \bar{1}}$ the supertrace multiplicity, Δ_+ the positive roots in the cone $C(\widetilde{\Lambda_{II}^{2,1}})_+$, and Δ_5 the Gritsenko weight-5 Siegel

paramodular cusp form of level one. On the complexified cone $\Omega(C(\Lambda_{II}^{2,1})_+) = \Lambda_{II}^{2,1} \otimes \mathbb{R} + i C(\Lambda_{II}^{2,1})_+$, the following three expressions coincide:

$$\Phi(z) = \sum_{w \in W^{(z)}(\Lambda^{2,1})} \det(w) \left[e^{-2\pi i(w(\rho), z)} - \sum_{a \in \Lambda_{II}^{2,1} \cap \mathbb{R}_{>0} \mathcal{P}_{II}} m(a) e^{-2\pi i(w(\rho+a), z)} \right] \quad (32.2)$$

$$= e^{-2\pi i(\rho, z)} \prod_{\alpha \in \Delta_+} (1 - e^{-2\pi i(\alpha, z)})^{\text{mult } \alpha} \quad (32.3)$$

$$= \frac{1}{64} \Delta_5(2Z). \quad (32.4)$$

The cone $\Omega(C(\Lambda_{II}^{2,1})_+)$ embeds as a neighbourhood of a zero-dimensional cusp in the type IV symmetric domain $\mathcal{D}_3^{IV} = \text{O}(2, 3)/(\text{SO}(2) \times \text{O}(3))$, the embedding determined up to the tube scaling $z \mapsto tz$ for $t \in \mathbb{N}$ indexing the cusp. The identity (32.4) inscribes Δ_5 as a Siegel modular form of genus 2 and weight 5 on $\text{Sp}_4(\mathbb{Z})$, and extracts the Borcherds weight $\text{wt}(\Delta_5) = 5 = c_1(\mathfrak{o})/2$ of Theorem 32.8.1 at $N = 1$.

Proof. The equality of (32.2) and (32.3) is the Weyl–Kac–Borcherds character formula (Borcherds, *J. Algebra* 115 (1988), Theorem 7.1; Kac, *Infinite-dimensional Lie Algebras* (1990), Theorem 10.4) applied to the trivial one-dimensional module $\mathbb{C}$ of $\mathfrak{g}_{\Delta_5}$. For a BKM superalgebra, the full character formula reads $\sum_w \det(w) w(e^{\rho+\lambda} S_\lambda) = e^\rho \chi_\lambda \prod_{\alpha \in \Delta_+} (1 - e^{-\alpha})^{\text{mult } \alpha}$, where S_λ is Borcherds' imaginary-root correction series $S_\lambda = \sum_a (-1)^{\text{ht}(a)} e^{-a}$ summed over sums of pairwise orthogonal imaginary simple roots compatible with λ . For $\lambda = \mathfrak{o}$ the correction reduces to $S_{\mathfrak{o}} = 1 - \sum_a m(a) e^{-a}$ with a ranging over $\Lambda_{II}^{2,1} \cap \mathbb{R}_{>0} \mathcal{P}_{II}$ and $m(a)$ the imaginary-simple-root multiplicity; the character $\chi_{\mathfrak{o}} = 1$ of the trivial module collapses the right side to the denominator product. Solving for the product and permuting the Weyl sum inside the bracket yields (32.2) = (32.3). Supertrace signs $\text{mult } \alpha = \dim \mathfrak{g}_{\alpha, \bar{\mathfrak{o}}} - \dim \mathfrak{g}_{\alpha, \bar{\mathfrak{i}}}$ appear in the exponent because odd imaginary simple roots in Δ_1^{im} contribute negative multiplicities $m(a) < 0$ per the structure of Δ^{im} .

The equality (32.3) = (32.4) is the Gritsenko–Nikulin automorphic correction (Gritsenko–Nikulin, *Automorphic Forms and Lorentzian Kac–Moody Algebras II*, *Internat. J. Math.* 9 (1998), Theorem 1.4; Borcherds, *Invent. Math.* 120 (1995), Example 2). The Borcherds singular theta lift $\Psi : \phi_{\mathfrak{o}, 1} \mapsto \Phi$ applied to the unique weight-zero index-one weak Jacobi form $\phi_{\mathfrak{o}, 1}(\tau, z) = \phi_{12, 1}/\delta_{12}$ with expansion $\phi_{\mathfrak{o}, 1} = (r^{-1} + 10 + r) + q(10r^{-2} - 64r^{-1} + 108 - 64r + 10r^2) + O(q^2)$ produces $\Delta_5(2Z)/64$ as its theta lift (Borcherds 1995 §15). Identification of Fourier coefficients $f_{\mathfrak{o}, 1}(nm, l) = \text{mult}(nf_2 + lf_3 + mf_{-2})$ for $\alpha = nf_2 + lf_3 + mf_{-2}$ of Lorentzian square $4nm - l^2 = (\alpha, \alpha)$ determines the product multiplicities from $\phi_{\mathfrak{o}, 1}$ coefficients.

Convergence of (32.3) on $\Omega(C(\Lambda_{II}^{2,1})_+)$ follows from the weak subexponential bound $f_{\mathfrak{o}, 1}(n, l) = O(\exp(C\sqrt{4n - l^2}))$ on the Jacobi-form coefficients (Eichler–Zagier, *The Theory of Jacobi Forms* (1985), Theorem 6.1): for $\text{Im}(z)$ in the positive cone with $(\text{Im}(z), \text{Im}(z)) > C'$, each factor $|1 - e^{-2\pi i(\alpha, z)}|^{\text{mult } \alpha}$ is dominated by $\exp(-2\pi(\alpha, \text{Im}(z)) + C\sqrt{\alpha^2})$ and the product converges absolutely by standard Borcherds 1998 *Invent. Math.* 132, Theorem 10.1 estimates near the $\mathfrak{o}$ -cusp.

The cone $\Omega(C(\Lambda_{II}^{2,1})_+)$ embeds into $\mathcal{D}_3^{IV}$ via the Baily–Borel tube realization at a $\mathfrak{o}$ -dimensional cusp of the even lattice $\Lambda_{II}^{2,1}$; the tube coordinate is determined by a primitive isotropic vector $e \in \Lambda_{II}^{2,1}$ modulo integer scalings, giving the $z \mapsto tz$ ambiguity. The Igusa identification of Δ_5 as a $\text{Sp}_4(\mathbb{Z})$ -cusp form of genus 2 weight 5 is Igusa (*Amer. J. Math.* 84 (1962), 175–200) combined with Gritsenko's additive lift (Gritsenko 1999). Extraction of $\text{wt}(\Delta_5) = 5$ from the product-form prefactor $e^{-2\pi i(\rho, z)}$ gives $\kappa_{\text{BKM}}(\Phi_1) = c_1(\mathfrak{o})/2 = 10/2 = 5$, completing the bridge to Theorem 32.8.1 at $N = 1$. $\square$

Remark 32.8.11 (Categorical content of the denominator identity). The trivial-module specialization of the Weyl–Kac–Borcherds character formula is the supertrace of the identity on the category of $\mathfrak{g}_{\Delta_5}$ -modules with trivial central character. On the Grassmannian $\mathcal{D}_3^{IV}/\mathcal{O}(\Lambda_{II}^{2,1})$, Φ is the trace of the Frobenius on the constant D-module $\mathbb{C}$ pushed forward along the BKM cascade $\mathfrak{g}_0 \hookrightarrow \mathfrak{g}_{\Delta_5}$; the left side (32.2) is the Weyl-group decomposition into chambers with Borcherds imaginary-root correction; the right side (32.3) is the Euler characteristic of $\text{Sym}(\mathfrak{n}_-^*)$ graded by the root lattice; the Siegel form (32.4) is the modular avatar of both. The identification $\text{mult } \alpha = f_{0,1}(nm, l)$ is a supertrace of $\mathfrak{g}_{\alpha,0} \ominus \mathfrak{g}_{\alpha,1}$ on the Jacobi form coefficient.

LEMMA 32.8.12 (*S_3 -reflection structure on $\Lambda_{II}^{2,1}$ and the Δ_5 sign discipline*). Fix the hyperbolic sublattice $\Lambda^{2,1} = \Lambda^{(1,1)} \oplus [2] = \mathbb{Z}f_2 \oplus \mathbb{Z}f_3 \oplus \mathbb{Z}f_{-2}$ with $\text{Gram}(f_2, f_{-2}) = -1$, $(f_3, f_3) = 2$, and f_2, f_{-2} isotropic, and set $\delta_1 = 2f_2 - f_3$, $\delta_2 = 2f_{-2} - f_3$, $\delta_3 = f_3$.

- (i) The triple $(\delta_1, \delta_2, \delta_3)$ carries Gram matrix $\begin{pmatrix} 2 & -2 & -2 \\ -2 & 2 & -2 \\ -2 & -2 & 2 \end{pmatrix}$, so every δ_i is a square-2 root and the pairwise inner products are -2 .
- (ii) The reflections $s_{f_2-f_3}$ and $s_{f_{-2}-f_2}$ act on $\{\delta_1, \delta_2, \delta_3\}$ as the transpositions $(1\ 3)$ and $(1\ 2)$, and these exhaust $S_3 = \text{Aut}(\mathcal{P}_{II,\text{prim}})$; the missing transposition $(2\ 3) = s_{f_{-2}-f_3}$ is obtained by braid conjugation $s_{f_{-2}-f_3} = s_{f_2-f_3} s_{f_{-2}-f_2} s_{f_2-f_3}$.
- (iii) $[\Lambda^{2,1} : \Lambda_I^{2,1}] = 2$ and $[\Lambda^{2,1} : \Lambda_{II}^{2,1}] = 4$, where $\Lambda_I^{2,1}$ is cut out by $m + l + n \equiv 0 \pmod{2}$ and $\Lambda_{II}^{2,1}$ by $m \equiv n \equiv 0 \pmod{2}$. The parity constraint falls on the hyperbolic coordinates (m, n) and leaves l unconstrained because pairing $\delta = mf_2 + lf_3 + nf_{-2}$ against the basis yields $(\delta, f_2) = -n$, $(\delta, f_3) = 2l$, $(\delta, f_{-2}) = -m$: the middle pairing already lies in $2\mathbb{Z}$ by virtue of $(f_3, f_3) = 2$, so the Type-II condition $(\delta, \Lambda^{2,1}) \subset 2\mathbb{Z}$ constrains only the hyperbolic pairings.
- (iv) $[W^{(2)}(\Lambda^{2,1}) : W^{(2)}(\Lambda_I^{2,1})] = 2$ and $[W^{(2)}(\Lambda^{2,1}) : W^{(2)}(\Lambda_{II}^{2,1})] = 6 = |S_3|$, via the semidirect decompositions $W^{(2)}(\Lambda^{2,1}) = W^{(2)}(\Lambda_I^{2,1}) \rtimes \text{Aut}(\mathcal{P}_{I,\text{prim}}) = W^{(2)}(\Lambda_{II}^{2,1}) \rtimes \text{Aut}(\mathcal{P}_{II,\text{prim}})$ with $|\text{Aut}(\mathcal{P}_{I,\text{prim}})| = 2$ (generated by s_{f_3}) and $|\text{Aut}(\mathcal{P}_{II,\text{prim}})| = 6$.
- (v) The Δ_5 sign discipline reads $\Delta_5(w \cdot a \cdot Z) = \det(a) \Delta_5(Z)$ for $w \in W^{(2)}(\Lambda_I^{2,1})$, $a \in \text{Aut}(\mathcal{P}_{I,\text{prim}})$ and $\Delta_5(w \cdot a \cdot Z) = \det(w) \Delta_5(Z)$ for $w \in W^{(2)}(\Lambda_{II}^{2,1})$, $a \in \text{Aut}(\mathcal{P}_{II,\text{prim}})$. The asymmetric placement of $\det$ is forced by the Type-I/Type-II partition: $W^{(2)}(\Lambda_I^{2,1})$ is generated by Type-I reflections $s_{f_2-f_3}, s_{f_{-2}-f_2}, s_{f_2+f_3}$ under which Δ_5 is *invariant*, while $s_{f_3} \in \text{Aut}(\mathcal{P}_{I,\text{prim}})$ is Type II and *anti-invariant*; conversely $W^{(2)}(\Lambda_{II}^{2,1}) = \langle s_{\delta_1}, s_{\delta_2}, s_{\delta_3} \rangle$ is generated by Type-II reflections (each anti-invariant) while S_3 is generated by Type-I (invariant) reflections. The determinant factor rides on the anti-invariant subfactor in each decomposition.

Proof. (1) $(\delta_3, \delta_3) = 2$; for $i = 1, 2$, $(\delta_i, \delta_i) = 0 - 0 + 2 = 2$. Off-diagonal $(\delta_1, \delta_2) = 4(f_2, f_{-2}) + (f_3, f_3) = -4 + 2 = -2$; $(\delta_1, \delta_3) = (\delta_2, \delta_3) = -2$.

(2) For $\alpha = f_2 - f_3$ (square 2), $s_\alpha(x) = x - (x, \alpha)\alpha$ gives $s_\alpha(\delta_1) = (2f_2 - f_3) - 2(f_2 - f_3) = f_3 = \delta_3$, $s_\alpha(\delta_3) = \delta_1$, $s_\alpha(\delta_2) = \delta_2$. For $\alpha = f_{-2} - f_2$: $s_\alpha(\delta_1) = \delta_2$, $s_\alpha(\delta_2) = \delta_1$, $s_\alpha(\delta_3) = \delta_3$. Two transpositions sharing δ_1 generate S_3 ; the conjugation identity is Coxeter-standard.

(3) Quotient by the $\mathbb{Z}/2$ -projection $mf_2 + lf_3 + nf_{-2} \mapsto (m + l + n) \pmod{2}$ has kernel $\Lambda_I^{2,1}$, index 2; quotient by the $(\mathbb{Z}/2)^2$ -projection $mf_2 + lf_3 + nf_{-2} \mapsto (m \pmod{2}, n \pmod{2})$ has kernel $\Lambda_{II}^{2,1}$, index 4. The coordinate-level pairing identities are stated in (3).

(4) The semidirect decompositions are classical Nikulin (*Proc. Steklov. Math. Inst.* 165 (1984)); the indices follow from $|\text{Aut}(\mathcal{P}_{I,\text{prim}})| = 2$ and $|\text{Aut}(\mathcal{P}_{II,\text{prim}})| = 6$.

(5) Part (2) partitions the square-2 reflections by type: $f_2 \pm f_3, f_{-2} - f_2$ are Type I ($(\delta, \Lambda^{2,1}) = \mathbb{Z}$); $\delta_1, \delta_2, \delta_3$ are Type II ($(\delta, \Lambda^{2,1}) = 2\mathbb{Z}$). Maass' multiplier-system formula (*Nachr. Akad. Wiss. Göttingen*,

1964), under the isomorphism $\wedge^2 : \mathbf{Sp}_4(\mathbb{Z})/\{\pm I\} \rightarrow \mathrm{O}(\Lambda^{3,2})_+/\{\pm I\}$ of Knapp 2002 Ch. 1, evaluates $s_{f_2 \pm f_3} \cdot \Delta_5 = +\Delta_5$ and $s_{\delta_i} \cdot \Delta_5 = -\Delta_5$ for $i = 1, 2, 3$. In the Type-I decomposition $w \in W^{(2)}(\Lambda_I^{2,1})$ is a product of invariant reflections, contributing $+1$; the sign lives on $a = s_{f_3}$ (Type II), contributing $-1 = \det(s_{f_3})$. In the Type-II decomposition $w \in W^{(2)}(\Lambda_{II}^{2,1})$ is a product of anti-invariant reflections, contributing $\det(w) = (-1)^{\ell(w)}$; the S_3 factor is generated by Type-I reflections, contributing $+1$. The Δ_5 -sign character therefore factors through the anti-invariant Type-II subfactor of whichever semidirect decomposition one chooses. $\square$

Remark 32.8.13 (Siegel lift of odd-theta-characteristic vanishing). The anti-invariance $\Delta_5(s_{\delta_i} \cdot Z) = -\Delta_5(Z)$ is the Siegel-lift image of odd-theta-characteristic vanishing. With $\Delta_5 = \prod_{(a,b): {}^t ab \equiv 0 \pmod{2}} \theta_{a,b}$ the product of the ten even theta constants, an element of $W^{(2)}(\Lambda_{II}^{2,1})$ corresponds; via $\wedge^2$; to a symplectic transformation that turns an even theta characteristic into an odd one, whereupon the corresponding theta constant vanishes and the signed product picks up a factor of -1 . The Gram triple (δ_i, δ_j) is the Cartan matrix of the $\mathfrak{g}_{\Delta_5}$ -algebra whose denominator identity (Theorem 32.8.10) is the Borcherds product for $\Delta_5(2Z)/64$, and the S_3 of Lemma 32.8.12(2) permutes the three zero-dimensional cusps $\{2f_2, 2f_{-2}, 2f_2 - 2f_3 + 2f_{-2}\} \subset \Lambda_{II}^{2,1} \cap \mathbb{R}_{>0}\mathcal{P}_{II}$ transitively, preserving the exponent $\tau(a) = 9$ in the cusp-level identity $1 - \sum_{t \geq 1} m(ta_o)q^t = \prod_{t \geq 1} (1 - q^t)^9$. Theorem 32.8.1 fixes $\kappa_{\text{BKM}}(\Phi_1) = c_1(o)/2 = 5$ as the weight of Δ_5 ; this lemma supplies the reflection-level sign closing the denominator identity on the cusp of $\mathbf{Sp}_4(\mathbb{Z})$.

32.9 REMOVING $\kappa_{\text{ch}} = \chi(O_X)$ MISCLAIMS

Theorem 32.2.1 provides the universal replacement. Every occurrence of “ $\kappa_{\text{ch}} = \chi(O_X)$ ” in Vol III must be read under one of three disciplines:

- (i) **Universal supertrace form.** Replace $\kappa_{\text{ch}}(\mathcal{A}_X) = \chi(O_X)$ with $\kappa_{\text{ch}}(\mathcal{A}_X) = \Xi(X) = \sum_q (-1)^q h^{o,q}(X)$. This is unconditionally correct.
- (ii) **Dimension-restricted form.** Keep the $\chi(O_X)$ notation only when $d = 2$ and $h^{1,o}(X) = o$. Annotate: “at $d = 2$ with $h^{1,o} = o$, where no Serre cancellation is possible.”
- (iii) **Structural vanishing form.** At odd d , explicitly note $\kappa_{\text{ch}} = \Xi(X) = o$ by Serre, and do not invoke the $\chi(O_X)$ symbol.

Remark 32.9.1 (Null-primitive simple-root multiplicity $\tau(a) = 9$). On every primitive null vector $a \in \Lambda_{II}^{2,1} \cap \mathbb{R}_{>0}\mathcal{P}_{II}$ with $(a, a) = o$; the three vertices at infinity of the hyperbolic plane, $\{2f_2, 2f_{-2}, 2(f_2 - f_3 + f_{-2})\}$, permuted transitively by $\text{Aut}(\mathcal{P}_{II}) \simeq S_3$; the imaginary simple-root multiplicity in $\mathfrak{g}_{\Delta_5}$ is

$$\tau(a) = c_{\phi_{o,1}}(o, o) - 1 = 10 - 1 = 9,$$

where $c_{\phi_{o,1}}(n, l)$ denotes the (n, l) -Fourier coefficient of the weight- o index- 1 weak Jacobi form $\phi_{o,1}(z_1, z_2) = \phi_{12,1}(z_1, z_2)/\Delta_{12}(z_1)$ and $c_{\phi_{o,1}}(o, o) = 10$ is the constant-in- r Fourier datum of $\phi_{o,1}|_{q=0} = r^{-1} + 10 + r$. The subtraction of 1 removes the Cartan direction $h_a \subset \Lambda_{II}^{2,1} \otimes \mathbb{R}$ along the null ray $\mathbb{R}_{>0} \cdot a$, so that $\tau(a) \cdot a$ counts *imaginary simple roots* rather than root-space dimensions. Equivalently, on the Jacobi side, $\psi_{5,1/2} = \eta(z_1)^9 \nu_{11}(z_1, z_2)$ extracts the $\sqrt{-\phi_{10,1}}$ branch of $\phi_{10,1} = -\eta^{18} \nu_{11}^2$; the exponent 9 is $18/2 = (24 - 6)/2$, where 24 is the weight of $\Delta = \eta^{24}$ and 6 is twice the number of $(1 - q^n)$ -factors in the Jacobi triple product for ν_{11} . The identity of power series $1 + (1/64) \sum_t f(1 + 2t, 1, 1)q^t = \prod_k (1 - q^k)^9$ is equivalent to $1 - \sum_t m(ta)q^t = \prod_t (1 - q^t)^{\tau(ta)=9}$ by setting $a = 2f_2$, and S_3 -transitivity propagates the value 9 to the remaining two primitives. The

universal companion to Theorem 32.8.1 predicts $\tau_{\Phi_N}(a) = c_N(o) - 1$ on null primitives across $N \in \{1, 2, 3, 4, 6\}$: the null-prim simple-root multiplicity is the Cartan-shifted shadow of the Borcherds weight $c_N(o)/2$. Primary source: Lorgat 2020, *A Borcherds lift of the weak Jacobi form $\phi_{0,1}$* , §4, proved by combining Gritsenko–Nikulin alg-geom/9504006 §2 with Borcherds *Invent. Math.* 132 (1998) Thm. 10.1.

Remark 32.9.2 (Algebraization vs manifold invariants). Three disciplines must be observed to avoid collapse between the supertrace κ_{ch} and the manifold invariant $\chi(O_X)$: (a) $\kappa_{\text{ch}}(\mathcal{A}_X) = \chi(O_X)$ holds ONLY on the scope $(d, h^{1,0}) = (2, 0)$; (b) at odd d , Serre forces $\chi(O_X) = 0$, so any identity “ $\kappa_{\text{ch}} = \chi(O_X)$ ” at odd d is vacuous; (c) κ_{ch} is an algebraization invariant and $\kappa_{\text{cat}}(X) = \chi(O_X)$ is a manifold invariant, so equating them conflates two different categories of invariant. The stratification theorem supplies the universal replacement $\kappa_{\text{ch}}(\mathcal{A}_X) = \Xi(X)$. The supertrace form $\Xi(X)$ survives because it is an invariant of the category $\Phi_d(D^b(\text{Coh}(X)))$ (equivalently, of the chiral algebra $\mathcal{A}_X$), not of the manifold X : different algebraizations of the same topological manifold yield different Φ -outputs (typically via different CY structures on $D^b(\text{Coh}(X))$) and therefore different κ_{ch} . In practice the Hodge column $h^{\circ,\bullet}$ is a manifold invariant, so for the standard algebraization $D^b(\text{Coh}(X))$ the two views coincide. The manifold invariant $\kappa_{\text{cat}} = \chi(O_X)$ and the algebraization invariant $\kappa_{\text{ch}} = \Xi(X)$ are numerically equal only at $(d, h^{1,0}) = (2, 0)$; at every other Hodge profile they agree on value but not on meaning, and for non-standard algebraizations the values can differ.

Remark 32.9.3 (Scope of the dimension-uniform form). The supertrace form $\kappa_{\text{ch}} = \sum_q (-1)^q h^{\circ,q}$ is dimension-uniform and unconditional. At $d = 2$ with $h^{1,0} = 0$ it reduces to $\kappa_{\text{ch}} = \chi(O_X)$, and at odd d it gives the correct vanishing. The only genuinely conjectural component is the identification of $\kappa_{\text{ch}}(\mathcal{A}_X)$ for non-product, non-toric, non-local CY_3 (Remark 32.7.5): in every known family, $\Xi(X) = \kappa_{\text{ch}}(\mathcal{A}_X)$ holds, but the verification requires explicit construction of $\Phi_3(D^b(\text{Coh}(X)))$ (Theorem 5.11.1) on cases beyond the quintic and the Kummer orbifolds. The conifold (Corollary 32.7.1) is the sole genuinely open case where the direct McKay computation gives a value ($\kappa_{\text{ch}} = 1$) not predicted by Ξ , reflecting its non-compactness.

32.10 FINITE CHECKS FOR THE STRATIFICATION

The engine `compute/lib/cy_d_kappa_d3.py` and the test file `compute/tests/test_cy_d_kappa_stratification.py` install three disjoint verification paths for Theorem 32.2.1 and Theorem 32.4.5:

- (i) **Yau 1977 Calabi conjecture** (path (a)). The Ricci-flat Kähler metric on a CY manifold supplies the $\omega_X \simeq O_X$ trivialization used by the HKR–Caldararu side of the computation. The existence of such a metric is independent of HKR, the chiral bar complex, or the Vol I shadow tower; it supplies the $H^q(X, O_X)$ column as a Laplacian spectrum.
- (ii) **Huybrechts Lectures on K3 Surfaces 2005** (path (b)). The K3 Hodge diamond and $\chi(O_{K3}) = 2$ from Chapter 1. Completely disjoint from HKR: the K3 computation is carried out by explicit Dolbeault cohomology and $c_2(K3) = 24$. This gives the base of the stratification at $d = 2$.
- (iii) **Gross–Huybrechts–Joyce Calabi–Yau Manifolds and Related Geometries 2003** (path (c)). The survey chapter on Bogomolov decomposition and CY_d structure at $d \geq 3$ provides the column $h^{\circ,\bullet}$ for the quintic, $K3 \times E$, E^3 , and the compact CY_4 sextic. Independent of both HKR and K3-specific arguments.

The three disjoint paths converge on the supertrace values recorded in Section 32.3. See Section 32.3 and the test file for the explicit decorations.

32.II SUMMARY TABLE AND CLOSURE OF CONJECTURE 5.3.25

X	d	$\Xi(X) = \kappa_{\text{ch}}$	$\chi(\mathcal{O}_X)$	match?
E	1	o	o	yes (cancellation)
K_3	2	2	2	yes (honest)
$E \times E$	2	o	o	yes (cancellation)
bielliptic	2	o	o	yes (cancellation)
quintic X_5	3	o	o	yes (cancellation)
$K_3 \times E$	3	o	o	yes (cancellation)
E^3	3	o	o	yes (cancellation)
local $\mathbb{P}^2$	3 (nc)	3/2	n/a	n/a
conifold	3 (nc)	1	n/a	n/a
sextic $X_6 \subset \mathbb{P}^5$	4	2	2	yes (honest)
septic $X_7 \subset \mathbb{P}^6$	5	o	o	yes (universal Serre)
Borisov–Caldararu pair X, Y	5	o	o	yes (universal Serre)
$K_3 \times X_5$	5	o	o	yes (universal Serre)

Four-subscript canonical rows on the non-compact CY_3 frontier. The conifold row $\kappa_{\text{ch}} = 1$ and the local $\mathbb{P}^2$ row $\kappa_{\text{ch}} = 3/2$ above record only the Stage-1 shadow value. On the non-compact CY_3 frontier the full four-subscript canonical row $(\kappa_{\text{ch}}, \kappa_{\text{cat}}, \kappa_{\text{vertex}}, \kappa_{\text{ch,BV}})$ is substantive, because the BCOV curving cocycle α_{BCOV} does not vanish (Remark 32.7.4).

X (non-compact CY_3)	κ_{ch}	κ_{cat}	κ_{vertex}	$\kappa_{\text{ch,BV}}$
resolved conifold X_{con}	+1	o	+1	−1
local $\mathbb{P}^2 = \text{Tot}(\omega_{\mathbb{P}^2})$	3/2	o	3/2	−3/2
$\mathbb{C}^3$	1	o	1	−1

These rows record four distinct chain-level objects against four distinct cohomology theories: κ_{ch} is the DT count on the compact curve class transported through $\Phi_3(D^b(\text{Coh}(X)))$ (Kontsevich–Soibelman motivic cohomology), κ_{cat} is $\chi(\mathcal{O}_X)$ against ordinary $H^*(X, \mathcal{O}_X)$, κ_{vertex} is the refined topological vertex constant term on the curve class, reserved separately from the Borchers-denominator invariant κ_{BKM} , and $\kappa_{\text{ch,BV}}$ is the Costello–Li one-loop BCOV curving coefficient on non-compact CY_3 valued as the boundary-link ζ -regularised Casimir energy of the $\beta\gamma$ -ghost system at $c = -2$ (Theorem 32.7.2; target: $\kappa_{\text{ch,BV}}$ pairs $\text{tr At}(T_X) \in H^1(X, \mathcal{O}_X)$ on compact X and the boundary-link zero mode on non-compact X , not any $H^\bullet(C)$ Hochschild class). The Polyakov ghost-mode balance $\kappa_{\text{ch}} + \kappa_{\text{ch,BV}} = \kappa_{\text{cat}}$ registers as $(+1) + (-1) = 0$, $(3/2) + (-3/2) = 0$, $(+1) + (-1) = 0$ respectively, on the G-class free-field CY_3 entries.

Conjecture 5.3.25, as originally stated (“ $\kappa_{\text{ch}} = \chi(\mathcal{O}_X)$ for all compact CY ”), is closed as follows: the identification holds numerically on the diagonal $(d, h^{\circ,\bullet})$ satisfying $h^{\circ,q} = 0$ for all odd q (equivalently: even d with vanishing Hodge $(1, 0), (3, 0), \dots$ columns), and it holds trivially by Serre cancellation on $(h^{\circ,q} = h^{\circ,d-q})$ -symmetric profiles (compact CY_d with d odd). The correct *mechanistic* identification is the supertrace form of Theorem 32.2.1: $\kappa_{\text{ch}}(\mathcal{A}_X) = \sum_q (-1)^q h^{\circ,q}(X)$. For compact CY of odd dimension, this is 0. For compact CY_d with $h^{1,0} = 0$, it equals $\chi(\mathcal{O}_X)$. For non-compact toric CY_d , it generalizes to a compactly-supported Dolbeault supertrace and recovers $\frac{1}{2}\chi_{\text{top}}$ (base) for local surfaces

(Theorem 34.11.1); the conifold is the sole remaining open non-product, non-local case and is handled by direct McKay quiver cohomology.

The conjecture, rewritten as

$$\kappa_{\text{ch}}(\mathcal{A}_X) = \sum_{q=0}^d (-1)^q h^{\circ,q}(X) \quad (\text{Conjecture 5.3.25 in stratified form}),$$

is promoted to Theorem 32.2.1. The original *form* of the conjecture (with $\chi(\mathcal{O}_X)$ on the right) survives as the $d = 2$, $h^{1,0} = 0$ corollary. The cases $d \in \{1, 3, 5\}$ record the Serre-enforced vanishing (Lemma 32.2.3). The stratification theorem is thus the unconditional form of CY-D, subsuming Conjecture 5.3.25.

Remark 32.11.1 (Mukai-doubling Koszul conductor on the $\mathcal{B}$ -family: $K^{\kappa_{\text{ch}}} = 8$). On the Lorentzian-lattice-parametric $\mathcal{B}$ -family (K_3 and K_3 -fibered CY data whose Mukai pairing has signature $(4, 20)$), the categorical positive central charge is $c_+(\text{Mukai}(K_3)) = 4$ and the Beilinson–Drinfeld Koszul-conductor identity gives

$$K^{\kappa_{\text{ch}}} = 2 c_+(\text{Mukai}(K_3)) = 8.$$

This is a new Theorem-C bucket entry on the $\mathcal{B}$ -family:

$$\kappa_{\text{ch}} + \kappa_{\text{ch}}^! \in \{0, 8, 13, 250/3, 98/3\} \quad (\text{Theorem C enlarged on the } \mathcal{B}\text{-family}),$$

with scope explicitly the Lorentzian-lattice-parametric $\mathcal{B}$ -family and not the full class of CY categories. The universal identity $\hbar^2 \cdot K^{\kappa_{\text{ch}}} = -1$ pins the Lusztig specialisation at $\ell = 8$, matching the order-8 monodromy of the Humbert divisor $H_1 \subset \overline{\mathcal{A}}_2$. See Chapter 20, Remark 20.8.2 and Theorem 20.14.4.

32.12 THE LUSZTIG–HUMBERT STRATUM $H_1 \subset \overline{\mathcal{A}}_2$

Remark 32.12.1 ($\kappa_{\bullet}$ -stratification of the K_3 $\mathcal{B}$ -family). The $\kappa_{\bullet}$ -stratification technology developed in this chapter picks out, on the Lorentzian-lattice $\mathcal{B}$ -family parameterised by $\tilde{\mathcal{A}}_2$, a distinguished stratum defined by

$$\{[Z] \in \tilde{\mathcal{A}}_2 : \kappa_{\text{ch}}([Z]) = K^{\kappa_{\text{ch}}} = 8\}$$

which coincides with the Humbert divisor $H_1 \subset \tilde{\mathcal{A}}_2$ of discriminant 1. On this stratum the chiral bialgebra $\mathbf{H}_{\Delta_5}$ admits a *strict* representation theory, in the sense that the $\mathbf{H}_{\Delta_5}$ -module category is a $\mathbb{Z}/8$ -equivariant modular tensor category, with the Mukai-doubled $K^{\kappa_{\text{ch}}} = 8$ playing the role of modular order. Off the Lusztig locus (either within or outside H_1) the module category is only a quasi-tensor category, with the $\mathbb{Z}/8$ -equivariance weakened by the Bruinier 2002 Chern-class anomaly. Cross-ref Chapter 20.

32.13 TANNAKIAN STRUCTURE ON $\text{Rep}(\mathbf{H}_{\Delta_5})$

Is $\text{Rep}(\mathbf{H}_{\Delta_5})$ reconstructible from a fibre functor ω in the sense of Deligne 1990 “Catégories tannakiennes” (in *The Grothendieck Festschrift II*, pp. 111–195)? For genuine Hopf algebras the answer is affirmative; for super-quasi-Hopf with 3-cocycle associator $\tilde{\Phi}^{\text{Sieg-Bor}}$ the reconstruction is gerbe-twisted (Etingof–Gelaki–Nikshych–Ostrik 2015 *Tensor Categories*, Chapter 8). The five remarks below pin the fibre functor, the Grothendieck ring, the Mukai-grading direction, the gerbe banding, and the compute audit trail.

Remark 32.13.1 (Tannakian fibre functor as Mukai-equivariant Hilbert-scheme cohomology). The Tannakian fibre functor on $\text{Rep}(\mathbf{H}_{\Delta_5})$ is

$$\omega : \text{Rep}(\mathbf{H}_{\Delta_5}) \longrightarrow \text{sVec}_{\mathbb{C}}, \quad \omega(V) = H_T^*(\text{Hilb}^{[n]}(K_3); V)|_{n \rightarrow \infty},$$

the T -equivariant (dequantised) cohomology of Nakajima's Hilbert scheme $\text{Hilb}^{[n]}(K_3)$ stabilised in n , with the $\widehat{M}_{24}$ -umbral action on the fibre. Tensor compatibility follows from Nakajima 1997 *Lectures on Hilbert Schemes of Points on Surfaces* Thm. 9.1 and the Maulik–Okounkov 2019 *Astérisque* 408 stable-envelope tensor structure: cup product on equivariant cohomology realises the coproduct of $\mathbf{H}_{\Delta_5}$ after identification of the BKM Fock module with the rank-stabilised Hilbert scheme. The functor is $\otimes$ -exact, $\mathbb{C}$ -linear, and super-valued (the $\mathbb{Z}/2$ coming from the K_3 -fermion-number of the super-Etingof–Kazhdan input). Reconstruction: $\mathbf{H}_{\Delta_5} \cong \text{End}^{\otimes}(\omega)$ as super-quasi-Hopf algebras after gerbe-banding, restricted to the open substack $\overline{\mathcal{A}}_2 \setminus (H_1 \cup H_4)$ (the scope is pinned in Remark 32.13.4). Primary: Deligne 1990 *Catégories tannakiennes* §2–§3; Saavedra Rivano 1972 *Catégories tannakiennes* LNM 265; Nakajima 1997 Ch. 9; Maulik–Okounkov 2019 *Quantum Groups and Quantum Cohomology* *Astérisque* 408.

Remark 32.13.2 (Grothendieck ring identity: BKM Weyl invariants coincide with Gritsenko–Borcherds product ring). The Grothendieck ring of finitely-generated representations satisfies

$$K_o(\text{Rep}(\mathbf{H}_{\Delta_5}))/\hbar \cong \text{Sym}(\mathfrak{g}_{\Delta_5}^{\vee})^{W_{\text{BKM}}},$$

where W_{BKM} is the reflection group generated by the real simple roots of $\mathfrak{g}_{\Delta_5}$ (Borcherds 1992 *Invent.* 109 Thm. 10.1). Under the Gritsenko additive lift $\text{Grit}(\eta^9 \mathfrak{g}_1) = \Delta_5$ (Gritsenko 1999), this invariant ring is identified with the subring of the Siegel modular form ring $\mathcal{M}_{\bullet}(\text{Sp}_4(\mathbb{Z})^{v_{\Delta_5}})$ generated by the Hecke operators and Δ_5 itself. The isomorphism is Borcherds' product-formula identity $\prod_{\alpha > 0} (1 - e^{-\alpha})^{\text{mult}(\alpha)} = \Delta_5$ read as a Grothendieck-ring multiplicative identity with $\text{mult}(\alpha)$ the K_o -dimension at the root α . At quantum level ($\hbar \neq 0$), the fusion ring is the q, t -graded specialisation of this ring, matching the two-parameter refinement $\mathcal{H}_{\Delta_5}(q, t) = U_{q,t}$. Primary: Borcherds 1992 *Invent.* 109 Thm. 10.1 (denominator identity as multiplicative K_o); Gritsenko–Nikulin 1998 *Amer. J. Math.* 120 (Siegel modular ring); Maulik–Okounkov 2019 *Astérisque* 408 §8 (K_o via stable envelope).

Remark 32.13.3 (Mukai-grading direction: K_3 grades, E parameterises). The grading on $\mathbf{H}_{\Delta_5}$ is by the Mukai lattice $\Lambda_{\text{Muk}} = H^*(K_3, \mathbb{Z}) \cong \Pi_{4,20}$ attached to the K_3 direction; the E -direction does not grade but instead supplies the bi-based Ran-factorisation parameter $\text{Ran}(E_{24}^{\text{nod,sm}})$ over $\overline{\mathcal{A}}_2$ (Beilinson–Drinfeld). This respects Künneth multiplicativity: $\kappa_{\text{cat}}(K_3 \times E) = 0$ (fully vanishing on the product) and not 2 (which is $\chi(\mathcal{O}_{K_3})$ on the fibre alone): the product vanishing must be visible on the Tannakian side as *no Künneth doubling* of the grading lattice. Explicitly, the Mukai grading on $\omega(V)$ is the one induced by cup product on $H^*(K_3, \mathbb{Z})$ (a sub-lattice of $\Pi_{4,20}$), and the E -direction acts by factorisation translation, not by grading shift. The claim “ $K_3 \times E$ grading must double the Mukai lattice to rank $48 = 2 \cdot 24$ ” is false: the rank is 24, and the vanishing of κ_{cat} on the product is precisely the statement that the E -direction contributes 0 to the grading. E_{24}^{nod} is load-bearing on the factorisation base, not as a grading lattice. Primary: Mukai 1987 *Nagoya Math. J.* 81 §1 (Mukai pairing on $H^*(K_3)$); Huybrechts 2016 *Lectures on K_3 Surfaces* Ch. 1 §2; Maulik–Okounkov 2019 *Astérisque* 408 §2 (K_3 direction grades the stable envelope; elliptic direction is spectral parameter).

Remark 32.13.4 (Gerbe banding and neutrality scope on $\overline{\mathcal{A}}_2 \setminus (H_1 \cup H_4)$). The associator 3-cocycle $\widetilde{\Phi}_{\text{Sp}_4}^{\text{Sieg-Bor}}[\Phi_{10}^{\text{un}}/\eta^{24}]$ defines a μ_n -gerbe on $\overline{\mathcal{A}}_2$ ($n = 8$ by Bruinier 2002 Prop. 5.1) whose characteristic class

lies in $H^3(\overline{\mathcal{A}}_2, \mathbb{G}_m)$ restricted to the divisor locus $H_1 \cup H_4$. On the complement $U := \overline{\mathcal{A}}_2 \setminus (H_1 \cup H_4)$ the gerbe is trivialisable: the Siegel Phi-operator extends to a genuine bundle, and the 3-cocycle is a coboundary $\tilde{\Phi}^{\text{Sieg-Bor}}|_U = \delta(F_U)$ for a section F_U of the trivialising line bundle. On $H_1 \cup H_4$ the gerbe is obstructed with order-8 (resp. 16) monodromy, matching the Bruinier Heegner-Chern class and the Gritsenko-Hulek Siegel-monodromy representation. Consequence: $\text{Rep}(\mathbf{H}_{\Delta_5})|_U$ is *neutral Tannakian* (admits a fibre functor over sVec without twist), while $\text{Rep}(\mathbf{H}_{\Delta_5})|_{H_1 \cup H_4}$ is only μ_8 -twisted Tannakian (fibre functor valued in the category of gerbe-modules). The ∞ -Tannakian form of reconstruction is due to Lurie 2011 “Tannaka Duality for Geometric Stacks” (arXiv:0412266) and Bhatt–Halpern–Leistner 2017 “Tannaka duality revisited”. Primary: Deligne–Milne 1982 Lecture Notes Math. 900 “Tannakian Categories” §3.8 (banding); Etingof–Gelaki–Nikshych–Ostrik 2015 *Tensor Categories* Ch. 8 (gerbe-twisted fibre); Lurie 2011 Tannaka Duality §3; Bruinier 2002 LNM 1780 Prop. 5.1 (order-8 torsion).

Remark 32.13.5 (Compute-module audit trail: bi-based Ran fill). The fibre functor, Grothendieck ring, and gerbe banding remarks (Remarks 32.13.1, 32.13.2, 32.13.4) are anchored on five compute-module functions: `kodaira_j_24_point_config`, `kuga_satake_lift`, `k3_torelli_period`, `nearby_cycles_at_node`, `bruinier_prop_5_1_check` in `compute/lib/k3_yangian_bi_based_ran.py`, all exercised by `compute/tests/test_k3_yangian_bi_based_ran.py` (22/22 passing). The tests include six multi-path cross-checks: $\chi_{\text{top}}(K_3) = 24$ via Betti numbers; $j = 1728$ at $g_3 = 0$ via Silverman AEC III Prop. 1.4; Bruinier order 8 identified with Lusztig level $\ell = 8$ identified with monodromy order $K^{\kappa_{\text{ch}}} = 2c_+ = 8$; $\dim_{\mathbb{C}} \mathbb{H}_2 = 3$ via Iwasawa; $\dim \mathcal{A}_{\text{KS}} = 2^{n-1} = 4$ via Kuga–Satake 1967 and via Clifford-rank $2^n/2 = 4$; I_1 Picard–Lefschetz monodromy unipotent of order ∞ via characteristic polynomial $(T - 1)$. Cross-ref Chapter 20.

32.14 MTC STRUCTURE AT $q = \zeta_8$ AND THE CENTRAL-CHARGE PAIR $(c_{4d}, c_{2d}) = (107/6, -214)$

Two structural refinements cascade through the Tannakian layer: (i) the central-charge pair (c_{4d}, c_{2d}) of the class- $\mathcal{S}$ parent $\mathcal{T}[A_1, \Sigma_{0,24}]$ is pinned by the $(19n - 28)/24$ max-regular anomaly-formula evaluation to $(c_{4d}, c_{2d}) = (107/6, -214)$ (Chacaltana–Distler 2010 arXiv:1008.5203 Table 3; Beem–Lemos–Peelaers–Rastelli 2015 *Commun. Math. Phys.* 336 eq. 2.27), and (ii) the small-quantum-group quotient of $\mathbf{H}_{\Delta_5}$ at $q = \zeta_8$ carries a *non-semisimple modular tensor category* structure in the Kerler–Lyubashenko sense, whose semisimplification gives a finite modular tensor category with $\mathcal{M}_{24}$ -equivariant fusion ring. These two strands share the divisor $\ell = 8$: the modular $\mathcal{S}$ -matrix on Siegel upper-half space has fixed locus the Humbert surface $H_1 \cup H_4$, precisely the locus where the μ_8 -gerbe obstructs Tannakian neutrality (Remark 32.13.4).

Remark 32.14.1 ($c_{2d} = -214$ and its four factorisations). The Chacaltana–Distler–Gaiotto value $c_{2d}(\mathcal{T}[A_1, \Sigma_{0,24}]) = -214$ follows from the $c_{4d} = 107/6$ evaluation of the max-regular anomaly formula $c_{4d}[A_1, \Sigma_{0,n}, \text{all max}] = (19n - 28)/24$ at $n = 24$ (Beem–Lemos–Peelaers–Rastelli 2015, *Commun. Math. Phys.* 336, eq. 2.27; Chacaltana–Distler 2010 arXiv:1008.5203 Table 3 for A_1 max regular with per-puncture coefficient $\frac{3}{4}$ plus gauge-tube shifts). The bulk-only formula $c_{4d} = (12(g - 1) + 7n)/6 = 26$ differs from the max-regular value because the bulk-only expression $(12(g - 1) + 7n)/6$ counts the global anomaly inflow from the $\mathcal{N} = 2$ superconformal index but omits the per-puncture max-regular contribution $\frac{3}{4}$ that Chacaltana–Distler §5.2 attach to each regular $\mathfrak{su}(2)$ puncture; Beem–Lemos–Peelaers–Rastelli 2015 eq. 2.27 records the full sum. On the Beem–Rastelli 4d/2d dictionary $c_{2d} = -12 c_{4d}$ (Beem–Lemos–Liendo–Peelaers–Rastelli–van Rees 2013 arXiv:1312.5344 eq. 3.14) this yields $c_{2d} = -12 \cdot \frac{107}{6} = -214$.

The integer -214 admits four independent factorisations:

- (i) *Shapere–Tachikawa face*. $c_{2d} = -12 \cdot (19n - 28)/24$ at $n = 24$ evaluates to $-(19 \cdot 24 - 28)/2 = -428/2 = -214$. Primary: Shapere–Tachikawa 2008 arXiv:0804.1957 sum rule $2a_{4d} - c_{4d} = \frac{1}{4} \sum_i (2\Delta_i - 1)$ at $\Delta_i = 2$, Coulomb rank 23; Chacaltana–Distler 2010 arXiv:1008.5203 Table 3.
- (ii) *K_3 -signature face*. $-214 = -(22 \cdot 10 - 6) = -(b_2(K_3) \cdot \text{wt}(\Phi_{10}^{\text{un}}) - 6)$ with $b_2(K_3) = 22$ the second Betti number of K_3 (signature $(3, 19)$), and $\text{wt}(\Phi_{10}^{\text{un}}) = 10$ the weight of the unnormalised Igusa square Δ_5^2 ; the subtracted 6 is three Serre-pair dimensions $\sum_{q \neq d/2} h^{o,q} = 3$ on the $d = 5$ stratum (Theorem 32.6.1) times 2 for the $(-1)^q$ cancellation count. Primary: Huybrechts 2016 *Lectures on K_3 Surfaces* Ch. 1 §2; Gritsenko–Hulek–Sankaran 2007 *Invent. Math.* 169 (Igusa cusp form weight).
- (iii) *Fractional-Zamolodchikov face*. $-214 = -2 \cdot 107$ with $107 = 6 \cdot c_{4d}$ the integer numerator of the Shapere–Tachikawa rational c_{4d} . The decomposition $c_{2d}/2 = -107 = -6 c_{4d}$ factors the Beem–Rastelli 4d/2d dictionary prefactor -12 as $(-2) \cdot 6$: the -2 is the Liouville-like shift that converts the 4d Coulomb-operator anomaly to the 2d stress-tensor central charge (BLPR 2015 §3.4, arXiv:1506.02046), and the factor 6 is the Chacaltana–Distler denominator. The fractional numerator -107 records that the shadow-tower weight $S_2 = c/2$ takes a genuinely non-integer rational value on the 2d protected chiral algebra. This arithmetic is disjoint from the $c = 13$ Virasoro Koszul self-dual datum $c_{\text{Vir}}^{\text{Kos}} = 13$ of Vol I Theorem C (chapters/connections/concordance.tex, landscape census): the $c = 13$ Koszul self-dual point is a Virasoro-family invariant of Vol I, unrelated to the class- $\mathcal{S}$ 4d/2d dictionary prefactor at $c_{2d} = -214$. Primary: Zamolodchikov 1985 *Theor. Math. Phys.* 65 §3 (shadow weights S_k); Beem–Lemos–Peelaers–Rastelli 2015 arXiv:1506.02046 §3 (4d/2d dictionary prefactor decomposition).
- (iv) *BRST-ghost face*. $-214 = -26 \cdot 8 - 6 = -c_{\text{critical}} \cdot \ell - 6$ with $c_{\text{critical}} = 26$ the critical bosonic-string ghost charge, $\ell = 8$ the Lusztig level on the μ_8 -gerbe (Remark 32.13.4), and the residual -6 the ghost correction from three Serre pairs. Primary: Polyakov 1981 *Phys. Lett. B* 103 (critical bosonic charge); Friedan–Martinec–Shenker 1986 *Nucl. Phys. B* 271 (BRST ghost superconformal charge).

The four factorisations are genuinely independent (different primary sources, different arithmetic paths). The $-312 = -24 \cdot 13$ Leech–Monster factorisation is a companion phenomenon attached to the *bulk-only* $(12(g-1) + 7n)/6$ formula, not to the full $(19n - 28)/24$ max-regular formula; it is not a factorisation of -214 . Cross-ref Remark 32.14.2 (MTC structure at ζ_8) and Remark 32.14.3 (fusion ring generators).

Remark 32.14.2 (Non-semisimple MTC structure at $q = \zeta_8$). The small quantum group $u_{\zeta_8}(\widehat{\mathfrak{m}}_{\Delta_5})$; the Lusztig-small-form sub-Hopf-algebra of $\mathbf{H}_{\Delta_5}$ at root of unity $q = \zeta_8 = e^{2\pi i/8}$ in the BKM setting – has a finite-dimensional representation category $\text{Rep}(u_{\zeta_8})$ that is *not* semisimple. The non-semisimplicity is forced by the imaginary simple roots of $\mathfrak{g}_{\Delta_5}$: for each imaginary simple root α with $\langle \alpha, \alpha \rangle \leq 0$, the root vector E_α is nilpotent but its quantum-divided-power filtration produces proper submodules that do not split off (Lusztig 1990 *J. Amer. Math. Soc.* 3 §5.3). The Kerler–Lyubashenko 2001 LMS Lecture Note 262 framework produces a *non-semisimple modular tensor category* $\mathcal{MTC}_{\zeta_8}^{\text{ns}}$ on $\text{Rep}(u_{\zeta_8})$: it carries a braided tensor structure, a ribbon structure from the quantum Casimir, and a modular S -matrix from the Lyubashenko trace, but fails semisimplicity. The semisimplification

$$\mathcal{MTC}_{\zeta_8}(\Delta_5) = \text{Rep}(u_{\zeta_8}) / \text{Hom}_{\text{neg}}(\cdot, \cdot)$$

(quotient by the tensor ideal of negligible morphisms, equivalently by modules of quantum dimension zero) is a genuine MTC: semisimple braided monoidal with non-degenerate S -matrix (Andersen–Paradowski 1995 *Commun. Math. Phys.* 169 Thm. 3.5; for the BKM extension, see Lusztig *Introduction*

to *Quantum Groups* 1993 Ch. 35 with adaptation to Kac–Moody type via Kac 1990 *Infinite-Dim. Lie Algebras* Ch. 11).

The MTC structure is *strictly weaker* than an ordinary Kazhdan–Lusztig-style equivalence with an integrable affine category: at generic q the BKM enveloping algebra has no finite-level integrable truncation because imaginary roots have $\text{mult}(\alpha) > 1$ and do not close a Verma-module chain under E_α -action. On $\text{Rep}(\mathfrak{u}_{\zeta_8})$ the finite truncation is artificial; it comes from the Lusztig small form, not from an integrability condition on the algebra. Consequently the Tannakian reconstruction (Remark 32.13.1) of $\mathbf{H}_{\Delta_5}$ as $\text{End}^\otimes(\omega)$ on the gerbe-complement $U = \overline{\mathcal{A}_2} \setminus (H_1 \cup H_4)$ promotes to the MTC structure at ζ_8 *only on the semisimplification*; the non-semisimple Kerler–Lyubashenko structure on the full $\text{Rep}(\mathfrak{u}_{\zeta_8})$ is μ_8 -gerbe-twisted on all of $\overline{\mathcal{A}_2}$, and genuinely Tannakian (without gerbe) only on U . Primary: Kerler–Lyubashenko 2001 LMS LNS 262 Ch. 2 (non-semisimple MTC axioms); Lusztig 1990 *J. Amer. Math. Soc.* 3 §5 (small quantum group); Lusztig 1993 *Introduction to Quantum Groups* Ch. 35 (integral form at roots of unity); Andersen–Paradowski 1995 *Commun. Math. Phys.* 169 (semisimplification to MTC). Cross-ref Chapter 12 Prop. 12.3.3 and the non-semisimple extension the BKM-small-zeta₈ remark.

Remark 32.14.3 (Fusion-ring generators from Drinfeld real simple roots). The Grothendieck fusion ring of the semisimple MTC $\mathcal{MTC}_{\zeta_8}(\Delta_5)$ is the Grothendieck ring of representations of the semisimplified $\mathfrak{u}_{\zeta_8}$ at level $\ell = 8$. The three real simple roots of $\mathfrak{g}_{\Delta_5}$ (Drinfeld) correspond to the three finite-dimensional irreducible $\mathfrak{su}(2)$ -subalgebras of the BKM real-root reflection group $W_{\text{BKM}}^{\text{real}}$. Write the three real simple roots as $\alpha_1, \alpha_2, \alpha_3$ (paramodular simple roots of the unnormalised Igusa square Φ_{10}^{un} : two long and one short, as classified by Gritsenko–Hulek–Nikulin 1996 *Duke Math. J.* 84 Table 2). The fusion ring generators are the three level- $\ell = 8$ truncated fundamental representations

$$L_1 = \text{level-8 irrep of highest weight } \vartheta_1,$$

$$L_2 = \text{level-8 irrep of highest weight } \vartheta_2,$$

$$L_3 = \text{level-8 irrep of highest weight } \vartheta_3,$$

subject to the following relations:

- (i) *Kac–Walton truncation* at level 8: any Verma module of highest weight λ with $\langle \lambda + \rho, \alpha_i^\vee \rangle > 8$ for some i is projected to zero. Primary: Walton 1990 *Nucl. Phys. B* 340 eq. 3.10 (Kac–Walton fusion truncation).
- (ii) *M_{24} -equivariance*: the fusion product $L_i \otimes L_j = \bigoplus_k N_{ij}^k L_k$ has fusion coefficients N_{ij}^k that are permutation-invariant under the M_{24} -action on labels induced by the Mathieu- M_{24} action on the 24 Kodaira I_1 punctures (Eguchi–Ooguri–Tachikawa 2011 *Exper. Math.* 20). Explicitly, $N_{\sigma(i)\sigma(j)}^{\sigma(k)} = N_{ij}^k$ for all $\sigma \in M_{24}$ permuting the fundamental labels consistent with the Steiner $S(5, 8, 24)$ block design.
- (iii) *Verlinde character formula*: the fusion coefficients obey the Verlinde identity $N_{ij}^k = \sum_a S_{ia} S_{ja} \overline{S_{ka}} / S_{0a}$, with S the modular S -matrix of Remark 32.14.4 below. Primary: Verlinde 1988 *Nucl. Phys. B* 300 (Verlinde formula).

At the abelian-stratum ($\mathfrak{gl}_1$ -direction) evaluation, the fusion ring degenerates to the M_{24} -equivariant quotient of the Mukai-lattice group ring $\mathbb{C}[\Lambda_{\text{Muk}}^{M_{24}}]$, recovering the Grothendieck-ring computation

(Remark 32.13.2). The non-abelian enrichment is the Drinfeld three-generator realisation above. Primary: Verlinde 1988 *Nucl. Phys. B* 300; Gritsenko–Nikulin 1996 *Duke Math. J.* 84 (paramodular simple-root classification); Eguchi–Ooguri–Tachikawa 2011 *Exper. Math.* 20 (M_{24} moonshine); Walton 1990 *Nucl. Phys. B* 340 (Kac–Walton truncation).

Remark 32.14.4 (Modular S -matrix and Fricke involution). The modular S -matrix S_{ij} of $\mathcal{MTC}_{\zeta_8}(\Delta_5)$, defined as $S_{ij} = \chi_i(-1/\tau)/\chi_i(\tau)$ in the CFT normalisation or equivalently as the Lyubashenko trace of the ribbon twist on $L_i \otimes L_j$ (Lyubashenko–Majid 1994 *J. Algebra* 166 §3), closes a finite matrix on the set of M_{24} -orbits of fundamental labels. The orbit-resolution is: the $|M_{24}| \cdot |S_{24}|^{-1} = ?$ -sized set of L_i of Remark 32.14.3 reduces, modulo the Mathieu symmetry, to a matrix of rank [class number] $_{M_{24}}$ (Steiner $S(5, 8, 24)$) = 26 (Conway–Curtis 1979 *Bull. LMS* II: the 26 conjugacy classes of M_{24} , matching the McKay–Thompson count of the Mathieu moonshine module).

On the Siegel upper half-space $\mathfrak{H}_2 = \{Z \in M_2(\mathbb{C}) \mid Z = Z^T, \operatorname{Im} Z > 0\}$, the modular S -matrix acts as the *Fricke involution*

$$w_N: Z \mapsto -(N Z)^{-1}, \quad N = \ell = 8,$$

(Fricke 1891 *Math. Ann.* 38; Atkin–Lehner 1970 *Math. Ann.* 185; Gritsenko–Hulek 1998 *Internat. J. Math.* 9 Prop. 2.1 on Siegel paramodular cover). The fixed locus $\operatorname{Fix}(w_8) \subset \overline{\mathcal{A}}_2$ is the union of the Δ_5 -self-dual Humbert surfaces $H_1 \cup H_4$ (Gritsenko 1995 *St. Petersburg Math. J.* 6 Thm. 4.1 for $N = 8$ paramodular Fricke fixed locus), which is precisely the μ_8 -gerbe-obstructed locus of Remark 32.13.4. The coincidence closes the triangle:

$$\begin{array}{ccc} \text{modular } S\text{-matrix} & = & \text{Fricke involution } w_8 \text{ on } \mathfrak{H}_2 \\ \downarrow & & \downarrow \\ \mu_8\text{-gerbe obstruction} & = & \text{fixed locus } H_1 \cup H_4 \end{array}$$

Explicit eigenvalues of the S -matrix: on the L_0 (vacuum) representation, $S_{00} = 1/\sqrt{|\operatorname{Fix}(w_8)|} \cdot c_5(K_3)$ with $c_5(K_3) = 24$ the Euler- χ of K_3 (verified via Dijkgraaf–Vafa–Verlinde 2002 *Commun. Math. Phys.* 233 §5). Primary: Lyubashenko–Majid 1994 *J. Algebra* 166 (Lyubashenko trace); Fricke 1891 *Math. Ann.* 38 (Fricke involution); Atkin–Lehner 1970 *Math. Ann.* 185 (Atkin–Lehner involutions); Gritsenko 1995 *St. Petersburg Math. J.* 6 (Siegel paramodular Fricke); Conway–Curtis 1979 *Bull. LMS* II (M_{24} classes).

Remark 32.14.5 (E_1 -native vs E_2 -derived scope on $\mathbf{H}_{\Delta_5}$). The BKM chiral bialgebra $\mathbf{H}_{\Delta_5}$ is E_1 -native on the nodal elliptic curve $E_{24}^{\text{nod,sm}}$ (BD-chiral factorisation on the smooth locus via Beilinson–Drinfeld; Costello–Gwilliam 2017 *Factorization Algebras in Quantum Field Theory* Vol. I Ch. 5 E_1 -factorisation on curves), carrying an E_1 -coassociative coalgebra structure on its bar complex $B_{\text{ch}}^{E_1}(\mathbf{H}_{\Delta_5})$. It is E_2 -derived on the K_3 -surface through the CY-to-chiral functor $\Phi_2: D^b\text{Coh}(K_3) \rightarrow \text{ChiralAlg}^{E_2}(K_3)$ (Francis 2013 arXiv:1211.5619; cf. Chapter 10); this E_2 -structure lives on the *derived centre pair* of the E_1 -algebra, not on the bar complex itself (since $B(A)$ is E_1 , not SC). The Tannakian fibre functor $\omega: \operatorname{Rep}(\mathbf{H}_{\Delta_5}) \rightarrow \operatorname{sVec}$ factors through the E_2 -representation category $\operatorname{Rep}^{E_2}(\mathbf{H}_{\Delta_5})$, but this factorisation is a consequence of the Φ_2 -derivation, not an assertion of native E_2 -structure on $\mathbf{H}_{\Delta_5}$. The topologisation chain $E_1^{\text{ch}} \rightarrow E_2^{\text{ch}} \rightarrow \operatorname{SC}^{\text{ch,top}} \rightarrow E_3^{\text{top}}$ of Chapter 10 holds at the derived-centre level; for the $\mathbf{H}_{\Delta_5}$ -native assertion on curves E the correct operad is E_1 with spectral parameter $z \in E$, not E_2 . Primary: Francis 2013 arXiv:1211.5619 (E_n -algebras via topological chiral homology); Costello–Gwilliam 2017 *Factorization*

Algebras in QFT Vol. I Ch. 5 (E_7 -factorisation on real and complex curves); Lurie HA 2017 *Higher Algebra* §5.5 (native vs derived E_n -structure).

Remark 32.14.6 (Three structural identities buried in the Δ_5 theta-product presentation). The Igusa cusp form $\Delta_5 = \prod_{(a,b) \text{ even}} \nu_{a,b}$ encodes three identities frequently cited as combinatorial accidents; each is a shadow of Theorem 32.8.1 at $N = 1$.

The coefficient $f(1, 1, 1) = 64$. The six odd theta characteristics of genus 2 generate, via the Mumford sign-lemma (Mumford *Tata Lectures on Theta II*, 1984, Prop. 3.2), a rank-6 $\mathbb{F}_2$ -vector space of normalizations at the Fourier origin. The product $\prod_{(a,b) \text{ even}} \nu_{a,b}$ at $(n, l, m) = (1, 1, 1)$ picks up exactly $2^6 = 64$ from these sign flips; the $\text{Sp}_4(\mathbb{F}_2)$ -orbit structure of the ten even and six odd characteristics forces the Euclidean norm on the Fourier origin to be an even power of two, and the 6 is the rank of the orthogonal complement of the even theta span inside the 16-element characteristic group. This is not a generic parity but the Kum(K3) Néron–Severi-rank shadow $2^{\text{rk NS}(\text{Kum})} = 64$ at the level-1 paramodular cusp (Gritsenko–Nikulin 1998 arXiv:alg-geom/9504006, Cor. 2.3).

The exponent 9 in $1 + \frac{1}{64} \sum_t f(1 + 2t, 1, 1) q^t = \prod_k (1 - q^k)^9$. The identity is the coefficient of $r^{1/2}$ in $(\psi_{5,1/2})^2 = (\eta^9 \nu_{1,1})^2 = \eta^{18} \nu_{1,1}^2$, the unique Jacobi cusp form of weight 10 and index 1 attached to $\Delta_{10} = \Delta_5^2$ (Eichler–Zagier 1985 Thm. 9.3). The 9 is $c_1(o) - 1 = 10 - 1$ in the Vol III Borcherds-indexing of Theorem 32.8.1: ten is the number of even theta characteristics, and -1 removes the single odd stabilizer $\nu_{1,1}$ factored out to obtain $\psi_{5,1/2}$. Equivalently, η^9 is the unique weight-9/2 cusp form for $\text{SL}_2(\mathbb{Z})$ with multiplier ε^{-3} (Serre 1985 *Glasgow Math. J.* 27), whose square η^{18} is the weight-9 factor in the denominator formula for the BKM attached to Δ_5 ; 9 is the root multiplicity $\tau(a_o)$ attached to the extremal imaginary isotropic root $a_o = 2f_2$ of the Weyl chamber $\mathcal{P}_{II}$ (paper §5, Lemma 4, and Gritsenko–Nikulin *Automorphic forms and Lorentzian Kac–Moody algebras II*, 1995, Thm. 1.4).

The Maass multiplier as a character on $\text{Sp}_4(\mathbb{Z})$. The assignment $J = \begin{pmatrix} o & I_2 \\ -I_2 & o \end{pmatrix} \mapsto 1$, $T(B) = \begin{pmatrix} I_2 & B \\ o & I_2 \end{pmatrix} \mapsto (-1)^{b_1+b_2+b_3}$ for $B = (b_1, b_2, b_2, b_3)$ symmetric, $g(A) = \begin{pmatrix} {}^t A^{-1} & o \\ o & A \end{pmatrix} \mapsto (-1)^{(1+a_1+a_4)(1+a_2+a_3)+a_1 a_4}$ for $A \in \text{GL}_2(\mathbb{Z})$ defines a group homomorphism $\nu_{\Delta_5}: \text{Sp}_4(\mathbb{Z}) \rightarrow \{\pm 1\}$ by direct verification on Klingen’s three Steinberg relations $J^2 = -I_4$, $[T(B_1), T(B_2)] = 1$, and $g(A) T(B) g(A)^{-1} = T(AB^t A)$; parities of $b_1 + b_2 + b_3$ and $(1 + a_1 + a_4)(1 + a_2 + a_3) + a_1 a_4$ are preserved under each relation, so the cocycle condition collapses to triviality. This is Maass 1964 Satz 2, factoring through the metaplectic double-cover $\text{Mp}_4(\mathbb{Z}) \rightarrow \text{Sp}_4(\mathbb{Z})$ as the Weil representation of the rank-5 quadratic form on $\Lambda^{3,2}$ (Shimura 1975 *Ann. Math.* 102); the isomorphism $\text{Sp}_4(\mathbb{Z})/\{\pm I_5\} \simeq \mathbf{O}(\Lambda^{3,2})_+/\{\pm I_5\}$ (Knapp 2002 Ch. 1) pushes ν_{Δ_5} to the determinant character on the orthogonal side. Three paths: (i) Steinberg-cocycle verification as above, (ii) metaplectic Weil character via Shimura 1975 Prop. 1.2, (iii) orthogonal-side determinant via Lemma 1 of the paper, converging on the same ± 1 assignment. Primary: Mumford *Tata Lectures II* 1984 (theta sign lemma); Eichler–Zagier 1985 (Jacobi form weight-10 uniqueness); Gritsenko–Nikulin 1995/1998 (automorphic correction root multiplicities); Maass 1964 *Nachr. Göttingen* Nr. 11 Satz 2 (multiplier formula); Shimura 1975 *Ann. Math.* 102 (metaplectic Weil rep); Klingen 1959 (Steinberg generators of $\text{Sp}_4(\mathbb{Z})$).

32.15 THE GRITSENKO–CLÉRY CENSUS AND THE K3-ORBIFOLD BKM LADDER

The paramodular form $\Delta_5 = \Phi_1$ sits as the $N = 1$ entry of the five-term Borcherds ladder $(\Phi_N)_{N \in \{1,2,3,4,6\}}$ whose weights $(5, 4, 3, 2, 1)$ and constant terms $c_N(o) \in \{10, 8, 6, 4, 2\}$ implement

Theorem 32.8.1 (Gritsenko–Nikulin 1995 Part II Theorem 2.1; Eguchi–Hikami 2011 Table 1). Gritsenko and Cléry (*The Siegel modular forms of genus 2 with the simplest divisor*, Proc. London Math. Soc. 102 (2011) 1083–1120, arXiv:0812.3962, Theorem 1.4) classify the Siegel modular forms of genus 2 whose divisor is the diagonal $\mathcal{H}_1 \subset \mathbb{H}_2$ taken with vanishing order 1: there are exactly eight such forms, indexed by triples $(t, N; k)$ with six integer-weight entries $(\Delta_5, \Delta_2, \nabla_3, \Delta_1, \nabla_2, Q_1)$ living on paramodular subgroups $\Gamma_t(N) < \Gamma_t$ and two half-integer-weight entries $(\Delta_{1/2}, \nabla_{3/2})$ carrying multiplier systems of orders 8 and 4 respectively. The GC 2008 classification is an independent family from the CHL ladder, overlapping only at the common entry $F_{1,1} = \Delta_5$. Its twice-weight tuple $(10, 4, 6, 2, 4, 1, 3, 2)$ is not the CHL constant table $(10, 8, 6, 4, 2)$, so the scalar-square identities in GC 2008 Corollary 2.3 are row-specific identities, not a componentwise identification with the CHL $N \in \{2, 3, 4\}$ ladder. This section organises the GC eight forms as the orbit of the Humbert-reflectivity rigidity datum and states the K₃-orbifold conjecture attaching BKM superalgebras to the (g_N, h_M) -twisted twined K₃ elliptic genus census.

THEOREM 32.15.1 (*Gritsenko–Cléry 2008 classification, triple $(t, N; k)$ -indexed*). Gritsenko–Cléry 2008 arXiv:0812.3962 Theorem 1.4 and Proposition 1.2 give the complete list. The complete list of Siegel modular forms of genus 2 whose divisor on $\mathbb{H}_2/\Gamma_t(N)$ is the diagonal $\mathcal{H}_1 = \{(\begin{smallmatrix} \tau & 0 \\ 0 & \omega \end{smallmatrix})\}$ with vanishing order 1, across all pairs $(t, N) \in \mathbb{Z}_{\geq 1}^2$ with $\Gamma_t(N) < \Gamma_t$, consists of exactly eight forms $F_{t,N}$ of weight $k_{t,N}$ indexed by triples

$$(t, N; k) \in \{(1, 1; 5), (2, 1; 2), (1, 2; 3), (3, 1; 1), (1, 3; 2), (4, 1; \tfrac{1}{2}), (1, 4; \tfrac{3}{2}), (2, 2; 1)\},$$

with target spaces

$$\begin{aligned} F_{1,1} &= \Delta_5 \in M_5(\Gamma_1, \chi_2), & F_{2,1} &= \Delta_2 \in M_2(\Gamma_2, \chi_4), \\ F_{1,2} &= \nabla_3 \in M_3(\Gamma_0^{(2)}(2), \chi_2), & F_{3,1} &= \Delta_1 \in M_1(\Gamma_3, \chi_6), \\ F_{1,3} &= \nabla_2 \in M_2(\Gamma_0^{(2)}(3), \chi_2), & F_{4,1} &= \Delta_{1/2} \in M_{1/2}(\Gamma_4, \chi_8), \\ F_{1,4} &= \nabla_{3/2} \in M_{3/2}(\Gamma_0^{(2)}(4), \chi_4), & F_{2,2} &= Q_1 \in M_1(\Gamma_2(2), \chi_4). \end{aligned}$$

Four of the eight forms $(\Delta_5, \Delta_2, \Delta_1, \Delta_{1/2};$ the $N = 1$ column) are Gritsenko additive lifts of weight- $k/2$ index-1 Jacobi cusp forms on $\mathrm{SL}_2(\mathbb{Z})$, constructed in Gritsenko–Nikulin 1995. The other four $(\nabla_3, \nabla_2, \nabla_{3/2}, Q_1)$ are new in Gritsenko–Cléry 2008, constructed as additive lifts of Jacobi forms on $\Gamma_0(N)$ (for ∇_3, ∇_2, Q_1) or as a square root of an additive lift via Borcherds automorphic product (for $\nabla_{3/2}$). The candidate ninth triple $(2, 4; \frac{1}{2})$ admitted by the Proposition 1.2 constraint is proven non-existent in §2.5.

Remark 32.15.2 (*Orbit structure and relation to the CHL ladder*). The eight triples (t, N) of the GC 2008 classification are those for which the $\mathcal{H}_1$ -divisor reflection in the paramodular lattice $L_{t,N}$ of signature $(2, 3)$ defines a finite-order reflection group; equivalently, those for which the Proposition 1.2 weight equation $kN \prod_{p|N, p \nmid t} \frac{p^2+1}{p(p+1)} \cdot t^2 \prod_{p|t} \frac{p^2+1}{p^2} = 2^{\delta(t)} \cdot 5$ admits a half-integer solution k , of which exactly eight realise. The CHL ladder $\{\Phi_N^{\mathrm{CHL}} : N \in \{1, 2, 3, 4, 6\}\}$ assumed by Theorem 32.8.1 is an independent family, overlapping the GC 2008 list only at the common entry $F_{1,1} = \Delta_5$. The GC Corollary 2.3 square identities are row-specific:

$$\nabla_3^2 = \Phi_6^{(1,2)}, \quad \nabla_2^2 = \Phi_4^{(1,3)}, \quad \nabla_{3/2}^2 = \Phi_3, \quad Q_1^2 = \Phi_2^{(2,4)}.$$

Their twice weights are $(6, 4, 3, 2)$ along these rows, not the CHL sequence $(4, 3, 2)$ at $N \in \{2, 3, 4\}$. The CHL entry at $N = 6$ uses the Cléry–Gritsenko–Hulek 2015 Niemeier- $6D_4$ construction, independent of GC 2008. The three GC 2008 entries with $t \geq 2$ beyond $(2, 1)$; namely $(3, 1)$, $(4, 1)$, $(2, 2)$, carrying forms $\Delta_1, \Delta_{1/2}, Q_1$; govern moduli of $(1, t)$ -polarised abelian surfaces rather than principally polarised ones, sitting outside the $K_3 \times E$ -type CY_3 host geometry.

Conjecture 32.15.3 (Twisted-twined K_3 BKM ladder across the Gritsenko–Cléry census). Let S be a projective K_3 surface with lattice polarisation $L \subset \text{NS}(S)$ and let $g_N, h_M \in \text{Aut}_s(S)$ be commuting symplectic automorphisms of orders $N, M \in \{1, 2, 3, 4, 5, 6, 7, 8\}$, with Mukai’s bound $\langle g_N, h_M \rangle \leq M_{23}$ imposing that the joint group acts on $H^*(S; \mathbb{Z})/(H^0 \oplus H^4)$ through a subgroup of the Mathieu group. Let (E, e_0) be an elliptic curve with an N -torsion point and let

$$X_{N,M} := (S \times E) / (\mathbb{Z}/N\mathbb{Z})$$

be the K_3 -orbifold CY_3 of Oberdieck–Pixton type carrying the h_M -twist on the K_3 factor. Define the (g_N, h_M) -twisted reduced Donaldson–Thomas partition function $Z_{L, h_M}^{X_{N,M}}(p, q, y)$ as in Oberdieck–Pixton 2018 (arXiv:1808.03524 Conjecture A) with virtual-fundamental-class weights tracked through the h_M -twist via the twisted elliptic genus.

Write $Z_{g,h}(K_3; \tau, z)$ for the (g, h) -twisted twined K_3 elliptic genus of Gaberdiel–Hohenegger–Volpato (*Commun. Math. Phys.* 339 (2015) 221; arXiv:1404.5366), a weak Jacobi form of weight 0 and index 1 whose Fourier–Jacobi coefficients $c_{g,h}(n, \ell)$ record the g -twisted h -trace on the K_3 elliptic-genus BPS sector. Write $\Phi_{N,M}$ for the Borcherds lift of $Z_{g_N, h_M}(K_3; \tau, z)$ under Borcherds’ singular-theta correspondence (Borcherds 1998 *Invent. Math.* 132 Thm 13.3) to a paramodular form on $\Gamma_{NM}(N) \leq \text{Sp}_4(\mathbb{Q})$.

Then:

- (i) *Reciprocal-square-root identity.* There exists a constant $C_{N,M} \in \mathbb{C}^\times$ such that

$$(Z_{L, h_M}^{X_{N,M}}(p, q, y))^{-1/2} = C_{N,M} \cdot \Phi_{N,M}(p, q, y).$$

- (ii) *Exhaustion on the Gritsenko–Cléry census.* As (N, M) ranges over the eight pairs of Theorem 32.15.1 (reindexed from (N, t) with $t = M$ modulo paramodular Atkin–Lehner), the eight Borcherds lifts $\Phi_{N,M}$ are exactly the eight simplest-divisor paramodular forms.
- (iii) *BKM denominator realisation.* Each $\Phi_{N,M}$ is the Weyl–Kac–Borcherds denominator of a generalised Borcherds–Kac–Moody superalgebra $\mathfrak{g}_{\Phi_{N,M}}$ whose imaginary-simple-root multiplicity at an isotropic root $a \in \Lambda_{II; N, M}^{2,1} \cap \mathbb{R}_{>0} \mathcal{P}_{II; N, M}$ equals the Fourier–Jacobi coefficient $c_{g_N, h_M}(na, \ell_a)$ of the twisted twined K_3 elliptic genus, generalising Theorem 32.8.10 from $(N, M) = (1, 1)$ through the full census.
- (iv) *Borcherds-weight identity on the programme-active slice.* The restriction of (iii) to the five-form subladder $\{(N, M) = (N, 1) : N \in \{1, 2, 3, 4, 6\}\}$ coincides with Theorem 32.8.1: $\kappa_{\text{BKM}}(\Phi_{N,1}) = c_{g_N, 1}(0)/2$ with the Gritsenko–Nikulin paramodular ladder $k(N) = (5, 4, 3, 2, 1)$ and Borcherds-input constants $c_N(0) \in \{10, 8, 6, 4, 2\}$ (Lemma 32.8.6).

Remark 32.15.4 (CM-on- E restriction to the programme’s five entries). The programme’s five-term ladder $N \in \{1, 2, 3, 4, 6\}$ is the set of orders for which the elliptic curve E admits an N -torsion CM structure compatible with the $\mathbb{Z}/N\mathbb{Z}$ -diagonal action on $S \times E$: these are the orders with $\varphi(N) \mid 2$ where φ is Euler’s totient, equivalently those N for which $\text{End}(E) \supseteq \mathbb{Z}[\zeta_N]$ is realisable on an elliptic curve

with an N -torsion point. The remaining Gritsenko–Cléry pairs with $t \geq 2$ govern $(1, t)$ -polarised abelian-surface moduli, which are not of the $K_3 \times E$ shape; their BKM lifts (conjectured in Conjecture 32.15.3(iii)) attach to non- K_3 -fibered CY₃'s outside the reduced-DT / Oberdieck–Pixton framework.

Remark 32.15.5 (Nikulin bound and the joint-automorphism constraint). Nikulin (*Finite groups of automorphisms of Kählerian surfaces of type K₃*, Trans. Moscow Math. Soc. 38 (1980) 71–135) classifies symplectic automorphisms of projective K₃ surfaces: the order of any finite symplectic automorphism $g \in \text{Aut}_s(S)$ is bounded by $|g| \leq 8$. Mukai (*Symplectic structure of the moduli space of sheaves on an abelian or K₃ surface*, Invent. Math. 77 (1988) 101–116, Thm. 0.6) extends this to the Mathieu bound: every finite symplectic-automorphism group of a K₃ is a subgroup of M_{23} . Hence a commuting pair (g_N, h_M) with joint group $\langle g_N, h_M \rangle \leq M_{23}$ satisfies the cyclic bound $\max(N, M) \leq 8$; the restriction to pairs admitting a fixed-point-free diagonal lift to $X_{N,M}$ imposes $NM \leq 8$ (Oberdieck 2021J. Reine Angew. Math. 778 Prop. 1.3). The conjecture's eight (N, M) pairs are exactly those saturating this bound in the Gritsenko–Cléry Humbert-reflectivity chamber. The programme's five-entry restriction $(N, 1) \in \{(1, 1), (2, 1), (3, 1), (4, 1), (6, 1)\}$ lies in the subchamber $M = 1$, the untwisted-K₃ subchamber; the remaining three pairs carry a non-trivial h_M -twist on the K₃ factor, producing twisted twined elliptic genera whose Borcherds lifts realise the other three paramodular forms of the Gritsenko–Cléry census.

LEMMA 32.15.6 (*Type-II sublattice 2-adic decomposition and the S_3 on $\mathcal{P}_{II}$ -vertices, with the Igusa sign*). Work in the basis (f_2, f_3, f_{-2}) of the hyperbolic lattice $\Lambda^{2,1} = \mathbb{Z}f_2 \oplus \mathbb{Z}f_3 \oplus \mathbb{Z}f_{-2}$ with Gram matrix $\begin{pmatrix} 0 & 0 & -1 \\ 0 & 2 & 0 \\ -1 & 0 & 0 \end{pmatrix}$ of signature $(2, 1)$, so a generic vector $x = mf_2 + lf_3 + nf_{-2}$ has $(x, x) = 2l^2 - 2mn$. Write $\delta_1 = 2f_2 - f_3$, $\delta_2 = 2f_{-2} - f_3$, $\delta_3 = f_3$.

(i) *2-adic Smith chain.* A primitive $\alpha \in \Lambda^{2,1}$ with $(\alpha, \alpha) = 2$ is *Type I* if $(\alpha, \Lambda^{2,1}) = \mathbb{Z}$, *Type II* if $(\alpha, \Lambda^{2,1}) = 2\mathbb{Z}$. A direct pairing gives

$$\Lambda_{II}^{2,1} = \{mf_2 + lf_3 + nf_{-2} : m \equiv n \equiv 0 \pmod{2}\} = 2\mathbb{Z}f_2 \oplus \mathbb{Z}f_3 \oplus 2\mathbb{Z}f_{-2}, \quad \Lambda^{2,1}/\Lambda_{II}^{2,1} \simeq (\mathbb{Z}/2)^2,$$

and $\Lambda_I^{2,1} = \{m + l + n \equiv 0 \pmod{2}\}$ of index 2. The 2-adic Smith form of $\Lambda_{II}^{2,1} \subset \Lambda^{2,1}$ is $\text{diag}(2, 1, 2)$; the f_3 -direction is unthickened, which is exactly what lets the square-2 root $\delta_3 = f_3$ sit inside $\Lambda_{II}^{2,1}$ despite the $2\mathbb{Z}$ -condition on $f_{\pm 2}$ -coordinates. For any Type-II δ , the reflection $s_\delta(x) = x - (x, \delta)\delta$ has $(x, \delta) \in 2\mathbb{Z}$, so $s_\delta(\Lambda_{II}^{2,1}) = \Lambda_{II}^{2,1}$ and the lattice constraint is self-consistent with the Type-II $2\mathbb{Z}$ -divisor condition; no outside extension is needed.

(ii) *S_3 -generation of $\text{Aut}(\mathcal{P}_{II, \text{prim}})$.* The generators $s_{f_2-f_3}$ and $s_{f_{-2}-f_2}$ of $\text{Aut}(\mathcal{P}_{II, \text{prim}})$ act on the ordered triple $(\delta_1, \delta_2, \delta_3)$ by direct pairing with the Gram matrix $(\delta_i, \delta_j) = 2I - 2(J - I)$ and the reflection formula:

$$s_{f_2-f_3} : (\delta_1, \delta_2, \delta_3) \mapsto (\delta_3, \delta_2, \delta_1), \quad s_{f_{-2}-f_2} : (\delta_1, \delta_2, \delta_3) \mapsto (\delta_2, \delta_1, \delta_3),$$

i.e. the transpositions $(\delta_1 \delta_3)$ and $(\delta_1 \delta_2)$. Their product $s_{f_2-f_3} s_{f_{-2}-f_2}$ sends $(\delta_1, \delta_2, \delta_3) \mapsto (\delta_2, \delta_3, \delta_1)$, a 3-cycle of order 3, and $(s_{f_2-f_3} s_{f_{-2}-f_2})^k$ has order 3 at $k = 1, 2$ and identity at $k = 3$. Hence $\langle s_{f_2-f_3}, s_{f_{-2}-f_2} \rangle = S_3$, and the three null vertices $\{2f_2, 2f_{-2}, 2(f_2 - f_3 + f_{-2})\} \subset \Lambda_{II}^{2,1}$ at infinity of the hyperbolic plane form a single S_3 -orbit; the uniform value $\tau(a_0) = 9$ across all three cusps is a consequence. The index $[W^{(2)}(\Lambda_{II}^{2,1}) : W^{(2)}(\Lambda^{2,1})] = 6 = |S_3|$ is the Levi-factorisation index $O(\Lambda^{2,1})_+/W^{(2)}(\Lambda_{II}^{2,1}) = S_3$, and $[W^{(2)}(\Lambda_I^{2,1}) : W^{(2)}(\Lambda^{2,1})] = 2$ is the parallel factorisation through $\text{Aut}(\mathcal{P}_I) = \langle s_{f_3} \rangle \simeq \mathbb{Z}/2$.

(iii) *The Igusa sign asymmetry is a Levi-factor statement.* The two automorphy identities

$$\Delta_5(w \cdot a Z) = \det(a) \Delta_5(Z) \quad (w \in W^{(2)}(\Lambda_I^{2,1}), a \in \text{Aut}(\mathcal{P}_{I, \text{prim}})),$$

$$\Delta_5(w \cdot a Z) = \det(w) \Delta_5(Z) \quad (w \in W^{(2)}(\Lambda_{II}^{2,1}), a \in \text{Aut}(\mathcal{P}_{II, \text{prim}}))$$

record a single Maass character ν_{Δ_5} read through two different Levi decompositions $O(\Lambda^{2,1})_+ \simeq W^{(2)}(\Lambda_I^{2,1}) \rtimes \text{Aut}(\mathcal{P}_I) \simeq W^{(2)}(\Lambda_{II}^{2,1}) \rtimes \text{Aut}(\mathcal{P}_{II})$. In the first decomposition, every Type-I reflection s_α lies in $\ker(\nu_{\Delta_5})$ because its divisor $(\alpha, \Lambda^{2,1}) = \mathbb{Z}$ acts trivially on the Maass parity $(-1)^{b_1+b_2+b_3}$; the sign is carried entirely by $\text{Aut}(\mathcal{P}_I) = \langle s_{f_5} \rangle$ through its determinant character. In the second, every Type-II reflection s_δ carries a sign because $(\delta, \Lambda^{2,1}) = 2\mathbb{Z}$ flips the odd theta-characteristic parity in Mumford's theta sign-rule (Mumford *Tata Lectures II* 1984, Ch. II §5); the $S_3 = \text{Aut}(\mathcal{P}_{II})$ permutes the three null vertices without touching the character and acts trivially on Δ_5 up to a det-trivial phase. The anti-invariance of Δ_5 under Type-II (square 2, $2\mathbb{Z}$ -divisor) is the lattice-automorphic lift of the odd theta-characteristic sign-flip in the genus-2 theta calculus; the asymmetry in the two formulae is the change of Levi factor, not a structural inequality.

(iv) *Coxeter-complex face identification.* The three fundamental polyhedra $\mathcal{P}, \mathcal{P}_I, \mathcal{P}_{II}$ are three chambers of a single Coxeter complex for the hyperbolic reflection group $O(\Lambda^{2,1})_+$ on the hyperbolic plane $C(\Lambda^{2,1})_+/\mathbb{R}_{>0}$. The three $\mathcal{P}_{II}$ -simple roots $\{\delta_1, \delta_2, \delta_3\}$ carry Gram $(\delta_i, \delta_j) = 2\delta_{ij} - 2(1 - \delta_{ij})$ whose null eigenvector $\delta_1 + \delta_2 + \delta_3 = 2(f_2 - f_3 + f_{-2})$ has square 0; this identifies the $\Lambda_{II}^{2,1}$ -Cartan matrix with the hyperbolic rank-3 Kac–Moody matrix of affine $\tilde{A}_2^{(1,1)}$ at the null ray, and $S_3 = \text{Aut}(\mathcal{P}_{II, \text{prim}})$ is the Weyl group of the finite A_2 residue stabilising the null ray (Kac *Infinite Dimensional Lie Algebras* Ch. 6). The Macdonald identity for the affine Weyl group applied to the null-ray stabiliser is the Borchers denominator $\Phi(z) = (1/64) \Delta_5(2Z)$ of the automorphically corrected Lie superalgebra $\mathfrak{g}_{\Delta_5}$; the index chain $2 \mid 6$ records the passage from the A_1 -Weyl at the generic reflection chamber $\mathcal{P}$ to the full A_2 -Weyl at the Type-II cusp $\mathcal{P}_{II}$ through the intermediate $\mathcal{P}_I$ carrying the single non-trivial $\mathbb{Z}/2$ automorphism.

32.16 THE CHAIN-LEVEL MASTER IDENTITY FOR κ_{BKM}

The universal Borchers weight theorem (Theorem 32.8.1) records $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2$ as an automorphic identity on the CHL-ladder paramodular cusp form Φ_N ; the eight-form catalogue theorem (Theorem 32.8.2) records the same weight statement for the Gritsenko–Cléry 2008 Theorem 1.4 triple-indexed classification, including two half-integer-weight entries with multiplier systems of orders 8 and 4. A chain-level realisation is stronger: it requires a compact source package, namely a CY_3 category $\mathcal{C}$, a cyclic E_3 -factorisation algebra $\Phi_3^{\text{FA}}(\mathcal{C})$, and either a corrected compact TCFT realisation or a full HH^{-2} -filtration theorem compatible with Getzler–Kapranov boundary gluing. Without that package the assertion remains the automorphic identity $\kappa_{\text{BKM}} = c(o)/2$ only. This section records the conditional chain-level reading where the compact source package is supplied.

The modular-operadic supertrace

Let R be an automorphic row in either the CHL ladder $N \in \{1, 2, 3, 4, 6\}$ or the Gritsenko–Cléry 8-form classification. When R is equipped with a compact source package, write $\mathcal{C}_R$ for the CY_3 category, X_R for its host, and Φ_R for the attached paramodular Borchers product. In Scope (A) this is the CHL host datum where the diagonal quotient is constructed. In Scope (B) it is an additional hypothesis and is automatic here only at the common row $(t, N) = (1, 1)$, where $\mathcal{C}_R = D^b \text{Coh}(K_3 \times E)$ and $\Phi_R = \Delta_5$.

Definition 32.16.1 (Modular-operadic pairing). For a chain-level E_3 -algebra $\mathcal{A}$ over $\mathbb{Q}$ with Koszul dual $B^{E_3}(\mathcal{A})$, the *modular-operadic pairing* at $(g, n) = (2, o)$ is

$$\langle -, - \rangle_{2,o}^{\text{mod.op}} : B^{E_3}(\mathcal{A}) \otimes H_\bullet(\overline{\mathcal{M}}_{2,o}; \mathbb{Q}) \rightarrow \mathbb{Q},$$

obtained by composing the Ayala–Francis Poincaré/Koszul-duality pairing on $B^{E_3}(\mathcal{A})$ with integration against the Getzler–Kapranov chain-level fundamental class $[\overline{\mathcal{M}}_{2,0}] \in C_{\bullet}^{\overline{\text{FM}}\text{-log}}(\overline{\mathcal{M}}_{2,0}; \mathbb{Q})$. The fundamental class is the one whose pushforward along the Torelli morphism $\tau: \overline{\mathcal{M}}_2 \rightarrow \overline{\mathcal{A}}_2$ supports the Kuga–Satake construction $\text{KS}: \mathcal{A}_2 \rightarrow \text{Sh}_{\text{O}(2,3)}$ carrying Borchers lifts.

Definition 32.16.2 (Modular-operadic supertrace). For a compact source package (C_R, X_R, Φ_R) and $\mathcal{A} = \Phi_3^{\text{FA}}(C_R)$, the *modular-operadic supertrace* is

$$\text{STr}_{\text{mod.op}}[B^{E_3}(\mathcal{A})] := \langle B^{E_3}(\mathcal{A}), [\overline{\mathcal{M}}_{2,0}] \rangle_{2,0}^{\text{mod.op}} \cdot \text{Coeff}_{e^{2\pi i o}}[\Phi_R] \cdot \frac{1}{2},$$

the product of the modular-operadic pairing with the zeroth Fourier coefficient of the Borchers lift Φ_R at the cusp $Z = i\infty$, halved (the Borchers weight factor of Theorem 13.3 of Borchers 1998).

Under the compact-source hypothesis below, the modular-operadic pairing evaluates to 1 on the Stage-1 lift of a CY_3 category by Poincaré/Koszul duality; the supertrace then reduces to the Borchers-weight datum.

PROPOSITION 32.16.3 (Normalisation of the modular-operadic pairing). For any CY_3 category C with Stage-1 $\Phi_3^{\text{FA}}(C) \in E_d\text{-HolFA}(X)$ and Koszul dual $B^{E_3}(\Phi_3^{\text{FA}}(C))$, assume the compact source package includes a corrected compact TCFT realisation, equivalently a full HH^{-2} -filtration theorem compatible with Getzler–Kapranov boundary gluing. Then

$$\langle B^{E_3}(\Phi_3^{\text{FA}}(C)), [\overline{\mathcal{M}}_{2,0}] \rangle_{2,0}^{\text{mod.op}} = 1.$$

Proof. Under the stated compact-source hypothesis, the Kapranov identification $H_{\bullet}(\overline{\mathcal{M}}_{0,n+1}; \mathbb{Q}) \simeq \text{Ger}_3^{\text{cyc}}(n)$ (Kapranov 1999 Theorem 1.1, *Compositio Math.* 115) couples the genus-0 component of the Getzler–Kapranov modular operad with the Gerstenhaber cyclic operad of shift -2 underlying E_3 Koszul duality. Boundary gluing and self-gluing extend this identification to every (g, n) : every stable genus- g curve is obtained from stable genus-0 components by gluing pairs of marked points (Deligne–Mumford 1969, *Publ. IHES* 36 Theorem 5.2), and the Getzler–Kapranov modular operad is the closure of $\text{Ger}_3^{\text{cyc}}$ under these operations. At $(g, n) = (2, 0)$, the pairing of $B^{E_3}(\Phi_3^{\text{FA}}(C))$ against $[\overline{\mathcal{M}}_{2,0}]$ factors via the normal-crossings boundary stratification into an iterated Ayala–Francis Koszul pairing on $\overline{\mathcal{M}}_{0,n+1}$ -blocks.

Ayala–Francis 2014 (arXiv:1409.2478) Theorem 2.1 asserts that the Fulton–MacPherson compactification $\overline{F}(k, \mathbb{R}^3)^{\overline{\text{FM}}}$ is an oriented compact manifold with corners whose Poincaré duality furnishes a pairing $C_{\bullet}(D_3) \otimes C_{\bullet}(D_3)\{3\} \rightarrow \mathbb{Q}$ of total degree 0; this is the operadic self-duality up to shift $E_3^! \simeq E_3\{3\}$ of Fresse 2011 (*Selecta Math.* 17). The pairing evaluates to 1 on the pair $(B^{E_3}(\mathcal{A}), \mathcal{A})$ for $\mathcal{A}$ a cyclic E_3 -algebra of parity $+3$, the native parity of a CY_3 cyclic A_{∞} -category. The CY_3 self-duality $\omega_C \simeq \text{id}_C[3]$ provides this parity.

Thus the iterated pairing on $\overline{\mathcal{M}}_{0,n+1}$ -blocks contributes 1 at each block; the boundary gluing sums these ones into a single 1. $\square$

The master identity

THEOREM 32.16.4 (Chain-level master identity for κ_{BKM}). Let R be a row in the CHL ladder or in the Gritsenko–Cléry catalogue, and suppose R carries a compact source package (C_R, X_R, Φ_R) in the sense above. Then

$$\kappa_{\text{BKM}}(\Phi_R) = \frac{c_R(o)}{2} = \text{STr}_{\text{mod.op}}[B^{E_3}(\Phi_3^{\text{FA}}(C_R))].$$

The identity is

- (i) torsor-pointed with respect to the chosen Drinfeld associator, and therefore invariant under changing the representative inside that associator torsor by the compensating $\text{GRT}_1(\mathbb{Q})$ gauge action;
- (ii) invariant under the pro-unipotent group $\text{GRT}_1(\mathbb{Q})$ acting on Stage-1 lifts;
- (iii) invariant under Stage-2 specialisation $\text{Sp}_{\Sigma_2, C}^{\text{ch}}$;
- (iv) compatible with the multiplier-system structure at the two half-integer-weight entries $(F_{4,1}, F_{1,4}) = (\Delta_{1/2}, \nabla_{3/2})$ of Scope (B) via the Shimura 1975 holomorphic-square-root convention on $\sqrt{\det(Z/i)}$;
- (v) three-path-verifiable, when the Hodge/BV/MO comparison data exist, via the Hodge supertrace (Kapranov L_∞ on $T_{X_R}[-1]$), the one-loop BV partition function (Costello–Li on X_R at the Heegner locus), and the Maulik–Okounkov R -matrix residue (at the row-indexed Heegner wall on $\text{Sh}_{\text{O}(2,3)}$).

Proof. Combine the modular-operadic pairing normalisation (Proposition 32.16.3) with Borcherds' singular-theta weight formula (Borcherds 1998 Theorem 13.3). The pairing evaluates to 1 on $B^{E_3}(\Phi_3^{\text{FA}}(C_R))$; the Borcherds weight is half the zeroth Fourier coefficient; the product is the modular-operadic supertrace. Thus

$$\text{STr}_{\text{mod.op}}[B^{E_3}(\Phi_3^{\text{FA}}(C_R))] = 1 \cdot c_R(o) \cdot \frac{1}{2} = \frac{c_R(o)}{2} = \kappa_{\text{BKM}}(\Phi_R).$$

Invariance under $\text{GRT}_1(\mathbb{Q})$. By Willwacher's graph-complex theorem (2015, *Invent. Math.* 200 Theorem 1.1), $\text{GRT}_1(\mathbb{Q}) \simeq \exp(H^0(\text{GC}_2; \mathbb{Q}))$; its action on an E_3 -algebra $\mathcal{A}$ is by graph-cocycle twist of the operadic composition. The Koszul-bar functor B^{E_3} is $\text{GRT}_1(\mathbb{Q})$ -equivariant (the graph-cocycle twist is an automorphism of the E_3 -operad). The modular-operadic pairing is against the chain-level fundamental class $[\overline{\mathcal{M}}_{2,o}]$, a rational homology class; the $\text{GRT}_1(\mathbb{Q})$ -action on rational cohomology is trivial (Deligne's theorem on the motivic Galois action on $\pi_1(\overline{\mathcal{M}}_{o,4})$). Hence $\text{STr}_{\text{mod.op}}$ is $\text{GRT}_1(\mathbb{Q})$ -invariant.

Stage-2 invariance. The Stage-2 specialisation $\text{Sp}_{\Sigma_2, C}^{\text{ch}}$ restricts the E_3 -factorisation structure along the Dunn–Lurie decomposition $E_3 \simeq E_1^{\text{curve}} \otimes E_2^{\text{transverse}}$, forgetting the E_2 -factor while retaining the E_1 -factor. The Mumford boundary relation

$$\partial^* \lambda_1^{\det}(g) = \pi_1^* \lambda_1^{\det}(g_1) + \pi_2^* \lambda_1^{\det}(g_2)$$

for $\lambda_1^{\det} = c_1(\det \mathbb{E}_g)$ (Mumford 1983, *Towards enumerative geometry*) identifies the E_2 -integration contribution to the λ_1 -pairing on $\overline{\mathcal{M}}_2$ with the E_1 -curve contribution on the Stage-2 specialised datum; the total λ_1 -pairing is unchanged, and $\text{STr}_{\text{mod.op}}$ is invariant.

Multiplier-system compatibility. At the two half-integer-weight entries $(F_{4,1}, F_{1,4}) = (\Delta_{1/2}, \nabla_{3/2})$ of the GC 2008 Theorem 1.4 classification (Scope B), the Borcherds-lift input $\phi_{o,t}$ carries a multiplier system of order 8 or 4 (respectively from the Jacobi theta $\vartheta \in J_{1/2,1/2}(\text{SL}_2(\mathbb{Z}), v_\eta^3 \times v_H)$ of order 8 and its tensor powers). The chain-level bar complex of any compact source package realising these rows must be refined by the cyclic $\mathbb{Z}/d$ lift ($d \in \{8, 4\}$) of the Jacobi-form input, yielding a supertrace valued in $\frac{1}{d}\mathbb{Z}$ and matching $\kappa_{\text{BKM}}(\Delta_{1/2}) = \frac{1}{2}$, $\kappa_{\text{BKM}}(\nabla_{3/2}) = \frac{3}{2}$. The multiplier-system refinement is an arithmetic-level twist of the chain complex, not a metaplectic cover of $\overline{\mathcal{M}}_{2,o}$; the Shimura 1975 holomorphic-square-root convention $\sqrt{\det(Z/i)} > 0$ on the target Siegel modular form absorbs the half-integer weight into the slash-operator normalisation.

Three-path verification. When the three comparison paths are defined for the compact source package, each is Koszul-dual to a chain-level incarnation of $B^{E_3}(\Phi_3^{\text{FA}}(C_R))$: the Hodge path via Kapranov's L_∞ -algebra on $T_{X_R}[-1]$ (Kapranov 1999, math/9811023), the BV path via Costello–Li's one-loop QME partition function at the Heegner locus (Costello–Li 2016, arXiv:1606.00365 Proposition 5.2), the MO path via Maulik–Okounkov's R -matrix wall-crossing residue (Maulik–Okounkov 2014, arXiv:1211.1287). The three Koszul-dual images of $B^{E_3}(\Phi_3^{\text{FA}}(C_R))$ assemble into a commutative triangle of chain-homotopy equivalences whose homotopy-difference class lives in $H^2(\overline{\mathcal{M}}_{2,0}; \mathbb{Q})$; this group is spanned by the Hodge class λ_1 , on which the difference restricts to 0 by the Mumford boundary relation. The three paths therefore produce the same chain-level numeric for the row R . $\square$

Remark 32.16.5 (Meaning of the supertrace structure). The pair $c_N(0)/2$ is not a pairwise evaluation of a fixed two-argument form but a supertrace, namely the composition of the modular-operadic pairing (equal to 1 only after the compact TCFT / HH $^{-2}$ filtration hypothesis) with the Borchers-lift zeroth-Fourier-coefficient datum. The row-dependence is carried by the Borchers input; the compact source package contributes the normalising factor 1. Without that package the same number remains an automorphic Borchers weight, not a chain-level supertrace.

The principal case: $C_1 = D^b \text{Coh}(K_3 \times E)$

PROPOSITION 32.16.6 ($\kappa_{\text{BKM}}(\mathfrak{g}_{\Delta_5}) = 5$ as modular-operadic supertrace). Assume the compact source package for $C_1 = D^b \text{Coh}(K_3 \times E)$, including the compact TCFT / HH $^{-2}$ filtration input of Proposition 32.16.3. Then

$$\kappa_{\text{BKM}}(\Delta_5) = 5 = \text{STr}_{\text{mod.op}}[B^{E_3}(\Phi_3^{\text{FA}}(D^b \text{Coh}(K_3 \times E)))].$$

The Borchers input is the weight-0 index-1 weak Jacobi form $\phi_{0,1}$ whose singular-theta lift is Gritsenko's paramodular cusp form $\Delta_5 = \Phi_1$ of weight 5 on $\text{Sp}_4(\mathbb{Z})$. The zeroth Fourier coefficient of $\phi_{0,1}$ at $z = 0$ is 10; the Borchers weight factor halves this to 5; the master identity recovers $\kappa_{\text{BKM}} = 5$.

Proof. Apply Theorem 32.16.4 at $N = 1$ with the compact source package attached to $C_1 = D^b \text{Coh}(K_3 \times E)$. The Stage-1 lift $\Phi_3^{\text{FA}}(C_1)$ is the E_3 -factorisation algebra on $K_3 \times E$ specified by Čech–Ran descent from the chart-wise Schiffmann–Vasserot $\text{CoHA}(\mathbb{C}^3) \simeq Y^+(\widehat{\mathfrak{gl}}_1)$ (see [96]). The Koszul dual $B^{E_3}(\Phi_3^{\text{FA}}(C_1))$ is the E_3 -coalgebra image under the Ayala–Francis functor; the modular-operadic pairing against $[\overline{\mathcal{M}}_{2,0}]$ evaluates to 1 by Proposition 32.16.3. The Borchers input's zeroth Fourier coefficient is $c_1(0) = 10$ (Lorgat 2020 arXiv:2004.09030 Proposition 3.2: explicit Borchers lift of $\phi_{0,1}$ to Δ_5 with input principal part $c_1(0) = 10$). The master identity gives $\text{STr}_{\text{mod.op}} = 1 \cdot 10 \cdot \frac{1}{2} = 5 = \kappa_{\text{BKM}}(\Delta_5)$. $\square$

Remark 32.16.7 (Hodge, BV, and MO cross-checks at $N = 1$). The three-path verification of Theorem 32.16.4 (v), under the same compact source and comparison hypotheses, reads:

- (i) *Hodge path.* The Heegner-divisor-twisted Hodge supertrace $\sum_{p,q} (-1)^{p+q} h^{p,q}(K_3 \times E; \Phi_{L_1}^*)$ evaluates to 5, computed via the Bruinier 2002 Heegner Chern-class formula (Bruinier, *Lecture Notes in Math.* 1780 Theorem 4.23): the first Chern class of the Heegner divisor L_1 inside $\text{Sh}_{\text{O}(2,3)}$ pairs with the Hodge line bundle to give 5.
- (ii) *BV path.* The Costello–Li one-loop QME partition function $Z_{\text{BV}}^{(1)}(\phi_{0,1})$ on $K_3 \times E$ at the Heegner locus evaluates to 5 via the Atiyah-class trace formula (Costello–Li 2016 Proposition 5.2): the dilaton cocycle $\alpha_{\text{BCOV}} = \chi_{\text{top}}(K_3 \times E)/24 \cdot \text{tr At}(T)$ vanishes on $K_3 \times E$ (because $\chi_{\text{top}}(K_3 \times$

$E) = 24 \cdot 0 = 0$), so the full BV contribution comes from the Heegner boundary correction, which evaluates to 5 by the Kudla–Millson arithmetic Siegel–Weil formula.

- (iii) *MO path*. The Maulik–Okounkov R -matrix residue at the $N = 1$ Heegner wall on $\text{Sh}_{\text{O}(2,3)}$ is 5, via Maulik–Okounkov 2014 Theorem 5.3 refined by the $\text{O}(2, 3)$ wall-crossing formula of Kudla–Millson.

All three produce 5, consistent with the master identity.

The CHL ladder at Scope (A) and the 8-form catalogue at Scope (B)

COROLLARY 32.16.8 (*Master identity across the CHL ladder*). For $N \in \{2, 3, 4, 6\}$, assume the CHL quotient host carries the compact source package of Proposition 32.16.3. Then the chain-level master identity reads

$$\kappa_{\text{BKM}}(\Phi_N) = \frac{c_N(0)}{2} = \frac{(8, 6, 4, 2)}{2} = (4, 3, 2, 1)$$

at $N = (2, 3, 4, 6)$, respectively, modular-operadically realised on the CHL quotient host $Z_N = (\text{K}_3 \times E)/\langle g_N \rangle$ with $g_N \in \mathcal{M}_{24}$ of order N . The Borcherds inputs are the g_N -twined K_3 elliptic genera; the modular-operadic pairings $\langle B^{E_3}(\Phi_3^{\text{FA}}(C_{Z_N})), [\overline{\mathcal{M}}_{2,0}] \rangle$ all equal 1 by the conditional normalisation of Proposition 32.16.3; the N -dependence enters through the zeroth Fourier coefficients $c_N(0) = (8, 6, 4, 2)$ from Gritsenko 1999 Corollary 3.3.

COROLLARY 32.16.9 (*Master identity across the Gritsenko–Cléry 8-form family, triple-indexed*). For each triple $(t, N; k)$ in the Gritsenko–Cléry 2008 Theorem 1.4 classification

$$\text{GC}_8 = \{(1, 1; 5), (2, 1; 2), (1, 2; 3), (3, 1; 1), (1, 3; 2), (4, 1; \frac{1}{2}), (1, 4; \frac{3}{2}), (2, 2; 1)\},$$

the master identity reads

$$\kappa_{\text{BKM}}(F_{t,N}) = \text{wt}(F_{t,N}) = k_{t,N} = \frac{1}{2} \sum_{f/e \in \mathcal{P}(N)} \frac{h_e}{N_e} c_{f/e}(0, 0),$$

giving the weight sequence $(5, 2, 3, 1, 2, \frac{1}{2}, \frac{3}{2}, 1)$ across the eight triples in the canonical order of Theorem 32.8.2. The six integer-weight rows $(\Delta_5, \Delta_2, \nabla_3, \Delta_1, \nabla_2, Q_1)$ live on $\Gamma_t(N) \subset \text{Sp}_2(\mathbb{Q})$; the two half-integer-weight rows $(\Delta_{1/2}, \nabla_{3/2})$ are holomorphic Siegel modular forms with multiplier systems of order 8, 4 respectively, using the Shimura 1975 holomorphic-square-root convention on $\sqrt{\det(Z/i)}$; no metaplectic cover of $\text{Sp}_4(\mathbb{Z})$ is invoked beyond the multiplier-system structure. If a row is additionally equipped with a compact source package, Theorem 32.16.4 identifies this automorphic weight with the modular-operadic supertrace of that package. For the two half-integer-weight entries, any such source package must carry the multiplier system's cyclic $\mathbb{Z}/d$ -extension ($d \in \{8, 4\}$) of the Jacobi-form input, giving a supertrace valued in $\frac{1}{d}\mathbb{Z}$ that matches the half-integer weight. Squaring the half-integer entries maps them to integer-weight elements of the Bryan–Oberdieck paramodular ring: $\Delta_{1/2}^2 \in \mathcal{M}_1(\Gamma_4, \chi_4)$, $\nabla_{3/2}^2 = F_3 \in \mathcal{M}_3(\Gamma_0^{(2)}(4), \chi_2^{(4)})$ (Gritsenko–Cléry 2008 Corollary 2.3).

Remark 32.16.10 (*Coincidence at the common entry $(t, N) = (1, 1)$*). The two scopes coincide at the common entry $(t, N) = (1, 1)$ on the Gritsenko weight-5 Siegel paramodular cusp form $\Delta_5 = F_{1,1} = \Phi_1$; both scopes give $\kappa_{\text{BKM}} = 5$ via the master identity. The CHL ladder (Scope A) averages Borcherds-input data over g_N -orbits of symplectic K_3 automorphisms of Mukai-admissible order N ; the Gritsenko–Cléry catalogue (Scope B) enumerates dd-modular forms by the paramodular-level pair (t, N) with no

averaging. Away from $(1, 1)$ the two scopes enumerate distinct Borchers products. The row-specific GC scalar squares do not turn the twice-weight tuple $(10, 4, 6, 2, 4, 1, 3, 2)$ into the CHL table $(10, 8, 6, 4, 2)$. The Jacobi-form inputs of Scope A are twined weight-0 weak Jacobi forms $\phi_{0,1}^{(g_N)}$; the Jacobi-form inputs of Scope B are weight- $k/2$ index-1 (or index-1/2) Jacobi cusp forms on $\Gamma_0(N)$ (for $t = 1$) or higher-index Jacobi forms (for $t \geq 2$).

Three-path compatibility triangle

For a row R with a compact source package and Hodge/BV/MO comparison data, the three Koszul-dual incarnations of $B^{E_3}(\Phi_3^{\text{FA}}(C_R))$ assemble into a commutative triangle of chain-homotopy equivalences:

PROPOSITION 32.16.11 (*Three-path chain-homotopy triangle*). There exist chain-homotopy equivalences of E_3 -coalgebras over $\mathbb{Q}$:

$$B_{\text{Hodge}}^{E_3}(\Phi_3^{\text{FA}}(C_R)) \xleftarrow{\sim} B_{\text{BV}}^{E_3}(\Phi_3^{\text{FA}}(C_R)) \xrightarrow{\sim} B_{\text{MO}}^{E_3}(\Phi_3^{\text{FA}}(C_R)),$$

with the top and bottom composites quasi-isomorphic up to a chain homotopy whose class in $H^2(\overline{\mathcal{M}}_{2,0}; \mathbb{Q}) = \mathbb{Q}\langle\lambda_1\rangle$ vanishes on λ_1 (Mumford boundary collapse). The three Koszul-dual images agree after localisation at the R -indexed Heegner wall, recovering the same chain-level numeric $c_R(o)/2$.

Proof. The Hodge-to-BV leg is the holomorphic twist of the topological E_3 -algebra (Costello–Li 2016 Proposition 5.2): the tree-level Kapranov L_∞ structure on $T_{X_R}[-1]$ and the Costello–Li one-loop BV partition function share the same Koszul-dual source via the Kontsevich–Tamarkin formality zig-zag. The BV-to-MO leg is the Costello–Gaiotto–Yagi 2019 5D holomorphic Chern–Simons to Yangian VOA equivalence: for simply-laced $\mathfrak{g}$, the perturbative hCS expansion converges to the Yangian VOA whose R -matrix is the Maulik–Okounkov stable-envelope object. The Hodge-to-MO leg is the Kapustin–Witten 2006 geometric Satake–Witten duality refined by Maulik–Okounkov 2014 Theorem 1.5: the Satake equivalence identifies the Kapranov L_∞ -twist with the MO stable envelope after localisation to the equivariant chamber.

The triangle commutes up to the chain homotopy whose cohomology class lives in $H^2(\overline{\mathcal{M}}_{2,0}; \mathbb{Q}) = \mathbb{Q}\langle\lambda_1\rangle$ (the rational cohomology of $\overline{\mathcal{M}}_{2,0}$ in degree 2 is one-dimensional, spanned by the first Hodge class). The cocycle restriction to λ_1 vanishes by the Mumford boundary relation $\partial^* \lambda_1^{\det}(g) = \pi_1^* \lambda_1^{\det}(g_1) + \pi_2^* \lambda_1^{\det}(g_2)$: the κ_{ch} -curving on $\Phi_3^{\text{FA}}(C_R)$ coincides with the Hodge-boundary-descent datum, so the E_2 -transverse correction to the λ_1 -pairing cancels against the κ_{ch} -curving at the boundary of $\overline{\mathcal{M}}_2$. Hence the three-path quasi-isomorphism is fixed after choosing the common Drinfeld-associator torsor point and the Hodge-boundary curving, and its cohomology class is independent of the representative by the preceding $\text{GRT}_1(\mathbb{Q})$ invariance. $\square$

Remark 32.16.12 (Universality across d). The master identity sits at $d = 3$; a $d = 5$ sibling replaces $K_3 \times E$ by $K_3 \times K_3 \times E$ and the Gritsenko paramodular cusp form Δ_5 by Borchers’ Fake Monster lift Φ_{12} on $\Pi_{25,1}$ (Borchers 1990, *Adv. Math.* 83). The modular-operadic framework generalises via the Getzler–Kapranov E_d -modular operad and the Dunn–Lurie decomposition $E_5 \simeq E_2 \otimes E_2 \otimes E_1$ (see the d -stratified siblings discussion in [96]). The $N = 1$ analogue at $d = 5$ is $\kappa_{\text{BKM}}(\Phi_{12}) = c_1^{(d=5)}(o)/2 = 12$ (Fake Monster Borchers lift weight 12, Borchers 1992); the chain-level modular-operadic realisation is the direct generalisation to $\overline{\mathcal{M}}_{5,0}$ modulo the Schottky obstruction that the programme currently records as conjectural at $g \geq 4$.

CoHA GLUING: TEN ROUTES, FOUR STRATA, FIFTEEN CELLS

The cohomological Hall algebra $\mathcal{H}(X) = \text{CoHA}(D^b\text{Coh}(X), \Omega_X)$ of a Calabi–Yau threefold is assembled from local data wherever the required critical charts, orientations, and equivariance data exist. This chapter classifies how the positive-half or sheaf-valued assembly happens: the four equivariance strata (toric T^d , reduced $\mathbb{G}_m + \text{Aut}$, orbifold inertia, lattice-polarised period), the fifteen non-empty power-set cells carrying explicit cocycles, and the separate stratum-free critical-CoHA fallback. Passage from these positive halves to a globally-defined Hall bialgebra or quantum vertex chiral group requires the additional pairing, completion, bracket, and centre data stated in the relevant sections. Each stratum sources a cocycle type: chart-transition cocycles in $H^1(\Sigma, \underline{\text{Pic}}_{T^d})$ on toric fans, connected-automorphism character cocycles on the reduced- $\mathbb{G}_m$ stratum, Galois cocycles on the orbifold-inertia stratum, and Fourier-coefficient cocycles of Gritsenko–Cléry weight- $k_\Psi = c_\phi(o, o)/2$ forms on the lattice-polarised-period stratum. A CY_3 with at least one explicit stratum datum has a non-empty stratum-set $\text{Str}(X) \subseteq \{\text{i, ii, iii, iv}\}$ and belongs to one of the fifteen non-empty cells. Compact examples with no such datum, such as the generic quintic branch, enter through the stratum-free critical-CoHA fallback rather than through the fifteen-cell cocycle classification.

The $(2, 1)$ -stack Stk_{Str} of equivariance strata organises the four strata; on constructed non-empty cells its stalks carry stable ∞ -categorical CoHA positive halves. The $K_3 \times E$ principal example sits at cell fifteen, where all four strata meet; the four gluing cocycles on $K_3 \times E$ produce the Heisenberg, Mukai-lattice-rank, Mathieu-twining, and Borchers- Δ_5 data from four logically independent constructions, with the associated $\kappa_\bullet$ -spectrum $\{0, 3, 5, 24\}$ registered at four distinct categorical locations. The compact- CY_3 -without- K_3 -fibration regime (quintic, Schoen bicubic) sits in the stratum-free cell and carries only the Davison–Meinhardt critical CoHA, an obstruction boundary sharpened in the closing sections.

Ten sections resolve ten constructions: abstract 2-categorical framework (§33.1); Čech gluing on toric atlases (§33.2); McKay and orbifold inertia (§33.3); Van den Bergh derived Morita via tilting and NCCR (§33.4); factorisation algebras on Ran spaces with the two-stage $\Phi_3 = \text{Sp}_{\Sigma_2, C}^{\text{ch}} \circ \Phi_3^{\text{FA}}$ (§33.5); Kontsevich–Soibelman wall-crossing (§33.6); lattice-polarised Borchers automorphic gluing (§33.7); the $K_3 \times E$ principal example (§33.8); obstructions on compact CY_3 (§33.9); and the unifying sheaf of CoHAs on the $(2, 1)$ -stack of equivariance strata (§33.10).

PROPOSITION 33.0.1 (*Finite Dolbeault–Weiss–Ran Rees gluing*). Let X be a smooth Calabi–Yau threefold with a DWR-good cover $\mathfrak{U}$ and finite bounds (N, r, L, m) for holomorphic jets, renormalisation order, charge, and Ran arity. Suppose that a multiplicative finite DWR/Ran cyclic critical atlas is fixed, in the sense of Definition 6.1.20. Put

$$\mathfrak{M}_{\text{hCS, Hall}}^{N, r, L, m}(\mathfrak{U}) := \text{Tot}_{\sigma \in \text{N}_{\leq m}^{\text{Ran}}(\mathfrak{U}; \Gamma_{\leq L})} \text{Hom}_{\text{cont}} \left(\text{BObs}_{\text{hCS}}^{q, \leq r, \leq N}(\sigma)_{\leq L}, \text{Hall}_{\sigma}^{\text{Rees, or}} \right),$$

with differential

$$D_{\text{tot}} = d_{\text{Hall}} \circ (-) - (-1)^{| \cdot |} (-) \circ d_{\text{BObs}} + \delta_{\check{C}/\text{Ran}}$$

and convolution bracket induced by the bar coproduct on hCS observables and the Rees Hall product. For a p -simplex σ , let

$$\theta_{\sigma}^{\text{rel}} : \text{BObs}_{\text{hCS}}^{q, \leq r, \leq N}(\sigma)_{\leq L} \longrightarrow \text{Hall}_{\sigma}^{\text{Rees, or}}(\Delta^p)$$

be the relative map produced by the face-compatible cyclic contraction over $\Omega^{\bullet}(\Delta^p)$. Then the Stokes sum

$$\Theta_{\text{hCS} \rightarrow \text{Hall}}^{\text{Rees, or}; N, r, L, m} := \sum_{0 \leq p \leq m} \sum_{\sigma \in \mathcal{N}_{p, \leq m}^{\text{Ran}}(\mathfrak{U}; \Gamma_{\leq L})} \int_{\Delta^p} \theta_{\sigma}^{\text{rel}}$$

is a Maurer–Cartan element of $\mathfrak{M}_{\text{hCS, Hall}}^{N, r, L, m}(\mathfrak{U})$:

$$D_{\text{tot}} \Theta_{\text{hCS} \rightarrow \text{Hall}}^{\text{Rees, or}; N, r, L, m} + \frac{1}{2} \left[\Theta_{\text{hCS} \rightarrow \text{Hall}}^{\text{Rees, or}; N, r, L, m}, \Theta_{\text{hCS} \rightarrow \text{Hall}}^{\text{Rees, or}; N, r, L, m} \right] = 0.$$

It is therefore a multiplicative natural transformation from finite hCS observables to the finite oriented Rees Hall complex on the DWR/Ran nerve. If the vertex maps are quasi-isomorphisms, the induced map on finite DWR/Ran descent is a quasi-isomorphism.

The cyclic contraction in the statement is the corrected TCFT/BV contraction. It is not the raw termwise pair-contraction on a strict cyclic $\mathcal{A}_{\infty}$ bar model. In a strict non-formal model the raw operator $B_{\text{term}}^{(2)}$ can satisfy

$$[m_3, B_{\text{term}}^{(2)}][a|a|a|b] = 2\alpha[b] \neq 0,$$

so raw cancellation does not produce the displayed Maurer–Cartan equation. The corrected Costello operator $B_{\text{TCFT}}^{(2)}$ and its total identity $\{b, B_{\text{TCFT}}^{(2)}\} = 0$ are part of the comparison datum.

The finite construction stops at the Rees Hall layer. A completed Rees comparison requires pro-compatibility in (N, r, L, m) and the Mittag–Leffler vanishing of the resulting inverse system. A realized critical CoHA requires a monoidal vanishing-cycle realization compatible with Thom–Sebastiani, compact-support pushforward, lci pullback, equivariance, orientations, shifts, Tate twists, and the chosen completions. A Hall–Drinfeld double requires, in addition, the realized positive half, a completed negative half, a Cartan factor, a non-degenerate Hopf pairing, cross-relations, and centre compatibility.

Proof. The cyclic homological perturbation theorem applied to the corrected TCFT/BV contraction over $\Omega^{\bullet}(\Delta^p)$ transfers the finite hCS structure on each simplex to a cyclic L_{∞} structure with Hamiltonian W_{σ} satisfying the relative BV master equation. The Fourier–BV Rees identification of Lemma 6.1.16 rewrites this identity as

$$(d_{\text{Hall}} + d_{\Delta^p})\theta_{\sigma}^{\text{rel}} - \theta_{\sigma}^{\text{rel}} d_{\text{BObs}} + \frac{1}{2} [\theta_{\sigma}^{\text{rel}}, \theta_{\sigma}^{\text{rel}}]_{\text{conv}} = 0$$

in the relative convolution dg Lie algebra over $\Omega^{\bullet}(\Delta^p)$.

Integration over Δ^p is a chain map of degree $-p$ up to the boundary term measured by Stokes’ formula:

$$\int_{\Delta^p} d_{\Delta^p} \eta = \sum_{j=0}^p (-1)^j \int_{\Delta^{p-1}} \partial_j^* \eta.$$

Face compatibility of the contractions gives $\partial_j^* \theta_{\sigma}^{\text{rel}} = \theta_{\partial_j \sigma}^{\text{rel}}$; hence these boundary terms are exactly the $\delta_{\check{C}/\text{Ran}}$ component of D_{tot} . The remaining summands are the Hall differential, the bar differential, and

the convolution bracket. Summing the integrated identity over all finite simplices gives the displayed Maurer–Cartan equation.

Multiplicativity follows from the atlas condition $W_{\sigma_1 \sqcup \sigma_2} = W_{\sigma_1} \boxplus W_{\sigma_2}$ and from the Rees Thom–Sebastiani identification, which carries external tensor product to Hall convolution. The finite DWR/Ran nerve is a finite diagram of complexes in the stated bounds; objectwise quasi-isomorphisms on vertices extend over faces by the same face-compatible contractions and induce a quasi-isomorphism on the finite totalisation.

The separation of the three subsequent operations is formal. The inverse limit in the four bounds is an exactness question for a pro-system. Vanishing-cycle realization is a monoidal functoriality question for critical sheaves. The Hall–Drinfeld double is a topological Hopf-pairing construction after realization. The raw $B_{\text{term}}^{(2)}$ commutator above shows that none is forced by termwise cyclic cancellation or by the Stokes assembly of the finite Rees element. $\square$

33.1 THE GLUING PROBLEM IN CATEGORICAL GENERALITY

The abstract set-up

Fix a Calabi–Yau variety X of complex dimension d , smooth or with at worst Gorenstein canonical singularities, equipped with a nowhere-vanishing holomorphic volume form $\Omega_X \in H^{d,0}(X)$. The cohomological Hall algebra $\text{CoHA}(X)$ of Kontsevich–Soibelman arXiv:1006.2706 is an associative graded algebra built from vanishing-cycle cohomology of moduli of objects in a Calabi–Yau category attached to X . The construction is *local-to-global by design*: critical cohomology lives on a stack glued from local charts, and the Hall convolution is defined in terms of local extension correspondences.

The local input is a quiver with potential (Q_α, W_α) , or more generally a finite cyclic critical model, presenting the local Calabi–Yau A_∞ algebra on a chart $U_\alpha \subset X$. Derksen–Weyman–Zelevinsky mutation and Keller–Yang kernels compare some such presentations on overlaps; they are not the global gluing mechanism. The global hCS–Hall comparison is a finite Dolbeault–Weiss–Ran problem: one must place hCS observables and oriented Rees critical Hall complexes on the same finite Ran nerve, solve the convolution Maurer–Cartan equation there, and only then ask for completion and vanishing-cycle realisation.

Definition 33.1.1 (Critical CoHA on a smooth chart, after Kontsevich–Soibelman 2011). Let Y be a smooth quasi-projective variety with an action of a reductive group G and let $f : Y \rightarrow \mathbb{C}$ be a G -invariant regular function. The *critical cohomological Hall algebra* of (Y, f, G) is the graded vector space

$$\mathcal{H}(Y, f, G) = H_G^*(Y, \varphi_f)$$

where φ_f is the sheaf of vanishing cycles of f ; the convolution product, when (Y, f, G) is equipped with a choice of extension correspondence, is $m(\alpha \otimes \beta) = q_* p^*(\alpha \boxtimes \beta)$ along

$$Y' \times Y'' \xleftarrow{p} Y'_c \xrightarrow{q} Y$$

twisted by the Joyce–Song sign (Kontsevich–Soibelman arXiv:1006.2706, Definition 2; Davison arXiv:1311.7172, Theorem A for regularity of φ_f under the equivariant structure; Davison–Meinhardt arXiv:1601.02479, Theorem A for associativity and the dimensional-reduction isomorphism).

The *quiver-with-potential form* is the specialisation $(Y, f, G) = (\text{Rep}(Q, \mathbf{d}), W_{\mathbf{d}}, G_{\mathbf{d}})$ with $G_{\mathbf{d}} = \prod_i GL(d_i)$, $W_{\mathbf{d}}$ the trace of the potential, and the extension correspondence given by short-exact-sequence stacks $0 \rightarrow V' \rightarrow V \rightarrow V'' \rightarrow 0$ in $\text{Rep}(Q)$. When this specialisation is available, $\mathcal{H}(Q, W) = \bigoplus_{\mathbf{d}} \mathcal{H}(\text{Rep}(Q, \mathbf{d}), W_{\mathbf{d}}, G_{\mathbf{d}})$ is $\mathbb{N}^{Q^0}$ -graded.

PROPOSITION 33.1.2 (*When a chart admits quiver presentation*). Let $U \subset X$ be an affine open in a Calabi–Yau threefold. The critical CoHA $\mathcal{H}(U) = \mathcal{H}(Y_U, f_U, G_U)$ of Definition 33.1.1 admits a quiver-with-potential presentation, i.e. an isomorphism $\mathcal{H}(U) \cong \mathcal{H}(Q, W)$ for some (Q, W) , under either of the following *global* hypotheses on U :

- (VdB) U admits a *Van den Bergh tilting bundle*: a coherent sheaf T on U with $\text{Ext}^{>0}(T, T) = 0$, $\text{End}(T)$ Noetherian, and the functor $R\text{Hom}(T, -) : D^b(\text{Coh}U) \rightarrow D^b(\text{End}(T)\text{-mod})$ an equivalence (Van den Bergh arXiv:math/0211064, Theorem A). Then (Q, W) is the Ginzburg quiver of $\text{End}(T)$, and $U = \text{Spec Jac}(Q, W)$ (Ginzburg arXiv:math/0612139, Theorem 3.6.4).
- (DM) U is toric without compact divisors, and the Rapcak–Soibelman–Yang–Zhao presentation of Davison–Meinhardt arXiv:1601.02479 Theorem A applies. Then (Q, W) is the Jacobi quiver of the toric fan.

Neither hypothesis is automatic: (VdB) fails on compact Calabi–Yau threefolds (a tilting bundle would force $H^0(U, \mathcal{O})$ to be Noetherian, incompatible with the Čech assembly of a projective CY₃); (DM) fails whenever U carries a compact 4-cycle.

Proof. Both implications (VdB) $\Rightarrow$ Jacobi and (DM) $\Rightarrow$ toric Jacobi are by direct quotation of the cited theorems; the negative statements are obstructions: any tilting bundle is concentrated in degree 0, and toric compact-divisor support forces the fan to have a compact cone, which then supports a non-zero higher-direct-image obstructing tilting. $\square$

Remark 33.1.3 (*Chart cover hypothesis, named explicitly*). The rest of the chapter fixes an open cover $\mathfrak{U} = \{U_\alpha\}$ of X with each U_α satisfying either (VdB) or (DM). Such a cover exists when X is either toric (DM, fine enough fan refinement) or admits a local-to-global Van den Bergh resolution on affine charts (Buchweitz–Hille arXiv:1404.3007 for the flop-local case; the compact CY₃ case requires a separate construction). The existence hypothesis is the chart-level input to the gluing; it does not imply a global tilting bundle on X , which would contradict compactness.

Finite DWR/Ran critical diagrams

Vanishing cycles are local on the critical target, while Hall convolution is local on extension correspondences. The descent site therefore has two directions. The Dolbeault–Weiss direction records holomorphic polydiscs and compact-support extension; the Ran direction records finite disjoint configurations and the factorisation product. For a cover $\mathfrak{U} = \{U_i\}_{i \in I}$, write $\mathbf{N}_{\text{DWR}}(\mathfrak{U})$ for the simplicial category whose p -simplices are finite families

$$\sigma = (S, \{P_s \subseteq U_{i_{s,0}} \cap \cdots \cap U_{i_{s,p}}\}_{s \in S})$$

of pairwise disjoint holomorphic polydiscs. Face maps forget one Čech index, degeneracies repeat one, refinements shrink the polydiscs, and Ran multiplication is disjoint union. A DWR-good cover is one for which finite intersections are refined by the same polydisc basis, compact-support extension is continuous, and Weiss descent is computed by the homotopy colimit over refinements.

Definition 33.1.4 (*Finite DWR/Ran Rees critical diagram*). Fix finite bounds

N (holomorphic jets), r (renormalisation order), L (charge/HN bound), m (Ran arity).

A finite DWR/Ran Rees critical diagram on $(X, \mathfrak{U})$ consists, for every

$$\sigma \in \mathbf{N}_{\leq m}^{\text{Ran}}(\mathfrak{U}; \Gamma_{\leq L}),$$

of the following data, where $N_{\leq m}^{\text{Ran}}(\mathbf{U}; \Gamma_{\leq L})$ denotes a chosen finite full sub-nerve in the stated arity and charge bounds.

- (i) A finite hCS observable complex $\text{Obs}_{\text{hCS}}^{q, \leq r, \leq N}(\sigma)_{\leq L}$ with bar coalgebra $B\text{Obs}_{\text{hCS}}^{q, \leq r, \leq N}(\sigma)_{\leq L}$.
- (ii) A finite cyclic critical model $(V_\sigma, W_\sigma, \omega_\sigma)$ over $\Omega^\bullet(\Delta^p)$ when σ is a p -simplex.
- (iii) A face-compatible cyclic contraction

$$\left(H_\sigma \xrightleftharpoons[p_\sigma]{i_\sigma} \text{Obs}_{\text{hCS}}^{q, \leq r, \leq N}(\sigma)_{\leq L} \otimes \Omega^\bullet(\Delta^p), h_\sigma \right)$$

with

$$d_{\text{tot}} h_\sigma + h_\sigma d_{\text{tot}} = 1 - i_\sigma p_\sigma, \quad \partial_j^*(i_\sigma, p_\sigma, h_\sigma) = (i_{\partial_j \sigma}, p_{\partial_j \sigma}, h_{\partial_j \sigma}).$$

- (iv) The oriented Rees critical Hall complex

$$\text{Hall}_\sigma^{\text{Rees, or}}(\Delta^p) = \left(C^\bullet(\mathfrak{g}_\sigma, \Gamma(V_\sigma, \wedge^\bullet T_{V_\sigma})[[\hbar]] \otimes \Omega^\bullet(\Delta^p))^{G_\sigma}, d_{\text{CE}} + \iota_{d_V W_\sigma} + \hbar \Delta_{\omega_\sigma} + d_{\Delta^p} \right) \otimes o_\sigma[s_\sigma](t_\sigma),$$

with orientation line, cohomological shift, and Tate twist compatible with every face and with disjoint union.

The diagram is multiplicative when $W_{\sigma_1 \sqcup \sigma_2} = W_{\sigma_1} \boxplus W_{\sigma_2}$ and the Rees twisted de Rham model sends external tensor product to the Thom–Sebastiani Hall product.

Remark 33.1.5 (DWZ mutation and DWR/Ran descent). Derksen–Weyman–Zelevinsky mutation and Keller–Yang kernels compare quiver-with-potential presentations on individual Hall charts. They do not by themselves supply a compact hCS–Hall comparison, a completed Hall object, or a monoidal vanishing-cycle realisation. The DWR/Ran diagram records the finite descent problem on which such chart maps must live.

Definition 33.1.6 (Finite hCS–Rees–Hall convolution dg Lie algebra). For a finite DWR/Ran Rees critical diagram put

$$\mathfrak{M}_{\text{hCS, Hall}}^{N, r, L, m}(\mathbf{U}) := \text{Tot}_{\sigma \in N_{\leq m}^{\text{Ran}}(\mathbf{U}; \Gamma_{\leq L})} \text{Hom}_{\text{cont}} \left(B\text{Obs}_{\text{hCS}}^{q, \leq r, \leq N}(\sigma)_{\leq L}, \text{Hall}_\sigma^{\text{Rees, or}} \right).$$

The differential is

$$D_{\text{tot}} = d_{\text{Hall}} \circ (-) - (-1)^{|-|} (-) \circ d_{B\text{Obs}} + \delta_{\check{C}/\text{Ran}},$$

and the bracket is the convolution bracket induced by the bar coproduct on $B\text{Obs}_{\text{hCS}}^q$ and the Rees Hall product.

LEMMA 33.1.7 (Maurer–Cartan equation for finite gluing). A degree-zero element

$$\Theta \in \mathfrak{M}_{\text{hCS, Hall}}^{N, r, L, m}(\mathbf{U})^\circ$$

is a multiplicative natural transformation from finite hCS bar observables to oriented Rees Hall complexes on $N_{\leq m}^{\text{Ran}}(\mathbf{U}; \Gamma_{\leq L})$ if and only if

$$D_{\text{tot}} \Theta + \frac{1}{2} [\Theta, \Theta] = 0.$$

Proof. The two internal parts of D_{tot} say exactly that the simplex component Θ_σ is a chain map. The $\check{C}/\text{Ran}$ part says that the restrictions to all faces of σ agree with the maps attached to those faces, after the refinement maps and compact-support extensions are inserted. The convolution bracket measures the difference between first multiplying on the hCS bar side and then applying Θ , and first applying Θ and then using Hall convolution. The displayed equation is therefore precisely the chain, face, and product compatibility of a natural transformation on the finite DWR/Ran nerve. $\square$

PROPOSITION 33.1.8 (*Finite simplex totalisation*). Let a finite DWR/Ran Rees critical diagram be given. Suppose each p -simplex σ carries a relative degree-zero map

$$\theta_\sigma^{\text{rel}}: \text{BObs}_{\text{hCS}}^{q, \leq r, \leq N}(\sigma)_{\leq L} \longrightarrow \text{Hall}_\sigma^{\text{Rees, or}}(\Delta^p)$$

whose relative convolution curvature vanishes over $\Omega^\bullet(\Delta^p)$ and whose restrictions to faces are the maps for the face simplices. Define

$$\Theta_\sigma^{(p)} := \int_{\Delta^p} \theta_\sigma^{\text{rel}} \in \text{Hom}_{\text{cont}}^{-p} \left(\text{BObs}_{\text{hCS}}^{q, \leq r, \leq N}(\sigma)_{\leq L}, \text{Hall}_\sigma^{\text{Rees, or}} \right)$$

and

$$\Theta_{\text{hCS} \rightarrow \text{Hall}}^{N, r, L, m} := \sum_{0 \leq p \leq m} \sum_{\sigma \in \mathbb{N}_{p, \leq m}^{\text{Ran}}(\mathfrak{U}; \Gamma_{\leq L})} \Theta_\sigma^{(p)}.$$

Then

$$\Theta_{\text{hCS} \rightarrow \text{Hall}}^{N, r, L, m} \in \text{MC} \left(\mathfrak{M}_{\text{hCS, Hall}}^{N, r, L, m}(\mathfrak{U}) \right).$$

If the vertex maps are quasi-isomorphisms and the contractions of Definition 33.1.4 are face-compatible quasi-isomorphism contractions, the induced map on finite DWR/Ran totalisations is a quasi-isomorphism.

Proof. For each simplex, the relative curvature identity is

$$(d_{\text{Hall}} + d_{\Delta^p})\theta_\sigma^{\text{rel}} - \theta_\sigma^{\text{rel}} d_{\text{BObs}} + \frac{1}{2} [\theta_\sigma^{\text{rel}}, \theta_\sigma^{\text{rel}}]_{\text{conv}} = 0.$$

Integrating over Δ^p turns the d_{Δ^p} term into the alternating sum of boundary restrictions:

$$\int_{\Delta^p} d_{\Delta^p} \eta = \sum_{j=0}^p (-1)^j \int_{\Delta^{p-1}} \partial_j^* \eta$$

with the standard cochain sign convention. Face compatibility identifies these boundary terms with $\partial_{\check{C}/\text{Ran}}$. The remaining terms are exactly the two internal differentials and the bar–Hall convolution bracket. Summing over the finite set of simplices gives the Maurer–Cartan equation in $\mathfrak{M}_{\text{hCS, Hall}}^{N, r, L, m}(\mathfrak{U})$.

The nerve is finite in the bounds (N, r, L, m) and the diagram consists of complexes. Object-wise quasi-isomorphisms therefore induce a quasi-isomorphism on the finite total complex. The face-compatible contractions identify every higher-simplex map with the corresponding refined vertex quasi-isomorphism, so the totalised comparison is a quasi-isomorphism. $\square$

The finite gluing category

PROPOSITION 33.1.9 (*Finite Rees gluing has no hidden higher cells*). For fixed (N, r, L, m) and a fixed DWR-good cover, the finite Rees gluing datum is completely encoded by the convolution dg Lie algebra $\mathfrak{M}_{\text{hCS}, \text{Hall}}^{N, r, L, m}(\mathfrak{U})$ and its Maurer–Cartan equation. No additional simplex of dimension $> m$ appears in the construction, and no completed inverse-limit datum is part of the finite object.

Proof. All simplices are objects of the chosen finite full sub-nerve $N_{\leq m}^{\text{Ran}}(\mathfrak{U}; \Gamma_{\leq L})$. The total differential contains the alternating face operator for every face of every simplex in this finite category. Multiplication is recorded by the convolution bracket. Lemma 33.1.7 therefore converts every chain, face, and product condition into one Maurer–Cartan equation. A simplex outside the arity bound, a higher charge, a higher jet, or a higher renormalisation term belongs to a different member of the inverse system, not to this finite totalisation. $\square$

Remark 33.1.10 (*Finite first, limits second*). The finite DWR/Ran object is an exact chain-level construction. Passing from it to an all-jet, all-charge, all-arity compact comparison is an inverse-limit problem; it is not a formal consequence of having one finite Maurer–Cartan element.

Definition 33.1.11 (*The finite gluing category* $\text{GluedCoHA}^{N, r, L, m}(X; \mathfrak{U})$). The category $\text{GluedCoHA}^{N, r, L, m}(X; \mathfrak{U})$ has:

- objects: finite DWR/Ran Rees critical diagrams on $(X, \mathfrak{U})$ together with a Maurer–Cartan element of $\mathfrak{M}_{\text{hCS}, \text{Hall}}^{N, r, L, m}(\mathfrak{U})$;
- morphisms: gauge equivalences of Maurer–Cartan elements induced by degree-zero elements of the positive DWR/Ran filtration and compatible with the orientation, shift, Tate, and Thom–Sebastiani transports;
- products: disjoint-union Ran products, transported through the Hall Thom–Sebastiani isomorphism.

The unbounded symbol $\text{GluedCoHA}(X)$ denotes the further object obtained only after a compatible inverse system in (N, r, L, m) and a monoidal vanishing-cycle realisation have been supplied.

PROPOSITION 33.1.12 (*Finite Rees comparison and the two further arrows*). Let X be a smooth Calabi–Yau threefold with a DWR-good cover $\mathfrak{U}$. A multiplicative finite DWR/Ran Rees critical diagram with face-compatible contractions determines the finite oriented Rees comparison

$$\Theta_{\text{hCS} \rightarrow \text{Hall}}^{\text{Rees, or}; N, r, L, m} : \text{Obs}_{\text{hCS}}^{q, \leq r, \leq N}(-)_{\leq L} \longrightarrow \text{Hall}_{\text{crit}}^{\text{Rees, or}, \leq N, \leq L}(-)$$

on $N_{\leq m}^{\text{Ran}}(\mathfrak{U}; \Gamma_{\leq L})$. The comparison is a quasi-isomorphism on finite DWR/Ran descent when the vertex maps are quasi-isomorphisms.

The completed Rees comparison requires compatible finite Maurer–Cartan elements under

$$N + 1 \rightarrow N, \quad r + 1 \rightarrow r, \quad \Gamma_{\leq L+1} \rightarrow \Gamma_{\leq L}, \quad N_{\leq m+1}^{\text{Ran}} \rightarrow N_{\leq m}^{\text{Ran}},$$

together with the Mittag–Leffler condition killing the corresponding $\varprojlim^1$ term. The critical-CoHA comparison further requires a monoidal vanishing-cycle realisation

$$R_{\text{vc}} : \text{Hall}_{\text{crit}}^{\text{Rees, or}, \wedge}(-) \longrightarrow \text{CoHA}_{\text{crit}}^{\text{or}, \wedge}(-)$$

preserving Thom–Sebastiani products, compact-support pushforward, lci pullback, equivariance, orientation lines, shifts, Tate twists, and the chosen completions.

Proof. The finite comparison is Proposition 33.1.8 applied to the relative maps produced by cyclic homological perturbation and the Fourier–BV Rees identification on every simplex. Thom–Sebastiani multiplicativity gives the product compatibility, and Lemma 33.1.7 packages the chain, face, and product conditions as the Maurer–Cartan equation.

For the completed Rees comparison, the finite Maurer–Cartan elements must form an inverse-system element in the completed convolution dg Lie algebras. The obstruction to commuting cohomology with this inverse limit is the usual derived-limit term; the Mittag–Leffler hypothesis removes it, so the limiting element again satisfies the Maurer–Cartan equation. The final displayed functor is a separate monoidal realisation from Rees critical complexes to vanishing-cycle Borel–Moore complexes. Its preservation properties are exactly the ones needed for the image of the completed Rees comparison to remain a degree-zero Hall product morphism with the same orientation and grading normalisations. $\square$

Remark 33.1.13 (Where the comparison can fail). For a compact Calabi–Yau threefold outside the known finite DWR/Ran constructions, the missing datum is not a formal $(2, 1)$ -categorical filler. It is a finite family of relative chart maps and face-compatible homotopies solving the convolution Maurer–Cartan equation, followed by inverse-limit compatibility and monoidal vanishing-cycle realisation.

Remark 33.1.14 (Relation to the categorical viewpoint). The finite Rees comparison is a chain-level statement on explicit complexes. The $(\infty, 1)$ -categorical CoHA of the Kontsevich–Soibelman stack of objects in $\text{Perf}(X)$ is a parallel categorical construction with its own descent and representability inputs. The finite DWR/Ran calculation is the surface on which the hCS–Hall map is presently constructed.

The four-stratum taxonomy

The finite Maurer–Cartan equation names the algebraic form of gluing; geometry supplies the cochains entering that equation. The known geometric sources of face-compatible homotopies sit in four places.

The four strata from the automorphism tower. Fix (X, Ω_X) . The available symmetry data lie in the tower

$$\text{Aut}^\circ(X, \Omega_X) \triangleleft \text{Aut}(X, \Omega_X) \triangleleft \widetilde{\text{Aut}}(X, \Omega_X) \triangleleft \Gamma_{\text{arith}}(\text{Period}(X)).$$

The rows are: continuous torus symmetry; a discrete automorphism of X itself; a finite symmetry visible only on a cover; and an arithmetic symmetry of the period domain.

(i) *Toric.* $\text{Aut}^\circ(X, \Omega_X)$ contains a volume-preserving torus $T^d = (\mathbb{C}^\times)^d$. Examples are $\mathbb{C}^3$, the resolved conifold, local $\mathbb{P}^2$, banana threefolds, and SPP.

(ii) *Reduced torus times automorphism.* $\text{Aut}^\circ(X, \Omega_X)$ contains the Ω_X -scaling $\mathbb{C}^\times$, and $\pi_0 \text{Aut}(X, \Omega_X)$ is non-trivial. Examples are K_3 , $K_3 \times E$, abelian surfaces, and elliptic fibrations with residual automorphism.

(iii) *Orbifold inertia.* $X = [Y/G]$ with $G \subset SU(d)$ finite acting on a smooth Calabi–Yau Y . The inertia stack

$$I(X) = \bigsqcup_{[g] \in G/\text{conj}} Y^g / C_G(g)$$

records the action after quotienting. Examples are $[\mathbb{C}^3/\mathbb{Z}_n]$, $[\mathbb{C}^3/G]$ with $G \subset SU(3)$ finite, and K_3 with Mathieu-type twining data.

(iv) *Lattice-polarised period.* The symmetry acts on the period domain $\mathcal{D}_L$ attached to a polarisation lattice $L \subset H^2(X, \mathbb{Z})$. The acting group is an arithmetic subgroup $\Gamma \subset O(L \otimes \mathbb{R})$. Examples are K_3 Humbert divisors, $K_3 \times E$ via Gritsenko Δ_5 , and the unnormalised Igusa square $\Phi_{10}^{\text{un}} = \Delta_5^2$ in the stable $K_3^{[n]}$ tower.

PROPOSITION 33.1.15 (*The four strata exhaust the tower*). A geometric source for DWR/Ran face homotopies acts in exactly one of the four ways above: on the identity component of $\text{Aut}(X, \Omega_X)$, on the discrete components acting on X , on a finite cover of X , or on the period domain. No fifth source is obtained from automorphisms of (X, Ω_X) .

Proof. A source acting on local charts acts either on X , on a cover $Y \rightarrow X$, or on the period datum of $H^d(X, \mathbb{C})$. The first case splits by connectedness: the identity component is stratum (i), while the discrete component acting on X is stratum (ii). The second case is stratum (iii). In the third case, Deligne’s monodromy theorem for regular singular connections and Dolgachev’s lattice-polarised K3 period map place integral period symmetries in an arithmetic subgroup, which is stratum (iv). A symmetry outside these three loci acts on none of the data entering a DWR/Ran simplex: not on its charts, not on a cover, and not on the period class used to transport the coefficients. $\square$

PROPOSITION 33.1.16 (*Four-stratum sources for finite gluing*). Let a finite DWR/Ran Rees critical diagram on $(X, \mathfrak{U})$ be fixed. Every geometric cochain used to construct the relative maps $\theta_\sigma^{\text{rel}}$ of Proposition 33.1.8 is supported in the strata (i)–(iv). In the four cases its natural coefficient target is

stratum	coefficient target
(i)	$H^1(X, \text{Pic}^{T^d})$
(ii)	$H^1(X/\text{Aut}_s(X), \underline{\text{Aut}_s(X)})$
(iii)	$H^1(I(X/G), \underline{G})$
(iv)	$H^1(\mathcal{D}_L/\Gamma_{\text{arith}}, \underline{\Gamma_{\text{arith}}})$

For X carrying several strata, these coefficient classes enter the same convolution dg Lie algebra $\mathfrak{M}_{\text{hCS}, \text{Hall}}^{N, r, L, m}(\mathfrak{U})$; finite gluing is the single Maurer–Cartan equation, not the independent vanishing of the rows.

Proof. In stratum (i), toric transition functions act on the quiver charts and their determinant lines; Davison–Meinhardt dimensional reduction and the torus-equivariant RSYZ construction place the resulting cochain in the torus-equivariant Picard sheaf. In stratum (ii), a residual volume-preserving automorphism transports chart presentations and orientation lines, giving an $\text{Aut}_s(X)$ -valued cochain on the quotient site. In stratum (iii), BKR McKay equivalence transports the critical charts through the inertia stack, hence gives the G -valued inertia cochain. In stratum (iv), Borchers and Gritsenko–Nikulin automorphic products transport the period-domain coefficients through the arithmetic group.

These cochains do not define four separate Hall algebras. They modify the face maps, orientation transports, and Thom–Sebastiani homotopies in one finite DWR/Ran diagram. Lemma 33.1.7 then identifies compatibility of all rows with the single equation $D_{\text{tot}}\Theta + \frac{1}{2}[\Theta, \Theta] = 0$. $\square$

Remark 33.1.17 (*Case-wise sources and uniform coefficient stacks*). For stratum (ii), K3 with Nikulin involution, abelian surfaces, and local K3-fibrations supply concrete automorphism cochains. For stratum (iv), each Borchers lift in the Gritsenko–Cléry catalogue supplies its own arithmetic cochain. A uniform stack of all residual $\text{Aut}_s(X)$ -cochains, or all Borchers-lift cochains, requires a separate stack presentation of the classifying sheaves.

Remark 33.1.18 (*Strata are sources, not the comparison*). A stratum supplies coefficients for face homotopies. It does not produce the finite hCS–Hall map without the relative simplex maps, the Maurer–Cartan correction, the vertex quasi-isomorphism datum, and the orientation, grading, Thom–Sebastiani,

and factorisation transports. For generic compact Calabi–Yau threefolds such as the quintic or Schoen bicubic, the absence of a toric, residual automorphism, orbifold, or arithmetic source leaves precisely the finite DWR/Ran primitive data of Proposition 33.1.12 to be constructed directly.

PROPOSITION 33.1.19 (*Overlap coherence inside the convolution complex*). Let $S \subset \{(i), (ii), (iii), (iv)\}$ be the set of strata whose coefficient cochains are used on X . The simultaneous gluing datum is a single element

$$\Theta_S \in \mathfrak{M}_{\text{hCS}, \text{Hall}}^{N, r, L, m}(\mathcal{U})^\circ \simeq \text{Tot Hom}_{\text{cont}} \left(B\text{Obs}_{\text{hCS}}^{q, \leq r, \leq N}(\sigma)_{\leq L}, \text{Hall}_\sigma^{\text{Rees, or}} \right).$$

For $|S| \geq 2$, pairwise overlap compatibility is the vanishing of the mixed part of $D_{\text{tot}}\Theta_S + \frac{1}{2}[\Theta_S, \Theta_S]$ on two-stratum faces. For $|S| \geq 3$, triple compatibility is the corresponding three-stratum component. Higher compatibility is already included because the finite DWR/Ran totalisation ranges over all simplices of arity $\leq m$.

Proof. Write $\Theta_S = \sum_{s \in S} \Theta_s + \Theta_{\text{mix}}$, where the first summands are the pieces obtained from the individual coefficient sources and Θ_{mix} is supported on overlaps of strata. The internal differential checks that each piece is a chain map on its own coefficient system. The $\delta_{\check{C}/\text{Ran}}$ term is exactly the alternating restriction to faces where two or more coefficient systems meet. The convolution bracket records incompatibility of the corresponding products and Thom–Sebastiani transports. Thus every pairwise, triple, and higher overlap condition is one component of the Maurer–Cartan curvature. Vanishing of the curvature is precisely the claimed coherence. $\square$

Remark 33.1.20 (*Strata overlap; the taxonomy is a power set*). The four strata are not a partition of the Calabi–Yau threefold landscape. A single X can carry several coefficient sources. Local $\mathbb{P}^2$ occupies $\{(i), (iii)\}$; K_3 occupies $\{(ii), (iii), (iv)\}$; and $K_3 \times E$ occupies the same triple cell, with a latent toric source on its local curve-stalk charts. The taxonomy is the subset lattice of the four sources.

Remark 33.1.21 (*The 16 cells of the four-source lattice*). The subset lattice $\mathcal{P}(\{(i), (ii), (iii), (iv)\})$ has 16 cells. The empty cell means that none of the four geometric sources supplies face homotopies; the finite hCS–Hall comparison may still be produced by a direct primitive construction, but not by this taxonomy. A non-empty cell records the available coefficient sources, not the completed critical CoHA. Completion and vanishing-cycle realisation remain the two further arrows of Proposition 33.1.12.

Example 33.1.22 (Per-cell realisability of the four-source lattice).

S	Realising geometry / source	cochain origin
$\emptyset$	quintic $\mathbb{P}^4[s]$, Schoen bicubic	direct primitive data required
$\{i\}$	$\mathbb{C}^3$, resolved conifold, banana, SPP	toric Picard
$\{ii\}$	abelian surface, elliptic E	residual automorphism
$\{iii\}$	$[\mathbb{C}^3/G]$, $G \subset SU(3)$	orbifold inertia
$\{iv\}$	generic lattice-polarised K_3	period arithmetic
$\{i,ii\}$	not constructed	toric plus residual automorphism
$\{i,iii\}$	local $\mathbb{P}^2 = \text{Tot}(K_{\mathbb{P}^2})$	toric plus McKay
$\{i,iv\}$	not constructed	toric plus period arithmetic
$\{ii,iii\}$	K_3 with Nikulin involution	automorphism plus quotient
$\{ii,iv\}$	abelian surface with CM lattice	automorphism plus CM period
$\{iii,iv\}$	K_3 with Mathieu M_{24}	inertia plus lattice
$\{i,ii,iii\}$	not constructed	triple source
$\{i,ii,iv\}$	not constructed	triple source
$\{i,iii,iv\}$	not constructed	triple source
$\{ii,iii,iv\}$	K_3 , $K_3 \times E$	master triple
$\{i,ii,iii,iv\}$	not constructed	four-source coincidence

Remark 33.1.23 (K_3 and $K_3 \times E$ at the master triple cell). K_3 and $K_3 \times E$ both occupy the cell $\{(ii), (iii), (iv)\}$. For $K_3 \times E$, stratum (ii) supplies the $\mathbb{C}^\times$ -scaling and $\text{Aut}(K_3) \times \text{Aut}(E)$ transports, stratum (iii) supplies Mathieu twining when the K_3 factor carries an M_{24} -class action, and stratum (iv) supplies the Borchers lift of the Gritsenko form Δ_5 with $\kappa_{\text{BKM}}(\mathfrak{g}_{\Delta_5}) = 5$. The four subscripted invariants $\kappa_{\text{cat}}(K_3 \times E) = 0$, $\kappa_{\text{ch}}^{\text{Heis}} = 3$, $\kappa_{\text{BKM}}(\mathfrak{g}_{\Delta_5}) = 5$, and $\kappa_{\text{fiber}} = 24$ come from four distinct constructions. The $K_3 \times E$ section constructs the curve-stalk positive-half surface and records the further hCS–Hall, completion, pairing, and Hall–Borchers requirements.

Abstract framework in one paragraph

The finite gluing object is the total complex over the bounded DWR/Ran nerve $N_{\leq m}^{\text{Ran}}(\mathfrak{U}; \Gamma_{\leq L})$. A comparison map is a degree-zero element of the convolution dg Lie algebra $\mathfrak{M}_{\text{hCS,Hall}}^{N,r,L,m}(\mathfrak{U})$ satisfying

$$D_{\text{tot}}\Theta + \frac{1}{2}[\Theta, \Theta] = 0.$$

Face-compatible cyclic contractions over $\Omega^\bullet(\Delta^p)$ produce the simplex maps; Stokes’ formula turns their boundary terms into the Čech/Ran differential. The four strata supply known geometric coefficient sources for those face homotopies. They do not replace the Maurer–Cartan solution, the inverse-limit completion, or the monoidal vanishing-cycle realisation.

§33.2 realises the finite framework on the toric source, beginning with the two-chart conifold.

33.2 CHART-WISE GLUING ON TORIC CY_3 (STRATUM I)

Stratum i is the toric regime: every top-dimensional cone of the fan contributes a $\mathbb{C}^3$ -chart whose local critical Hall algebra is the Schiffmann–Vasserot positive half $Y^+(\widehat{\mathfrak{gl}}_1)$. The gluing object in this section

is finite: after a DWR/Ran refinement of the toric atlas and finite bounds (N, r, L, m) , the chart data form an oriented Rees Hall coefficient system on the finite Čech/Ran nerve. The output is the Maurer–Cartan element in the total convolution dg Lie algebra; completion, vanishing-cycle realisation, Drinfeld doubling, and vertex-algebra evaluation are separate operations. Thus a $\mathbb{C}^3$ chart contributes $Y^+(\widehat{\mathfrak{gl}}_1)$, not $\mathcal{W}_{1+\infty}$, and the finite assembly below is not a compact CoHA. The simplest non-trivial instance is the resolved conifold $\mathbf{Y} = \text{Tot}(\mathcal{O}_{\mathbb{P}^1}(-1) \oplus \mathcal{O}_{\mathbb{P}^1}(-1))$ with its two-chart atlas $\mathbf{Y} = U_+ \cup U_-$. The multi-chart generalisation indexes over a toric fan; the compact-4-cycle obstruction separates zero-interior-point diagrams from diagrams requiring McKay resolution; the zero-interior case isolates the finite Rees layer available before realisation.

Čech gluing of two charts: the conifold paradigm

The obstruction resolved by a two-chart atlas is the absence of a global $\mathbb{C}^3$ -parametrisation: the resolved conifold $\mathbf{Y}$ is a rank-2 vector bundle over $\mathbb{P}^1$, not an affine variety. Any chart-wise Schiffmann–Vasserot construction must name the transition datum that turns two copies of $\mathbb{C}^3$ into $\mathbf{Y}$, then transport that datum through every intermediate step; the $(3, 0)$ -form, the polyvector fields, the Hall product, and the orientation line.

THE TWO-CHART ATLAS

Let $z \in \mathbb{P}^1$ be the standard affine coordinate on the base, with $\tilde{z} = z^{-1}$ on the complementary chart. On the total space $\mathbf{Y} = \text{Tot}(\mathcal{O}_{\mathbb{P}^1}(-1) \oplus \mathcal{O}_{\mathbb{P}^1}(-1))$ introduce fibre coordinates u_+, v_+ in the trivialisation over the z -chart and u_-, v_- in the trivialisation over the $\tilde{z}$ -chart. The cover

$$U_+ = \{z \neq \infty\} \times \mathbb{C}^2 \cong \mathbb{C}^3, \quad U_- = \{\tilde{z} \neq \infty\} \times \mathbb{C}^2 \cong \mathbb{C}^3,$$

has overlap $U_+ \cap U_- = (\mathbb{P}^1 \setminus \{0, \infty\}) \times \mathbb{C}^2 \cong \mathbb{C}^\times \times \mathbb{C}^2$. A section of $\mathcal{O}_{\mathbb{P}^1}(-1)$ is a function $f(z)$ on U_+ that transforms to $\tilde{z}f(\tilde{z}^{-1}) = z^{-1}f(z)$ on U_- . Writing $u_\pm, v_\pm$ as the fibre coordinates of the two $\mathcal{O}(-1)$ summands one finds the transition

$$\tilde{z} = z^{-1}, \quad u_- = z u_+, \quad v_- = z v_+, \quad (33.1)$$

as the natural datum forced by the $\mathcal{O}(-1) \oplus \mathcal{O}(-1)$ twist. The standard atlas of $\mathbb{P}^1$ carries an orientation flip across $z \leftrightarrow \tilde{z}$: the holomorphic 1-form $dz = -\tilde{z}^{-2} d\tilde{z}$ reverses sign through the change of chart, and this sign propagates to the $(3, 0)$ -form computation of the next subsection.

JACOBIAN OF THE TRANSITION ON THE $(3, 0)$ -FORM

The Calabi–Yau $(3, 0)$ -form $\Omega_{\mathbf{Y}}$ is specified on U_+ by the requirement that it trivialise the canonical bundle of $U_+ \cong \mathbb{C}^3$:

$$\Omega_{\mathbf{Y}}|_{U_+} = dz \wedge du_+ \wedge dv_+.$$

To transport $\Omega_{\mathbf{Y}}$ to U_- one computes the Jacobian of the transition (33.1) step by step. The exterior derivatives are

$$dz = -\tilde{z}^{-2} d\tilde{z}, \quad du_+ = d(z^{-1}u_-) = -z^{-2}u_- dz + z^{-1}du_-, \quad dv_+ = -z^{-2}v_- dz + z^{-1}dv_-,$$

so that

$$dz \wedge du_+ = dz \wedge z^{-1}du_-, \quad dz \wedge du_+ \wedge dv_+ = dz \wedge z^{-1}du_- \wedge z^{-1}dv_- = z^{-2}dz \wedge du_- \wedge dv_-.$$

Substituting $dz = -\tilde{z}^{-2} d\tilde{z}$ and the fibre Jacobian $z^{-2} = \tilde{z}^2$:

$$\Omega_{\mathbf{Y}}|_{U_+} = dz \wedge du_+ \wedge dv_+ = \underbrace{z^{-2}}_{\text{fibre twist}} \underbrace{dz}_{-\tilde{z}^{-2} d\tilde{z}} \wedge du_- \wedge dv_- = \underbrace{\tilde{z}^2 \cdot (-\tilde{z}^{-2})}_{=-1} d\tilde{z} \wedge du_- \wedge dv_- = -d\tilde{z} \wedge du_- \wedge dv_- . \quad (33.2)$$

The two factors $\tilde{z}^2$ (fibre twist, one $\tilde{z}$ per $\mathcal{O}(-1)$ summand) and $-\tilde{z}^{-2}$ (cotangent coefficient from dz) cancel exactly, leaving no residual $\tilde{z}^\pm$ and only the base-orientation sign -1 of $\mathbb{P}^1$. This is the statement that $K_{\mathbf{Y}}$ is trivial; the transition cocycle on $U_+ \cap U_-$ collapses to a constant -1 , with no $\tilde{z}$ -dependence; and is precisely the cancellation required by the Calabi–Yau condition $c_1(\mathcal{O}(-1) \oplus \mathcal{O}(-1)) = -2H = -c_1(T_{\mathbb{P}^1})$ (degrees of the two $\mathcal{O}(-1)$ -summands sum to $-\deg K_{\mathbb{P}^1} = -2$).

RESOLVED-CONIFOLD HCS DESCENT BEFORE THE HALL COMPARISON

Let $U_{+-} = U_+ \cap U_-$. For an admissible open $V \subset \mathbf{Y}$, put

$$\mathcal{E}_{\text{hCS},c}(V, \mathfrak{g}) := \Omega_c^{\circ, \bullet}(V, \mathfrak{g})[1], \quad Q_{\text{hCS}} = \bar{\partial},$$

where $\mathfrak{g}$ is a finite-dimensional metric Lie algebra. The classical hCS action on V is

$$I_V(\alpha) = \int_V \Omega_{\mathbf{Y}} \wedge \left(\frac{1}{2} \langle \alpha, \bar{\partial} \alpha \rangle + \frac{1}{6} \langle \alpha, [\alpha, \alpha] \rangle \right),$$

with the $(0, 3)$ -part taken before integration. The corresponding classical observable complex is

$$\text{Obs}_{\text{hCS}}^{\text{cl}}(V, \mathfrak{g}) := \left(\widehat{\text{Sym}}(\mathcal{E}_{\text{hCS},c}(V, \mathfrak{g})^\vee[-1]), d_{\bar{\partial}} + \{I_V, -\}_{\text{BV}} \right),$$

completed by polynomial degree in the continuous dual topology. For disjoint opens $V_1, \dots, V_k \subset V$, the factorisation product is the usual product of functionals after restriction of fields from V to the V_i .

THEOREM 33.2.1 (*Resolved-conifold hCS factorisation descent*). Let

$$\mathbf{Y} = \text{Tot}_{\mathbb{P}^1}(\mathcal{O}_{\mathbb{P}^1}(-1) \oplus \mathcal{O}_{\mathbb{P}^1}(-1)) = U_+ \cup U_-$$

with transition (33.1), and orient $\mathbf{Y}$ by the holomorphic volume form whose U_+ -expression is $dz \wedge du_+ \wedge dv_+$. Then the local E_3 -holomorphic hCS factorisation algebra on $U_+ \simeq \mathbb{C}^3$ and $U_- \simeq \mathbb{C}^3$ descends to a global classical BV factorisation algebra

$$\text{Obs}_{\text{hCS}}^{\text{cl}}(-, \mathfrak{g})$$

on $\mathbf{Y}$. More precisely:

(i) on U_{+-} the pullback

$$T_{+-}^{\text{BV}} : \Omega_c^{\circ, \bullet}(U_{+-}, \mathfrak{g})[1]_- \longrightarrow \Omega_c^{\circ, \bullet}(U_{+-}, \mathfrak{g})[1]_+, \quad \alpha \longmapsto (\tilde{z} = z^{-1}, u_- = zu_+, v_- = zv_+)^* \alpha,$$

is an isomorphism of cyclic BV L_∞ -algebras;

(ii) the compactly supported hCS fields satisfy the Mayer–Vietoris descent sequence of complexes

$$0 \longrightarrow \mathcal{E}_{\text{hCS},c}(U_{+-}, \mathfrak{g}) \xrightarrow{(j_{+*}, -j_{-*})} \mathcal{E}_{\text{hCS},c}(U_+, \mathfrak{g}) \oplus \mathcal{E}_{\text{hCS},c}(U_-, \mathfrak{g}) \xrightarrow{j_{+*} + j_{-*}} \mathcal{E}_{\text{hCS},c}(\mathbf{Y}, \mathfrak{g}) \longrightarrow 0,$$

where equality on the overlap is read through T_{+-}^{BV} ;

- (iii) if $\mathbf{U}_Y = \{U_+, U_-\}$ and $\text{DWR}(\mathbf{U}_Y)$ is the Ran–Weiss category of finite disjoint unions of holomorphic polydiscs, each polydisc lying in one of U_+ , U_- , or U_{+-} , then the canonical descent map

$$\text{hocolim}_{P \in \text{DWR}(\mathbf{U}_Y)/V} \text{Obs}_{\text{hCS}}^{\text{cl}}(P, \mathfrak{g}) \xrightarrow{\sim} \text{Obs}_{\text{hCS}}^{\text{cl}}(V, \mathfrak{g})$$

is a quasi-isomorphism of prefactorisation algebras for every admissible open $V \subset \mathbf{Y}$. In particular, taking $V = \mathbf{Y}$ gives a genuine non-affine global hCS E_3 -factorisation algebra obtained by gluing two standard $\mathbb{C}^3$ charts.

The construction is the resolved-conifold descent case. It uses the exceptional zero-section $\mathbb{P}^1 \subset \mathbf{Y}$ and is therefore not the single affine $\mathbb{C}^3$ calculation. It also makes no compact-CoHA or Hall–Drinfeld-double assertion.

Proof. First, the transition is cyclic. Since the map $(z, u_+, v_+) \mapsto (\tilde{z}, u_-, v_-) = (z^{-1}, zu_+, zv_+)$ is holomorphic, its pullback commutes with $\tilde{d}$ and with the pointwise Lie bracket on $\mathfrak{g}$ -valued Dolbeault forms. The Jacobian calculation (33.2) says exactly that the holomorphic volume form changes by the constant orientation sign forced by the base coordinate and by no residual power of z . Absorbing that sign into the U_- -trivialisation of Ω_Y , the change-of-variables formula gives

$$\int_{U_{+-}} \Omega_Y \wedge \langle T_{+-}^{\text{BV}} \alpha, T_{+-}^{\text{BV}} \beta \rangle = \int_{U_{+-}} \Omega_Y \wedge \langle \alpha, \beta \rangle,$$

and the same equality for the quadratic and cubic terms in I . Thus T_{+-}^{BV} preserves the BV pairing, bracket, action, and classical master equation.

Second, compactly supported Dolbeault fields are a cosheaf for ordinary open covers. For the two-chart cover this is the displayed exact Mayer–Vietoris sequence. Injectivity is clear because a compactly supported field on U_{+-} has a smooth extension by zero to both charts. If two chart fields have the same extension to $\mathbf{Y}$, their difference is supported on the overlap and comes from the first term. Surjectivity follows by choosing a smooth partition of unity ρ_+, ρ_- subordinate to U_+, U_- and writing a compactly supported field α on $\mathbf{Y}$ as $\rho_+ \alpha + \rho_- \alpha$. All arrows commute with $\tilde{d}$, hence the sequence is exact as a sequence of complexes.

Third, the preceding two paragraphs give a global elliptic local L_∞ -algebra on $\mathbf{Y}$, namely $\Omega_c^{\circ, \bullet}(-, \mathfrak{g})[1]$ with Dolbeault differential, pointwise bracket, cyclic pairing, and cubic hCS local functional. The Costello–Gwilliam factorisation-envelope construction applied to this global local L_∞ -algebra is exactly the displayed completed classical BV observable complex, with differential $d_{\tilde{d}} + \{I, -\}_{\text{BV}}$. Its structure maps are induced by restriction of fields and multiplication of polynomial functionals, so they are compatible with the Mayer–Vietoris differential and with the transition T_{+-}^{BV} .

Finally, refine the two-chart cover by the Ran–Weiss category $\text{DWR}(\mathbf{U}_Y)$. Every finite subset of an admissible open $V \subset \mathbf{Y}$ is contained in a finite disjoint union of holomorphic polydiscs adapted to U_+ , U_- , and U_{+-} , and the transition on a component lying in U_{+-} is the already constructed T_{+-}^{BV} . On each polydisc the observable complex is the standard $\mathbb{C}^3$ hCS E_3 -algebra; for disjoint unions the structure map is multiplication after restriction of fields. These maps commute with the Čech differential and with T_{+-}^{BV} , so the Ran–Weiss homotopy colimit identifies with $\text{Obs}_{\text{hCS}}^{\text{cl}}(V, \mathfrak{g})$. This proves descent as a holomorphic E_3 -factorisation algebra. $\square$

Definition 33.2.2 (Anomaly-free hCS gauge datum). For a finite-dimensional metric Lie superalgebra $\mathfrak{g}$, let

$$\mathfrak{a}_{\mathfrak{g}} \in H_{\text{loc}}^1(\mathbb{C}^3, \text{Dens}_{\mathbb{C}^3}) \otimes (\text{Sym}^4 \mathfrak{g}^\vee)^{\mathfrak{g}}$$

be the Costello one-loop holomorphic-Chern–Simons anomaly, represented on a polydisc by the wheel graph with four external hCS fields. Its Lie-theoretic coefficient is the cyclic symmetrisation of

$$(x_1, x_2, x_3, x_4) \mapsto \text{Str}_{\mathfrak{g}}(\text{ad}_{x_1} \text{ad}_{x_2} \text{ad}_{x_3} \text{ad}_{x_4}).$$

The datum $(\mathfrak{g}, \langle -, - \rangle)$ is *bCS-anomaly-free in complex dimension 3* when this local cohomology class vanishes. Abelian metric Lie algebras and matrix Lie superalgebras whose fourth adjoint supertrace is zero satisfy the condition.

THEOREM 33.2.3 (*Resolved-conifold quantum bCS descent*). Let $\mathfrak{g}$ be an anomaly-free hCS gauge datum in the sense of Definition 33.2.2. The resolved conifold $\mathbf{Y}$ carries a renormalised quantum hCS factorisation algebra

$$\text{Obs}_{\text{hCS}}^q(-, \mathfrak{g}) = \left(\mathcal{O}_{\text{ren,loc/multiloc}}(\Omega_c^{\circ,\bullet}(-, \mathfrak{g})[1])[[\hbar]], \bar{\partial} + \{I[\ell], -\}_{\text{BV}} + \hbar \Delta_\ell \right)$$

whose restriction to U_+ and U_- is the standard Costello–Gwilliam hCS quantisation on $\mathbb{C}^3$, and whose overlap transition is T_{+-}^{BV} . For every pair of scales $0 < \epsilon < \ell < \infty$, the propagator is

$$P_{\epsilon, \ell} = \int_{\epsilon}^{\ell} (\bar{\partial}_h^* \otimes 1) K_t dt,$$

where h is any complete Kähler metric of bounded geometry on $\mathbf{Y}$, K_t is the heat kernel of $\Delta_{\bar{\partial}, h} = [\bar{\partial}, \bar{\partial}_h^*]$, and $\bar{\partial}_h^*$ is the adjoint determined by h and $\Omega_{\mathbf{Y}}$. The effective interaction is the renormalised formal graph sum

$$I[\ell] = \lim_{\epsilon \rightarrow 0} \left(\sum_{\Gamma} \frac{\hbar^{b_1(\Gamma)}}{|\text{Aut } \Gamma|} \mathcal{W}_{\Gamma}(P_{\epsilon, \ell}, I_{\text{hCS}}) + I_{\epsilon}^{\text{CT}} \right),$$

with local counterterm I_{ϵ}^{CT} , and it satisfies the quantum master equation

$$(\bar{\partial} + \hbar \Delta_\ell) e^{I[\ell]/\hbar} = 0.$$

The resulting quantum observables satisfy the same DWR/Ran descent as Theorem 33.2.1.

Proof. The total space of $\mathcal{O}_{\mathbb{P}^1}(-1) \oplus \mathcal{O}_{\mathbb{P}^1}(-1)$ admits a complete Kähler metric of bounded geometry: take the Fubini–Study metric on $\mathbb{P}^1$, Hermitian metrics on the two $\mathcal{O}(-1)$ -summands, and replace the fibre metric outside a compact set by a cylindrical radial metric. The associated Dolbeault Laplacian has a smooth heat kernel with the small-time asymptotic expansion required by Costello’s renormalisation theorem. The propagator $P_{\epsilon, \ell}$ is therefore a well-defined smooth kernel away from the diagonal and has the standard local singularity on every holomorphic polydisc.

The counterterms are local functionals depending only on the finite jet of the metric, the holomorphic volume form, and the hCS interaction at the diagonal. On U_{+-} the transition (33.1) is holomorphic and (33.2) preserves the CY density up to the constant orientation sign already absorbed in the cyclic trivialisation. Hence T_{+-}^{BV} conjugates $\bar{\partial}$, the BV pairing, the heat-kernel parametrix, and the local counterterm density. If two gauge fixings are used, their propagators differ by the Costello renormalisation-group homotopy; the corresponding effective interactions are canonically equivalent.

The obstruction to solving the quantum master equation is the local one-loop class $\mathfrak{a}_{\mathfrak{g}}$. It is local on $\mathbb{C}^3$, natural under holomorphic volume-preserving coordinate changes, and has no additional global component on the resolved conifold because the two-chart Čech cocycle for $\Omega_{\mathbf{Y}}$ is constant. The vanishing

hypothesis on $\mathfrak{g}$ kills the obstruction. Costello's recursive construction then supplies local counterterms I_ϵ^{CT} and effective interactions $I[\ell]$ solving the displayed QME at every order in $\hbar$. The solution is unique up to contractible renormalisation-group equivalence.

For disjoint opens the factorisation product is multiplication of renormalised multilocal functionals after restriction of fields. These maps commute with T_{+-}^{BV} and with compact-support Mayer–Vietoris. The DWR/Ran descent argument of Theorem 33.2.1 therefore applies to the renormalised quantum complexes. $\square$

THE CHART-WISE SCHIFFMANN–VASSEROT CoHA

Each chart $U_\pm \cong \mathbb{C}^3$ carries the Jordan-triple quiver with potential

$$Q_{\text{Jor}} : \underbrace{\bullet}_{\circ} \text{ with three loops } x_\pm, y_\pm, z_\pm, \quad W_\pm = \text{tr}(x_\pm[y_\pm, z_\pm]).$$

The critical CoHA of $(Q_{\text{Jor}}, W_\pm)$ is the positive half of the affine Yangian of $\widehat{\mathfrak{gl}}_1$ (Schiffmann–Vasserot 2012 arXiv:1202.2756; Tsymbaliuk 2014 arXiv:1404.5240),

$$\text{CoHA}(U_\pm, W_\pm) \cong Y^+(\widehat{\mathfrak{gl}}_1),$$

with generators $\ell_r^{(\pm)}, f_r^{(\pm)}, h_r^{(\pm)}$ indexed by $r \in \mathbb{Z}_{\geq 0}$ and structure functions given by the RSYZ shuffle kernel (Rapcak–Soibelman–Yang–Zhao 2020 arXiv:1810.10402 §5, equation (5.3), specialised to the single-vertex Jordan-triple case). At weight $(1, 1)$ the shuffle kernel evaluates to

$$\varphi_{\text{II}}(u_1; u_2) = \frac{1}{(u_1 - u_2 - \varepsilon_1)(u_1 - u_2 - \varepsilon_2)} \xrightarrow{u_2 \rightarrow u_1} \frac{1}{\varepsilon_1 \varepsilon_2}, \quad (33.3)$$

the structure constant that every downstream computation must reproduce.

FOURIER–MUKAI TRANSITION KERNEL

On the overlap $U_+ \cap U_- = \mathbb{C}^\times \times \mathbb{C}^2$ the derived category $D^b(\text{Coh}(U_+ \cap U_-))$ carries the autoequivalence implementing the transition (33.1) at the level of sheaves. Its integral kernel is

$$K_{+-} = \mathcal{O}_\Delta \otimes \pi_1^* \mathcal{O}_{\mathbb{P}^1}(-1) \in D^b(\text{Coh}(U_+ \cap U_-) \times (U_+ \cap U_-)), \quad (33.4)$$

with Δ the diagonal and π_1 the projection onto the first factor. The transform $T_{+-}(\mathcal{F}) := \pi_{2,*}(\pi_1^* \mathcal{F} \otimes K_{+-})$ acts on polyvector fields $\text{PV}^\bullet(U_\pm) = \bigoplus_p \wedge^p T_{U_\pm}$ through the chain rule applied to (33.1) combined with the $\mathcal{O}_{\mathbb{P}^1}(-1)$ -twist.

Chain rule on the cotangent basis. Differentiate (33.1) to obtain

$$du_+ = d(z^{-1}u_-) = -z^{-2}u_- dz + z^{-1}du_-, \quad dv_+ = -z^{-2}v_- dz + z^{-1}dv_-.$$

On the vertical (fibre-degree) sector; the sector entering the Schiffmann–Vasserot Hall product; only the $z^{-1}du_-$ and $z^{-1}dv_-$ terms survive (the dz -terms drop under pairing with the Jordan-triple fibre polyvectors by (33.3)). The cotangent multiplier is therefore z^{-1} per fibre slot, giving $z^{-(a+b)}$ on a fibre-form $du_+^a \wedge dv_+^b$.

Polyvector transport via Ω_Y -duality. The critical CoHA identifies polyvectors with differential forms via Serre duality against the $(3, 0)$ -form Ω_Y :

$$\Lambda^p T_Y \cong \Omega_Y^{3-p} \otimes K_Y^{-1} \cong \Omega_Y^{3-p}$$

using triviality of K_Y (equation (33.2)). Under this identification the fibre-polyvector $\partial_{u_+}^a \partial_{v_+}^b$ corresponds (up to sign) to the fibre-form $du_+^a \wedge dv_+^b$ contracted against the base dz -direction of Ω_Y . Its transport under T_{+-} is the cotangent transformation $du_+^a \wedge dv_+^b = z^{-(a+b)} du_-^a \wedge dv_-^b$.

$\mathcal{O}(-1)$ -kernel twist. The factor $\pi_1^* \mathcal{O}_{\mathbb{P}^1}(-1)$ in K_{+-} contributes a further multiplier z^{-1} tracking the base- $\mathbb{P}^1$ line-bundle weight carried by CoHA sections (the critical CoHA acts on φ_W -twisted sheaves that inherit the $\mathcal{O}(-1)$ -weight of the superpotential $W_{\pm} = \text{tr}(x_{\pm}[\gamma_{\pm}, z_{\pm}])$ along the compact base): a section g of $\mathcal{O}_{\mathbb{P}^1}(-1)$ expressed as $g(z)$ on U_+ reads $\tilde{z} g(\tilde{z}^{-1}) = z^{-1} g(z)$ on U_- .

Net multiplier on polyvector sections. The CoHA-relevant sections are polyvector densities $f \cdot \partial^a \partial^b$ with f a section of $\mathcal{O}(-1)$ (the superpotential line bundle restricted to the overlap), not a scalar function. Combining the cotangent chain rule (fibre-form multiplier $z^{-(a+b)}$) and the $\mathcal{O}(-1)$ -kernel twist (scalar-section multiplier z^{-1}),

$$\underbrace{\left[z^{-(a+b)} \right]}_{\text{cotangent chain rule, fibre slots}} \cdot \underbrace{\left[z^{-1} \right]}_{\mathcal{O}(-1)\text{-kernel twist, base weight}} = z^{-(1+a+b)}.$$

The Fourier–Mukai transport of a Jordan-triple fibre polyvector density therefore reads

$$T_{+-}^* : f(z, u_+, v_+) \partial_{u_+}^a \partial_{v_+}^b \mapsto f(\tilde{z}^{-1}, \tilde{z} u_-, \tilde{z} v_-) z^{-(1+a+b)} \partial_{u_-}^a \partial_{v_-}^b, \quad (33.5)$$

with f understood as a section of $\mathcal{O}(-1)$ on the base. The base-polyvector sector (powers of ∂_z) picks up the base-orientation multiplier $(-\tilde{z}^2)$ per ∂_z -slot; the Jordan-triple selection rule (33.3) restricts the Hall product to the fibre sector $\alpha = 0$ on which the base orientation enters only through the global sign of (33.2).

FINITE ČECH/RAN REES GLUING

The pair (U_+, U_-) with overlap $U_+ \cap U_-$ is an ordinary Čech spine, not a Weiss cover. Factorisation locality enters only after a DWR/Ran refinement. Fix finite bounds

$$N \quad (\text{holomorphic jets}), \quad r \quad (\text{renormalisation order}), \quad L \quad (\text{charge}), \quad m \quad (\text{Ran arity}).$$

Let $\mathfrak{U}_Y$ be a DWR-good refinement of the two toric charts by polydiscs subordinate to U_+ , U_- , and $U_+ \cap U_-$. A p -simplex of the finite Ran nerve has the form

$$\sigma = (S, \{P_s \in U_{\epsilon_{s,0}} \cap \cdots \cap U_{\epsilon_{s,p}}\}_{s \in S}), \quad \epsilon_{s,j} \in \{+, -\},$$

with $|S| \leq m$ and charge bounded by $\Gamma_{\leq L}$. On a vertex lying in $U_{\pm}$ the finite cyclic critical model is the Jordan triple $(Q_{\text{Jor}}, W_{\pm})$ truncated at (N, r, L) ; on an edge lying in $U_+ \cap U_-$ it is transported by the Fourier–Mukai kernel K_{+-} and the multiplier (33.5).

LEMMA 33.2.4 (*Conifold Čech/Ran cyclic atlas*). For every finite bound (N, r, L, m) the data above form a multiplicative finite DWR/Ran cyclic critical atlas on $\mathfrak{U}_Y$. Its 0-simplex Hall cohomology is the local positive half

$$H^0(\text{Hall}_{U_{\pm}}^{\text{Rees, or}}/\hbar) \cong Y^+(\widehat{\mathfrak{gl}}_1),$$

and the edge restriction is the same positive half transported by K_{+-} ; no vertex of the atlas is a $\mathcal{W}_{1+\infty}$ -module.

Proof. The Jacobian calculation (33.2) gives a constant transition for the holomorphic volume form, hence transports the cyclic pairing without a residual Laurent monomial. The chain rule and the $\mathcal{O}(-1)$ kernel give exactly the fibre multiplier of (33.5); face restriction of a polydisc in $U_+ \cap U_-$ is therefore the pullback of the vertex cyclic model by the same Fourier–Mukai transition. On the triple faces of the refined nerve the two possible restrictions are equal because the line-bundle transition cocycle of $\mathcal{O}(-1)$ is multiplicative and the diagonal kernels compose by convolution.

For a disjoint Ran family $\sigma_1 \sqcup \sigma_2$ the finite potential is $W_{\sigma_1} \boxplus W_{\sigma_2}$ and the cyclic form is the external orthogonal sum. Thom–Sebastiani identifies the corresponding Rees Hall complex with the completed tensor product of the two Rees Hall complexes. The vertex computation is the Schiffmann–Vasserot $\mathbb{C}^3$ theorem applied to the Jordan triple, so the local cohomology is $Y^+(\widehat{\mathfrak{gl}}_1)$. The construction has used only critical Hall polyvectors and Rees deformation; no vertex-algebra representation or Drinfeld double has been supplied. $\square$

Let

$$\mathfrak{M}_{\text{hCS, Hall}}^{N, r, L, m}(\mathfrak{U}_Y) = \text{Tot}_{\sigma \in \mathbb{N}_{\leq m}^{\text{Ran}}(\mathfrak{U}_Y; \Gamma_{\leq L})} \text{Hom}_{\text{cont}}(B\text{Obs}_{\text{hCS}}^{q, \leq r, \leq N}(\sigma)_{\leq L}, \text{Hall}_{\sigma}^{\text{Rees, or}})$$

with differential $D_{\text{tot}} = d_{\text{Hall}} \circ (-) - (-1)^{|-|}(-) \circ d_{B\text{Obs}} + \delta_{\check{C}/\text{Ran}}$ and convolution bracket induced by the bar coproduct and the Rees Hall product.

Construction 33.2.5 (*The finite hCS–Rees–Hall chart map*). Let $P \Subset U_{\epsilon}$, $\epsilon \in \{+, -, +-\}$, be a holomorphic polydisc with coordinates w_1, w_2, w_3 . Fix finite bounds (N, r, L) . The Dolbeault–Taylor projection

$$\pi_{P, N} : \Omega_c^{\bullet}(P, \mathfrak{gl}_{\leq L})[1] \longrightarrow \mathfrak{gl}_{\leq L} \otimes \mathbb{C}[w_1, w_2, w_3]/(w_1, w_2, w_3)^{N+1}[1]$$

is the Dolbeault contraction of P onto holomorphic functions followed by Taylor truncation at the centre of P . Choose the Bochner–Martinelli homotopy h_P and a compactly supported inclusion $i_{P, N}$ of truncated jets. The triple $(i_{P, N}, \pi_{P, N}, h_P)$ is cyclic for the residue pairing induced by Ω_Y .

The cyclic homological perturbation lemma transfers the cubic hCS Hamiltonian to the finite jet space by the tree formula

$$W_{P, N}^{\text{tr}} = \sum_{T \text{ rooted}} \frac{1}{|\text{Aut } T|} \pi_{P, N} I_{\text{hCS}}(h_P I_{\text{hCS}})^T i_{P, N}^{\otimes \text{leaves}(T)}.$$

For the constant $\mathfrak{gl}_{\leq L}$ -framing this transferred Hamiltonian is the Jordan-triple potential

$$W_{P, N}^{\text{tr}} = \text{tr}(X[Y, Z]) \quad \text{modulo } (w_1, w_2, w_3)^{N+1}$$

on the finite representation space of triples $(X, Y, Z) \in \text{End}(\mathbb{C}^d)^3$, $d \leq L$. Let

$$\mathfrak{F}_{\omega_P} : B\text{Obs}_{\text{hCS}}^{q, \leq r, \leq N}(P)_{\leq L} \longrightarrow \text{Hall}_P^{\text{Rees, or}}$$

be the BV Fourier transform determined by the finite cyclic volume $\omega_P = \Omega_Y|_P$: a polynomial functional is contracted with ω_P , and the differential becomes $\iota_{dW_{P,N}^{\text{tr}}} + \hbar\Delta_{\omega_P}$. The chart map is

$$\theta_P^{N,r,L} := \mathfrak{F}_{\omega_P} \circ B(\pi_{P,N}) \circ \text{HPL}_{P,N,r,L}.$$

Here $\text{HPL}_{P,N,r,L}$ is the filtered homological perturbation quasi-isomorphism from the scale- ℓ , loop-order $\leq r$, charge- $\leq L$ bar observable complex to the transferred finite jet BV complex determined by $(i_{P,N}, \pi_{P,N}, h_P)$. Its Taylor coefficients are the rooted-tree operators displayed in the formula for $W_{P,N}^{\text{tr}}$, with internal edges labelled by h_P and vertices by the cubic hCS bracket. For a Ran simplex $\sigma = (S, \{P_s\})$, put $\theta_\sigma^{\text{rel}} = \widehat{\otimes}_{s \in S} \theta_{P_s}^{N,r,L}$ and extend over $\Omega^\bullet(\Delta^p)$ by the relative cyclic contraction.

LEMMA 33.2.6 (*Overlap conjugacy of the conifold chart map*). On U_{+-} , the maps of Construction 33.2.5 satisfy

$$\theta_+^{N,r,L} B(T_{+-}^{\text{BV}}) = T_{+-}^{\text{PV}} \theta_-^{N,r,L},$$

where T_{+-}^{PV} is the Fourier–Mukai/Rees polyvector transport with multiplier (33.5). The same identity holds on every face of the finite DWR/Ran nerve.

Proof. The Dolbeault–Taylor projection is natural under holomorphic coordinate change: Taylor monomials transform by the Jacobian of (33.1), and the Bochner–Martinelli homotopy changes by a $\bar{\partial}$ -exact homotopy. The cyclic residue pairing is preserved by (33.2). Cyclic HPL therefore transfers the hCS Hamiltonian to the same Jordan potential on the overlap, written in the two coordinate systems. The BV Fourier transform is natural for cyclic linear isomorphisms; after Ω_Y -duality the coordinate change is precisely the polyvector transport computed in (33.5). Tensoring over a disjoint Ran family and restricting to faces preserves the equality. $\square$

PROPOSITION 33.2.7 (*Conifold Čech/Ran Maurer–Cartan equation*). The relative chart maps of Construction 33.2.5, with the overlap conjugacy of Lemma 33.2.6, assemble to

$$\Theta_Y^{\text{Rees},N,r,L,m} := \sum_{0 \leq p \leq m} \sum_{\sigma \in \mathcal{N}_{p, \leq m}^{\text{Ran}}(\mathcal{U}_Y; \Gamma \leq L)} \int_{\Delta^p} \theta_\sigma^{\text{rel}} \in \mathfrak{M}_{\text{hCS}, \text{Hall}}^{N,r,L,m}(\mathcal{U}_Y),$$

and this element satisfies

$$D_{\text{tot}} \Theta_Y^{\text{Rees},N,r,L,m} + \frac{1}{2} [\Theta_Y^{\text{Rees},N,r,L,m}, \Theta_Y^{\text{Rees},N,r,L,m}] = 0.$$

Thus the conifold atlas gives a finite oriented hCS-to-Rees-Hall comparison on the Čech/Ran nerve. It does not identify the conifold with $\mathcal{W}_{1+\infty}$, with a compact CoHA, or with a Hall–Drinfeld double.

Proof. On every simplex the cyclic homological perturbation transfer gives a relative Hamiltonian W_σ over $\Omega^\bullet(\Delta^p)$ satisfying the BV master equation. The relative Fourier–BV identification rewrites this equation as

$$(d_{\text{Hall}} + d_{\Delta^p}) \theta_\sigma^{\text{rel}} - \theta_\sigma^{\text{rel}} d_{B\text{Obs}} + \frac{1}{2} [\theta_\sigma^{\text{rel}}, \theta_\sigma^{\text{rel}}]_{\text{conv}} = 0.$$

Integration over Δ^p converts the d_{Δ^p} term into the alternating sum over faces by Stokes’ formula. Face compatibility in Lemma 33.2.4 identifies that boundary sum with $\delta_{\check{C}/\text{Ran}}$ in D_{tot} . Summing over the finite nerve gives the displayed Maurer–Cartan equation. The last non-identification follows because the finite Rees Hall complex precedes vanishing-cycle realisation, Hopf pairing, completion, and vertex-algebra evaluation. $\square$

Orientation sign in the finite Rees product. The base-orientation flip in $\Omega_Y|_{U_-} = -d\tilde{z} \wedge du_- \wedge dv_-$ enters the orientation line o_σ of the edge Rees Hall complex. On cross-chart Hall products the sign is the Koszul sign in the Thom–Sebastiani transport, hence a coefficient of the Maurer–Cartan element above. A super-Yangian presentation may be recovered only after the separate realised quiver–Hall identification with the Klebanov–Witten conifold quiver; it is not the output of the finite Čech/Ran equation.

Coefficient check for the $(1, 1)$ term. The $(1, 1)$ structure constant in the finite Rees Hall product equals $(\varepsilon_1 \varepsilon_2)^{-1}$ through three independent computations:

- (i) *Čech two-chart gluing:* the limit $u_2 \rightarrow u_1$ of the chart-wise Jordan shuffle (33.3).
- (ii) *Van den Bergh tilting:* the integral of the φ_W -twisted Euler class over $\text{Ext}^1(S_o, S_1) = \mathbb{C}^2$, the rank-2 Ext-space between the simple modules of the Klebanov–Witten quiver.
- (iii) *Klebanov–Witten super-shuffle:* the Jordan kernel residue at $z_1 = z_2$ of the direct super-shuffle algebra.

Agreement across these computations pins $(\varepsilon_1 \varepsilon_2)^{-1}$ as the local coefficient carried by the finite Rees Hall comparison.

Multi-chart toric fan generalisation

The two-chart finite Rees assembly generalises to any local toric CY_3 . The obstruction resolved is the absence of a global affine chart: a toric variety is covered by affine opens U_σ indexed by the maximal cones σ of the fan, and the finite Rees Hall coefficient system is assembled by running the Čech/Ran machinery along the face lattice of the fan.

TORIC FAN AND CHART DECOMPOSITION

Let $X = X_\Sigma$ be a smooth toric CY_3 with fan Σ in the lattice $N \cong \mathbb{Z}^3$. The Calabi–Yau condition is that the primitive generators of all rays of Σ lie in a common affine hyperplane, equivalently that there exists a lattice vector $m \in M = N^\vee$ such that $\langle m, v_\rho \rangle = 1$ for every ray generator v_ρ . A natural choice places all ray generators at height 1 along the last coordinate; the toric diagram is then the 2-dimensional polytope obtained by projecting the rays to the plane $\{x_3 = 1\}$.

Chart structure at top cones. Each maximal (top-dimensional) cone $\sigma \in \Sigma(3)$ of a smooth toric CY_3 is generated by exactly three rays ρ_1, ρ_2, ρ_3 forming a $\mathbb{Z}$ -basis of N , and determines an affine chart

$$U_\sigma = \text{Spec } \mathbb{C}[\sigma^\vee \cap M] \cong \mathbb{C}^3.$$

Coordinates $(x_1^\sigma, x_2^\sigma, x_3^\sigma)$ on U_σ are the characters of the dual basis of $\sigma^\vee$. The Jordan-triple potential on each chart is

$$W_\sigma = \text{tr}(x_1^\sigma [x_2^\sigma, x_3^\sigma]),$$

and the chart-wise CoHA is $\text{CoHA}(U_\sigma, W_\sigma) \cong Y^+(\widehat{\mathfrak{gl}}_1)$ by the Schiffmann–Vasserot theorem applied to each $\mathbb{C}^3$ with the standard Jordan-triple.

Equivariant weights and the CY condition. The three-torus $T^3 = (\mathbb{C}^\times)^3$ acts on each $U_\sigma \cong \mathbb{C}^3$ with equivariant weights $(\varepsilon_1^\sigma, \varepsilon_2^\sigma, \varepsilon_3^\sigma)$. The Calabi–Yau constraint on W_σ to be a tri-vector of vanishing weight is

$$\varepsilon_1^\sigma + \varepsilon_2^\sigma + \varepsilon_3^\sigma = 0,$$

which specialises the chart-wise weights to those of a local CY_3 . Along a compact direction (a ray ρ in $\Sigma(1)$ whose dual edge in the toric diagram is an internal edge) the equivariant parameter vanishes: the two fixed points of the compact $\mathbb{P}^1$ -base on that edge would carry opposite weights, obstructing global regularity of sections. This is the mechanism that set $\varepsilon_3 = 0$ for the conifold base in §33.2.

PROPOSITION 33.2.8 (*Affine hCS BV chart and CY transition law*). Let $U_\sigma \simeq \mathbb{C}^3$ be a maximal-cone chart of a smooth toric CY_3 , with coordinates $x_1^\sigma, x_2^\sigma, x_3^\sigma$, and write

$$\Omega_X|_{U_\sigma} = \lambda_\sigma dx_1^\sigma \wedge dx_2^\sigma \wedge dx_3^\sigma, \quad \lambda_\sigma \in \mathcal{O}(U_\sigma)^\times.$$

For a metric Lie algebra $\mathfrak{g}$, the affine-chart hCS BV complex is

$$\mathcal{E}_{\text{hCS},c}(U_\sigma, \mathfrak{g}) = \Omega_c^{\circ, \bullet}(U_\sigma, \mathfrak{g})[1], \quad Q_{\text{hCS}} = \bar{\partial},$$

with pairing and classical action

$$(\alpha, \beta)_\sigma = \int_{U_\sigma} \Omega_X \wedge \langle \alpha, \beta \rangle, \quad I_\sigma(\alpha) = \int_{U_\sigma} \Omega_X \wedge \left(\frac{1}{2} \langle \alpha, \bar{\partial} \alpha \rangle + \frac{1}{6} \langle \alpha, [\alpha, \alpha] \rangle \right).$$

An element of Dolbeault degree q has BV cohomological degree $q - 1$. The pairing is non-zero only on components with $q_1 + q_2 = 3$, hence has degree -1 on $\Omega_c^{\circ, \bullet}[1]$; the displayed superfield action means taking the $(0, 3)$ -component before integrating. On non-compact charts the compact-support convention is understood after restriction to the overlap on which the transition map is applied. If $U_\sigma \cap U_{\sigma'} \neq \emptyset$ and $\phi_{\sigma\sigma'}$ is the holomorphic transition map from σ -coordinates to σ' -coordinates, then

$$\lambda_\sigma = (\lambda_{\sigma'} \circ \phi_{\sigma\sigma'}) \det \left(\frac{\partial x_a^{\sigma'}}{\partial x_b^\sigma} \right)_{a,b=1}^3.$$

The transition map

$$T_{\sigma\sigma'}^{\text{BV}}: \mathcal{E}_{\text{hCS},c}(U_{\sigma'}, \mathfrak{g})|_{U_\sigma \cap U_{\sigma'}} \longrightarrow \mathcal{E}_{\text{hCS},c}(U_\sigma, \mathfrak{g})|_{U_\sigma \cap U_{\sigma'}}, \quad \alpha \longmapsto \phi_{\sigma\sigma'}^* \alpha,$$

commutes with $\bar{\partial}$, preserves the BV pairing and action, and satisfies the Čech cocycle identity on triple overlaps. The same Jacobian identity transports the finite Rees Hall divergence by conjugacy:

$$T_{\sigma\sigma'}^{\text{PV}} \Delta_{\omega_{\sigma'}} = \Delta_{\omega_\sigma} T_{\sigma\sigma'}^{\text{PV}}, \quad T_{\sigma\sigma'}^{\text{PV}} \iota_{dW_{\sigma'}} = \iota_{dW_\sigma} T_{\sigma\sigma'}^{\text{PV}},$$

whenever $W_\sigma = \phi_{\sigma\sigma'}^* W_{\sigma'}$. Equivalently $T_{\sigma\sigma'}^{\text{PV}}$ conjugates the finite Rees differential $\iota_{dW} + \hbar \Delta_\omega$. Here $\omega_\sigma = \Omega_X|_{U_\sigma}$ is the finite cyclic volume form.

Proof. The formula for λ_σ is the equality $\Omega_X|_{U_\sigma} = \phi_{\sigma\sigma'}^*(\Omega_X|_{U_{\sigma'}})$ written in coordinates. Since $\phi_{\sigma\sigma'}$ is holomorphic, $\phi_{\sigma\sigma'}^* \bar{\partial} = \bar{\partial} \phi_{\sigma\sigma'}^*$. The change of variables formula and the displayed Jacobian identity give

$$\int_{U_{\sigma'}} \Omega_X \wedge \langle \alpha, \beta \rangle = \int_{U_\sigma} \Omega_X \wedge \langle \phi_{\sigma\sigma'}^* \alpha, \phi_{\sigma\sigma'}^* \beta \rangle,$$

and the same calculation applies to the quadratic and cubic terms of I_σ , using invariance of $\langle -, - \rangle$. Thus the degree- (-1) BV pairing, bracket, and master equation are transported without an extra density. On triple overlaps the coordinate transitions compose, and the determinants multiply; hence the transition maps form a Čech cocycle. The divergence operator Δ_ω is characterised on polyvectors by $\mathfrak{F}_\omega(\Delta_\omega \xi) = d \mathfrak{F}_\omega(\xi)$, equivalently by $L_\xi \omega = (\Delta_\omega \xi) \omega$ for vector fields. Since $\mathfrak{F}_{\omega_\sigma} T_{\sigma\sigma'}^{\text{PV}} = \phi_{\sigma\sigma'}^* \mathfrak{F}_{\omega_{\sigma'}}$, the same Jacobian conjugates Δ_ω ; the equality $W_\sigma = \phi_{\sigma\sigma'}^* W_{\sigma'}$ gives the contraction term. This is precisely the finite Rees compatibility used by Lemma 6.1.16. $\square$

THEOREM 33.2.9 (*Smooth toric CY_3 hCS factorisation descent*). Let Σ be a finite smooth three-dimensional fan in $N \simeq \mathbb{Z}^3$, let $X = X_\Sigma$, and assume the toric Calabi–Yau condition: there is $m_o \in M = N^\vee$ with $\langle m_o, v_\rho \rangle = 1$ for every ray generator v_ρ . Let Ω_X be the corresponding toric holomorphic volume form. For every finite-dimensional metric Lie algebra $\mathfrak{g}$, the affine hCS BV factorisation algebras on the maximal-cone charts $U_\sigma \simeq \mathbb{C}^3$ glue over the face lattice to a global classical BV holomorphic E_3 -factorisation algebra

$$\text{Obs}_{\text{hCS}}^{\text{cl}}(-, \mathfrak{g}) = \left(\widehat{\text{Sym}} \left(\Omega_c^{\circ, \bullet}(-, \mathfrak{g})[1]^\vee[-1] \right), d_{\bar{\partial}} + \{I_X, -\}_{\text{BV}} \right),$$

where

$$I_X(\alpha) = \int_X \Omega_X \wedge \left(\frac{1}{2} \langle \alpha, \bar{\partial} \alpha \rangle + \frac{1}{6} \langle \alpha, [\alpha, \alpha] \rangle \right).$$

If $\mathfrak{U}_\Sigma$ is the toric affine cover and $\text{DWR}(\mathfrak{U}_\Sigma)$ is any Ran–Weiss refinement by holomorphic polydiscs, then for every admissible open $V \subset X$ the canonical descent morphism

$$\text{hocolim}_{P \in \text{DWR}(\mathfrak{U}_\Sigma)/V} \text{Obs}_{\text{hCS}}^{\text{cl}}(P, \mathfrak{g}) \xrightarrow{\simeq} \text{Obs}_{\text{hCS}}^{\text{cl}}(V, \mathfrak{g})$$

is a quasi-isomorphism of prefactorisation algebras. If, in addition, X is equipped with a complete bounded-geometry Kähler metric and $\mathfrak{g}$ is anomaly-free in the sense of Definition 33.2.2, the same statement holds for the renormalised quantum hCS factorisation algebra.

Proof. For a maximal cone $\sigma = \langle v_1, v_2, v_3 \rangle$, smoothness makes v_1, v_2, v_3 a $\mathbb{Z}$ -basis of N , hence $U_\sigma = \text{Spec } \mathbb{C}[\sigma^\vee \cap M] \simeq \mathbb{C}^3$. Let $m_1^\sigma, m_2^\sigma, m_3^\sigma$ be the dual basis and $x_i^\sigma = \chi^{m_i^\sigma}$. The Calabi–Yau condition gives $m_o = m_1^\sigma + m_2^\sigma + m_3^\sigma$, so on U_σ

$$\Omega_X = \lambda_\sigma dx_1^\sigma \wedge dx_2^\sigma \wedge dx_3^\sigma$$

with λ_σ an invertible monomial. If σ, σ' share a face, the transition is monomial:

$$x_a^{\sigma'} = \prod_b (x_b^\sigma)^{A_{ab}}, \quad A \in GL_3(\mathbb{Z}).$$

The equality of the two expressions for m_o forces the CY Jacobian identity for Ω_X ; the determinant contributes only the orientation sign of the lattice basis. Proposition 33.2.8 therefore supplies cyclic BV isomorphisms $T_{\sigma\sigma'}^{\text{BV}}$ on every overlap.

Finite intersections of affine toric charts are face charts

$$U_{\sigma_0} \cap \cdots \cap U_{\sigma_p} = U_\tau, \quad \tau = \sigma_0 \cap \cdots \cap \sigma_p,$$

with $U_\tau \simeq \mathbb{C}^{\dim \tau} \times (\mathbb{C}^\times)^{3-\dim \tau}$. On triple overlaps the monomial matrices multiply, determinants multiply, and pullbacks compose; hence the $T_{\sigma\sigma'}^{\text{BV}}$ form a strict Čech cocycle on the face lattice.

Compactly supported Dolbeault fields are a cosheaf. Since the fan is finite, the augmented Čech complex

$$\cdots \rightarrow \bigoplus_{\sigma_0 < \cdots < \sigma_p} \Omega_c^{\circ, \bullet}(U_{\sigma_0} \cap \cdots \cap U_{\sigma_p}, \mathfrak{g})[1] \rightarrow \cdots \rightarrow \bigoplus_{\sigma} \Omega_c^{\circ, \bullet}(U_\sigma, \mathfrak{g})[1] \rightarrow \Omega_c^{\circ, \bullet}(X, \mathfrak{g})[1] \rightarrow 0$$

is exact, with equality on overlaps read through the cyclic transition maps. The proof is the smooth partition-of-unity argument; compact support makes extension by zero smooth and produces no boundary term at infinity.

The preceding paragraph constructs the global elliptic local L_∞ -algebra $\Omega_c^{\bullet,*}(-, \mathfrak{g})[1]$ with its cyclic pairing and hCS Hamiltonian. The Costello–Gwilliam classical observable envelope gives the displayed factorisation algebra. A toric affine cover is not itself Weiss-local, so it is refined by holomorphic polydiscs and closed under finite disjoint unions. Every finite point configuration in V lies in such a disjoint union, and the Ran–Weiss homotopy colimit computes the factorisation algebra on V .

For the quantum statement, the heat-kernel construction of Theorem 33.2.3 is local on the diagonal and natural under the same CY transition maps. The anomaly class is the universal local class $\mathfrak{a}_{\mathfrak{g}}$, so its vanishing kills every chart obstruction and the Čech cocycle introduces no new one. $\square$

GLUING COCYCLE ON THE FACE LATTICE

Two top cones σ, σ' of $\Sigma(3)$ sharing a common face $\tau = \sigma \cap \sigma' \in \Sigma(2)$ of codimension one define an overlap $U_\sigma \cap U_{\sigma'} = U_\tau$. The face τ is a two-dimensional cone, generated by two rays; the corresponding overlap is

$$U_\tau \cong \mathbb{C}^\times \times \mathbb{C}^2,$$

with the $\mathbb{C}^\times$ -factor encoding the direction transverse to τ within the full three-dimensional lattice. The transition between the chart coordinates $(x_1^\sigma, x_2^\sigma, x_3^\sigma)$ and $(x_1^{\sigma'}, x_2^{\sigma'}, x_3^{\sigma'})$ follows the lattice change of basis between $\sigma^\vee$ and $(\sigma')^\vee$: when σ' differs from σ by a toric flop sending ray ρ_1 to ρ'_1 across the shared face τ (generated by ρ_2, ρ_3), the conifold-type transition is

$$x_1^{\sigma'} = (x_1^\sigma)^{-1}, \quad x_i^{\sigma'} = x_1^\sigma \cdot x_i^\sigma \text{ for } i = 2, 3,$$

in direct analogy with the conifold transition (33.1). More generally, if the toric flop twists the fibre ρ_1 -direction with multiplicity (k_2, k_3) along ρ_2, ρ_3 (equivalently, the fibre bundle over the shared $\mathbb{P}^1_\tau$ is $\mathcal{O}(-k_2) \oplus \mathcal{O}(-k_3)$), the transition reads $x_i^{\sigma'} = (x_1^\sigma)^{k_i} x_i^\sigma$ on the i -th fibre coordinate. The Fourier–Mukai kernel on the overlap is

$$K_{\sigma\sigma'} = \mathcal{O}_\Delta \otimes \pi_1^* \mathcal{O}_{\mathbb{P}^1_\tau}(-1),$$

the $\mathcal{O}(-1)$ -twist sourced by the compact $\mathbb{P}^1_\tau$ -base transverse to τ ; the polyvector multiplier $(x_1^\sigma)^{-(1+k_2, a+k_3, b)}$ generalises (33.5) with a, b the fibre polyvector indices. The Jacobian argument of §33.2 carries over with z replaced by x_1^σ on each codimension-one face, and with the fibre twist exponents (k_2, k_3) replacing the conifold's $(1, 1)$; the Calabi–Yau condition $k_2 + k_3 = 2$ (sum of $\mathcal{O}(-k_i)$ -degrees equals $-\deg K_{\mathbb{P}^1_\tau} = -2$) enforces triviality of $K_X|_{\mathbb{P}^1_\tau}$.

The face lattice cocycle. The collection $\{K_{\sigma\sigma'}\}_{\sigma, \sigma' \text{ adjacent}}$ forms a cocycle on the face lattice of Σ : at any triple overlap $U_\sigma \cap U_{\sigma'} \cap U_{\sigma''}$ (corresponding to a codimension-two face $\tau = \sigma \cap \sigma' \cap \sigma''$), the compatibility

$$K_{\sigma\sigma''} = K_{\sigma'\sigma''} \circ K_{\sigma\sigma'}$$

holds up to canonical isomorphism, because each kernel is the pullback of $\mathcal{O}_{\mathbb{P}^1}(-1)$ along a $\mathbb{P}^1$ -fibre direction and the fibre directions compose additively in the toric fan. The cocycle class is the derivative of the data on the fan's 1-skeleton and is classified by the sheaf cohomology group $H^1(\Sigma, \underline{\text{Pic}}(\mathbb{P}^1))$ on the fan viewed as a CW complex.

GALAKHOV–LI–YAMAZAKI BOND FACTORS

Galakhov–Li–Yamazaki (2021 arXiv:2106.01230; Li–Yamazaki 2020 arXiv:2003.08909 eq (8.125)) present the multi-chart gluing data via *bond factors* $\varphi^{a \Rightarrow b}(u)$ indexed by ordered pairs (a, b) of vertices in the toric quiver. The convention is:

$$\varphi^{a \Rightarrow b}(u) = \frac{\prod_{I \in \text{Arr}(a \rightarrow b)} (u + h_I^{a \rightarrow b})}{\prod_{J \in \text{Rel}(a \rightarrow b)} (u + h_J^{a \rightarrow b})}, \quad (33.6)$$

with $h_I^{a \rightarrow b}$ the equivariant weight of the I -th arrow from vertex a to vertex b , and $h_J^{a \rightarrow b}$ the equivariant weight of the J -th Jacobi relation $(\partial W / \partial(\text{arrow}))$ tying arrows from a into and out of a trip through b . The *numerator is arrow weights; the denominator is Jacobi-relation weights*; the $(u + h)$ -convention signs track the Drinfeld shifted- R -matrix normalisation (Neguț 2015 arXiv:1512.06473 eq (1.6); Tsymbaliuk 2014 arXiv:1404.5240).

Conifold bond factor from first principles. The conifold quiver (Klebanov–Witten 1998 hep-th/9807080) has two vertices $\{0, 1\}$, two arrows $a_1, a_2 : 0 \rightarrow 1$ with equivariant weights h_1, h_2 , two arrows $b_1, b_2 : 1 \rightarrow 0$ with weights $-h_1, -h_2$, and the Klebanov–Witten superpotential $W_{\text{con}} = \text{tr}(a_1 b_1 a_2 b_2 - a_1 b_2 a_2 b_1)$ of T_{CY}^2 -weight zero. For the bond $0 \Rightarrow 1$, the numerator of (33.6) enumerates the two $0 \rightarrow 1$ arrows with weights h_1, h_2 , giving $(u + h_1)(u + h_2)$. The denominator enumerates the two Jacobi relations tied to $0 \Rightarrow 1$, namely the F-term ideal generators $\partial W / \partial b_1, \partial W / \partial b_2$ read as elements of the weight-graded path algebra at vertex 0: the KW ideal admits a canonical generating pair $(\mathbf{r}_{\text{sym}}, \mathbf{r}_{\text{asym}}) = (a_1 b_1 + a_2 b_2, a_1 b_2 a_2 b_1 - a_1 b_1 a_2 b_2)$ of T_{CY}^2 -weights 0 (symmetric moment-map trace) and $h_1 + h_2$ (Hessian-quadratic deformation direction) respectively, matching the Neguț–Tsymbaliuk rank-2 shuffle presentation (arXiv:1404.5240 §4). Substituting into the GLY formula (33.6):

$$\varphi_{\text{con}}^{0 \Rightarrow 1}(u) = \frac{(u + h_1)(u + h_2)}{u \cdot (u + h_1 + h_2)}, \quad (33.7)$$

matching Neguț’s conifold shuffle kernel (Neguț 2015 arXiv:1512.06473 eq (1.6)) and Li–Yamazaki’s BPS-quiver-algebra master formula (arXiv:2003.08909 eq (8.125)). At the Calabi–Yau torus-equivariant slice $\varepsilon_1 + \varepsilon_2 + \varepsilon_3 = 0$, the conifold weights are $h_1 = \varepsilon_1, h_2 = \varepsilon_2$, and $h_1 + h_2 = \varepsilon_1 + \varepsilon_2 = -\varepsilon_3$; substituting into (33.7):

$$\varphi_{\text{con}}^{0 \Rightarrow 1}(u) = \frac{(u + \varepsilon_1)(u + \varepsilon_2)}{u(u + \varepsilon_1 + \varepsilon_2)} = \frac{(u + \varepsilon_1)(u + \varepsilon_2)}{u(u - \varepsilon_3)}.$$

Both presentations are equivalent through the Calabi–Yau constraint $\varepsilon_3 = -\varepsilon_1 - \varepsilon_2$.

Arrow-weight / relation-weight trace on the toric diagram. The arrow count $|\text{Arr}(a \rightarrow b)|$ matches the number of toric diagram edges joining the dual vertices of a and b ; the Jacobi-relation count $|\text{Rel}(a \rightarrow b)|$ matches the number of toric triangles sharing the edge. For the conifold (2 arrows, 2 relations per direction) the $2 + 2$ tally reflects the two-edge, two-triangle diagram. For local $\mathbb{P}^2$ the bond factors are labelled by the three $\mathbb{Z}_3$ -characters of the McKay quiver (Beilinson nine-arrow structure, §33.2); for the banana threefold, by the three edges of the banana diagram; for the suspended pinch point, by the pinch-point bond structure.

EXAMPLES

$\mathbb{C}^3/\mathbb{Z}_n$ (*linear toric*). The fan has n maximal cones arrayed along the toric diagram edge, each $\mathbb{C}^3$; the face lattice is a linear chain with $n - 1$ codimension-one faces; the gluing cocycle is a chain of $n - 1$ FM kernels, each a $O(-1)$ -twist. The finite Rees atlas carries the $\mathcal{A}_{n-1}$ -type McKay quiver-Hall coefficient system, matching the Beasley–Plesser antisymmetric quiver on $\mathbb{C}^3/\mathbb{Z}_n$ after the orbifold realisation.

Banana threefold. Three ray clusters meeting at a common vertex produce a fan with three maximal cones and three codimension-one faces. The finite Čech/Ran atlas requires three FM kernels on a triangular face lattice; the finite Rees coefficient system is a triangular gluing of three Schiffmann–Vasserot $Y^+(\widehat{\mathfrak{gl}}_1)$ copies, governed by the three-arrow banana quiver with cubic potential after quiver-Hall realisation.

Suspended pinch point. The SPP singularity $\{xy = zw^2\} \subset \mathbb{C}^4$ has toric diagram the trapezoid $\{(0, 0), (2, 0), (1, 1), (0, 1)\}$ with minimal triangulation into three triangles sharing a common internal edge (the “pinch”). The fan has three maximal cones and three codimension-one faces; the Čech/Ran cocycle is defined on this triangulated trapezoid; the finite Rees coefficient system carries the SPP quiver of Uranga (1999 hep-th/9811004) and Aganagic–Karch–Lüst–Miemiec (1999 hep-th/9903093) after the realised quiver-Hall step.

The compact 4-cycle obstruction

The obstruction resolved here is subtle: a local toric CY_3 with a compact divisor; a maximal cone whose dual vertex lies in the *interior* of the toric diagram; admits a chart-wise $\mathbb{C}^3$ cover, but the boundary Čech/Ran Rees atlas of §33.2 misses the wheel term of the compact divisor.

INTERIOR LATTICE POINTS AND COMPACT DIVISORS

Let X_Σ be a local toric CY_3 with toric diagram Δ_Σ a lattice polygon in the plane $\{x_3 = 1\}$. The duality between toric fans and toric diagrams identifies:

$$\text{rays of } \Sigma \longleftrightarrow \text{vertices of } \Delta_\Sigma, \quad \text{maximal cones} \longleftrightarrow \text{internal triangulation triangles},$$

and one distinguishes:

- *boundary rays*: rays whose dual vertex lies on the boundary of Δ_Σ ; these correspond to non-compact divisors in X ;
- *interior rays*: rays whose dual vertex lies in the interior of Δ_Σ ; these correspond to compact divisors, i.e. compact 4-cycles in X .

The resolved conifold has no interior lattice point: its toric diagram is a unit square with vertices $(0, 0), (1, 0), (0, 1), (1, 1)$ and no interior lattice point, consistent with $\chi(\mathbf{Y}) = 2$ and no compact 4-cycle. Local $\mathbb{P}^2 = \text{Tot}(K_{\mathbb{P}^2})$ has exactly one interior lattice point: its toric diagram is the triangle with vertices $(1, 0), (0, 1), (-1, -1)$ (the three non-compact divisor rays at height 1) and the interior lattice point $(0, 0)$ at the origin; the ray $(0, 0, 1)$ attached to this interior point generates the zero-section $\mathbb{P}^2 \subset K_{\mathbb{P}^2}$, a compact 4-cycle.

WHY CHART-WISE GLUING MISSES THE COMPACT DIVISOR

The boundary Čech/Ran Rees atlas of §33.2 has three ingredients on each chart: the Schiffmann–Vasserot $Y^+(\widehat{\mathfrak{gl}}_1)$, the equivariant torus action, and the FM kernel on codimension-one overlaps. None of these detect the cohomology of a compact divisor:

- The chart-wise polyvector complex $PV^\bullet(U_\sigma)$ is concentrated in $(0, *)$ -degree (holomorphic polyvector fields on $\mathbb{C}^3$), and has no contribution from the class of a compact surface.
- The FM kernels $K_{\sigma\sigma'}$ transport polyvectors across codimension-one faces but do not generate new cohomology classes: they are sheaves of derived Morita data, not cycle classes.
- The T^3 -equivariant localisation concentrates all integrals at the fixed points of the torus action, i.e. the maximal cones; the contribution of a compact divisor is the *sum over the fixed points contained in the divisor*, which must be computed by a separate procedure.

The Neguț wheel-condition corrections; the shuffle-algebra relations forced by the presence of an interior lattice point; are missed by the boundary Čech/Ran Rees atlas. For local $\mathbb{P}^2$ with single interior point at the origin of the triangulation, the correct shuffle algebra is the $\mathbb{Z}_3$ -McKay variant of $Y^+(\widehat{\mathfrak{gl}}_1)$ whose kernel carries an additional wheel-condition multiplier tracking the $\mathbb{Z}_3$ -orbit of the interior lattice point (Neguț 2015 arXiv:1512.06473; Rapcak–Soibelman–Yang–Zhao 2020 arXiv:2001.10549). The direct multi-chart Čech/Ran Rees atlas of §33.2 picks up only the boundary contributions to $\varphi_{a \Rightarrow b}$ and misses this wheel-condition multiplier.

RESOLUTION VIA MCKAY/ORBIFOLD ROUTE

The standard resolution of the obstruction is to pass to the orbifold quotient: local $\mathbb{P}^2 = [\mathbb{C}^3/\mathbb{Z}_3]^{\text{res}}$ (the crepant resolution of the McKay orbifold), and apply the Bridgeland–King–Reid equivalence

$$D^b(\text{Coh}(K_{\mathbb{P}^2})) \simeq D^b(\text{Coh}^{\mathbb{Z}_3}(\mathbb{C}^3))$$

(Bridgeland–King–Reid 2001 arXiv:math/9908027 Thm. 1.2). The right-hand category is a single $\mathbb{C}^3$ -chart with $\mathbb{Z}_3$ -equivariance; the finite Hall model of this orbifold chart carries the Neguț wheel-condition multipliers automatically, since the $\mathbb{Z}_3$ -action on $\mathbb{C}^3$ produces exactly the interior-point shifts at each orbit element. The compact 4-cycle cohomology is recovered as the $\mathbb{Z}_3$ -fixed part of the $\mathbb{C}^3/\mathbb{Z}_3$ inertia stack.

Alternatively, one may keep the multi-chart cover and enrich each chart-wise shuffle kernel with a higher-rank Neguț correction: replace $\varphi_{a \Rightarrow b}(u)$ by the shuffle kernel $\varphi_{a \Rightarrow b}^{\text{rank}-r}(u)$ of the rank- r shuffle algebra, with r the number of interior lattice points of the toric diagram. The two resolutions; McKay/orbifold route (§33.3) and higher-rank shuffle correction; are Morita-equivalent under the Rapcak–Soibelman–Yang–Zhao toric theorem (2020 arXiv:2001.10549 Thm. B), but differ in their chart-wise presentations.

PROPOSITION 33.2.10 (Compact-4-cycle obstruction). Let X_Σ be a local toric CY₃ with toric diagram Δ_Σ carrying $r \geq 1$ interior lattice points. The direct multi-chart Čech/Ran Rees atlas of §33.2, built only from chart-wise single-vertex Jordan triples, presents the boundary positive halves and misses the interior-lattice wheel terms. A finite Rees atlas for the full toric quiver Hall layer must replace the local chart data by either:

- (a) the G -equivariant Schiffmann–Vasserot data on $[\mathbb{C}^3/G]$, where $G \subset \text{SU}(3)$ is the McKay group whose crepant resolution $\widetilde{\mathbb{C}^3/G}$ recovers X_Σ (McKay/orbifold route; applies when Δ_Σ is a McKay triangle, including $X_\Sigma = K_{\mathbb{P}^2}$ with $G = \mathbb{Z}_3$);
- (b) the multi-vertex Neguț shuffle algebra $Y^+(Q_X, W_X)$ whose vertex set matches the full toric quiver of X_Σ (interior and boundary lattice points together) and whose bond factors carry the wheel-condition multipliers tracking the interior-point positions (higher-rank shuffle route).

The boundary multi-chart Rees atlas with only the chart-wise $Y^+(\widehat{\mathfrak{gl}}_1)$ data therefore stops at the boundary Rees Hall coefficient system.

Proof. The chart-wise single-vertex polyvectors generate only the boundary-vertex portion of the full toric quiver shuffle algebra; the interior-vertex portion is generated by compositions extending into the G -McKay inertia (Bridgeland–King–Reid 2001 arXiv:math/9908027 Thm. 1.2). In the McKay route the finite critical chart is $[C^3/G]$, so the twisted sectors of the inertia stack supply exactly the missing interior weights. In the higher-rank shuffle route the finite critical chart is the full toric quiver (Q_X, W_X) ; the Neguţ wheel factors are relations in the Rees Hall product and are visible before any completion. Rapcak–Soibelman–Yang–Zhao (2020 arXiv:2001.10549 Thm. B) identifies these two presentations of the same toric quiver shuffle data. The single-vertex atlas lacks both the twisted sectors and the wheel relations, hence cannot produce the interior-lattice terms. $\square$

Finite zero-interior Rees assembly

The combination of §§33.2–33.2 has a sharp zero-interior consequence. Boundary cones and codimension-one faces supply all Rees Hall coefficients; no compact-divisor wheel term remains to be added.

PROPOSITION 33.2.11 (*Finite zero-interior toric Rees assembly*). Let X_Σ be a smooth local toric Calabi–Yau threefold whose toric diagram Δ_Σ has zero interior lattice points. Choose a DWR-good refinement $\mathfrak{U}_\Sigma$ of its finite toric C^3 -atlas and finite bounds (N, r, L, m) . Then:

- (1) the chart Jordan triples $(Q_{\text{Jor}}, W_\sigma)$ on maximal cones, together with the Fourier–Mukai transitions on common faces, form a multiplicative finite DWR/Ran cyclic critical atlas on $\mathfrak{U}_\Sigma$;
- (2) the Stokes sum

$$\Theta_{X_\Sigma}^{\text{Rees}, N, r, L, m} = \sum_{0 \leq p \leq m} \sum_{\sigma \in \mathcal{N}_{p, \leq m}^{\text{Ran}}(\mathfrak{U}_\Sigma; \Gamma_{\leq L})} \int_{\Delta^p} \theta_\sigma^{\text{rel}}$$

satisfies the Čech/Ran Maurer–Cartan equation in the finite convolution dg Lie algebra $\mathfrak{M}_{\text{hCS, Hall}}^{N, r, L, m}(\mathfrak{U}_\Sigma)$;

- (3) every 0-simplex lying in a toric chart has local Hall cohomology $Y^+(\widehat{\mathfrak{gl}}_1)$, and the positive-half quiver presentation attached to the toric diagram is obtained only after the separate realised quiver-Hall identification.

This constructs the finite oriented Rees Hall comparison on the Čech/Ran nerve. It does not construct $\mathcal{W}_{1+\infty}$, a compact CoHA, a completed critical CoHA, or a Hall–Drinfeld double.

Proof. The fan has finitely many maximal cones and codimension-one faces. On each maximal cone the local model is the Jordan triple on C^3 , whose critical Hall cohomology is $Y^+(\widehat{\mathfrak{gl}}_1)$ by Schiffmann–Vasserot. On a shared face the transition is the toric lattice change of basis; its Fourier–Mukai kernel is the same line-bundle transport as in (33.4), with multiplier computed by (33.5) after replacing the conifold exponents by the face exponents (k_2, k_3) . The Calabi–Yau condition makes the holomorphic-volume Jacobian constant on the face, so the cyclic pairing restricts compatibly.

On codimension-two intersections the toric line-bundle cocycle condition makes the two composites of Fourier–Mukai kernels canonically isomorphic. On disjoint Ran configurations the potentials add by $W_{\sigma_1 \sqcup \sigma_2} = W_{\sigma_1} \boxplus W_{\sigma_2}$, and Thom–Sebastiani gives the Rees Hall product. These two compatibilities are precisely the face and multiplicative axioms of a finite DWR/Ran cyclic critical atlas.

The relative BV master equation on every simplex becomes, after the relative Fourier–BV Rees identification,

$$(d_{\text{Hall}} + d_{\Delta^p})\theta_{\sigma}^{\text{rel}} - \theta_{\sigma}^{\text{rel}} d_{B\text{Obs}} + \frac{1}{2}[\theta_{\sigma}^{\text{rel}}, \theta_{\sigma}^{\text{rel}}]_{\text{conv}} = 0.$$

Integrating over Δ^p and summing over the finite nerve converts the simplex boundary term to $\delta_{\check{C}/\text{Ran}}$, hence gives the Maurer–Cartan equation for $\Theta_{X_{\Sigma}}^{\text{Rees}, N, r, L, m}$. Zero interior lattice points remove the Negut wheel corrections described in Proposition 33.2.10; the atlas therefore contains exactly the boundary face coefficients and no compact-divisor term. Rapcak–Soibelman–Yang–Zhao identify the realised toric quiver shuffle algebra after the quiver-Hall realisation is supplied; that identification is not part of the finite Rees construction proved here. $\square$

The class of local toric CY_3 covered by Proposition 33.2.11 (zero interior lattice points in Δ_{Σ}) includes:

- $\mathbb{C}^3$ (one chart, no overlaps, local positive half $Y^+(\widehat{\mathfrak{gl}}_1)$); toric diagram = triangle $\{(0, 0), (1, 0), (0, 1)\}$, 0 interior points;
- the resolved conifold (two charts, one overlap, finite Rees comparison with Klebanov–Witten quiver-Hall realisation available after the separate realisation step); toric diagram = unit square $\{(0, 0), (1, 0), (0, 1), (1, 1)\}$, 0 interior points;
- the banana threefold (local model: three $\mathbb{P}^1$'s meeting at two common nodes; three maximal cones, three overlaps, three-loop fan); local toric diagram with no interior lattice points;
- the suspended pinch point $\text{SPP} = \{x y = z w^2\} \subset \mathbb{C}^4$ (three maximal cones, three overlaps); toric diagram the trapezoid $\{(0, 0), (2, 0), (1, 1), (0, 1)\}$, 0 interior lattice points;
- generalised conifolds $X_{n, m} = \text{Tot}(\mathcal{O}(-n) \oplus \mathcal{O}(-m) \rightarrow \mathbb{P}^1)$ with $n + m = 2$ (two charts, one overlap with $\mathcal{O}(-n) \oplus \mathcal{O}(-m)$ -twist); toric diagram an elongated quadrilateral with no interior lattice points.

The class outside the proposition comprises exactly those local toric CY_3 with one or more interior lattice points. Among toric smooth surfaces giving local CY_3 , these are: local $\mathbb{P}^2 = K_{\mathbb{P}^2}$ (one interior point $(0, 0)$), local $\mathbb{P}^1 \times \mathbb{P}^1 = K_{\mathbb{P}^1 \times \mathbb{P}^1}$ (one interior point), local Hirzebruch $\mathbb{F}_n$ for $n \geq 1$ (one interior point), and local toric del Pezzo $dP_k = \text{Bl}_k \mathbb{P}^2$ for $k = 1, 2, 3$ (the only toric del Pezzos beyond $\mathbb{P}^2$; each with one interior point in its toric diagram). Non-toric del Pezzos dP_k for $k \geq 4$ fall outside the toric framework entirely. These all carry compact 4-cycles and must pass through Proposition 33.2.10's McKay/orbifold or higher-rank shuffle resolutions. §33.3 takes up this resolution, replacing the boundary chart-wise Čech/Ran atlas by the BKR equivalence and the inertia-stack decomposition of the orbifold route; in particular, the nine-arrow Beilinson quiver of local $\mathbb{P}^2$ enters through the $[\mathbb{C}^3/\mathbb{Z}_3]$ chart and its $\mathbb{Z}_3$ skew-group algebra, not through the boundary $\mathbb{C}^3$ -chart atlas alone.

The finite Rees assembly of Stratum i is determined by three data: the face-lattice cocycle with values in $H^1(\Sigma, \text{Pic})$; the bond-factor presentation of Galakhov–Li–Yamazaki on the toric diagram edges; the zero-interior-point criterion that separates the boundary-chart diagrams from those requiring McKay resolution. §33.3 addresses the McKay route for diagrams with one or more interior points, and §33.4 takes up derived Morita gluing for the Van den Bergh tilting presentation common to both. The master instance $K_3 \times E$, which combines Stratum i with Strata ii–iv, is resolved in §33.8 via the full four-stratum decomposition.

33.3 MCKAY AND ORBIFOLD GLUING

An orbifold $[X/G]$ with $G \subset \mathrm{SU}(d)$ finite is a CY_d category whose atlas is not a union of Čech charts but a single chart bearing the G -action. The gluing cocycle is not valued in H^1 of the overlap nerve; it is valued in the representation category $\mathrm{Rep}(G)$ attached to each conjugacy class of G , assembled over the inertia stack. The categorical content is the Bridgeland–King–Reid equivalence

$$D^b([X/G]) \simeq D_G^b(X),$$

and its CoHA-level incarnation: every local CoHA on $[X/G]$ pulls back to a G -equivariant CoHA on X , and the global Hall product is the G -invariant part after the inertia decomposition is unpacked.

Two examples organise the material. Local $\mathbb{P}^2 = [\mathbb{C}^3/\mathbb{Z}_3]^{\mathrm{res}}$ admits two compatible presentations: a single-chart skew-group presentation via the nine-arrow Beilinson quiver, and a three-chart Čech presentation on its crepant resolution $\mathrm{Tot}(K_{\mathbb{P}^2})$. The orbifold CoHA matches the chart-wise CoHA exactly when a compact-4-cycle Neğüt wheel-correction is installed. Mathieu $\mathcal{M}_{24}$ on K_3 occupies the intersection of Stratum (iii) with Stratum (iv): the orbifold gluing against a sporadic simple group is realised by twined elliptic genera whose weight- $1/2$ mock modular coefficients are the CoHA characters in each twisted sector.

Orbifold inertia and the Bridgeland–King–Reid equivalence

THE INERTIA STACK, ELEMENTARILY

Let $G \subset \mathrm{SU}(3)$ be finite, acting on $\mathbb{C}^3 = \mathrm{Spec} \mathbb{C}[x, y, z]$ preserving the holomorphic volume form $dx \wedge dy \wedge dz$. The quotient stack $[\mathbb{C}^3/G]$ has coherent sheaves presented as G -equivariant sheaves on $\mathbb{C}^3$:

$$\mathrm{Coh}([\mathbb{C}^3/G]) \simeq \mathrm{Coh}_G(\mathbb{C}^3).$$

This identification is elementary: a coherent sheaf on the stack $[\mathbb{C}^3/G]$ pulls back to a coherent sheaf on the atlas $\mathbb{C}^3$, equipped with descent data for the groupoid $G \times \mathbb{C}^3 \rightrightarrows \mathbb{C}^3$, and descent data for a groupoid whose unit arrows are group elements is precisely G -equivariant structure.

The *inertia stack* $I([\mathbb{C}^3/G])$ is the stack of pairs (p, g) with $p \in [\mathbb{C}^3/G]$ a point and $g \in \mathrm{Aut}(p)$ an automorphism. For an orbifold point p represented by $x \in \mathbb{C}^3$, the automorphism group $\mathrm{Aut}(p)$ is the stabiliser $G_x \subset G$, and an inertia datum is an element $g \in G_x$; equivalently, a pair (x, g) with $g \cdot x = x$. The inertia stack is the fibre product $[\mathbb{C}^3/G] \times_{[\mathbb{C}^3/G] \times [\mathbb{C}^3/G]} [\mathbb{C}^3/G]$ along the diagonal, which rewrites as the quotient $[\{(x, g) : g \cdot x = x\}/G]$ with G acting by simultaneous conjugation $h \cdot (x, g) = (h \cdot x, hgh^{-1})$.

Slicing this groupoid by G -conjugacy on the second factor: pick a representative g_o of each conjugacy class $[g] \in \mathrm{Conj}(G)$, and restrict to the slice $\{(x, g_o) : g_o \cdot x = x\} = \mathbb{C}^{3, g_o}$ (the fixed locus of g_o). The residual G -action on this slice is by the centraliser $C_G(g_o) \subset G$ (elements commuting with g_o). Summing over conjugacy classes,

$$I([\mathbb{C}^3/G]) = \bigsqcup_{[g] \in \mathrm{Conj}(G)} [\mathbb{C}^{3, g}/C_G(g)].$$

The identity class $[e]$ yields $[\mathbb{C}^{3, e}/G] = [\mathbb{C}^3/G]$, the *untwisted sector*. Each non-identity class $[g] \neq [e]$ yields a *twisted sector* indexed by g . For G abelian, every element is its own conjugacy class, $C_G(g) = G$, and the decomposition becomes $\bigsqcup_{g \in G} [\mathbb{C}^{3, g}/G]$.

The physics content is Dixon–Harvey–Vafa–Witten (*Nucl. Phys. B* 261, 1985; 274, 1986), the mathematical age-grading is Chen–Ruan (math/0004129): the orbifold cohomology of $[\mathbb{C}^3/G]$ is

$$H_{\text{orb}}^\bullet([\mathbb{C}^3/G]) = \bigoplus_{[g]} H^{\bullet-2 \operatorname{age}(g)}(\mathbb{C}^{3,g}/C_G(g)),$$

with $\operatorname{age}(g) = \sum_i a_i$ for g acting on a tangent frame by $\operatorname{diag}(e^{2\pi i a_1}, e^{2\pi i a_2}, e^{2\pi i a_3})$ with $a_i \in [0, 1)$. The $\operatorname{SU}(3)$ -condition $\det g = 1$ forces $\sum_i a_i \in \mathbb{Z}$; combined with the range constraint $\sum_i a_i \in [0, 3)$, the age lies in $\{0, 1, 2\}$.

SKEW-GROUP ALGEBRA AND MORITA EQUIVALENCE

The skew-group algebra $R\#G$ with $R = \mathbb{C}[x, y, z]$ is

$$R\#G = R \otimes \mathbb{C}[G] \quad \text{with multiplication} \quad (r \otimes g)(r' \otimes g') = r \cdot g(r') \otimes gg'.$$

Equivalently: $R\#G$ is the free R -module with basis G , and multiplication records the twist of the action. This is not an arbitrary algebra; it is the arrow algebra of the action groupoid $G \times \mathbb{C}^3 \rightrightarrows \mathbb{C}^3$, and its representation category is exactly G -equivariant sheaves:

$$(R\#G)\text{-mod} \simeq \operatorname{Coh}_G(\mathbb{C}^3) \simeq \operatorname{Coh}([\mathbb{C}^3/G]).$$

The first equivalence is the passage from arrow-algebra modules to equivariant modules; the second is the atlas identification from Section 33.3. Morita equivalence of $R\#G$ with its basic algebra (the endomorphism ring of a minimal projective generator) is the passage from infinite-dimensional to quiver-presented form.

BRIDGELAND–KING–REID, FIRST-PRINCIPLES SKETCH

The Bridgeland–King–Reid theorem (math/9908027) asserts: for $G \subset \operatorname{SL}(n, \mathbb{C})$ finite, $n \leq 3$, with $Y := G\text{-Hilb}(\mathbb{C}^n)$ the equivariant Hilbert scheme of G -clusters, the Fourier–Mukai transform with kernel the universal G -cluster $\mathcal{Z} \subset Y \times \mathbb{C}^n$ is an equivalence

$$\Phi_{\mathcal{Z}}: D^b(Y) \xrightarrow{\sim} D_G^b(\mathbb{C}^n) \simeq D^b([\mathbb{C}^n/G]).$$

The first-principles content:

- *Crepancy*: For $G \subset \operatorname{SL}(n)$ with $n \leq 3$, Y is smooth and the canonical class $K_Y = 0$; equivalently, the resolution $Y \rightarrow \mathbb{C}^n/G$ is crepant. The CY structure on $[\mathbb{C}^n/G]$ transports to a CY structure on Y .
- *Equivariant Hilbert scheme*: A G -cluster is a G -invariant 0-dimensional subscheme $Z \subset \mathbb{C}^n$ with $H^0(\mathcal{O}_Z) \cong \mathbb{C}[G]$ as G -representation. The moduli $G\text{-Hilb}(\mathbb{C}^n)$ parametrising these is the natural candidate resolution.
- *Universal kernel*: The universal family $\mathcal{Z} \subset Y \times \mathbb{C}^n$ is the incidence locus. Its structure sheaf, equipped with its G -equivariant structure via the second projection, is an object of $D^b(Y \times_G \mathbb{C}^n) \simeq D_G^b(Y \times \mathbb{C}^n)$.
- *Bridgeland–King–Reid criterion* (math/9908027 *Thm. 1.1*): The Fourier–Mukai transform $\Phi_{\mathcal{Z}}$ is an equivalence when the fibre-dimension bound

$$\dim(Y \times_{X_0} Y) \leq n + 1, \quad X_0 := \mathbb{C}^n/G,$$

holds, with Bondal–Kapranov spanning sufficing to upgrade fully-faithful to equivalence (BKR Lemma 3.1). For $G \subset \mathrm{SL}(n, \mathbb{C})$ with $n \leq 3$, crepancy of $Y = G\text{-Hilb}(\mathbb{C}^n) \rightarrow X_o$ (Nakamura math/0003023 at $n = 3$) forces this bound; the authors verify $n \leq 3$ by explicit fibrewise analysis. The complementary Bondal–Orlov spanning-class criterion (math/9712029) applies to smooth projective varieties and is logically distinct: it supplies sufficient conditions via ample generation, whereas BKR exploits the specific crepant-resolution geometry.

- *CoHA transport*: The Hall product on $D^b(Y)$ pulls back along Φ_Z to a Hall product on $D_G^b(\mathbb{C}^n)$, which in turn decomposes via the inertia splitting into a conjugacy-class-indexed direct sum of twisted-sector CoHAs. This is the CoHA shadow of Chen–Ruan orbifold cohomology.

The BKR equivalence is thus the gluing cocycle for Stratum (iii): it assembles the G -equivariant critical CoHA on $\mathbb{C}^n$ with the $\mathbb{C}^3$ -Jordan-triple potential $W = \mathrm{tr}(x[y, z])$ into the CoHA of the crepant resolution Y , with the inertia decomposition recording the conjugacy-class-graded structure. On the resolution side, Y is a smooth toric CY_3 when G is abelian, and the chart-wise Stratum-(i) machinery applies; on the orbifold side, the skew-group presentation $R\#G$ provides a single global datum. The BKR kernel is the gluing cocycle reconciling the two.

Class-group obstruction to McKay presentation. The applicability of BKR is governed by an arithmetic invariant of the singular base $X_o = \mathbb{C}^n/G$: its divisor class group $\mathrm{Cl}(X_o)$. Watanabe’s theorem (1974, *Osaka J. Math.* 11) identifies

$$\mathrm{Cl}(\mathbb{C}^n/G) \cong G^{\mathrm{ab}} = G/[G, G]$$

for $G \subset \mathrm{SL}(n, \mathbb{C})$ acting without pseudo-reflections (the SL-condition suffices), so the class group is finite of order dividing $|G|$. Any Gorenstein CY singularity whose class group is *infinite* cannot be of the form $\mathbb{C}^n/G$ and lies outside BKR’s scope. The conifold $X_o^{\mathrm{con}} = \{xy - zw = 0\} \subset \mathbb{C}^4$ is the canonical outlier: $\mathrm{Cl}(X_o^{\mathrm{con}}) = \mathbb{Z}$, generated by the Weil divisor $\{x = z = 0\}$ (its pair $\{y = w = 0\}$ differs by the Cartier class of a hyperplane section; their difference is the class of the $\mathbb{P}^1$ exceptional of either small resolution). The infinite class group excludes any McKay presentation. The conifold’s NCCR is the Klebanov–Witten two-node Kronecker quiver with quartic potential $W_{\mathrm{con}} = \mathrm{tr}(a_1 b_1 a_2 b_2 - a_1 b_2 a_2 b_1)$ (Szendrői arXiv:0705.3419), contrasting with the Beilinson nine-arrow quiver’s cubic potential. The degree is forced by the quiver type: the McKay quiver for $\mathbb{C}^3/G$ is G -partite with coordinate-graded arrows, so cycles close at length three (Bocklandt math/0603558); the conifold’s two-node Kronecker quiver has four arrows closing at length four (Hanany–Kennaway hep-th/0503149; Franco–Hanany–Kennaway–Vegh–Wecht hep-th/0511063 brane-tiling dictionary).

Local $\mathbb{P}^2$ as $[\mathbb{C}^3/\mathbb{Z}_3]$ and the nine-arrow quiver

Local $\mathbb{P}^2$ is $\mathrm{Tot}(\mathcal{O}_{\mathbb{P}^2}(-3))$, the total space of the canonical bundle on $\mathbb{P}^2$. As a toric CY_3 , it has a compact 4-cycle (the zero-section $\mathbb{P}^2$ itself) and is not a union of $\mathbb{C}^3$ -charts without corrections. The orbifold route produces it as a crepant resolution $\mathrm{Tot}(K_{\mathbb{P}^2}) = [\mathbb{C}^3/\mathbb{Z}_3]^{\mathrm{res}}$, and the CoHA story becomes transparent through the Beilinson nine-arrow quiver.

THE $\mathbb{Z}_3$ ACTION AND ITS AGE DATA

Let $\zeta = e^{2\pi i/3}$. The group $\mathbb{Z}_3 = \langle \sigma \rangle$ acts on $\mathbb{C}^3$ by

$$\sigma \cdot (x, y, z) = (\zeta x, \zeta y, \zeta z).$$

The weights of σ on the tangent frame are $(1/3, 1/3, 1/3)$, with age

$$\text{age}(\sigma) = 1/3 + 1/3 + 1/3 = 1 \in \mathbb{Z},$$

confirming $\sigma \in \text{SU}(3)$ and the CY orbifold condition. The three conjugacy classes $\{e, \sigma, \sigma^2\}$ (abelian, every element its own class) give ages 0, 1, 2 respectively. The fixed loci are $\mathbb{C}^{3,e} = \mathbb{C}^3$, $\mathbb{C}^{3,\sigma} = \{0\}$, $\mathbb{C}^{3,\sigma^2} = \{0\}$, and the inertia decomposition is

$$I([\mathbb{C}^3/\mathbb{Z}_3]) = [\mathbb{C}^3/\mathbb{Z}_3] \sqcup B\mathbb{Z}_3 \sqcup B\mathbb{Z}_3.$$

The untwisted sector carries the ambient CY_3 structure; the two twisted sectors are point classes at the origin with age-shifts 1 and 2. McKay identifies them with the cohomology of the exceptional divisor $\mathbb{P}_{\text{exc}}^2 = \pi^{-1}(0)$ on the crepant resolution $\pi : \text{Tot}(K_{\mathbb{P}^2}) \rightarrow \mathbb{C}^3/\mathbb{Z}_3$: the age-1 twisted-sector point class maps to the hyperplane class $H \in H^2(\mathbb{P}_{\text{exc}}^2, \mathbb{C})$; the age-2 point class maps to $H^2 \in H^4(\mathbb{P}_{\text{exc}}^2, \mathbb{C})$; and the untwisted-sector class 1 maps to the fundamental class $1 \in H^0(\mathbb{P}_{\text{exc}}^2, \mathbb{C})$ (equivalently, to the $\text{Tot}(K_{\mathbb{P}^2})$ -unit, via the zero-section embedding). Batyrev–Denef–Loeser stringy cohomology confirms: $\chi_{\text{stringy}}([\mathbb{C}^3/\mathbb{Z}_3]) = 3 = \chi(\text{Tot}(K_{\mathbb{P}^2}))$, the ranks $(1, 1, 1)$ at degrees $(0, 2, 4)$ matching on both sides.

THE BEILINSON NINE-ARROW QUIVER

The skew-group algebra $\mathbb{C}[x, y, z] \# \mathbb{Z}_3$ has three indecomposable projectives corresponding to the three irreducible representations ρ_0, ρ_1, ρ_2 of $\mathbb{Z}_3$ (characters $1, \zeta, \zeta^2$). Its basic algebra is the path algebra of the quiver Q with three vertices $\{0, 1, 2\}$ (one for each character) and nine arrows

$$X_i, Y_i, Z_i : i \longrightarrow i + 1 \pmod{3}, \quad i \in \mathbb{Z}/3,$$

one triple (X_i, Y_i, Z_i) for each vertex, corresponding to the three coordinates (x, y, z) of $\mathbb{C}^3$. Because σ acts on each coordinate by the same weight ζ , each coordinate raises the ρ -degree by $+1 \pmod{3}$, producing the cyclic $0 \rightarrow 1 \rightarrow 2 \rightarrow 0$ arrow pattern with three arrows per step.

The Jacobi potential is the cubic

$$W = \sum_{i \in \mathbb{Z}/3} \text{tr}(X_i Y_{i+1} Z_{i+2} - X_i Z_{i+1} Y_{i+2}),$$

the cyclic unfolding of $\text{tr}(x[y, z]) = \text{tr}(xyz - xzy)$ across the three vertex-types, with each monomial a closed length-three cycle $i \rightarrow i + 1 \rightarrow i + 2 \rightarrow i$ of the quiver. The Jacobi relations $\partial W / \partial X_i = Y_{i+1} Z_{i+2} - Z_{i+1} Y_{i+2}$ (and cyclic permutations in X, Y, Z) encode the commutativity $[x, y] = [y, z] = [x, z] = 0$ unfolded across the three vertex-types. The pair (Q, W) is the *nine-arrow Beilinson quiver with cubic potential*, and Bocklandt (math/0603558, Thm. 3.2) proved $\text{Jac}(Q, W) \cong \mathbb{C}[x, y, z] \# \mathbb{Z}_3$, a Ginzburg CY_3 algebra (math/0612139, §4.3). The potential degree is three because the $\mathbb{Z}_3$ -character grading cycles in three steps: each coordinate raises the ρ -grading by $+1 \pmod{3}$, and three coordinates suffice to close the cycle. The conifold's quartic potential $W_{\text{con}} = \text{tr}(a_1 b_1 a_2 b_2 - a_1 b_2 a_2 b_1)$ arises instead on a two-node Kronecker quiver with four arrows, where cycles must traverse $0 \rightarrow 1 \rightarrow 0 \rightarrow 1$ at length four. This cubic is the Hall-side McKay/Beilinson potential. It is not to be replaced by a higher transferred hCS potential unless a separate cyclic HPT calculation identifies that transfer with the same Jacobi algebra and then proves orientation, Thom–Sebastiani, Hall-product, and DWR/Ran coherence.

The equivalence with Beilinson's derived description of $\mathbb{P}^2$:

$$D^b(\mathbb{P}^2) \simeq D^b(\text{End}(O \oplus O(1) \oplus O(2))\text{-mod}),$$

is the classical Beilinson resolution. The three line bundles $\mathcal{O}, \mathcal{O}(1), \mathcal{O}(2)$ are the three indecomposable summands of the tilting bundle; the nine arrows are global sections $H^0(\mathbb{P}^2, \mathcal{O}(1)) = \langle x, y, z \rangle$ between consecutive summands. Under BKR, the Beilinson tilting bundle on $\mathbb{P}^2$ pulls up along the projection $\text{Tot}(K_{\mathbb{P}^2}) \rightarrow \mathbb{P}^2$ to a tilting bundle on local $\mathbb{P}^2$ whose endomorphism ring is precisely the Jacobi algebra $\text{Jac}(Q, W)$.

THE COHA VIA SCHIFFMANN–VASSEROT EQUIVARIANTISED

The Schiffmann–Vasserot theorem constructs the CoHA of $\mathbb{C}^3$ (with the Jordan-triple potential $W_{\mathbb{C}^3} = \text{tr}(x[y, z])$) as the positive half $Y^+(\widehat{\mathfrak{gl}}_1)$ of the affine Yangian of $\mathfrak{gl}_1$:

$$\mathcal{H}_{\mathbb{C}^3} = \bigoplus_n H_{\bullet}^{T^3}(\text{crit}(W)|_{\mathcal{M}_n^{\mathbb{C}^3}}) \cong Y^+(\widehat{\mathfrak{gl}}_1).$$

Equivariantising by the $\mathbb{Z}_3$ -action gives the CoHA of $[\mathbb{C}^3/\mathbb{Z}_3]$:

$$\mathcal{H}_{[\mathbb{C}^3/\mathbb{Z}_3]} = (\mathcal{H}_{\mathbb{C}^3})^{\mathbb{Z}_3} \oplus \mathcal{H}_{\mathbb{C}^3}^{\text{tw}, \sigma} \oplus \mathcal{H}_{\mathbb{C}^3}^{\text{tw}, \sigma^2},$$

where the second and third summands are the twisted-sector contributions indexed by the non-trivial conjugacy classes. The twisted sectors are modules over the untwisted invariant ring $Y^+(\widehat{\mathfrak{gl}}_1)^{\mathbb{Z}_3}$, in a manner that matches the age-graded decomposition. Explicitly: the equivariant parameters $(\epsilon_1, \epsilon_2, \epsilon_3)$ of T^3 pick up a $\mathbb{Z}_3$ -equivariant refinement; the $\mathbb{Z}_3$ -invariant combination $\epsilon_1 + \epsilon_2 + \epsilon_3 = 0$ (the CY relation) survives, and the twisted-sector generators carry additional ζ -charge compatible with age.

THE CHART-WISE COVER OF THE CREPANT RESOLUTION

Local $\mathbb{P}^2$ as a toric variety has fan Σ with three top-dimensional cones, corresponding to the three torus-fixed points of $\mathbb{P}^2$, each carrying a local $\mathbb{C}^3$ -chart (the affine toric patch trivialising $K_{\mathbb{P}^2}$ over that chart). Label the charts U_o, U_1, U_2 ; each is $\cong \mathbb{C}^3$ with local coordinates (u, v, w) such that the Jordan-triple potential $\text{tr}(u[v, w])$ holds on the chart.

The atlas reconciles with the orbifold presentation as follows: on the singular base $\mathbb{C}^3/\mathbb{Z}_3$ the resolution $\pi : \text{Tot}(K_{\mathbb{P}^2}) \rightarrow \mathbb{C}^3/\mathbb{Z}_3$ is an isomorphism away from the unique singular point $o \in \mathbb{C}^3/\mathbb{Z}_3$, and the preimage $\pi^{-1}(o) = \mathbb{P}^2$ is the exceptional divisor. The three toric charts U_o, U_1, U_2 cover $\text{Tot}(K_{\mathbb{P}^2})$ with pairwise overlaps $U_i \cap U_j \cong \mathbb{G}_m \times \mathbb{C}^2$ (one inverted ratio between adjacent $\mathbb{P}^2$ -charts, times the $K_{\mathbb{P}^2}$ -fibre $\mathbb{C}$) and triple overlap $U_o \cap U_1 \cap U_2 \cong (\mathbb{G}_m)^2 \times \mathbb{C}$ (the open torus orbit of $\mathbb{P}^2$ times the canonical-bundle fibre). Each chart U_i intersects the exceptional $\mathbb{P}^2$ in an $\mathbb{A}^2$ -patch centred at a torus-fixed point of $\mathbb{P}^2$, and the three patches assemble to the standard toric $\mathbb{A}^2$ -atlas of $\mathbb{P}^2$. On the resolution side the three smooth toric $\mathbb{C}^3$ -patches fully cover $\text{Tot}(K_{\mathbb{P}^2})$; on the orbifold side the single $[\mathbb{C}^3/\mathbb{Z}_3]$ -stacky chart at the origin is what BKR intertwines with the three-chart toric cover.

The gluing cocycle on the overlaps $U_i \cap U_j$ is the toric transition; the Schiffmann–Vasserot CoHA lives on each chart as $Y^+(\widehat{\mathfrak{gl}}_1)$, and the multi-chart CoHA is the homotopy limit over the Čech nerve. Because of the compact $\mathbb{P}^2$ -divisor, this limit picks up *internal-lattice contributions*: the Negeu wheel-condition corrections. Concretely, the Do-brane moduli on local $\mathbb{P}^2$ contain the torus-fixed points U_o, U_1, U_2 together with 1-parameter families of brane configurations *inside* the compact $\mathbb{P}^2$ -divisor, whose cohomological contribution is non-trivial and must be integrated separately.

RECONCILING THE TWO ROUTES

The orbifold CoHA via Schiffmann–Vasserot equivariantised on $[\mathbb{C}^3/\mathbb{Z}_3]$, and the chart-wise CoHA on the three-chart atlas of local $\mathbb{P}^2$, agree under the BKR-transport. The reconciliation proceeds through:

- (i) BKR gives $D^b(\text{local } \mathbb{P}^2) \simeq D_{\mathbb{Z}_3}^b(\mathbb{C}^3)$ as triangulated categories.
- (ii) The CoHA Hall product is preserved, because Hall multiplication is defined from the extension stack $\text{Ext}(\mathcal{E}, \mathcal{F})$, and extensions are preserved by BKR as an equivalence of derived categories.
- (iii) The orbifold side's inertia-graded decomposition $\mathcal{H}_{\text{orb}} = \mathcal{H}_{\text{untw}} \oplus \mathcal{H}_{\sigma} \oplus \mathcal{H}_{\sigma^2}$ matches the chart-wise side's cohomology-grading via the toric fan's three top-cones: each cone contributes one summand, with the Neğüt wheel-condition corrections encoding exactly the age-shifted contributions of the twisted sectors.
- (iv) Explicitly: the age-1 twisted sector on the orbifold side corresponds to the contribution from the exceptional $\mathbb{P}^2$ of the resolution in the chart-wise route; age-2 corresponds to the Poincaré-dual class of $\mathbb{P}^2$.

This is the first worked example of stratum overlap (i) $\cap$ (iii): local $\mathbb{P}^2$ is simultaneously toric (stratum i) and orbifold (stratum iii), and the two gluing cocycles agree through BKR. The skew-group presentation via the nine-arrow quiver is the most economical form; the chart-wise Čech presentation with Neğüt corrections is the most geometric form. Both compute the same CoHA, equal to the module-theoretic Jacobi-algebra CoHA of (Q, W) .

Mathieu M_{24} on K_3

The Mathieu moonshine of Eguchi–Ooguri–Tachikawa arXiv:1004.0956 is an orbifold gluing not against a geometric group action on K_3 , but against a sporadic simple group M_{24} acting by derived symmetries of the elliptic genus of a K_3 surface. This sits at the intersection of Stratum (iii) orbifold and Stratum (iv) lattice-polarised. The geometric-symmetry layer is Mukai's theorem (Mukai 1988, *Invent. Math.* 94): every finite group of symplectic automorphisms of a K_3 surface embeds in $M_{23} \subset M_{24}$ with orbit-count ≥ 5 on $\{1, \dots, 24\}$; the full Mathieu group M_{24} is *not* realised as automorphisms of any single K_3 . The stringy-symmetry layer is Gaberdiel–Hohenegger–Volpato arXiv:1008.0725: symmetries of any consistent K_3 $\mathcal{N} = (4, 4)$ sigma model embed in the Conway group Co_0 , giving a larger family than Mukai's geometric classification but still strictly smaller than M_{24} . The M_{24} of EOT emerges only at the level of the *BPS Hilbert space*; the graded Fourier coefficients of the $\mathcal{N} = 4$ -decomposed elliptic genus ϕ_{K_3} ; where all 26 conjugacy classes of M_{24} act, even though no single sigma model hosts the full action. The assembly of twined elliptic genera is therefore indexed by M_{24} -conjugacy classes with each ϕ_g a weak Jacobi form on $\mathbb{H} \times \mathbb{C}$ whose mock modular $\mathcal{N} = 4$ -massive component is a weight-1/2 mock form on $\mathbb{H}$.

THE EGUCHI–OOGURI–TACHIKAWA OBSERVATION

The K_3 elliptic genus is the weight-0 index-1 weak Jacobi form

$$\phi_{K_3}(\tau, z) = 2 \phi_{0,1}(\tau, z) = 8 \sum_{\alpha=2,3,4} \left(\frac{\theta_{\alpha}(\tau, z)}{\theta_{\alpha}(\tau, 0)} \right)^2,$$

with $\phi_{0,1}$ the generator of $J_{0,1}$ normalised by Eichler–Zagier, and the factor of two encoding the Euler characteristic $\chi(K_3) = 24 = \phi_{K_3}(\tau, 0)$ (Eguchi–Ooguri–Taormina–Yang 1989, *Nucl. Phys. B* 315). The $\mathcal{N} = 4$ superconformal character-decomposition of ϕ_{K_3} reads

$$\phi_{K_3}(\tau, z) = 24 \cdot \chi_{1/4,0}(\tau, z) + \Sigma(\tau) \cdot \chi_{1/4,1/2}(\tau, z),$$

where $\chi_{1/4,h}$ are the $\mathcal{N} = 4$ Ramond characters at central charge $c = 6$ and conformal weight h , and

$$\Sigma(\tau) = 2q^{-1/8}(-1 + 45q + 231q^2 + 770q^3 + 2277q^4 + \dots).$$

The numerical observation of Eguchi–Ooguri–Tachikawa: the Fourier coefficients $\{45, 231, 770, 2277, \dots\}$ are dimensions of irreducible representations of M_{24} .

TWINED ELLIPTIC GENERA AND MOCK MODULARITY

For each $g \in M_{24}$, define the *twined elliptic genus*

$$\phi_g(\tau, z) = \text{tr}_{\mathcal{H}_{K_3}}(g \cdot (-1)^{F_L+F_R} q^{L_0-\bar{c}/24} \bar{q}^{\bar{L}_0-\bar{c}/24} y^{J_0}),$$

with $\mathcal{H}_{K_3}$ the Hilbert space of the K_3 sigma model, $F_{L/R}$ left/right fermion numbers, J_0 the $U(1)$ current of the $\mathcal{N} = 4$ superconformal algebra. The $g = e$ case recovers ϕ_{K_3} . For general g , the $\mathcal{N} = 4$ decomposition gives

$$\phi_g(\tau, z) = \chi_g \cdot \chi_{1/4,0}(\tau, z) + \Sigma_g(\tau) \cdot \chi_{1/4,1/2}(\tau, z),$$

with χ_g the character of g acting on $H^\bullet(K_3)$ (a finite integer depending only on the M_{24} -conjugacy class) and Σ_g a weight- $1/2$ *mock modular form* of a specified shadow and multiplier system.

Cheng arXiv:1005.5415 exhibited the twined Σ_g and their $\Gamma_0(|g|)$ transformation laws; Cheng–Duncan–Harvey (*Res. Math. Sci.* 1, arXiv:1204.2779) packaged the result into the umbral-moonshine programme, assigning each conjugacy class of M_{24} a weight- $1/2$ mock modular form with specified shadow and multiplier. Gannon (*Commun. Number Theory Phys.* 10, arXiv:1211.5531) proved positivity and uniqueness of the M_{24} -representation decomposition of the Fourier coefficients. Gaberdiel–Hohenegger–Volpato arXiv:1008.0725 classified the symmetry groups of consistent $\mathcal{N} = (4, 4)$ K_3 sigma models as subgroups of the Conway group Co_0 acting on $\Pi_{4,20}$ with rank- ≥ 4 fixed lattice; strictly enlarging Mukai’s geometric classification yet not exhausting M_{24} ; consequently no single K_3 sigma model realises the full M_{24} -action, which lives only at the level of the graded $\Sigma(\tau)$ -Fourier coefficients.

COHA TWISTED BY AN M_{24} -CONJUGACY CLASS

For each conjugacy class $[g] \in M_{24}$, there is a twisted CoHA $\mathcal{H}_{K_3}^g$ whose graded character is the twined elliptic genus ϕ_g after $\mathcal{N} = 4$ -decomposition. The twist-structure:

- The untwisted CoHA $\mathcal{H}_{K_3}^e$ has graded character ϕ_{K_3} , with BPS multiplicity $\phi_{K_3}(\tau, 0) = \chi(K_3) = 24$ in the massless $\mathcal{N} = 4$ sector and non-BPS multiplicities $2 \cdot \{45, 231, 770, 2277, \dots\}$ in the massive sector (from $\Sigma(\tau)$), both encoding Hall-positive-half BPS multiplicities. The Yangian or vertex-algebra structure enters only after the specified double/VOA construction.
- A twisted CoHA $\mathcal{H}_{K_3}^g$ has graded character ϕ_g and interprets the g -fixed BPS states: for $g \in M_{24}$ of cycle shape $\prod_i k_i^{n_i}$, the character $\chi_g(K_3) = \phi_g(\tau, 0) \in \mathbb{Z}$ is the Frame-shape-graded Euler characteristic, and the mock modular discrepancy Σ_g encodes the twisted-sector shadow.
- The full orbifold CoHA on $[K_3/M_{24}]$ assembles as

$$\mathcal{H}_{K_3}^{M_{24}\text{-orb}} = \bigoplus_{[g] \in \text{Conj}(M_{24})} (\mathcal{H}_{K_3}^g)^{C_{M_{24}}(g)},$$

with $C_{M_{24}}(g)$ the centraliser of g in M_{24} , acting on the twisted sector to extract the invariant piece. The cardinality of $\text{Conj}(M_{24})$ is 26, matching the table of M_{24} -conjugacy classes.

STRATUM (III) $\cap$ (IV) AND AUTOMORPHIC ASSEMBLY

Mathieu M_{24} on K_3 sits in stratum (iii) because K_3 has no global M_{24} -action on the variety itself but carries a derived M_{24} -symmetry of its $\mathcal{N} = 4$ chiral algebra; the symmetry acts on the BPS Hilbert space

(equivalently, on the CoHA). It sits in stratum (iv) because the twined elliptic genera ϕ_g are weak Jacobi forms on the K_3 lattice $\Pi_{4,20}$, and their assembly into a consistent system is an automorphic datum.

The two strata mesh through the Gritsenko lift. The K_3 elliptic genus $\phi_{K_3} = 2\phi_{0,1}$ lifts via Borchers–Gritsenko to the paramodular form $\Delta_5 \in M_5(\mathrm{Sp}_4(\mathbb{Z}))$ on the Siegel upper half-space; this is the stratum-(iv) face. Each twined elliptic genus ϕ_g lifts analogously to a Borchers–Gritsenko product $\Delta_g \in M_{k_g}(\Gamma_g)$ on a congruence Siegel modular group, and these $\{\Delta_g\}_{[g] \in \mathrm{Conj}(M_{24})}$ span the gluing cocycle for the M_{24} -orbifold CoHA. On the CHL sub-sequence $N \in \{1, 2, 3, 4, 6\}$ the weights are $k_N = c_N(\mathfrak{o})/2 \in \{5, 4, 3, 2, 1\}$ (Gritsenko 1999, *Abh. Math. Sem. Hamburg* 69, Thm. 6.1; Borchers 1998, *Invent. Math.* 132 Thm. 10.1), so $\kappa_{\mathrm{BKM}}(\Phi_N) = c_N(\mathfrak{o})/2$ across the ladder, with $N = 1$ recovering $\Delta_e = \Delta_5$ at cycle shape 1^{24} . The full Gritsenko–Cléry 8-form atlas carries weights $(5, 2, 1, 1, 1/2, 1, 1/4, 0)$ (Gritsenko–Cléry 2013, *J. Reine Angew. Math.* 678, §3), half-integral and fractional entries lifted under double-cover paramodular groups.

The stratum overlap is therefore concrete: the orbifold side is the assembly

$$\mathcal{H}_{K_3}^{M_{24}\text{-orb}} = \bigoplus_{[g]} \mathcal{H}_{K_3}^g,$$

and the lattice-polarised side is the assembly

$$\{\Delta_g\}_{[g]} \subset \bigoplus_{[g]} M_{k_g}(\Gamma_g),$$

and the *twining consistency* between the two sides is the assertion that the Fourier-coefficient matrix of $\{\Delta_g\}$ matches the M_{24} -character table evaluated on the BPS-spectrum graded dimensions. This is the content of Mathieu moonshine at the level of Vol III CoHA theory.

WEIGHT-1/2 MOCK MODULAR SHADOW AND THE M_{24} -TWINING COCYCLE

The shadow S_g of Σ_g is a weight-3/2 holomorphic cusp form on $\Gamma_0(|g|)$ fixed by Zwegers’ completion: $\widehat{\Sigma}_g(\tau, \bar{\tau}) = \Sigma_g(\tau) + R_g(\tau, \bar{\tau})$ with R_g the non-holomorphic Eichler-integral completion whose $\bar{\partial}$ -derivative recovers $S_g(\tau)$ through the standard shadow-pairing $\bar{\partial}_{\bar{\tau}} R_g = (2i)^{1/2} \overline{S_g(\tau)} (\tau - \bar{\tau})^{-3/2}$. For $g = e$, $S_e(\tau) \propto \eta(\tau)^3$ (the weight-3/2 generator of the shadow space; Eguchi–Hikami 2009, *J. Phys. A* 42). For general g , S_g is a specific linear combination of η -quotients and Jacobi theta series indexed by the centraliser structure of g (Cheng–Duncan–Harvey 2014).

The shadow encodes the failure of Σ_g to be modular: Σ_g transforms under $\Gamma_0(|g|)$ modulo the lift of S_g across $\mathbb{H}$. In CoHA terms, the shadow records the deviation from a holomorphic global assembly: the M_{24} -twined CoHA is only mock-modularly consistent, with a precise shadow controlling the obstruction.

The twining cocycle is the assignment $g \mapsto (\phi_g, \Sigma_g, S_g)$ compatible with M_{24} -conjugation: $\phi_{hgh^{-1}} = \phi_g$, $\Sigma_{hgh^{-1}} = \Sigma_g$, etc. This cocycle is the orbifold-gluing datum of Stratum (iii) refined by the mock-modular Stratum (iv) data.

K_3 CoHA AS ORTHOGONAL YANGIAN $Y_{\hbar}(\mathfrak{so}(4, 20))$

The K_3 CoHA is conjecturally the orthogonal Yangian $Y_{\hbar}(\mathfrak{so}(4, 20))$ of Molev–Ragoucy [68] (or its Hodge-parity $\mathbb{Z}/2$ -super-extension $Y_{\hbar}(\mathfrak{so}(4 | 20))$, programme-specific and non-Kac), with $(4, 20)$ the signature of the Mukai lattice’s Hodge involution-eigenspace decomposition: $H^0 \oplus H^4 \oplus (H^{2,0} \oplus H^{0,2})_{\mathbb{R}}$ is 4-dimensional of signature $(4, 0)$, and $H_{\mathrm{prim}}^{1,1}(K_3, \mathbb{R}) = \mathbb{R}^{20}$ carries signature $(0, 20)$. On both graded parts the Mukai pairing is symmetric; this excludes Kac $\mathfrak{osp}(4 | 20)$, whose defining form is

symplectic on the 20-dimensional odd part. The orthogonal Yangian carries the Zamolodchikov rational R -matrix on $V = \mathbb{C}^{24}$, satisfying Yang–Baxter; its positive half is the K_3 -CoHA. See Chapter 18 for the $\mathfrak{so}(4, 20)$ versus Kac– $\mathfrak{osp}(4 \mid 20)$ trichotomy discussion.

The M_{24} -twining is compatible with this envelope: conjugation by $g \in M_{24}$ preserves the $(4, 20)$ -split (because M_{24} acts by symplectic automorphisms of K_3 , preserving the Hodge involution), and the twisted sector $\mathcal{H}_{K_3}^g$ is a $Y_h(\mathfrak{so}(4, 20))^{\langle g \rangle}$ -module, with the centraliser $C_{M_{24}}(g)$ -invariant part giving the global twisted CoHA.

Summary: orbifold gluing in the four-stratum taxonomy

The orbifold stratum (iii) provides three distinct gluing modes, each illustrated in this part:

- (i) *Global abelian orbifold action*, e.g., $[\mathbb{C}^3/\mathbb{Z}_3]$ for local $\mathbb{P}^2$. Gluing cocycle: BKR equivalence with kernel the universal G -cluster on $G\text{-Hilb}(\mathbb{C}^3)$. CoHA construction: either skew-group Schiffmann–Vasserot equivariantised, or chart-wise on the crepant resolution with Neguţ wheel-corrections. The two agree as derived Hall structures.
- (ii) *Finite non-abelian orbifold*, e.g., $[\mathbb{C}^3/G]$ for $G = \mathbb{Z}_n \times \mathbb{Z}_n$ or G the binary tetrahedral / octahedral / icosahedral group. Gluing cocycle: BKR extended to non-abelian case; the inertia decomposition becomes non-trivial with twisted sectors indexed by conjugacy classes rather than individual elements.
- (iii) *Sporadic / chiral orbifold symmetry*, e.g., Mathieu M_{24} on K_3 . Gluing cocycle: weight-1/2 mock modular forms Σ_g with shadow S_g , assembled into a twining system compatible with M_{24} -conjugation. This sits in Stratum (iii) $\cap$ (iv): the orbifold group M_{24} acts on the chiral-algebra side of Φ , and the Borchers–Gritsenko lifts $\{\Delta_g\}$ provide the automorphic gluing.

Each example passes through the same categorical pattern: a single G -equivariant chart X (or chiral-algebra action of G) carrying a CoHA structure, with the inertia-stack decomposition $I([X/G]) = \sqcup_{[g]} [X^g/C_G(g)]$ stratifying the global assembly into untwisted and twisted sectors. The global CoHA is the direct sum over conjugacy classes, each summand weighted by the age-shift and twisted-sector character. On the derived-category side, BKR (or its chiral generalisation for Mathieu) is the universal cocycle intertwining the orbifold presentation with the resolution presentation.

The K_3 -CoHA / $Y_h(\mathfrak{so}(4, 20))$ conjecture carries three coupled data: the orthogonal Yangian’s positive half as the K_3 -CoHA, the Mathieu M_{24} -action as its sporadic symmetry, and the Borchers lift $\Delta_5 \in M_5(\text{Sp}_4(\mathbb{Z}))$ as the resulting Siegel modular form with $\kappa_{\text{BKM}}(\mathfrak{g}_{\Delta_5}) = 5$ the Gritsenko weight. The three are three faces of a single gluing cocycle straddling Strata (ii), (iii), (iv).

The compact CY₃ manifold $K_3 \times E$ inherits all three faces and adds a fourth through the E -factor’s translation equivariance; its treatment in §33.8 uses the orbifold tools of this section together with the other strata.

Transition to §33.4. The orbifold stratum admits a refinement: the gluing cocycle can also be presented as a *derived Morita equivalence* by a tilting object whose endomorphism algebra is the skew-group algebra. §33.4 develops this Van den Bergh tilting-bundle viewpoint, with local $\mathbb{P}^2$ reappearing there as the three-line-bundle tilting example, and the Serre-equivariant quasi-NCCR of $K_3 \times E$ emerging as the Morita-gluing obstruction that §33.3’s orbifold methods alone cannot resolve.

33.4 VAN DEN BERGH DERIVED MORITA GLUING

Parts I–III assembled global CoHAs from Čech, toric, and McKay atlases: each overlap carried a geometric transition; a Fourier–Mukai kernel, a toric cocycle, a BKR equivalence. §33.4 replaces the atlas by a single object. A *tilting bundle* T on a projective CY_3 (or a local CY_3) collapses the derived category of coherent sheaves onto the derived category of modules over a finite-dimensional algebra $\mathcal{A} = \mathrm{End}(T)$: all gluing information on X is encoded in the multiplicative structure of $\mathcal{A}$. The Hall product on critical cohomology transports along this collapse. Mutations of T act as the chamber-changing automorphisms of the associated CoHA.

Van den Bergh tilting bundles

THE OBSTRUCTION: $D^b(\mathrm{Coh}X)$ IS NOT COMPACTLY GENERATED FROM BELOW

For X a smooth projective variety, $D^b(\mathrm{Coh}X)$ admits no canonical generator. Locally one trivialises $\mathrm{Coh}X$ by $\mathrm{Coh}U \simeq \text{mod } R_U$ with $R_U = \Gamma(U, \mathcal{O}_X)$ a commutative affine ring, but the local presentations are incompatible: R_U is Morita-trivial (its module category is generated by the regular module R_U itself), whereas $D^b(\mathrm{Coh}X)$ globally admits no such single-generator description. A tilting bundle is the object that repairs this failure *globally*.

Definition 33.4.1 (Tilting bundle; Bondal–Kapranov 1990). Let X be a smooth variety. A coherent sheaf $T \in \mathrm{Coh}(X)$ is a *tilting bundle* if

- (T1) T is locally free of finite rank;
- (T2) $\mathrm{Ext}_{\mathcal{O}_X}^i(T, T) = 0$ for all $i \geq 1$ (“vanishing higher self-Ext”);
- (T3) T generates $D^b(\mathrm{Coh}X)$ as a triangulated category: the smallest full triangulated subcategory of $D^b(\mathrm{Coh}X)$ closed under shifts, cones, and direct summands and containing T is $D^b(\mathrm{Coh}X)$ itself.

The algebra $\mathcal{A} = \mathrm{End}_{\mathcal{O}_X}(T)^{\mathrm{op}}$ is called the *tilting algebra*.

Conditions (T1)–(T2) force $\mathrm{RHom}(T, T) = \mathrm{End}(T) = \mathcal{A}$ concentrated in degree zero; condition (T3) is the generation property. The reason for passing to the opposite algebra is that $\mathrm{RHom}(T, -)$ produces a *right* $\mathrm{End}(T)$ -module and, by convention, one wishes to write these as left $\mathcal{A}$ -modules.

THEOREM 33.4.2 (Derived Morita via tilting; Bondal 1989; Rickard 1989 for algebras; Bondal–Van den Bergh 2003, arXiv:math/0204218 Thm. 3.1.1). Let T be a tilting bundle on X and $\mathcal{A} = \mathrm{End}(T)^{\mathrm{op}}$. The pair

$$L = T \otimes_{\mathcal{A}}^L (-) : D(\mathcal{A}\text{-mod}) \longrightarrow D_{\mathrm{qc}}(X), \quad R = \mathrm{RHom}_{\mathcal{O}_X}(T, -) : D_{\mathrm{qc}}(X) \longrightarrow D(\mathcal{A}\text{-mod})$$

is an adjoint pair $L \dashv R$. Two hypotheses make it an equivalence after restriction to the compact part:

- (H1) (*Compact generation*) T is a compact generator of $D_{\mathrm{qc}}(X)$: the smallest localising subcategory of $D_{\mathrm{qc}}(X)$ closed under arbitrary coproducts and containing T is all of $D_{\mathrm{qc}}(X)$, and T is compact (Bondal–Van den Bergh *loc. cit.*, Thm. 3.1.1);
- (H2) (*Higher Ext vanishing*) $\mathrm{Ext}_{\mathcal{O}_X}^{>0}(T, T) = 0$, so that the unit $\mathcal{A} \rightarrow R(L(\mathcal{A})) = \mathrm{RHom}(T, T \otimes_{\mathcal{A}}^L \mathcal{A}) = \mathrm{RHom}(T, T)$ is an isomorphism in $D(\mathcal{A}\text{-mod})$ concentrated in degree zero.

Under (H1)–(H2), $L \dashv R$ is a pair of mutually quasi-inverse equivalences

$$D_{\mathrm{qc}}(X) \simeq D(\mathcal{A}\text{-mod}), \quad \mathrm{Perf}(X) \simeq \mathrm{Perf}(\mathcal{A}) = D^{\mathrm{perf}}(\mathcal{A}\text{-mod}).$$

Restricting to bounded coherent objects on the left and finitely presented modules on the right yields the classical equivalence $D^b(\text{Coh} X) \simeq D^b(A\text{-mod})$.

Proof. The adjunction $L \dashv R$ is the standard tensor–Hom adjunction for the $A\text{-}\mathcal{O}_X$ bi-module T : for $M \in D(A\text{-mod})$ and $\mathcal{F} \in D_{\text{qc}}(X)$, $\text{Hom}_{D_{\text{qc}}(X)}(T \otimes_A^L M, \mathcal{F}) = \text{Hom}_{D(A)}(M, \text{RHom}_{\mathcal{O}_X}(T, \mathcal{F}))$ functorially. The unit $\eta_A: A \rightarrow R(L(A)) = \text{RHom}(T, T)$ is an isomorphism by (H2), which forces $\text{Ext}^{>0}(T, T) = 0$ and identifies $\text{RHom}(T, T) \simeq \text{End}(T) = A^{\text{op}}$ concentrated in degree zero; since A generates $D(A\text{-mod})$, this upgrades to $\eta_M: M \xrightarrow{\sim} R(L(M))$ for all $M \in D(A\text{-mod})$. The counit $\varepsilon_{\mathcal{F}}: L(R(\mathcal{F})) \rightarrow \mathcal{F}$ is an isomorphism on the compact generator T by the same computation, and T compactly generates $D_{\text{qc}}(X)$ by (H1), so ε is an isomorphism on all of $D_{\text{qc}}(X)$ (Bondal–Van den Bergh arXiv:math/0204218, Thm. 3.1.1: a compact generator with bounded Ext produces an equivalence with modules over its endomorphism dg-algebra, here concentrated in degree zero by (H2)). $\square$

NON-COMMUTATIVE CREPANT RESOLUTIONS

The obstruction on singular X is sharper: X admits no smooth model within its birational class without blowing up, but one may ask for a *non-commutative* smooth substitute.

Definition 33.4.3 (NCCR; Van den Bergh 2004, arXiv:math/0211064). Let R be a commutative Noetherian normal Gorenstein domain. A *non-commutative crepant resolution* of R is an R -algebra $A = \text{End}_R(M)$, for some reflexive R -module M , such that

- (N1) A is *homologically homogeneous*: all simple A -modules have the same projective dimension, equal to $\dim R$;
- (N2) A is a *maximal Cohen–Macaulay* R -module;
- (N3) A is generically Azumaya and M is a reflexive generator.

“Crepant” means $\omega_A \cong A$ as A -bimodules: the canonical class is trivial, matching the CY condition on $\text{Spec } R$.

THEOREM 33.4.4 (*Van den Bergh equivalence, arXiv:math/0211064 Thm. 6.6.1 and §8*). Let $Y \rightarrow X = \text{Spec } R$ be a crepant resolution (in the commutative sense) with R as in Definition 33.4.3, and suppose $\dim R \leq 3$. Then there exists a tilting bundle T_Y on Y with $\text{End}(T_Y)^{\text{op}} = A$ an NCCR of R in the sense of Definition 33.4.3, and the adjoint pair $L \dashv R$ of Theorem 33.4.2 is an equivalence

$$D^b(\text{Coh} Y) \simeq D^b(A\text{-mod}).$$

Both sides realise the same abstract triangulated category; when R is Gorenstein of dimension three with trivial dualising module, the *Ginzburg dg-lift* $\Gamma = \Gamma(Q, W)$ of A (Ginzburg 2006, arXiv:math/0612139 Thm. 5.3.1) carries a CY_3 structure: Γ is exact 3-Calabi–Yau as a dg-algebra, meaning the inverse dualising complex satisfies bimodule self-duality $\text{RHom}_{\Gamma^e}(\Gamma, \Gamma \otimes \Gamma)[3] \simeq \Gamma$ in the derived category of Γ -bimodules; the $[3]$ -shift is the bimodule incarnation of the PTVV shift $(d, \text{shift}, E_n^{\text{cl}}) = (3, -1, E_1)$ on CY_3 geometry. The Jacobi algebra $J = \text{Jac}(Q, W) = H^0(\Gamma)$ is not itself a CY_3 algebra; the self-duality is a property of the dg-lift, and descent to J requires the quasi-isomorphism $\Gamma \simeq J$ in Proposition 33.4.6(c).

Scope of existence. The hypothesis $\dim R \leq 3$ is sharp. Beyond dimension three, the existence of an NCCR is not guaranteed and *fails* in the cases most of interest: projective K_3 surfaces with generic polarisation (where $H^{0,2}(X) \neq 0$ obstructs higher Ext-vanishing), the quintic and other generic projective CY_3 without toric or orbifold presentation, and compact hyperkähler manifolds of dimension ≥ 4 . The

Van den Bergh existence theorem covers precisely the local three-dimensional crepant setting: toric CY_3 , orbifolds $\mathbb{C}^n/G$ with $G \subset \text{SU}(n)$ of dimension $n \leq 3$, (-3) -curve contractions, and their relatives.

On the conifold $R = \mathbb{C}[x, y, z, w]/(xw - yz)$ the NCCR is the *Klebanov–Witten quiver algebra* with tilting bundle $T = \mathcal{O} \oplus \mathcal{O}(1)$ on the resolved conifold $\tilde{Y} = \mathcal{O}_{\mathbb{P}^1}(-1) \oplus \mathcal{O}_{\mathbb{P}^1}(-1)$. On local $\mathbb{P}^2 = \text{Tot}(\mathcal{O}_{\mathbb{P}^2}(-3))$ the NCCR is the nine-arrow Beilinson algebra, with $T = \mathcal{O} \oplus \mathcal{O}(1) \oplus \mathcal{O}(2)$. On (-3) -curve contractions $\tilde{Y} \rightarrow X$ with $\tilde{Y}$ containing a $\mathbb{P}^1$ of self-intersection $(-1, -1, -1, -1)$ on its normal bundle, Craw’s tilting bundles (Craw 2008, building on Craw–Ishii 2004) play the same role. In each case, an explicit tilting object T reduces all geometric CoHA questions on X to finite-dimensional Hall-algebra questions on $\mathcal{A} = \text{End}(T)^{\text{op}}$; the superpotential $\mathcal{W}$ reconstructing $\mathcal{A}$ as a Jacobi algebra is uniquely determined (up to right-equivalence) from the cyclic $\mathcal{A}_\infty$ -structure on the tilting algebra (Bocklandt 2008, arXiv:math/0603558 Thm. 3.1).

EXISTENCE AND FAILURE

The Van den Bergh theorem (Theorem 33.4.4) guarantees the existence of a tilting bundle in precisely the *local three-dimensional* crepant setting: X obtained as a crepant resolution of an affine Gorenstein singularity $\text{Spec } R$ with $\dim R \leq 3$. This covers toric CY_3 , orbifolds $\mathbb{C}^n/G$ with $G \subset \text{SU}(n)$ of dimension $n \leq 3$, (-3) -curve contractions, and their relatives. Beyond this scope, global tilting *fails*. Three cases are central:

- (a) *Projective K3 surface S with generic polarisation.* The obstruction is $\text{Ext}_{\mathcal{O}_S}^2(\mathcal{F}, \mathcal{F}) \neq 0$ for any locally-free $\mathcal{F}$: Serre duality on a CY_2 identifies $\text{Ext}^2(\mathcal{F}, \mathcal{F}) \cong \text{Hom}(\mathcal{F}, \mathcal{F})^\vee \neq 0$. The higher-Ext vanishing hypothesis (H2) of Theorem 33.4.2 cannot hold. The K3 category admits compact generation (by Bondal–Van den Bergh, Thm. 3.1.1) but no tilting generator.
- (b) *Quintic threefold $X \subset \mathbb{P}^4$.* The obstruction is the non-triviality of $H^{\circ,3}(X) = \mathbb{C}$ (the holomorphic volume form), which combined with Serre duality forces $\text{Ext}_{\mathcal{O}_X}^3(\mathcal{F}, \mathcal{F}) \neq 0$ for non-zero $\mathcal{F}$. No $\text{Ext}^{>0}$ -vanishing tilting generator exists globally.
- (c) *Compact hyperkähler manifold of dimension ≥ 4 .* Hyperkähler symmetry forces $h^{\circ,p}(X) = 1$ for all p even, $0 \leq p \leq \dim X$; the higher Ext-vanishing hypothesis is obstructed at every even degree $\leq \dim X$.

The general pattern: at $d \geq 3$, if $H^{\circ,q}(X) \neq 0$ for some $1 \leq q \leq d$, then $\text{Ext}^q(T, T) \supseteq H^{\circ,q}(X) \neq 0$ for any locally-free T with $\mathcal{O}_X$ as a summand; the hypothesis (H2) of Theorem 33.4.2 fails. In such cases, no global tilting exists; only local tilting on Zariski patches, and the gluing of Parts I–III (or §33.5 via factorisation algebras) applies.

Tilting as gluing presentation

The tilting bundle is a *presentation* of X by a single quiver-with-potential: the quiver vertices are the summands of $T = \bigoplus_i T_i$, the arrows are extensions among them, and the potential encodes the exact 3-Calabi–Yau constraint on the Ginzburg dg-lift $\Gamma(Q, \mathcal{W})$.

THE DECOMPOSITION $T = \bigoplus_i T_i$

Write $T = \bigoplus_{i \in I} T_i$ as a finite direct sum of indecomposable summands. This decomposition is canonical up to isomorphism of summands (Krull–Schmidt on the additive category generated by T). Then

$$\mathcal{A} = \text{End}(T)^{\text{op}} = \bigoplus_{i,j \in I} \text{Hom}_{\mathcal{O}_X}(T_i, T_j)^{\text{op}}$$

is a matrix algebra over the “diagonal” algebras $\text{End}(T_i)$, indexed by pairs (i, j) . The off-diagonal block $\text{Hom}_{\mathcal{O}_X}(T_i, T_j)$ is the *arrow space* from i to j : its basis is the space of morphisms $T_i \rightarrow T_j$ in $\text{Coh}(X)$ modulo scaling.

In the conifold example $T = \mathcal{O} \oplus \mathcal{O}(-1)$:

$$\text{Hom}(\mathcal{O}, \mathcal{O}(-1)) = H^0(\mathbb{P}^1, \mathcal{O}(-1)) \oplus H^0(\mathbb{P}^1, \mathcal{O}(-1)) = \mathbb{C}^2 \oplus 0 = \mathbb{C}a_1 \oplus \mathbb{C}a_2,$$

and $\text{Hom}(\mathcal{O}(-1), \mathcal{O}) = H^0(\mathcal{O}(-1)) \oplus H^0(\mathcal{O}(-1)) = 0 \oplus \mathbb{C}^2 = \mathbb{C}b_1 \oplus \mathbb{C}b_2$ (the second term arises via the $\mathcal{O}(-1) \oplus \mathcal{O}(-1)$ fibre direction). Similarly $\text{End}(\mathcal{O}) = \text{End}(\mathcal{O}(-1)) = \mathbb{C}$. The Klebanov–Witten quiver with vertices $\{\circ, \bullet\}$, arrows $a_1, a_2: \circ \rightarrow \bullet$ and $b_1, b_2: \bullet \rightarrow \circ$, and superpotential $W = a_1b_1a_2b_2 - a_1b_2a_2b_1$ emerges *directly* from the cohomology count.

THE JACOBI ALGEBRA, THE POTENTIAL, AND THE GINZBURG DG-LIFT

The endomorphism algebra of a tilting bundle on a smooth local CY_3 carries a cyclic derivation structure: there exists a superpotential $W \in \mathbb{C}Q_{\text{cyc}} = \mathbb{C}Q/[CQ, CQ]$ in the cyclic quotient of the path algebra such that the relations among the arrows are precisely the cyclic derivatives $\partial_a W = 0$. The pair (Q, W) is the quiver with potential; the *Jacobi algebra* is

$$J = \text{Jac}(Q, W) = \mathbb{C}Q / \langle \partial_a W : a \in Q_1 \rangle.$$

The CY_3 property is carried not by J but by its *Ginzburg dg-lift*.

Definition 33.4.5 (Ginzburg dg-algebra; Ginzburg 2006, arXiv:math/0612139 §5). Given a quiver with potential (Q, W) , the *Ginzburg dg-algebra* $\Gamma(Q, W)$ is the tensor algebra on the graded quiver

- arrows of Q in degree 0;
- one reverse arrow $a^*: j \rightarrow i$ in degree -1 for each $a: i \rightarrow j$ in Q_1 ;
- one loop $t_i: i \rightarrow i$ in degree -2 at each vertex $i \in I$,

equipped with the differential $da = 0$, $da^* = \partial_a W$, and $dt_i = \sum_{a \in Q_i} [a, a^*] \cdot e_i$ (the total commutator at vertex i).

PROPOSITION 33.4.6 (*CY₃ property lives on Γ , not on J ; Ginzburg 2006, arXiv:math/0612139 Thm. 5.3.1 for the exact CY property of $\Gamma(Q, W)$; Keller 2011 arXiv:1102.4148 §6 for the descent of the CY_3 class to derived Morita*). For (Q, W) a quiver-with-potential arising from a local CY_3 :

- The dg-algebra $\Gamma(Q, W)$ is *exact 3-Calabi–Yau*: its inverse dualising complex satisfies $\text{RHom}_{\Gamma^e}(\Gamma, \Gamma \otimes \Gamma)[3] \simeq \Gamma$ as Γ -bimodules, with the CY_3 shift degree $+3$ matching the PTVV shift $(d, \text{shift}, E_n^{\text{cl}}) = (3, -1, E_1)$ under dg-Hochschild Serre duality.
- The Jacobi algebra $J = H^0(\Gamma(Q, W))$ is the degree-zero cohomology of Γ ; it is *not* by itself a CY_3 algebra. Calling J “ CY_3 ” conflates two distinct structures (J has no intrinsic shift structure). The three-dimensional duality is an assertion about Γ -bimodules.
- For Q connected and W suitably non-degenerate, $H^{<0}(\Gamma(Q, W)) = 0$, so $\Gamma \simeq J$ in the derived category of Γ (hence derived Morita between Γ and J), and only via this quasi-isomorphism does the CY_3 structure on Γ descend to the derived categorical structure $D^b(J\text{-mod})$.

THEOREM 33.4.7 (*Tilting-via-quiver presentation; Ginzburg 2006, Keller 2011 arXiv:1102.4148*). Let $T = \bigoplus_{i \in I} T_i$ be a tilting bundle on a smooth local CY_3 X . Let Q be the quiver with vertex set

I and arrow spaces $Q_i(i, j) = \text{Ext}_{\mathcal{O}_X}^1(T_i, T_j)^*$. There exists a quasi-homogeneous superpotential $W \in \mathbb{C}Q_{\text{cyc}}$, unique up to gauge, such that

$$\text{Jac}(Q, W) = \text{End}_{\mathcal{O}_X}(T)^{\text{op}}, \quad \Gamma(Q, W) \simeq \text{RHom}_{\mathcal{O}_X}(T, T) \text{ as dg-algebras,}$$

and the CY_3 structure on $\text{Perf}(X)$ transports (via Theorem 33.4.2 applied to Γ) to the exact CY_3 structure on Γ of Proposition 33.4.6(a).

Proof sketch. The arrow spaces are Ext-spaces: under (H2) the underived and derived $\text{Hom}(T_i, T_j)$ agree in degree zero, so the first non-trivial term for $i \neq j$ is $\text{Ext}^1(T_i, T_j)$, which Serre-dualises to $\text{Ext}^2(T_j, T_i)$ on the CY_3 ; the potential encodes the m_3 Massey product. The construction of W is the Kontsevich–Costello reconstruction of a cyclic A_∞ -algebra from its degree-zero piece plus Serre duality: the m_3 on Ext^1 evaluated against Serre duality reproduces the degree-3 piece of W , higher m_k give higher-degree corrections, and quasi-homogeneity follows from the internal CY_3 grading on Γ . The quasi-isomorphism $\text{RHom}(T, T) \simeq \Gamma(Q, W)$ is Keller’s derived-equivalence theorem (Keller 2011 §A.15). The CY_3 property, as Proposition 33.4.6 records, is a property of Γ as a dg-algebra; the statement “ J is CY_3 ” is shorthand for “ Γ is CY_3 and $J = H^0(\Gamma)$ ”. $\square$

CANONICAL EXAMPLES

Conifold $\tilde{Y} = \mathcal{O}_{\mathbb{P}^1}(-1)^{\oplus 2}$. Tilting $T = \mathcal{O} \oplus \mathcal{O}(1)$. Quiver: two vertices, two arrows each way. Potential $W = a_1 b_1 a_2 b_2 - a_1 b_2 a_2 b_1$ (Klebanov–Witten, Szendrői 2008).

Local $\mathbb{P}^2 = \text{Tot}(\mathcal{O}_{\mathbb{P}^2}(-3))$. Tilting $T = \mathcal{O} \oplus \mathcal{O}(1) \oplus \mathcal{O}(2)$ (Beilinson 1978). Quiver: three vertices, $3 \times 3 = 9$ arrows grouped as three Koszul strands (Beilinson triple $\mathcal{O}, \mathcal{O}(1), \mathcal{O}(2)$). Potential $W_{p_2} = \sum_{\sigma \in S_3} \text{sgn}(\sigma) x_{\sigma(1)} y_{\sigma(2)} z_{\sigma(3)}$: the antisymmetric McKay cubic (Beasley–Plesser 2001).

(−3)-curves. Let $\tilde{Y}$ contain a rational curve $C \cong \mathbb{P}^1$ with normal bundle $N_{C/\tilde{Y}} = \mathcal{O}(-1) \oplus \mathcal{O}(-1)$ that can be contracted to a singular point of X . Craw 2008 (building on the Craw–Ishii 2004 analysis of $\mathbb{C}^3/G$ -Hilb schemes) constructs tilting $T_C = \mathcal{O}_{\tilde{Y}} \oplus \mathcal{O}_{\tilde{Y}}(C)$ (or an explicit line-bundle refinement with intersection numbers read off from $N_{C/\tilde{Y}}$). The associated tilting algebra is derived-equivalent to the quiver from the contracted singularity; tilting automorphisms realise the flop $\tilde{Y} \dashrightarrow \tilde{Y}^+$ as derived Morita on the same CY_3 category.

$\mathbb{C}^3/\mathbb{Z}_n$ orbifolds. Tilting $T = \bigoplus_{k=0}^{n-1} \mathcal{O} \otimes \chi_k$ on the resolved orbifold, where χ_k are the characters of $\mathbb{Z}_n$. Quiver: n vertices arranged on a cycle; arrows per McKay graph; potential cubic (type A McKay).

QUIVER-WITH-POTENTIAL AS UNIVERSAL GLUING DATA

The force of Theorem 33.4.7 is that for every tilting presentation, a single pair (Q, W) plays the role of the entire Čech atlas plus all its transition functors. One algebra $\mathcal{A} = \text{Jac}(Q, W)$ encodes everything. In particular:

- The Čech nerve $\{U_\alpha\} \cup \{U_\alpha \cap U_\beta\} \cup \dots$ on X collapses to the vertex set I and the arrow set Q ;
- The transition functors between charts collapse to the relations $\partial_a W = 0$;
- The higher cocycle data on triple overlaps collapses to the higher A_∞ structure on $\Gamma(Q, W)$.

The tilting presentation is therefore the *economy* of the gluing: one single finite-dimensional algebra replaces the infinite-dimensional Čech diagram.

Transport of Hall product along derived Morita

The CoHA on X is defined via the moduli stack of coherent sheaves $\mathcal{M}(X)$ with its critical cohomology ring structure (Kontsevich–Soibelman 2008, Davison–Meinhardt 2020 arXiv:1601.02479). On the NCCR side, the same construction yields the CoHA on the moduli stack $\mathcal{M}(A)$ of finite-dimensional A -modules. The derived Morita equivalence lifts to these moduli stacks, and Davison–Hennecart–Schlegel Mejia (DHSM) 2023 arXiv:2303.12592 prove that the Hall product transports. The assertion of this section is the precise form of that transport and its first-principles derivation.

MODULI-STACK LIFT OF DERIVED MORITA
